CNNs are a popular deep learning architecture for image-based tasks. The efficacy of CNNs in this domain can be attributed to their simple yet effective design. In the contemporary era, there exists a plethora of models that are founded upon the fundamental CNN design, which serve a diverse array of purposes [7]. The distinguishing feature of CNN architecture that sets it apart from classical neural networks is its capacity to substantially minimize the number of parameters necessary during the feature extraction stage [8]. In a CNN, various components such as the number of convolutional layers, the number of kernels, and the dropout rate are considered CNN parameters. A significant benefit of CNN architectures is their capacity to operate with a suitable set of hyperparameters. However, this architecture presents a challenge in the selection of hyperparameters that will optimally solve the problem. Hyperparameter optimization is employed to address these challenges and to identify the most suitable solution. Nevertheless, given the considerable number of parameters, this process can be costly and time-consuming. It is customary for these hyperparameters to be configured manually. A variety of hyperparameter optimization algorithms have been employed to automate this adjustment process. When such modifications are performed with suitable algorithms, they have been shown to yield positive contributions in terms of time and cost for many studies [9].

In this study, a MobileNetV2-based CNN model, pre-trained on the ImageNet dataset, was applied to classify pes planus images. In the initial phase, the baseline CNN model was trained using a set of hyperparameters (learning rate, dropout rate, data augmentation intensity, etc.), and performance metrics such as accuracy were obtained on the test sets. Subsequently, to increase and improve the accuracy score achieved by this baseline model, the hyperparameters were optimized using metaheuristic optimization techniques such as Genetic Algorithm (GA), Grey Wolf Optimization (GWO), and Particle Swarm Optimization (PSO). For each metaheuristic algorithm, CNN models were retrained by testing different hyperparameter settings and combinations. The optimal GA, GWO, and PSO solutions derived from these combinations were subsequently evaluated on the test set, and the outcomes were contrasted with the baseline CNN model based on MobileNetV2.

A review of the literature reveals studies in which pes planus and metaseptic methods have been used in medical datasets. For instance;

In a study conducted by Kim and colleagues, a transfer learning-based method relying on deep learning was proposed for pes planus classification. In this study, a pre-trained architecture such as VGG16 was utilized, and a model exhibiting high prediction performance was created using data augmentation methods. The model was trained using a dataset consisting of a total of 176 images (88 pes planus and 88 normal feet). In order to ascertain the efficacy of this novel approach, a comparison experiment was conducted with a standard CNN model. The baseline CNN model demonstrated training, validation, and test accuracies of 77.27%, 61.36%, and 59.09%, respectively. In contrast, the proposed innovative model achieved training accuracy of 94.32%, validation accuracy of 86.36%, and test accuracy of 84.09%. In light of these findings, it is evident that the newly developed model attains markedly superior outcomes in terms of classification performance in comparison to the standard CNN model [10].

In a separate study conducted by Dogan and colleagues, the objective was to enhance the precision of flatfoot (pes planus) diagnosis. In order to achieve this objective, an innovative fusion model was developed by combining the VGG16 CNN architecture with the ViT-B/16 Vision Transformer. This hybrid model capitalizes on the local feature capture ability of CNNs and the global context understanding power of ViT structures, demonstrating higher

performance compared to current methods in the literature. Furthermore, researchers have employed ensemble learning methodologies to enhance the model's reliability and its capacity for generalization. The findings of the model, evaluated through a ten-fold cross-validation approach, substantiate its capacity to attain a commendable level of performance. The sensitivity recorded was 97.4%, the specificity 96.4%, and the F1 score 96.8% [11].

As posited by Aguerchi et al., breast cancer is among the most prevalent forms of cancer on a global scale. Medical imaging techniques are among the most critical methods used in the detection and diagnosis of breast cancer. CNNs, which are extensively employed in image classification tasks, present certain challenges in selecting the appropriate architecture and hyperparameters. This research has led to the development of a new CNN model that has the capacity to diagnose breast cancer with a high degree of accuracy from mammography images. The proposed model utilizes Particle Swarm Optimization (PSO) to enhance the CNN architecture and hyperparameters. The PSO-based CNN model demonstrated accuracy rates of 98.23% and 97.98% on the DDSM and MIAS datasets, respectively, showing better performance compared to similar studies in the literature [12].

2-MATERIAL AND METHODS

2.1 Data Set

In this thesis research, the dataset compiled by Gül and colleagues and publicly shared on the Kaggle platform was utilized [13,14]. The dataset under consideration comprises 842 X-ray images of 439 patients aged between 14 and 47 years who were referred to the Radiology Department of Elazığ Fethi Sekin City Hospital with suspected pes planus. The images were obtained using a Philips dual-detector digital X-ray machine (65 kV, 6.3 mAs) and stored in the data pool in JPG file format. However, the dataset was subject to a process of filtration, resulting in the exclusion of images deemed to be of substandard quality. Finally, the reduced dataset utilized in this study was organized using a data augmentation method to ensure class balance. Figure 1 presents a series of images drawn from the dataset.

Figure 1. Images from the data sets.

2.2 CNN Model

In the contemporary era, CNNs have become a prominent exemplar of artificial neural networks, owing to their remarkable efficacy in the domain of deep learning algorithms [15]. CNNs have been successful in completing a number of tasks that were previously considered to be impossible. These tasks include face recognition, autonomous vehicle operation, robotic perception, and various solutions in the healthcare sector. The provision of such conveniences

serves to demonstrate that CNN is one of the most groundbreaking and transformative technologies in existence today [16].

CNNs have been shown to offer distinct advantages over traditional artificial neural networks [17]. It has been demonstrated that the capacity to discern spatial and temporal relationships in input data without the necessity for human intervention constitutes a significant advantage [18]. The automatic feature extraction process of CNNs eliminates the need for this process, which must be done manually in traditional models. This increase in processing speed enables more accurate results in the studies conducted [17].

2.3 Metaheuristic Algorithms

The term "meta" has seen a marked increase in usage across various disciplines in recent years, typically signifying "beyond something itself" or "at a higher level." This concept, which remains without a precise and universally accepted mathematical definition, is referred to in the literature as meta-heuristic methods. These are defined as higher-level search strategies that manage, organize, or develop different heuristic methods [19]. Optimization algorithms are a class of computational methods that select from a given set of candidate solutions to achieve maximum results for the problem at hand, and do so continuously. Meta-heuristic algorithms represent a significant category of optimization methods [20]. The meta-heuristic algorithms employed in the present study are, respectively: Genetic Algorithms, Grey Wolf Optimization, and Particle Swarm Optimization.

2.3.1 Genetic Algorithm

The development of the genetic algorithm was informed by Darwin's theory of "survival of the fittest," which draws inspiration from the process of biological evolution [21]. The algorithm under discussion is fundamentally based on three main operations: selection, reproduction, and mutation. The survival of the fittest is the principle on which the selection phase is based. However, it also allows for the improvement of relatively undeveloped individuals and the transmission of this improvement to subsequent generations. Organisms in nature are characterized by a set of rules or plans that govern their characteristics. These small hereditary units are known as genes. Genes are known to form long sequences of DNA, known as chromosomes [22, 23]. In a standard Genetic Algorithm (GA), the initial set of potential solutions is generated using a random method. Subsequently, evolutionary operators are applied to transform this population; this cycle is repeated until a specified termination condition is met. The modeling of evolutionary mechanisms in natural settings has facilitated the utilization of this efficient and powerful system in optimization and search problems in engineering [23].

2.3.2 Grey Wolf Optimization

The Grey Wolf Optimization (GWO) algorithm mimics the social structure and hunting methods of gray wolves in their natural habitat. These wolves typically live in packs of 5 to 12 individuals in the wild [24]. The pack is usually led by leaders called Alphas, consisting of one male and one female. The Alpha makes decisions alone on important matters such as hunting plans or choosing resting places. However, it has been noted that in some cases, even the Alpha listens to other members and exhibits cooperative decision-making behavior. Beta wolves occupy the second position in the social hierarchy. Beta wolves are subordinate to the Alpha; they support the leader in the pack's daily affairs and decision-making processes. This individual advises the Alpha, maintains discipline within the pack, relays the leader's orders, and feeds back opinions from the group. At the bottom of the hierarchy are the Omega wolves. Omegas must obey all dominant members. Although they appear to be the least valuable members of the pack, it has been observed that when an Omega is missing, serious internal

turmoil arises within the group. There is also an intermediate level called Delta. Delta wolves obey the Alpha and Beta, but are in a higher position than the Omega [25].

2.3.3 Particle Swarm Optimization

The method called Particle Swarm Optimization (PSO) was developed and introduced by Russell C. Eberhart and James Kennedy [26]. This optimization technique was discussed in detail in a scientific paper co-authored by these two scientists and first published in 1995 [27]. Derived from the concept of swarm intelligence, this approach is based on research into the movement dynamics of flocks of birds and schools of fish. Birds searching for food either move randomly or travel together (in flocks) until they locate the exact location of the food source. When birds move from one area to another in search of food, an individual that can predict the location of food more accurately than others or has the best information usually emerges. During the search, birds constantly share this valuable information, especially the location of the best source, with each other, and eventually cluster around the area where the food is located, guided by this accurate information [26].

2.4 Performance Metrics

The evaluation of the success of artificial intelligence-based algorithms and the selection of the most effective prediction model is a significant area that has been examined in detail in the majority of the studies conducted. In this type of research, various evaluation metrics such as accuracy, precision, recall, and F1 score are generally used to demonstrate the best predictive solution developed. It is widely acknowledged that the prediction accuracy score is a pivotal metric for evaluating the efficacy of a model, as it provides a quantitative measure of its predictive capabilities. This criterion is one of the most popular used to determine the most appropriate prediction solution, regardless of the structure of the data set or the distribution of target classes [28]. The confusion matrix is a tool employed in prediction analysis that compares the results obtained by the model with the actual data. The utilization of a comparison table facilitates the calculation of vital performance metrics, including accuracy, precision, sensitivity, and the F1 score. The matrix structure under consideration contains four fundamental elements that arise in classification processes: True positives, false positives, true negatives and false negatives [29]. These elements are presented in the confusion matrix in Figure 2.

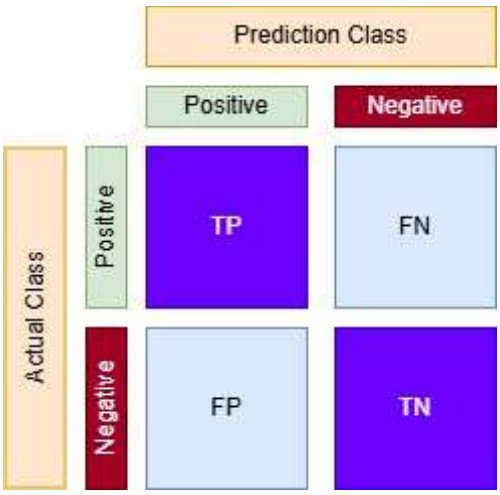

Figure 2. Confusion Matrix

3. EXPERIMENTAL RESULTS

This section presents a comparative analysis of CNN models optimized using Genetic Algorithm (GA), Grey Wolf Optimization (GWO), and Particle Swarm Optimization (PSO) parameters with the basic CNN model. In the context of the results obtained, the validation and test accuracy values of the models are shown in Figure 3.

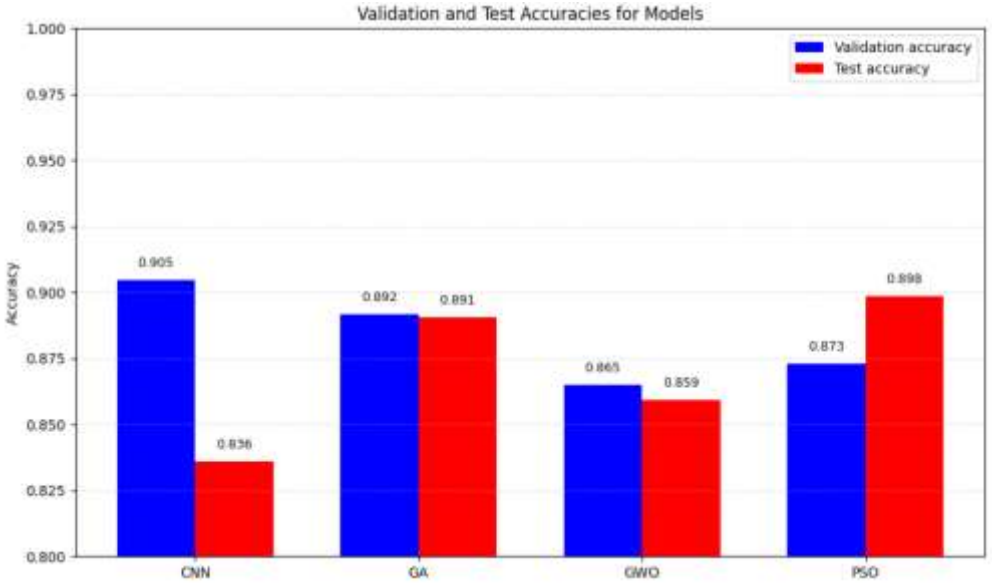

Figure 3. Validation and test accuracies of basic CNN and meta-heuristic-optimized CNN models

The validation and test success rates of the four proposed models are collectively presented in Figure 3. It is evident that the fundamental CNN model attained an accuracy level of approximately 90.5% in the validation dataset; nevertheless, its test accuracy persisted at around 83.6%. This discrepancy suggests that the fundamental model exhibits a satisfactory fit with the training and validation data, yet demonstrates limited capacity for generalization in the testing phase. In the model that has been optimized using the Genetic Algorithm (GA), the validation accuracy is 89.2%, while the test accuracy is approximately 89.1%. The observation that the validation and test performances are so close to each other indicates that the hyperparameters determined by GA adjust the model more evenly and reduce the risk of over fitting. In a similar vein, the validation accuracy of the model that was optimized using Grey Wolf Optimization (GWO) was recorded as 86.5%, while the test accuracy was 85.9%. Despite the fact that these values are lower than the results obtained with GA and Particle Swarm Optimization (PSO), the minor discrepancy between validation and test scores suggests that the model's generalization behaviour is stable.

In the context of the results obtained, the confusion matrices of the models are shown in Figure 4.

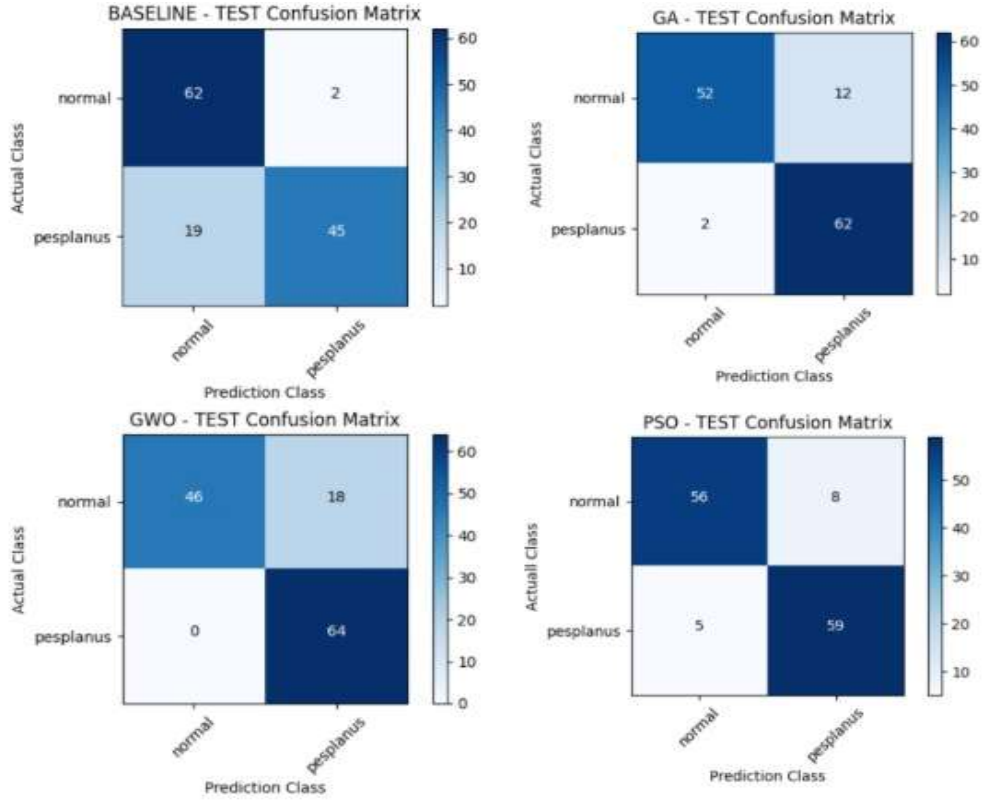

Figure 4. Confusion matrices of basic CNN and meta-heuristic-optimized CNN models

As illustrated in Figure 4, the confusion matrices for the test set of models that have been optimized with meta-heuristic algorithms, employing the basic CNN architecture, are displayed. While all four models generally produce successful results, there are significant differences in terms of error distribution and inter-class balance. In the fundamental CNN model, the normal class is predominantly classified correctly (62/64), whereas 19 pes planus examples are designated as normal (45/64 correct). This finding suggests that the model demonstrates a high level of proficiency in distinguishing between normal and pathological feet; however, it exhibits reduced sensitivity for pes planus, with occasional instances of "missing" the pathological class. In the GA-optimized model, misclassification in the pes planus class is significantly reduced, with only 2 pes planus examples being labeled as normal (62/64 correct). Conversely, 12 examples from the normal class are classified as pes planus. Consequently, the model obtained with the genetic algorithm increases sensitivity in pes planus detection while producing a marginally higher number of "false positives". The GWO-based model demonstrated an accuracy of 64/64 in correctly identifying the pes planus class in the test set, thus exhibiting no errors in this particular classification. However, 18 examples from the normal class were labeled as pes planus. This structure signifies a model profile with elevated pes planus sensitivity, a feature that could prove advantageous in screening scenarios where the precision of diagnosis is paramount. Conversely, the model that has been optimized with PSO evinces balanced performance in both classes. The model demonstrated a 56/64 accuracy in the normal class and a 59/64 accuracy in the pes planus class. It is noteworthy that the number of false negatives (pes planus classified as normal) and false positives were reduced to a more balanced level in comparison to other models. The findings indicate that the model which has been tuned with particle swarm optimization offers the most balanced solution in terms of overall accuracy and inter-class balance.

Table 1 presents performance metrics such as precision, sensitivity, F1-score, and accuracy for basic CNN and metaheuristic-optimized CNN models.

Table 1. Average performance metrics of basic CNN and meta-heuristic-optimized CNN models

	Precision	Recall	F1-Score	Accuracy
Baseline CNN	0.8614	0.8359	0.8330	0.8359
Genetic Algorithm	0.9004	0.8906	0.8900	0.8906
Grey Wolf Optimization	0.8902	0.8594	0.8565	0.8594
Particle Swarm Optimization	0.8993	0.8984	0.8984	0.8984

The following section presents a comparison of the mean performance metrics of models developed using the basic CNN model and metaheuristic algorithms (Genetic Algorithm (GA), Grey Wolf Optimization (GWO), and Particle Swarm Optimization (PSO)). These are set out in Table 1. The performance metrics of the fundamental CNN architecture were evaluated, yielding a precision of 0.8614, a recall of 0.8359, an F1-score of 0.8330, and an accuracy of 0.8359. The findings indicate that the model performs adequately in general, yet it exhibits a certain degree of inaccuracy when distinguishing between positive and negative classes, suggesting potential for enhancement. The performance metrics of the GA-optimized model demonstrated a substantial enhancement, with precision reaching 0.9004, sensitivity reaching 0.8906, F1-score reaching 0.8900, and accuracy reaching 0.8906. This increase, observed in all metrics when compared to the baseline CNN, indicates that GA combines hyperparameters such as learning rate, dropout rate, trainable layer ratio, and class balancing strategies in a more suitable combination, thereby improving the model's ability to predict true positives and true negatives. The model obtained with GWO reported a precision value of 0.8902, sensitivity of 0.8594, F1-score of 0.8565, and accuracy of 0.8594. Despite the enhancement in each metric of the GWO model in comparison to the fundamental CNN, it exhibited marginal inferiority to GA and PSO with regard to F1 and accuracy values. This result demonstrates that GWO exhibits a more cautious approach, particularly in certain class examples, and offers relatively balanced performance between sensitivity and precision. The model that was trained with PSO demonstrated the most balanced and highest performance of the four models, with precision of 0.8993, sensitivity of 0.8984, F1-score of 0.8984, and accuracy of 0.8984. The observation that the sensitivity and accuracy values in the PSO model are closely aligned suggests that the proportion of correctly classified examples is significant and that the model makes consistent generalizations across different classes. In conclusion, it can be stated that all metaheuristic algorithms have demonstrated an enhanced performance in comparison to the basic CNN architecture. In particular, the GA and PSO models have been shown to provide more effective solutions to the pes planus classification problem with high precision, sensitivity, F1, and accuracy values.

4- DISCUSSION

The dataset utilized in this study comprises foot images categorized into the "normal" and "pes planus" classes. The deep learning model was prepared for utilization by means of preprocessing these images. For the classification task, MobileNetV2, a CNN architecture pre-trained on ImageNet, was utilized as a foundation; fully connected layers were incorporated into this backbone to engineer a structure that would yield a two-class output. The findings unequivocally demonstrate that the fundamental CNN architecture exhibited suboptimal

performance in comparison to models that have been optimized through the utilization of metaheuristic algorithms. The CNN model demonstrated an approximate accuracy of 83.6%, with comparable metrics, including precision, sensitivity, and F1-score, being produced. A thorough examination of models that have been optimized with metaheuristic algorithms has revealed that all methods provide substantial enhancements in terms of accuracy and other performance indicators when compared to the fundamental CNN structure. The model that was optimized with the Genetic Algorithm (GA) achieved an accuracy score of approximately 89.1%. A significant increase in F1-score and sensitivity was recorded in comparison to the basic model. The model obtained with Grey Wolf Optimization (GWO) demonstrates an approximate accuracy of 85.9%. This model demonstrated a superior structural design in comparison to the fundamental CNN, particularly with regard to sensitivity and inter-class balance. In the field of machine learning, Particle Swarm Optimization (PSO) has been shown to demonstrate superior performance when compared to other algorithms, with an accuracy of approximately 89.8%. This performance is noteworthy for its consistency and reliability, making it a noteworthy contender in the search for optimal machine learning models. The PSO-based model has been demonstrated to reduce misclassification rates while maintaining class balance, thus resulting in a clinically more reliable classification profile. This fundamental CNN model functioned as the baseline for the duration of the study. However, in order to enhance the model's performance, the utilization of metaheuristic optimization algorithms was deemed to be a superior approach in comparison to the manual adjustment of hyperparameters. In this context, critical hyperparameters such as learning rate, dropout rate, trainable base layer ratio, data augmentation density, oversampling, and class weights have been automatically adjusted using Genetic Algorithm (GA), Grey Wolf Optimization (GWO), and Particle Swarm Optimization (PSO).

ÖZET

Fitoterapi, tedavi edici, hastalıkları iyileştirici ve hastalıkları önleyici olarak tanımlanmış, tıbbi bitkiden doğrudan doğruya; ya da bitkinin belli kısımlarından yararlanılarak gerçekleştirilen tedavi yöntemidir. Fitoterapi tarihsel olarak çok eski dönemlere, antik medeniyetlere kadar uzanmaktadır. İlk izlerine Mısır, Çin, Hindistan ve Yunan medeniyetlerinde rastlanır. Antik Mısır'da bitkisel ilaçlar, tıbbi uygulamalarda ve hayvanlardaki çeşitli rahatsızlıkların tedavisinde kullanılmıştır. On sekizinci yüzyılın sonları ve on dokuzuncu yüzyıl başlarında bitkilerin kimyasal içeriği hakkında fazla bir bilgi olmadığından bitkilerin, koruma ve tedavi edici etkileri yıllar boyunca elde edilmiş tecrübeleri temel almıştır. Günümüzde yapılan son araştırmalar ise bitkilerde bulunan sekonder matabolitler ve bu matabolitlerin hayvan verimi, sağlığı ve kalitesi üzerine olmuştur. Bu bileşikler hem rumen sağlığı hem de hayvansal üretim açısından önem ihtiva etmektedir. Fenolik bileşikler içeren bitkiler ile beslenen hayvanlarda yem tüketimi ile birlikte hayvansal ürünlerde verim ve kalite de artmaktadır. Sekonder metabolitler antioksidan ve antimikrobiyal özellikleri ile ruminant hayvanlarda şişkinlik ve asidoz gibi beslenme bozukluklarını kontrol altına almaktadır. Söz konusu metabolitler doğal antibiyotik olarak da işlevsel görev üstlenmektedir. Bu durum dışarıdan sentetik antibiyotik kullanılmasını sınırlandırırken, hayvan sağlığı, kalitesi, verimi açısından önem arz etmektedir. Ayrıca biyoaktif bileşenler hayvansal kaynaklı küresel ısınmaya azaltılmasına katkı sunması açısından da önem arz etmektedir. Fitoterapik özellik gösteren birçok bitki bulunmaktadır. Bu bitkilerin bazılarının tarımı yapılırken, bazıları ise doğada yabani formda bulunmaktadır. Bu derlemede, fitoterapinin hayvan sağlığı ve beslemesi açısından önemi ile fitoterapik bitkiler hakkında bilgi verilmesi amaçlanmıştır.

Anahtar kelimeler: Fitoterapi, , sekonder metabolit, hayvan sağlığı, hayvan besleme.

PHYTOTHERAPY IN ANIMAL HEALTH AND NUTRITION: PHYTOTHERAPEUTIC PLANTS

ABSTRACT

Phytotherapy is defined as a therapeutic method that utilizes medicinal plants directly, or certain parts of plants, for healing, treatment, and disease prevention purposes. The history of phytotherapy dates back to ancient times and early civilizations. Its first traces can be found in Egyptian, Chinese, Indian, and Greek civilizations. In ancient Egypt, herbal medicines were used in medical practices and for the treatment of various animal ailments. At the end of the eighteenth century and the beginning of the nineteenth century, there was limited knowledge about the chemical composition of plants; therefore, the protective and healing effects of plants were based on years of accumulated experience. Modern research, however, has focused on the secondary metabolites found in plants and their effects on animal productivity, health, and quality. These compounds are important for both rumen health and overall animal production.Animals fed with plants containing phenolic compounds show increased feed intake, as well as improvements in yield and quality of animal products. Secondary metabolites, with their antioxidant and antimicrobial properties, help control nutritional disorders such as bloating and acidosis in ruminants. These metabolites also act as natural antibiotics, thereby reducing the need for synthetic antibiotics and contributing positively to animal health, productivity, and product quality. In addition, bioactive compounds are significant due to their potential to reduce livestock-related global warming. There are many plants with phytotherapeutic properties-some are cultivated, while others grow naturally in the wild. This review aims to provide information about the importance of phytotherapy in terms of animal health and nutrition, as well as to introduce various phytotherapeutic plants.

Keywords: Phytotherapy, secondary metabolite, animal health, animal nutrition.

1. Giriş

Tıbbi nitelik taşıyan bitkiler, son yıllarda hayvan hastalıklarının tedavisinde alternatif bir yaklaşım olarak öne çıkmaya başlamıştır. Avrupa ve Asya kökenli tarihsel kaynaklarda bu bitkilerin hayvan sağlığı açısından önemi uzun zaman önce belirtilmiş olsa da, nicel verilere dayanan araştırmaların azlığı nedeniyle gerçek değerleri tam olarak ortaya konulamamıştır (Mayer ve ark., 2014). Günümüze kadar yapılan çalışmaların çoğu, bu bitkilerin tanımlanması, uçucu yağ bileşenleri ve insan sağlığına yönelik etkileri üzerinde yoğunlaşmıştır. Buna karşılık, hayvan besleme açısından taşıdıkları yem değeri konusunda oldukça sınırlı sayıda araştırma bulunmaktadır. Oysa bu bitkiler, çeşitli bakteriyel patojenlere karşı doğal antibiyotik özellik gösteren organik bileşikler içermektedir (Sipponen ve ark., 2012). Kowalczyk ve ark. (2013), hayvan beslenmesinde kullanılan dış kaynaklı antibiyotik katkılarının 2006 yılında yasaklanmasıyla birlikte, sekonder metabolitler bakımından zengin olan tıbbi bitkilerin antibiyotiklere potansiyel bir alternatif haline geldiğini ifade etmektedir.

Son yıllarda ruminant beslenmesine yönelik araştırmalar, sekonder metabolitlerin rumen fonksiyonları ve hayvansal performans üzerinde kritik bir role sahip olduğunu ortaya koymuştur (Patra ve ark., 2006; Lee ve ark., 2017; Rochfort ve ark., 2008). Dohi ve ark. (1997), fenolik bileşikler içeren bitkilerle beslenen hayvanlarda yem tüketiminin arttığını ve bunun üretim parametrelerine olumlu katkı sağladığını rapor etmiştir. Santos Neto ve ark. (2009) ile Frozza ve ark. (2013) ise bu bileşiklerin güçlü antioksidan ve antimikrobiyal özellikler taşıdığını vurgulamaktadır. Ayrıca flavonoidler ve fenolik bileşiklerin rumen fermentasyonunun düzenlenmesi, şişkinlik ve asidoz gibi beslenmeye bağlı sorunların kontrolünde etkili olduğu belirlenmiştir (Seradj ve ark., 2014; Paula ve ark., 2016).

Bu derlemede, fitoterapinin hayvan sağlığı ve beslemesi açısından önemi ile fitoterapik bitkiler hakkında bilgi verilmesi amaçlanmıştır.

2. Fitoterapi

Tarihte ilk kez Fransız hekim Henri Leclerc (1870-1955) tarafından kullanılan bir terim olan fitoterapi; tedavi edici, hastalıkları iyileştirici ve hastalıkları önleyici olarak tanımlanmış tıbbi bitkiden doğrudan doğruya; ya da bitkinin belli kısımlarından yararlanılarak gerçekleştirilen tedavi yöntemidir (Faydalıoğlu ve Sürücüoğlu, 2011). Fitoterapi insan ve hayvan sağlığı ile beslenmesinde önemli bir rol oynar. Doğal tedavi seçenekleri sunarak kimyasal ilaçlara alternatif oluşturur ve kimyasal ilaçların kullanımını azaltmaktadır.

Fitoterapi tarihsel olarak çok eski dönemlere, antik medeniyetlere kadar uzanmaktadır. İlk izlerine Mısır, Çin, Hindistan ve Yunan medeniyetlerinde rastlanmaktadır. Antik Mısır'da bitkisel ilaçlar, tıbbi uygulamalarda ve çeşitli rahatsızlıkların tedavisinde kullanılmıştır. Yine Babil–Asur tabletlerinde çok sayıda bitki (güzel avrat otu, tatula, keten, servi, sedir ağacı, incir ağacı, soğan) tedavi amaçlı kullanım açısından tanımlanmıştır (Makarska-Bialokoz, 2019).

Fitoterapi, insanlık tarihinin en eski dönemlerine uzanan bir uygulama olup, zamanla toplumların kültürel yapısına ve günlük yaşamına yerleşmiş, çoğu kişinin sorgulamadan benimsediği bir tedavi yöntemi hâline gelmiştir. Günümüzde dünya nüfusunun yaklaşık %80'inin tercih ettiği bitkisel tedaviler, Tıbbın babası kabul edilen Hipokrat da dâhil olmak üzere birçok önemli tarihi ismin katkılarıyla şekillenmiştir. Yüzyıllar önce tarif edilen bitkisel ilaçların kişiden kişiye değişen etkiler gösterebileceği ve deneysel çalışmalarla çeşitli karışımların oluşturulabileceği bilgisi, modern tıp dünyasında uygulanan tedavi yaklaşımlarının temelini oluşturmuştur (Özdemir ve Erdal, 2021).

Bitkilerin ürettiği doğal ürünler olan sekonder metabolitler (Terpenler, fenolik bileşikler ve azotlu bileşikler) doğrudan ve dolaylı olarak fitoterapinin kaynağını oluşturmaktadır. Bitkilerin

büyümeleri ve gelişmeleri sırasında çok fazla işlevleri olmayan çok sayıda ve çeşitli organik bileşikler olan sekonder metabolitler, ikincil ürünler veya doğal ürünler olarak da adlandırılırlar (Tiring ve ark., 2021). Daha sonra yapılan çalışmalarda sekonder metabolitlerin bitkilerin zararlılara, hastalıklara, olumsuz çevre koşullarına karşı dayanıklılık oluşturması ve bazı yabancı otlara karşı allelopatik etki göstermesinden dolayı bitkinin yaşamsal işlevi açısından en az birincil metabolitler kadar önemli olduğu tespit edilmiştir.

Sekonder metabolitler canlıların sağlığı üzerinde koruyucu ve destekleyici etkileri nedeniyle günümüzde pek çok endüstride ham madde olarak değerlendirilmektedir. Tıp ve eczacılıkta yaygın kullanım alanı bulmalarının yanı sıra fonksiyonel gıdalar ve besin takviyelerinde de önemli bir yere sahiptirler. İlk kez 1891 yılında tanımlanan bu bileşikler, antiinflamatuar, antioksidan, hipoglisemik ve hipolipidemik etkiler göstermektedir. Ayrıca söz konusu bileşikler tromboz ve kanser gelişimine karşı koruyucu nitelik taşıyabildikleri de ortaya konulmuştur. Bu çok yönlü biyolojik aktiviteler, söz konusu bileşiklerin obezite, diyabet, metabolik sendrom, dislipidemi, kardiyovasküler hastalıklar ve kanser gibi çeşitli kronik hastalıkların önlenmesinde potansiyel bir rol üstlenebileceğini düşündürmektedir (Ülger ve Ayhan, 2020).

3. Hayvan Sağlığı ve Beslenmesinde Fitoterapi

Dünya nüfusunun hızla artmasıyla birlikte gıda talebi de önemli ölçüde yükselmiş, bu ihtiyacı karşılamak amacıyla bitkisel ve hayvansal üretimde çeşitli kimyasal maddelerin ve ilaçların kontrolsüz biçimde daha yoğun kullanılmaya başlandığı görülmüştür. Özellikle antibiyotikler başta olmak üzere birçok kimyasalın gıdalarda bıraktığı kalıntılar, tüketicilerde gıda güvenliği konusunda ciddi endişelere yol açmaktadır. Bu kaygıları azaltmak amacıyla gelişen organik üretim anlayışı, son yıllarda pek çok ülkede organik hayvancılığın hızla yaygınlaşmasına neden olmuştur. Organik hayvancılıkta sentetik veteriner ilaçlarının ve antibiyotiklerin kullanımına yönelik kısıtlamalar, alternatif tedavi seçeneklerinin araştırılmasını zorunlu kılmaktadır. Bu doğrultuda, hem insan hem de hayvan sağlığında hastalıkların önlenmesi ve mevcut semptomların hafifletilmesi amacıyla bitkisel kaynaklı ürünlerin kullanılmasını ifade eden fitoterapi uygulamaları önemli bir seçenek olarak öne çıkmaktadır (Yanar ve Aktaş, 2021; Kaymaz ve Gülümser, 2023).

İkinci bileşikler hem rumen fonksiyonlarının korunması hem de hayvansal üretimde verimliliğin artırılması açısından önemli bir yere sahip olduğu çeşitli araştırmalarda ortaya konmuştur. Söz konusu bileşiklerce zengin bitkilerle beslenen hayvanlarda yem tüketiminin yükseldiği ve bunun da ürün miktarı ile kalitesine olumlu yansıdığı bildirilmektedir. Ayrıca flavonoidler ve fenolik maddeler, belirgin antioksidan ve antimikrobiyal aktiviteleri sayesinde ruminantlarda şişkinlik ve asidoz gibi beslenmeye bağlı sorunların kontrol altına alınmasına katkı sağlamaktadır. Doğal antibiyotiklere duyulan ihtiyacı azaltarak hayvan sağlığı ve verimliliği açısından önemli bir avantaj sunmaktadır. Nitekim 2006 yılında hayvan beslemede antibiyotik kullanımına getirilen kısıtlamalar sonrasında, sekonder metabolit içeren bitkiler doğal antimikrobiyal kaynaklar olarak öne çıkmış ve alternatif bir seçenek hâline gelmiştir (Rochfort ve ark., 2008; Santos Neto ve ark., 2009; Frozza ve ark., 2013; Seradj ve ark., 2014; Paula ve ark., 2016; Patra ve ark., 2016; Lee ve ark., 2017; Kaymaz ve Gülümser, 2023).

4. Fitoterapide Öne Çıkan Bazı Bitkiler

Bitkiler, hastalık ve zararlılara karşı savunma amacıyla işlev gören, aynı zamanda çeşitli fizyolojik süreçlerde sinyal molekülü olarak rol alan geniş bir ikincil bileşikler üretmektedir. Bu bileşikler, sahip oldukları çok yönlü biyolojik ve farmakolojik etkiler nedeniyle dikkat çekmektedir. Nitekim pek çok bitki ya da onlardan elde edilen türevler, geçmişten günümüze enfeksiyonların, sağlık bozukluklarının ve çeşitli hastalıkların tedavisinde doğal bir kaynak

olarak kullanılmaya devam etmektedir. Bitkiler ve bitki özütleri ile yapılan birçok çalışmalarda ikincil bileşiklerin çeşitli hasatlıklara karşı kullanılma imkânlarının değerlendirilmesi amacıyla yürütülmüştür (Meenakshisundaram ve ark., 2016; Da Silva ve ark., 2017; Hajaji ve ark., 2018; Giovanelli ve ark., 2018; Saddiqe ve ark., 2019).

4.1. Aslan dişi (*Taraxacum officinale L.*): Papatyagiller (Asteraceae) familyasından, Avrasya'ya özgü, yenilebilir, otsu, çok yıllık bir yabani çiçek veya ottur. Bitkinin yaygın adı, dişli koyu yeşil yapraklarına atıfta bulunarak "aslan dişi" anlamına gelmektedir. Aslan dişinin kültürel olarak yetiştirilmesi yaygın olmamakla birlikte, geleneksel uygulamalarda kök ve yapraklarının çeşitli amaçlarla kullanıldığı bilinmektedir. Besin içeriği incelendiğinde, özellikle yapraklarının protein, karbonhidrat, kalsiyum, magnezyum ve B grubu vitaminler açısından zengin bir bileşime sahip olduğu görülmektedir.

4.2. Sinir otu (*Plantago* spp.): Plantaginaceae familyasından yaklaşık 200 çiçekli bitki türünü kapsayanbir cins olan sinir otu, yüzyıllardır tıbbi amaçlarla kullanılan bir bitki olup geçmişte köpek ısırıkları, astım ve diş ağrısı gibi çeşitli sağlık sorunlarının tedavisinde yararlanılmıştır. Günümüzde ise en uygun değerlendirme alanının mera karışımları olduğu belirtilmekte; ayrıca bitkinin özellikle kalsiyum ve magnezyum bakımından zengin mineral içeriği ile dikkat çektiği bildirilmektedir.

4.3. Hindiba (*Cichorium intybus L.*): Asteraceae familyasından, genellikle parlak mavi, nadiren beyaz veya pembe çiçeklere sahip, odunsu, çok yıllık bir otsu bitkidir. Avrupa'ya özgü olan bu bitki, Amerika ve Avustralya'ya da getirilmiştir. Hindibanın insan tarafından kullanımı çok eski dönemlere uzanmakta olup, Antik Mısır'da kanı ve karaciğeri arındırdığına ve kalp rahatsızlıklarının tedavisinde yararlı olduğuna inanıldığı bilinmektedir. Çiftlik hayvanları tarafından da iştahla tüketilen bu bitki, daha sonra Yeni Zelanda'da ticari olarak yetiştirilerek piyasaya sunulmuştur.

4.4. Soda otu (*Salsola* spp.): Kazayağıgiller (Chenopodiaceae) familyası içerisindeki "Soda otu" (Salsola) içerisinde yer alan endemik bir türdür. Tuzlu, kurak ve ılıman ekosistemlerde yaygın olarak yetişebilen bu bitkiler, yüksek sıcaklık ve tuzluluk düzeylerinde dahi yüksek tohum ve ot verimi sağlayabilmektedir. Diğer kültür bitkilerinin kuruyarak besin değerini kaybettiği dönemlerde ise yüksek protein içerikleri sayesinde alternatif ve değerli bir yem kaynağı olarak öne çıkmaktadır.

4.5. Çayır düğmesi (Sanguisorba spp.): Gülgiller (Rosaceae) familyasından çok yıllık bir bitki türü olan çayır düğmesinin anavatanı batı, orta ve güney Avrupa olmasına karşın, Kuzeybatı Afrika ve Batı Asya'nın güneybatısında ve en çok da Kuzey Amerika'da doğallaşmış durumdadır. Çayır düğmesinin otu, hayvanlar tarafından iştahla tüketilen, lezzetli ve yüksek besleme değerine sahip bir yem bitkisidir. Yeşil olarak otlatıldığında bile şişkinliğe yol açmaması, sindirilebilirliğinin yüksek olmasını göstermektedir. Her ne kadar bazı bitkilere göre protein içeriği daha düşük olsa da, sindirilebilirliği nedeniyle hayvan beslemesinde tercih edilmesi önerilmektedir.

4.6. Yem pancarı (*Beta vulgaris* var.): Etli ve şişkin kökü için yetiştirilen iki yıllık bir bitkidir. Yem pancarı, kolay sindirilebilmesi, yüksek enerji içeriği ve süt ile et verimini artırıcı etkileri nedeniyle değerli bir yem bitkisi olarak kabul edilmektedir. Yüksek kuru madde verimi sayesinde silaj yapımında da kullanılabilen bu bitki, özellikle süt veriminde belirgin artış sağlamasıyla dikkat çekmektedir.

4.6. Taş yoncaları (*Melilotus* spp): Sarı ve beyaz çiçekli olan taş yoncaları, Fabaceae familyasından baklagiller bitkileridir. Azot sabitleyici özelliğe sahip olan Melilotus albus, değerli bir bal bitkisi olarak kabul edilir, nektar kaynağıdır ve genellikle yem bitkisi olarak yetiştirilir. Taş yoncaları, düşük tanen içeriği sayesinde besin maddelerinin emilimini artırırken, yüksek lif oranı sindirim sisteminin sağlıklı işleyişine katkı sağlar; bu özellikleri ruminant hayvanlar için büyük önem taşımaktadır. Ayrıca yüksek protein, vitamin ve mineral içeriği ile besleyici bir yem kaynağı olan taş yoncası, özellikle süt inekleri ve besi hayvanları için ideal bir tercih olarak öne çıkmaktadır.

4.7. Şerbetçi otu (*Humulus lupulus* L.): Cannabaceae (kendirgiller) familyasından Temmuz-Eylül ayları arasında yeşilimsi-beyaz renkli çiçekler açan, 2–5 m yüksekliğinde, sarılıcı gövdeli, iki evcikli otsu bir bitki türüdür. Şerbetçi otu, içerdiği sekonder metabolitler sayesinde hayvanların büyümesini destekler ve rumende amonyak üretimini inhibe ederek hayvansal kaynaklı sera gazı emisyonlarının azaltılmasına katkıda bulunur. Ayrıca doğal bir antibiyotik işlevi görmesi, dışarıdan sentetik antibiyotik kullanımını sınırlayarak hayvan sağlığı ve üretiminde önemli avantajlar sağlar.

Tablo 1. Farklı bitkilerde belirlenen bazı ikincil bileşikler

Bitki Adı	KT	TFN	TFL	DPPH	TA
Sinir otu (*Plantago* spp.)	1.0-5.0	11.73	9.74	18.27-86	0.1-0.5
Hindiba (*Cichorium intybus* L.)	0.5-1.5	16.2	5.38	20-79	0.1-5.0
Aslandişi (*Taraxacum officinale* L.)	5.0-10.0	40.50	33.58	30-90	1.0-5.0
Soda otu (*Salsola* spp.)	3.0-5.0	10.7	20.00-50.00	27.3-90	0.1-1.0
Çayır düğmesi (*Sanguisorba* spp.)	1.0-3.0	15.00	10.00-30.00	25-90	0.1-4.0
Yem pancarı (*Beta vulgaris*)	0.1-0.5	40.06	30.08	7.79-75	0.01-0.1
Şerbetçi otu (*Humulus lupulus* L.)	1.38-5.42	11.38-43.41	11.87-13.32	15.6-81.7	2.95-3.72
Taş Yoncası (*Melilotus officinalis*)	0.5-1.5	10.00-50.00	20.00-150.00	40-80	0.1-0.5

KT: Kondanse tanen (%); TFN: Toplam fenolik (mg GA g^{-1}); TFL: Toplam flavonoid (mg QE g^{-1}); DPPH: Radikal kovucu aktivite (%); Total alkaloit (%).

Farklı araştırmacılar tarafından yapılan çalışmalarda bazı bitkilerde belirlenen ikincil bileşikler Tablo 1'deverilmiştir (Uyar, 2012; Yıldırım, 2018; Karadağ, 2019; Kaymaz ve Gülümser, 2023). Bitkilere bakıldığında içerikler bakımından varyasyonu geniş olduğu görülmektedir.

5. Sonuç

Fitoterapi, geçmişten günümüze hem insan hem de hayvan sağlığında önemli bir yere sahip olan, doğal ve etkili bir tedavi yaklaşımıdır. Tıbbi bitkilerin içerdiği sekonder metabolitler; antioksidan, antimikrobiyal, antiinflamatuar ve rumen fonksiyonlarını düzenleyici özellikleri sayesinde hayvan besleme ve sağlığında güçlü bir alternatif oluşturmaktadır. Ruminantlarda şişkinlik, asidoz gibi beslenmeye bağlı problemlerin kontrol altına alınmasında, yem tüketiminin iyileştirilmesinde ve hayvansal ürünlerin verim ile kalitesinin artırılmasında fitoterapik bileşiklerin önemli rol oynadığı çeşitli araştırmalarla ortaya konmuştur. Ayrıca bu bileşiklerin doğal antibiyotik olarak işlev görmesi, özellikle antibiyotik kullanımının sınırlandırıldığı modern hayvancılıkta büyük avantaj sağlamaktadır.

Fitoterapik özellikler taşıyan bitkilerin hem yüksek besleme değerleri hem de fizyolojik süreçlere olumlu etkileri, bu bitkilerin hayvan besleme programlarına entegre edilmesini cazip hâle getirmektedir. Özellikle sürdürülebilir hayvancılık, organik üretim ve çevresel etkilerin azaltılması açısından sekonder metabolitlerce zengin bu bitkilerin kullanımının yaygınlaştırılması önem arz etmektedir.

Sonuç olarak, fitoterapi; hayvan sağlığının korunması, verimliliğin artırılması, antibiyotik kullanımının azaltılması ve çevresel sürdürülebilirliğin desteklenmesi açısından modern hayvancılıkta güçlü bir tamamlayıcı unsur olarak öne çıkmaktadır. Bu alanda yapılacak daha kapsamlı ve kontrollü çalışmalar, bitkisel bileşiklerin hayvansal üretimde daha bilinçli ve etkin kullanımına katkı sağlayacaktır.

ÖZET

Ülkemizde tarım işletmelerin genel anlamda küçük aile işletmeleri şeklinde olması ve bu işletmelerin tarımsal risklerle baş etmede zorluk yaşamaları, üreticilerin gelir dağılımında eşitsizlikleri ortaya çıkarmış ve bu da tarımın desteklenmesini zorunlu hale getirmiştir. Gelişmiş ya da gelişmekte olan birçok ülkede tarım sektörü yıllardır desteklenmektedir. Bu desteklerin çeşidi ve miktarı yıllara göre değişiklik göstermekte olup, tarım kesimindeki gelir dağılımını düzenlemeyi ve bu kesimin refah düzeyini yükseltmeyi amaçlamaktadır. Bu doğrultuda kırsal kalkınma projeleri, tarımla uğraşan kesime yönelik en önemli politikalardan biri olmuştur. Bilecik ilinin son verilere göre nüfusu 228.673 kişi olup, bu nüfusun sadece %15'i kırsalda ikamet etmektedir. Bilecik ili 8 adet ilçeye ve 243 adet köye sahiptir. İlin toplam tarım alanı 125.000 ha iken, ÇKS (Çiftçi Kayıt Sistemi) sistemine kayıtlı çiftçi sayısı 9.000 kişi, HBS (Hayvancılık Bilgi Sistemi) kayıtlı işletme sayısı 4.900 dür. Kırsal Kalkınma Destekleri kapsamında yapılan projeler ile çiftçilere son 20 yılda toplam 1.851 adet projeye 198 milyon TL hibe desteği verilmiştir. Kırsalda yaşayan gençlere teşvik kapsamsında bitkisel ve hayvansal üretim amaçlı projeler ile 385 kişiye istihdam sağlanmıştır. Kırsal kalkınma projelerinin amacı tarımda makineleşmenin artırılarak işgücü maliyetini düşürmek, entansif yetiştiricilikle daha kontrollü bir üretim sağlamak ve yapılan ges projeleriyle yenilenebilir enerji üreterek dışa bağlı enerji ihtiyacını azaltmaktır. Kırsal kalkınma projelerinin diğer bir amacı da eğitim, sağlık ve sosyal alanlar da yatırımlar yaparak köyden kente göçün önüne geçmektir. Bilecik ili de kırsal da çok fazla göç veren iller arasında yer almaktadır. Bu doğrultuda kırsala olan yatırımlar önem taşımaktadır. Bu derleme ile Bilecik ilinde yapılan tarımsal desteklerin kırsal kalkınma üzerindeki etkilerinin ortaya konması amaçlanmaktadır.

Anahtar kelimeler: Bilecik, kırsal kalkınma, tarımsal destekleme, göç.

THE SITUATION OF RURAL DEVELOPMENT SUPPORTS IN BILECIK

ABSTRACT

In our country, the fact that agricultural enterprises are generally small family farms and that these farms have difficulties coping with agricultural risks has led to income inequalities among producers, making it necessary to support agriculture. In many developed and developing countries, the agricultural sector has been supported for many years. The type and amount of these supports vary from year to year and aim to regulate income distribution in the agricultural sector and increase the welfare level of this population. In this context, rural development projects have become one of the most important policies for those engaged in agriculture. According to the latest data, the population of Bilecik is 228.673, of which only 15% reside in rural areas. Bilecik has 8 districts and 243 villages. The total agricultural land of the province is 125.000 hectares, with 9.000 registered farmers in the Farmer Registration System and 4.900 registered enterprises in the Livestock Information System. Within the scope of Rural Development Supports, a total of 1.851 projects have received 198 million TL in grant support over the last twenty years. Through projects promoting plant and animal production, 385 young people living in rural areas have been provided with employment opportunities. The aim of rural development projects is to increase mechanization in agriculture to reduce labor costs, ensure more controlled production through intensive farming, and decrease dependence on external energy sources by producing renewable energy through solar energy projects. Another aim of rural development projects is to prevent rural-to-urban migration by investing in education, health, and social fields. Bilecik Province is among the regions with a high rate of outmigration from rural areas. In this regard, investments in rural regions are of great importance. This review aims to reveal the effects of agricultural support programs on rural development in Bilecik.

Keywords: Bilecik, rural development, agricultural support, migration.

1. Giriş

Kırsal kalkınma, tarımsal üretimin sürdürülebilirliği, gelir dağılımındaki dengesizliklerin azaltılması ve kırsal yaşam kalitesinin yükseltilmesi açısından büyük önem taşır (Özdemir ve Polat, 2019). Kırsal bölgelerde yürütülen kalkınma çalışmaları, modern üretim tekniklerinin yaygınlaşmasını sağlayarak verimliliği artırırken, eğitim, sağlık, ulaşım ve altyapı hizmetlerinin geliştirilmesiyle sosyal refahı güçlendirir. Ayrıca ekonomik faaliyetlerin çeşitlendirilmesi, kırsal nüfusun kentlere göç etme eğilimini azaltır ve bölgesel kalkınma farklarının kapanmasına katkıda bulunur. Çevresel sürdürülebilirliğin desteklenmesi ve doğal kaynakların bilinçli kullanımı da kırsal kalkınmanın temel unsurları arasında yer alır. Bu nedenle kırsal kalkınma, hem toplumun genel refahı hem de ülkenin ekonomik ve sosyal dengesi için stratejik bir önem taşır (Ata ve Dallı, 2024).

Ülkemizde tarım işletmelerinin çoğunlukla küçük ölçekli aile yapısında olması ve bu işletmelerin tarımsal riskler karşısında yeterince dayanıklı olamaması, üreticiler arasında gelir dengesizliklerinin ortaya çıkmasına yol açmıştır. Bu durum, tarım sektörüne yönelik desteklerin kaçınılmaz hâle gelmesine neden olmuştur. Gerek gelişmiş gerekse gelişmekte olan pek çok ülkede tarım sektörü uzun yıllardır çeşitli şekillerde desteklenmektedir. Söz konusu desteklerin türü ve kapsamı zaman içinde değişse de temel amaç, tarımsal gelirlerin daha adil bir şekilde dağılmasını sağlamak ve tarım kesiminin yaşam standartlarını yükseltmektir (Coşkun ve İnan, 2016).

Bilecik, 4.307 km² yüzölçümü ile Türkiye'de iller arasında alan bakımından küçük sayılır. Ekonomi büyük ölçüde tarım ve hayvancılığa dayanır; ilde tarla bitkileri, sebze-meyve üretimi, seracılık, meyvecilik, ipekböcekçiliği, arıcılık ve hayvancılık gibi üretim faaliyetleri yaygındır. Ancak, tarım alanlarının toplam arazi içindeki payı sınırlıdır. Bilecik'te yaklaşık %29'u tarım alanı, % 53'ü orman, %1.4'ü çayır-mera ve geriye kalan kısım yerleşim ya da tarıma elverişsiz arazilerden oluşur (Anonim, 2025a).

Bu derleme ile Bilecik ilinde tarımsal desteklemelerinin kırsal kalkınma üzerindeki etkilerinin ortaya konması planlanmaktadır.

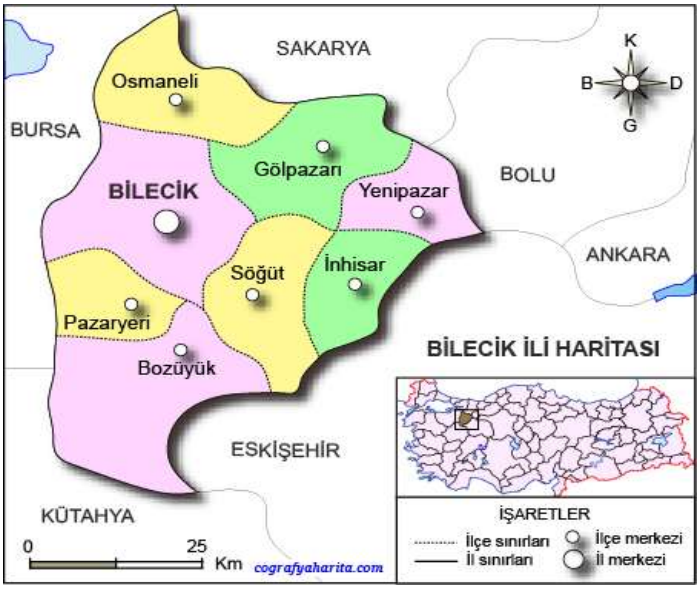
2. Bilecik ilinde gerçekleşen tarımsal desteklemeler

Tablo 1'de Bilecik ilinin son 20 yıldaki tarımsal desteklemeleri verilmiştir. Sayı bakımından makine ekipmanları ilk sırayı alırken, bunu 412 adet proje ile gen çiftçi yatırımları izlemiştir. Diğer taraftan en fazla bütçe 46 milyon ile diğer projeler (Et-süt işleme tesisi, boza üretim tesisi, yumurta paketleme, su ürünleri üretimi işleme ve paketleme tesisi ve meyve sebze paketleme tesisleri) ile 40 milyon ile kümes yapımlarının olduğu görülmektedir. Son dönemlerde dikkat çeken güneş enerji sistemleri (GES) Bilecik ilinde de gitgide popüler bir yatırım haline gelmiştir. Bilecik ilinin tarımsal yelpazesi oldukça geniştir. Örtü altı yetiştiriciliğinin de yoğun olarak yapıldığı ilde, söz konusu tarımsal üretim için 23 adet proje desteklenmemiştir (Anonim, 2025b).

Bilecik ilinde son 20 yılda uygulanan tarımsal desteklemeler, kırsal kalkınmayı hem ekonomik hem de yapısal açıdan önemli ölçüde güçlendirmiştir. Özellikle makine ve ekipman desteklerinin sayı bakımından ilk sırayı alması, üretimde modernizasyonun hızlandığını ve çiftçilerin verimliliklerinin arttığını göstermektedir. Genç çiftçi yatırımlarının 412 proje ile yüksek bir paya sahip olması, genç nüfusun tarımsal faaliyetlerde kalmasını teşvik ederek kırsal alanda istihdamı ve demografik canlılığı desteklemiştir. Et-süt işleme, paketleme tesisleri ve kümes yapıları gibi yüksek bütçeli yatırımlar ise tarımsal katma değer yaratma kapasitesini artırarak yerel ekonominin çeşitlenmesine katkı sağlamıştır. Son yıllarda popülerleşen GES projeleri, kırsal alanda yenilenebilir enerji kullanımını yaygınlaştırarak sürdürülebilir

kalkınmayı desteklemiştir. Örtü altı yetiştiriciliği ve kırsal turizm gibi farklı alanlardaki yatırımlar da Bilecik'in tarımsal yelpazesini genişletmiş, kırsal ekonomiyi çok yönlü hale getirmiştir. Toplamda 1851 projenin 197 milyon TL bütçeyle desteklenmiş olması, bu yatırımların Bilecik'te kırsal kalkınmayı hem ekonomik hem sosyal açıdan önemli ölçüde teşvik ettiğini ortaya koymaktadır.

Tablo 1. 2004-2024 yılları Toplam Proje Durumu



Proje Konusu	**Sayısı**	**Hibe Tutarı**
Kırsal Turizm Kapsamında Otel Projesi	2	2.707.974,69
GES Projeleri	7	19.130.462,53
Ahır-Ağıl Yatırımları	7	18.741.725,27
Örtüaltı Yetiştiriciliği	23	30.721.784,86
Broiler Kümes	21	40.277.568,71
Genç Çiftçi Projeleri	412	12.360.000,00
Makine Ekipman	1.340	27.033.586,58
Diğer Projeler	39	46.977.109,52
Toplam	**1.851**	**197.950.212,16**

3. Bilecik ili nüfusu

Bilecik ilinin toplam nüfusu 2024 yılı sonu itibarıyla **228.495** kişidir. Bu nüfusun yaklaşık %50.56'sı erkek (115.524 kişi), %49.44'ü ise kadın (112.971 kişi) olarak kaydedilmiştir. İl merkezinin nüfusu (merkez ilçe) 2024'te **82.403** kişi olarak açıklanmıştır. İlçe bazında bakarsak; 2024 itibarıyla en kalabalık ilçeleri sırasıyla merkez ile Bozüyük ilçesi (80.865 kişi) izlemektedir (Anonim, 2025a).

4. Bilecik ili tarımsal potansiyeli

Marmara, Karadeniz, İç Anadolu ve Ege Bölgelerinin kesim noktaları üzerinde, dört coğrafi bölgede toprakları olan Türkiye'deki tek ildir. Kuzey Anadolu dağlarının denizden içeriye doğru ikinci serisi olan Köroğlu Dağları ilin topraklarında başladığından arazinin batıdan doğuya doğru birden yükselmesine neden olur. Bozüyük Ovası ve Sakarya ırmağı ile kuzey-güney yönünde iki bölüme ayırır ve dağlar bu ırmağın her iki yakasında devam eder. Bilecik ilinin deniz seviyesinden yüksekliği 500 metredir. İlin en yüksek noktası Bozüyük ilçesinin batı ve güneybatısında yer alan yükseltiler üzerindeki Kala Dağı'dır (1906 m). Genellikle Sakarya Irmağı boyunca uzanan çok geniş olmayan düzlükler şeklinde ovalar il topraklarının % 7'lik bir bölümünü kaplar. Bozüyük, Gölpazarı, Osmaneli ve Pazaryeri Ovaları başlıca düzlük alanlardır. İlde yayla tanımı içerisine sokulabilecek düzlükler çok azdır. Yağış yönünden yeterli miktara sahip olan Bilecik ili, yüzölçümünün %47'sinin ormanlık alan olması nedeniyle hem bitki hem de hayvan bakımından zenginleşmesini sağlamıştır (Anonim, 2025c).

Şekil 1. Bilecik ili ve ilçeleri (Anonim, 2025d)

Bilecik ilinin **yaklaşık % 29.0**'u tarım arazisi, **% 1.4**'ü çayır-mera, **% 53.1** kadarı orman arazisi ve geriye kalanı (yaklaşık %16.5) yerleşim alanı ile tarıma elverişsiz arazi olarak dağılım göstermektedir. Tarım arazilerinin içinde ise tahıl (buğday, arpa, yulaf, vb), yem bitkileri, endüstri bitkileri, sebze ve meyve yetiştiriciliği gibi farklı kategoriler yer almaktadır. Özellikle son yıllarda örtü altı (sera) üretimi, sebze ve meyve bahçeciliği, yağlık ayçiçeği gibi endüstri bitkileri, meyvecilik ve sebzecilik gibi üretim dallarında çeşitlilik vardır. Örneğin, ilde yağlık ayçiçeği ekim alanı 2024 itibarıyla 90.000 dekara ulaşmış; bu alanda dekardan 350 kg'a yaklaşan verim alınmakta; üretim miktarı ve verim artışı ile Bilecik yağlık ayçiçeği üretiminde öne çıkan illerden biri haline gelmiştir.

5. Sonuç

Bilecik ilinde son 20 yılda uygulanan kırsal kalkınma desteklemeleri, hem tarımsal üretimin çeşitliliğini hem de kırsal yaşamın ekonomik gücünü önemli ölçüde artırmıştır. Makine-ekipman yatırımlarından genç çiftçi projelerine, örtü altı yetiştiriciliğinden GES uygulamalarına kadar geniş bir yelpazede sağlanan 1.851 proje ve yaklaşık 198 milyon TL'lik destek, ilde tarımsal modernleşmenin hızlanmasına katkı sağlamıştır. Coğrafi ve ekolojik çeşitliliği ile farklı üretim desenlerine elverişli olan Bilecik, özellikle yağlık ayçiçeği, sebze-meyve yetiştiriciliği ve örtü altı üretimde bölgesel ölçekte rekabet gücünü artırmaktadır. Kırsal turizm ve yenilenebilir enerji yatırımlarının da desteklenmesi, kırsal ekonominin sadece tarım odaklı değil, daha çok yönlü bir yapıya doğru evrildiğini göstermektedir. Genel olarak değerlendirildiğinde, Bilecik ilinde verilen tarımsal desteklerin kırsal kalkınmayı güçlendirdiği, üretici gelirlerini artırdığı ve kırsal alanda sürdürülebilir ekonomik büyüme için önemli fırsatlar sunduğu söylenebilir. Bu kapsamda, mevcut desteklerin niteliğinin geliştirilmesi ve üretici ihtiyaçlarına göre çeşitlendirilmesi, ilin tarımsal potansiyelinin daha etkin şekilde kullanılmasına katkı sağlayacaktır.

SUMMARY

Solid tumours remain one of the most challenging forms of cancer due to poor drug penetration, immunosuppressive tumour microenvironments, and systemic toxicity associated with conventional therapies. Stimuli-responsive nanoparticles (NPs) enable controlled and targeted drug delivery by responding to internal stimuli, such as pH, enzymes, and redox potential, or external triggers, such as light, heat, and ultrasound. When combined with immunotherapy, NPs enhance cytotoxic T cell activation, improve antigen presentation, and modulate immunosuppressive cells, boosting anti-tumour immune responses. Preclinical studies demonstrate improved therapeutic efficacy and reduced toxicity with NP-assisted immunotherapy (Srivastava et al., 2023). This paper explores NP design, stimuli-responsive mechanisms, synergistic immunotherapy, multifunctional theranostic platforms, challenges, and future directions for clinical translation.

INTRODUCTION

Solid tumours account for the majority of cancer-related deaths worldwide. Conventional chemotherapy and immunotherapy often fail due to limited penetration into the tumour and the immunosuppressive tumour microenvironment. Immunotherapy—including checkpoint inhibitors and adoptive T cell therapies—has significantly advanced cancer treatment; however, its effectiveness against solid tumours is often restricted by poor immune cell infiltration and inadequate antigen presentation (Chen et al., 2022).

Nanotechnology provides innovative solutions for these challenges. Stimuli-responsive nanoparticles (NPs) can release therapeutic payloads selectively at the tumour site. Internal triggers such as acidic pH, elevated enzyme activity, and reactive oxygen species (ROS) levels enable selective activation within the tumour microenvironment. External triggers, such as near-infrared (NIR) light, focused ultrasound, or mild hyperthermia, provide spatiotemporal control over payload release (Wang et al., 2021; Srivastava et al., 2023).

By integrating NP-mediated delivery with immunotherapy, this approach enhances tumour targeting, boosts immune response, and reduces systemic toxicity. This interdisciplinary strategy, bridging materials science, biomedical engineering, and immunology, offers a promising avenue for next-generation cancer treatment.

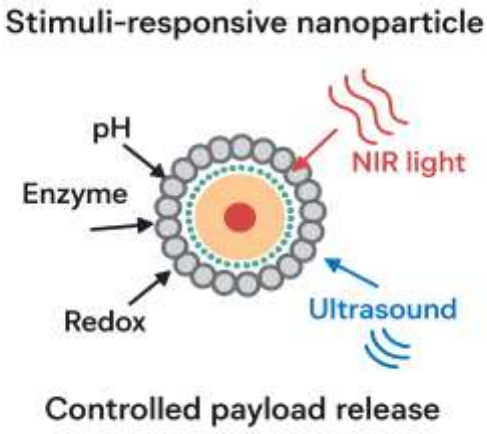

Figure 1: Schematic of Stimuli-Responsive Nanoparticle Mechanisms

Figure 1 illustrates the core mechanisms of stimuli-responsive nanoparticles, including TME-triggered cargo release, improved immune cell infiltration, and enhanced antigen presentation.

RESEARCH AND FINDINGS

Design of Stimuli-Responsive Nanoparticles

Stimuli-responsive NPs are engineered to respond to specific triggers, allowing controlled release at the tumour site.

Internal stimuli include:

- **pH-sensitive NPs:** Degrade in acidic tumour microenvironments.
- **Enzyme-responsive NPs:** Activated by matrix metalloproteinases (MMPs) overexpressed in tumours.
- **Redox-responsive NPs:** Triggered by elevated intracellular ROS levels.

External stimuli include

NIR light, focused ultrasound, magnetic fields, and heat.

NP platforms include lipid-based, polymeric, and inorganic systems:

- **Lipid NPs:** High biocompatibility, prolonged circulation.
- **Polymeric NPs:** Tunable degradation, multifunctional capacity.
- **Inorganic NPs:** (e.g., gold, silica) photothermal therapy and imaging capabilities (Liu et al., 2020; Srivastava et al., 2023).

Table 1. Summary of Preclinical Studies

NP Type	Stimulus	Immunotherapy Combined	Outcome	Reference
Polymeric NP	pH-sensitive	Checkpoint inhibitor	Tumour regression	Wang et al., 2021
Lipid NP	Enzyme-sensitive	T cell therapy	Reduced systemic toxicity	Chen et al., 2022
Gold NP	NIR light	Cytokine delivery	Enhanced T cell infiltration	Liu et al., 2020
RBC Membrane-coated NP	Single-wavelength NIR	Biomarker estimation	Tumour delineation and immune modulation	Srivastava et al., 2023

Mechanisms for Controlled Drug Release

Stimuli-responsive NPs release immunotherapeutic agents selectively at the tumour site. For instance, pH-sensitive polymeric NPs degrade in acidic environments, releasing checkpoint inhibitors directly into tumour tissues. Enzyme-responsive NPs activate in the presence of MMPs. External triggers, such as NIR light, allow on-demand release, providing high spatiotemporal precision and minimizing systemic toxicity (Shi et al., 2017; Srivastava et al., 2023).

Synergy with Immunotherapy

NPs enhance immunotherapy by improving:

- Cytotoxic T cell infiltration
- Antigen presentation
- Reduction of regulatory T cells and myeloid-derived suppressor cells (MDSCs)

Preclinical studies indicate that NP-assisted immunotherapy combined with checkpoint inhibitors or adoptive T cell therapy significantly improves tumour regression and reduces off-target toxicity (Chen et al., 2022; Wang et al., 2021; Srivastava et al., 2023).

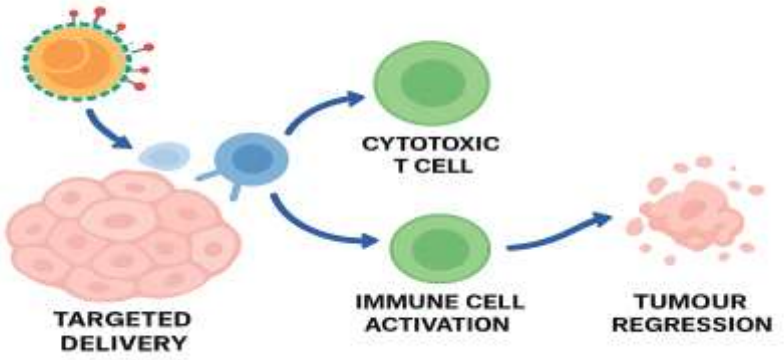

Figure 2 Overview of Nanoparticle–Immune System Interactions

Figure 2 shows major interactions between nanoparticles and the immune system, including dendritic cell activation, antigen cross-presentation, and activation of cytotoxic T lymphocytes (CTLs).

Multifunctionality and Theranostics

Multifunctional NPs integrate therapy and imaging (theranostics). Imaging agents such as fluorescent dyes or MRI contrast agents can be incorporated into the NPs, allowing monitoring of NP distribution and treatment efficacy. Recent studies show that RBC membrane-coated nanoparticles can delineate tumour regions and estimate biomarker expression with a single excitation wavelength, highlighting the versatility of NP platforms for both therapeutic and diagnostic applications (Srivastava et al., 2023).

Challenges and Optimization

Despite promising results, challenges remain:

- Biocompatibility and long-term safety of NPs.
- Tumour heterogeneity, affecting NP penetration and uniformity.
- Stability and shelf-life of NPs.

Optimization strategies include surface functionalization with targeting ligands, size control, and multifunctional design for combined therapy and imaging.

CONCLUSION

Stimuli-responsive nanoparticle-assisted immunotherapy provides a versatile strategy to overcome limitations of conventional solid tumour treatments. By combining nanotechnology with immunotherapy, this approach enables targeted, controlled, and safer therapy while enhancing immune responses. RBC membrane-coated and other functionalized nanoparticles demonstrate potential for combined therapy and real-time diagnostic imaging. Future research should focus on clinical translation, optimizing NP biocompatibility, tumour specificity, and the development of multifunctional theranostic platforms. This interdisciplinary approach bridges engineering and biomedical sciences, paving the way for next-generation cancer therapeutics.

ABSTRACT

This study evaluated the growth performance and feed utilization efficiency of *Clarias gariepinus* fed diets with graded levels of Beni seed meal substituting fish meal. A total of three hundred and sixty (360) *Clarias gariepinus* of the same age, with a size of 5.0±0.20 cm, were stocked in six dietary treatments (DT1 to DT6) with varying levels of Beni seed meal (0% to 100%) and monitored over the experimental period. Feed formulation followed Pearson's square method, maintaining a 40% crude protein level. Data on weight gain, specific growth rate (SGR), feed conversion ratio (FCR), and protein efficiency ratio (PER) were statistically analyzed using ANOVA. Results indicated that diet DT4 (50% Beni seed, 50% fishmeal) yielded the best performance, with the highest final length (25.67±2.5 cm), weight gain (8.47±5.04 g), SGR (1.22±0.18), PER (7.80±0.97), and lowest FCR (3.24±0.40). Complete replacement (DT6) significantly reduced growth and feed utilization, likely due to the presence of anti-nutritional factors. Survival rates were generally high across treatments, with DT4 and DT3 achieving the highest rates (99.00% and 98.67%, respectively). In conclusion, partial substitution of fishmeal with Beni seed meal up to 50–75% significantly enhances growth rate and feed efficiency in *Clarias gariepinus*, making it a sustainable and cost-effective alternative. It is recommended that further studies explore processing techniques (e.g., fermentation) to reduce anti-nutritional factors and evaluate the use of Beni seed meal in other fish species.

Keywords: Growth performance, fish feed, *Clarias gariepinus*, Beni seed, and diets

INTRODUCTION

Fish farming (aquaculture) has also become a valuable source of global food security, needing to offer humanity a stable source of protein (FAO, 2020; Naylor et al., 2000). Catfish (*Clarias gariepinus*) farming is one of the most promising ventures in the aquaculture sector in Nigeria, and this is attributed to their rapid growth and ability to withstand. *Clarias gariepinus* has been identified as among the most popular cultivated freshwater fish in Nigeria, since it can be adapted to suit differing environmental factors, grows fast, and can be reared in an intensive way. It is favored among fish farmers because of its economic significance as a source of income and food security, where it is flourishing in a variety of culture systems throughout the country. Its ability to endure, withstand diseases, and high-feed ratio ensures that its use is preferred in the aquaculture industry in Nigeria, which is playing a critical role in fulfilling the growing demand for fish protein locally and internationally (Olaleye et al., 2024; Olapade and George, 2019). The most conventional protein meal in fish meals and diets is fish meal, which is a necessary source of essential amino acids that enable optimal growth; nevertheless, its high cost and insufficient supply have prompted the search for low-cost and, at the same time, sustainable alternatives (Abdelhedi et al., 2021). As alternatives, partial substitutes have been tested using plant-based sources of protein like the soybean meal and sunflower meal, which are readily available and contain reasonably good protein content. Research indicates that substitution of fish meal with these vegetable proteins, which usually contain synthetic amino acids, may sustain or even improve growth performance, feed consumption, and health condition of *C. gariepinus* in a way that there is no negative effect on liver and kidney functions (Abdelhedi et al., 2021; Adeyemo et al., 2024). However, the most common plant-based source of protein utilized in the composition of fish meal is soybean (Adesina, 2017; Ndatsu et al., 2022). Nature has excess plants, which may be used as a source of plant-based protein that would substitute soybeans, which are economical and easily accessible, and thus help reduce the price of fish meal (Adesina, 2017; Ndatsu et al., 2022). Beni seed (*Sesamum indicum*) is a Pedaliaceae species that is prevalent in Asian and African nations (Dossa et al., 2023; Garbia et al., 2000). But it is generally referred to as Beniseed in Nigeria. The small, round grain is consumable and tastes like milk and flowers. The oil is also used in cooking and to make margarine and pharmaceuticals. Beni seed oil has also been reported to have the antioxidant beta-carotene and steroids (Wei et al., 2022). A report by Njoku et al. (2010) indicates that *Sesame indicum* seed oil and oil extracts have practical applications as nutritional supplements in animal diets. It is a significant oil resource, which was deemed to have originated in tropical Africa, where the rank of diversity is the most incredible (Raw Materials Research and Development Council [RMRDC], 2004). The seed is eaten fresh, dried, or fried, or mixed with sugar. As a paste, it is also used in certain local soups. Beni seed has been extensively utilized as a protein supplement in fish diets because of its good nutritional composition in terms of digestibility, growth, and use of the feed in domestic animals (Madina and Agbaji, 2021; Otuu and Obeta, 2024). According to Yakubu et al. (2020), Beni seed meal supplementation of *Clarias gariepinus* diets showed an excellent effect on growth parameters, such as weight gain, specific growth rate, protein efficiency ratio, feed intake, and survival rate. Due to its decreasing supply and increasing price, fish meal has created significant problems in the aquaculture sector since it is an essential ingredient of food demand (FAO, 2023). As a result, alternative sources of protein, which are affordable, sustainable, and nutritionally competent to be added to aquafeed, are urgently required (Serra et al., 2024). Although Beni seed meal has potential as a fish meal alternative, other species have not been studied extensively (Yakubu et al., 2022). Thus, the purpose of this study is to assess growth performance and feed utilization of *Clarias gariepinus* at graded levels of Beni seed meal that replaces fishmeal in the diets of African mud catfish.

2. MATERIALS AND METHODS

The diet was formulated using beniseed (white cultivar), fishmeal, groundnut cake, and maize bought at Lapai market. Then, healthy *Clarias gariepinus* were purchased at White Light Fish Farm and General Enterprise, along Lapai-Agaie in Niger State.

Sample preparation

Sample processing was done in the Department of Biochemistry laboratory at Ibrahim Badamasi Babangida University, Lapai, Niger State. The white cultivar of Beni seed (*Sesame indicum*) was used for the experiment. The feed ingredients were first sun-dried to constant weight, and then they were subjected to milling to decrease the moisture content. The ingredients were then ground separately in a RICHI SFSP56×40 feed hammer mill (China) that was equipped with a 1.0 mm mesh size, ensuring that all materials were ground to a consistent particle size. The ground ingredients were weighed in the desired proportions for each diet. The amount of each ingredient was determined with a sensitive weighing balance (TH-2000, Hangzhou Gongheng Weighing Equipment Co., Ltd., China). Once the ingredients were mixed thoroughly, cassava starch was introduced as a binding agent to help keep the feed together. The incorporation of hot water resulted in the production of dough for pelleting with a pelleting machine (Hobart A-2007, Hobart LTD, London) that was equipped with a 2 mm die mincer. The dried pellets were then packaged and stored until use.

Stocking and acclimatization of experimental Fish

A total of three hundred sixty (360) *Clarias gariepinus* (African mud catfish) of the same age, with a size of 5.0±0.20 cm, were culled and bought from White Light Fish Farm and General Enterprise, which is situated along the Lapai-Agaie road in Niger State. The fish were carried in aerated containers early in the morning (6:00 am-7:00 am) to the Animal House at Ibrahim Badamasi Babangida University, Lapai, Niger State. They underwent a 2-week acclimatization period and were fed commercial feed twice daily at a rate of 3% of their body weight. Fish were starved for 24 hours before the feeding trial commenced. The length and weight of the fish were recorded as the initial measurements. The water quality parameters, such as temperature, pH, and dissolved oxygen, were continuously monitored, and the water in each tank was replaced when there was a considerable buildup of residual feed and feces as a fish health maintenance measure. The range of water temperature was between 25.00 and 34.00°C, pH varied from 6.00 to 9.2, and the oxygen demand was between 4.00 and 6.10 mg/l.

Feed Formulation and Experimental Design

A total of six diets containing 40% crude protein were designed with the help of the Pearson square method following the NRC (1993) guidelines. They were adjusted according to the methods of Yakubu et al. (2020) and Taheri Mirghaed et al. (2022). A total of six experimental diets consisting of different percentages of Beni (sesame) seed and soybean were made, and the labels were given 1, 2, 3, 4, 5, and 6. The control diet (commercial diet) was represented by Diet 1. Diet 2 contained 0% Beni seed meal and 100% soybean meal, while Diet 3 had 25% Beni seed meal and 75% soybean meal. Diet 5 was composed of 75% Beni seed meal and 25% soybean meal, and Diet 6 consisted of 100% Beni seed meal and no soybean meal.

Experimental Treatment and Design

The experiment consisted of a total of eighteen (18) transparent plastic tanks (60 x 30 x 30 cm), six dietary treatments with three replicates each. Each tank contained 20 fish and was protected by a net to avoid predators. The trial lasted for 12 weeks (90 days), during which fish were fed

the formulated diet at 5% body weight daily (Kumar et al., 2011; Nisarat et al., 2021; Antony et al., 2022).

Sampling of Fish

Fish were sampled every two (2) weeks. Standard length, total length, and weight were determined using a weighing balance and a measuring board. Mortality was also observed and recorded each time a dead fish was found, and the fish was then taken out of the tank.

Growth Performance

Length gain of the fish

This was calculated using the Roberson *et al.* (2000) formula as:

$$\text{Gain in length (cm)} = \text{Mean final length (cm)} - \text{mean initial length(cm)}$$

This was calculated using the Roberson *et al.* (2000) formula as:

$$\text{Weight gain (g)} \quad \text{Mean final weight (g)} - \text{Mean initial weight (g)}$$

Nutrient Utilization

Specific Growth Rate (SGR)

The SGR for each treatment group of the study was estimated using the formula of Effiong *et al.* (2019) as:

$$SGR = \frac{\ln MFW - \ln MIW}{T2 - T1} \times 100$$

Where T1 = time (days) at stocking, T2 = final time (days) at catch,

LnMFW-lnMIW is the difference between the natural logarithm of MFW and MIW

Food conversion ratio (FCR)

$$\text{The FRC was estimated as (FCR)} = \frac{\text{Total Feed Give}}{\text{Total Weight Gain}}$$

The food conversion ratio expresses the rate at which fish convert the food consumed into weight gain (Effiong *et al.*, 2019).

Protein efficiency ratio (PER)

The protein fed to each fish was estimated as the total feed given multiplied by the feed's crude protein percentage.

$$\text{PER was estimated as (PER)} = \frac{\text{Total weight gain of fish}}{\text{Total protein fed of fish}}$$

Survival rate (%)

The number of fish harvested from each treatment at the end of the experiment, along with the initial data collected, was used to calculate the fish's survival rate. The survival rate was determined using the formula of Roberson *et al.* (2000):

$$\text{Survival rate (SR)} = \frac{\text{Number of harvested fishes}}{} \times 100$$

Statistical analysis

The collected data were subjected to one-way Analysis of Variance (ANOVA) and expressed as mean ± SD to test for differences in diet at $p<0.05$ (Zar, 2010). A post-hoc test (Tukey test) was used to rank the differences in means. Statistical Package for Social Sciences (SPSS) version 27 was used as a statistical tool.

3. RESULTS

Growth Performance of Clarias *gariepinus* fed graded levels of Beni seed diets

Table 4.1 indicates the growth response of *Clarias gariepinus* fed experimental diets with graded concentrations of beniseed meal (*Sesame indicum*) as a substitute for fish meal. Diets DT1, DT2, DT3, and DT6 exhibited a lower insignificant difference value of mean length gain (MLG) as 3.86±1.10, 3.40±1.21, 3.07±0.99, and 3.80±1.20 cm, respectively, compared to diets DT4 and DT5, 5.74±1.2 cm and 5.11±1.60 cm. Furthermore, a significantly higher mean weight gain (MWG) was observed in the treatment diets (DT4 and DT5) at 8.47±5.04 and 8.04±5.22 g, respectively, compared to the other diets (DT1, DT2, DT3, and DT6) (Table 4.2).

Table 1: Growth Performance of *Clarias gariepinus* fed graded levels of Beni seed diets

DIETS	IL (cm)	FL (cm)	MLG (cm)	IW(g)	FW(g)	MWG(g)
DT1	19.47±1.62^{a}	23.33±2.3^{a}	3.86±1.10^{a}	6.27±1.58^{a}	11.40±4.30^{a}	4.13±3.28^{a}
DT2	19.93±0.81^{a}	23.33±0.5^{a}	3.40±1.21^{a}	6.77±0.85^{a}	11.20±3.08^{a}	4.43±3.54^{a}
DT3	19.93±0.81^{a}	23.00±1.7^{a}	3.07±0.99^{a}	6.23±2.44^{a}	11.73±0.25^{a}	4.50±2.66^{a}
DT4	19.93±0.81^{a}	25.67±2.5^{b}	5.74±1.2^{b}	6.93±0.93^{a}	15.40±4.98^{b}	8.47±5.04^{c}
DT5	19.89±0.69^{a}	25.00±0.5^{b}	5.11±1.60^{b}	6.63±1.06^{a}	14.67±3.71^{b}	8.04±5.22^{c}
DT6	19.17±1.50^{a}	23.27±0.5^{b}	3.80±1.20^{a}	6.73±2.84^{a}	11.50±6.21^{a}	5.77±4.48^{b}

Data are shown as mean ± SD of three replicates. Means with different superscript letters in each column are significantly different ($p<0.05$). IL: initial length, FL: final length, MLG: mean

length gain, IW: initial weight, FW: final weight, MWG: mean weight gain, DT refers to diets, and DT1 is the commercial diet. DT2 is formulated with 0% Beni seed meal and 100% soybean meal, DT3 is formulated with 25% Beni meal and 75% soybean meal, DT4 contains 50% Beni seed meal, and 50% soybean meal, DT5 is composed of 75% Beni seed meal and 25% soybean meal, DT6 is 100% Beni seed meal and 0% soybean meal.

Feeding Utilization of *Clarias gariepinus* Fed Graded Levels of Beni Seed Diets.

Table 2 shows the feed utilization efficiency of *Clarias gariepinus* fed experimental rations containing various concentrations of Beni seed as a fish meal substitute. There were significant differences ($p < 0.05$) between the control (DT1) and other treatment groups. Specific growth rate (SGR) was significantly greater in fish fed on DT4 and DT5 diets (1.22±0.18 and 1.01±0.43) when compared to fish fed the other diets. The feed conversion ratio, however, was greater in fish fed diets DT1-DT3 (5.88±1.31, 6.86±3.80, and 5.06±0.71) when compared to fish fed diets DT4 and DT5. Tab. 2. Nevertheless, there was no statistically significant difference in survival rate (SR) between fish fed on all diets, except for fish fed on the control diet (DT1), whose SR was (84.67±4.16).

Table 2: Feeding Utilization of *Clarias gariepinus* fed graded levels of Beni seed diets.

DIETS (%)	SGR	FCR	PER	SR
DT1	0.80±0.13^{a}	5.88±1.31^{a}	2.38±0.88^{a}	84.67±4.16^{a}
DT2	0.57±0.36^{a}	6.86±3.80^{a}	3.98±2.78^{a}	93.33±3.51^{b}
DT3	0.70±0.42^{a}	5.06±0.71^{a}	4.16±2.55^{b}	98.67±1.53^{c}
DT4	1.22±0.18^{b}	3.24±0.40^{b}	7.80±0.97^{c}	99.00±1.00^{c}
DT5	1.01±0.43^{b}	4.00±1.70^{b}	7.11±3.15^{c}	94.33±3.79^{b}
DT6	0.56±0.28^{a}	5.06±6.96^{a}	3.81±2.09^{a}	93.00±2.45^{b}

Data are shown as mean ± SD of three replicates. Means with different superscript letters in each column are significantly different ($p<0.05$). DT refers to diets, SGR: specific growth rate, FCR: feed conversion rate, PER: protein efficiency ratio, SR: survival rate, and DT1 is the commercial diet. DT2 is formulated with 0% Beni seed meal and 100% soybean meal, DT3 is formulated with 25% Beni meal and 75% soybean meal, DT4 contains 50% Beni seed meal, and 50% soybean meal, DT5 is composed of 75% Beni seed meal and 25% soybean meal, DT6 is 100% Beni seed meal and 0% soybean meal.

5. DISCUSSION

In any culture system, the growth response of fish indicates how fish respond to feed, whereby they grow in size (Ndatsu et al., 2020). This may mean that the treated fish are using the experimental diets to grow; this is evidenced by the insignificance of the recorded differences in final length, mean length gained, final weight, and mean weight gained when fish are exposed to diets containing DT4 and DT5. Also, there is a possibility that the experimental fish used S. Indicum seed meal, with different percentage ratios, and it was effective, leading to good weight and length gain. This growth may be caused by better absorption of nutrients. There was a significant difference ($p < 0.05$) in initial weight and length among the experimental fish in the

dietary groups, indicating that fish with similar weights in the same stock or age group had different lengths. The ability of Beni seed meal and soybean meals to combine to create an optimal blend of amino acids and fatty acids could also be the cause of the highest growth performance reported in fish fed the diets DT4 and DT5. This is in line with the results of Adebayo and Quadri (2005), who affirm that well-balanced diets of plant protein can be similar to those made of fishmeal. This has been confirmed by recent studies, which indicate that the addition of fishmeal, partially with other plant proteins such as Beni seed meal, can improve the growth of fish in proper proportions (Hussain et al., 2025). Adewolu et al. (2023) suggest that adding up to 50% of alternative plant-based meals to the feeding of *Clarias gariepinus* enhanced the growth parameters and did not affect health. According to Yakubu et al. (2020), Beni seed meal is rich in essential fatty acids and proteins that have the potential to improve the growth of fish. The weight gain indicates that a 50% substitution is an appropriate ratio of the nutrients, though it comes with the cost of poor digestibility. Nevertheless, this decreased growth performance at the levels of DT1, DT2, DT3, and DT6 might be linked to the partial replacement of fish meal at this graded level, which resulted in an unbalanced protein profile that could have influenced the growth performance. The result is in line with the study that has been carried out by Eyo et al. (2020), who propose that a gradual replacement of fish meal with plant-based protein sources needs to be implemented gradually to prevent anti-nutritional factors that may have an influence on digestion. The reduced growth performance in DT6 indicates that a total replacement of fish meal with Beni seed meal may not provide all the essential amino acids for growth. The presence of anti-nutritional compounds, including phytic acid and tannins, which occur at high levels in Beni seed meal, might harm digestibility (Samtiya et al., 2020). The fiber content of Beni seed might also inhibit nutrient absorption, resulting in a decreased growth rate.

Additionally, the utilization of feed by fish within the culture system is also determined by the measurement of important parameters in feed trials. These parameters are specific growth rate (SGR), feed conversion ratio (FCR), protein efficiency ratio (PER), and survival rate (SR), among others. SGR is a term employed in aquaculture to calculate fish production in a given timeframe (Enyidi, 2014; Ndatsu et al., 2022). The increased levels of SGR, which indicated an insignificant difference in fish fed diets (DT4 and DT5), suggest that diets (DT4 and DT5) prepared with different proportions of inclusion percentages of Beni seeds enhanced the growth performance. The observed specific growth rate (SGR) was lower in comparison to values presented in the study of Enyidi (2014) and Fagbero (2000), who recorded considerably higher growth rates. The lowest SGR of the fish-fed diet DT6 is probably due to reduced growth, which may slow down the production rates. One of the key performance indicators (KPI) is a feed conversion ratio (FCR): the ratio of feed measured in kilograms per kilogram of feed consumed to produce a kilogram of fish, and the lower the ratio, the better the feed meal and the feed efficiency. These findings have been supported by the recent investigations that show the fact that reducing FCR diets will lead to better use of nutrients and growth production. It has been established that more positive growth traits are correlated with low values of FCR, and this confirms the efficiency of the feed utilization in aquaculture species (Shi et al., 2024). Furthermore, systematic reviews and meta-analyses have determined that with proper nutritional balance, the replacement of fish meal by plant-protein sources can sustain and even enhance the growth, feed ratio, and the whole health of fish (Hussain et al., 2025; Ahmed et al., 2024). These studies indicate that the optimized plant-protein diets can produce the same results as the traditional fishmeal diets, and this fact supports the application of sustainable and economic aquaculture. The diets of DT4 and DT5 were not significantly differentiated ($p < 0.05$) in the values of FCR but were differentiated significantly compared to other dietary treatments, which means the conversion of this diet toward product is efficient. This could be

the reason why the increase in body weight was high when feeding the fish with DT4 and DT5 was carried out earlier in this study. In addition, the weight gain/protein intake ratio is the weight gain/protein intake. This means that the protein, which is absorbed, may be used completely during growth or an increase in weight. The fact that there is an optimal range of protein use might explain the fact that there is an increase in the value of PER of fish fed diets (DT4 and DT5), which, however, does not differ significantly ($p < 0.05$) from values of the fish fed diets with other dietary treatments. Digestibility and palatability: As Olukunle and Onuegbu (2023) observed, the parameters of digestibility and palatability greatly influence fish feeding with DT Survival Rate (SR), which prevents the negative views of low efficiency of fish fed with DT Survival Rate against available feed in a growth response study. It is employed in order to determine the level of success in any production. It is also required in the establishment of this parameter in feeding trials, as it is the one that is used in establishing the safe level of inclusion of ingredients in formulating the feeds. It prevents increased mortality because there was a higher survival of fish in the experimental diet compared to the control. This may have been attributed to the fact that ammonia content was lower and the stress of the experimental diet was less than that of the control group. This observation falls in line with that of Idowu and Afolayan (2013), though it is not consistent with that of Olapade and George (2019).

Conclusion

Conclusion: This research showed that different proportions of Beni seed (*S. indicum*)-based meal as an alternative to fish meal in *C. gariepinus* diets could be used to increase the growth, feed efficiency, and health and well-being of the fish. The total replacement, however, can lead to nutritional deficiencies, stress, and a slow growth rate because of anti-nutritional factors, and in addition to this, may cause the health and well-being of the fish to degrade. In addition to that, substituting the meal feed of *C. gariepinus* with Beniseed meal may be an economically and nutritionally feasible way of raising a sustainable and economical feed to optimize fish growth. On these results, it might be concluded that the formulated diets (DT4 and DT5) with the inclusion of Beni seeds at 50 percent and 75 percent, respectively. Thus, diets (DT4 and DT5) can emerge to be even more promising than the rest of the diets as they positively impact sufficient growth performance and nutrient use in *C. gariepinus* and can be adopted to create products of different food industries.

Conflict of interest

The authors state that there is no conflict of interest in the article.

Acknowledgments

The authors would also like to acknowledge the guidance and contribution of Dr. Ndatsu Yakubu of the Biochemistry Department and Dr. Mohammed Isah Chado of the Department of Biological Science of Ibrahim Badamasi Babangida University, Lapai, Niger State, to the success of this research study.

ÖZET

Bir akışkan sisteminin performansını belirleyen temel etmenler; sıcaklık, basınç, debi ve basınç yüksekliğidir. Tasarım sürecinde bu parametrelerin dikkate alınması, hedeflenen sistem veriminin sağlanması açısından büyük önem taşır. Bu nedenle, söz konusu değişkenlerin birbirleriyle olan etkileşimlerinin doğru biçimde analiz edilmesi gereklidir. Bu çalışmada, bu dört parametre arasındaki ilişkiyi incelemek amacıyla modüler bir deney düzeneği tasarlanmıştır. Düzenek; akışkana gerekli basıncı sağlayan santrifüj pompa, sıcaklık değişimi için ısıtıcı, debi ölçümü için hacimsel debimetre ve seviye kontrolü için dereceli tanktan oluşmaktadır. Pompa, üç fazlı bir elektrik motoru ile çalıştırılarak sistem basıncının ayarlanabilir olması sağlanmıştır. Tasarım süreci, pompa seçimi ve basınç hesaplarıyla başlatılmış; 0,5 Hp gücünde bir santrifüj pompa tercih edilmiştir. Akış hızı ve debimetre değerleri doğrultusunda boru çapları belirlenmiş, sürtünme kayıpları Darcy–Weisbach denklemiyle hesaplanmıştır. Bu kapsamda borulardaki basınç kaybı 100–200 Pa/m olarak bulunmuş ve DN20 boru tipi seçilmiştir. Farklı akışkanların sıcaklık değişimleriyle test edilebilmesi için 2 kW gücünde bir ısı eşanjörü kullanılmıştır. Elektronik kontrol sistemi için pano tasarımı yapılmış, sistem bileşenleri ağırlık dağılımına göre yerleştirilmiş ve şasi sonlu elemanlar yöntemi (SEY) ile analiz edilmiştir. Von Mises kriterine göre yapılan değerlendirmede şasinin maksimum gerilmesi 6.6 MPa, maksimum yer değiştirmesi ise 0.239 mm olarak hesaplanmıştır. Çalışma, eğitim ve endüstriyel uygulamalarda kullanılabilecek düşük maliyetli, modüler bir test sisteminin geliştirilmesine katkı sağlamaktadır.

Anahtar Kelimeler: Akışkan sistemi, deney düzeneği tasarımı, sonlu elemanlar analizi

DESIGN AND ANALYSIS OF AN EXPERIMENTAL TEST SETUP FOR MULTI-PARAMETER FLUID MEASUREMENTS

ABSTRACT

Temperature, pressure, flow rate, and head are the main parameters that determine the performance of a fluid system. Considering these parameters during the design phase is crucial to achieve the targeted efficiency. Therefore, understanding the interactions among these variables is essential for accurate system analysis. In this study, a modular experimental setup was designed to examine the relationships between these four parameters. The setup consists of a centrifugal pump to provide system pressure, a heater to control fluid temperature, a volumetric flow meter to measure flow rate, and a graduated tank to monitor fluid level. The pump is driven by a three-phase electric motor, allowing adjustable system pressure. The design process began with the selection of the pump and pressure calculations, resulting in the choice of a 0.5 Hp centrifugal pump. Pipe diameters were determined based on the flow rate and flow meter values, while friction losses were calculated using the Darcy–Weisbach equation. The pressure loss in the pipes was found to be between 100–200 Pa/m, and DN20 pipes were selected accordingly. To enable testing with different fluids and temperature variations, a 2 kW heat exchanger was integrated into the system. An electrical control panel was designed, and the components were placed according to weight distribution. The chassis was analyzed using the Finite Element Method (FEM) and evaluated based on the Von Mises criterion. The maximum stress on the chassis was calculated as 6.6 MPa, and the maximum displacement was 0.239 mm. The results indicate that the developed setup provides a low-cost, modular testing system suitable for both educational and industrial applications.

Keywords: Fluid system, experimental setup design, finite element analysis

1.GİRİŞ

Akışkan sistemlerinde sıcaklık, basınç, debi ve seviye; proses mühendisliğinin temel kontrol parametreleri arasında yer almaktadır. Bu değişkenlerin farklı sensör ve düzenekler ile ayrı ayrı ölçülmesi hem zaman hem maliyet açısından verimsiz olmakta, ayrıca senkronizasyon hataları nedeniyle ölçüm doğruluğunu düşürebilmektedir. Bu doğrultuda hazırlanan çalışmanın amacı, söz konusu dört parametrenin tek bir deney düzeneği üzerinde entegre halde ölçülebildiği ve kontrol edilebildiği bir sistem tasarlamaktır.

Analog göstergeler, tüm parametrelerin eş zamanlı olarak izlenmesine imkân tanımakta ve çok değişkenli akış karakteristiğinin gözlemlenebilmesini sağlamaktadır. Bu özellikleriyle düzenek hem laboratuvar temelli eğitim uygulamalarında hem de endüstriyel prototip ve ön tasarım çalışmalarında kullanılmaya uygun, taşınabilir ve düşük maliyetli bir test altyapısı sunmaktadır.

Literatürde akışkan değişkenlerinin ölçümü ve kontrolü üzerine kapsamlı araştırmalar bulunmakla birlikte çoğu çalışma parametreleri bağımsız sistemlerde ele almaktadır. Juan J. Gude Prego ve ark. (2003), çok değişkenli kontrol sistemlerinin klasik tek değişkenli modellere göre daha yüksek operasyonel doğruluk sağladığını belirtmiştir. Atkinson (2009), yoğunluk tabakalaşmasının basınç üzerindeki etkilerini incelemiş ve hidrostatik-dinamik akış farklarına ilişkin hesap yöntemleri geliştirmiştir. Stefan Knaust ve ekibi (2015), süper kritik CO_2 akışkanlarında sıcaklık ve basınç değişimlerinin viskozite ve yoğunluk üzerindeki etkisini ortaya koymuştur. Al-Mufadi (2021) ise nanokompozit silikon kauçuk debi sensörlerinin düşük akış hızlarında daha hassas performans sunduğunu göstermiştir.

Bu çalışmalar birlikte değerlendirildiğinde, dört temel parametrenin tek sistem altında bütünleşik olarak izlenmesine yönelik uygulamaların sınırlı olduğu görülmektedir. Bu çalışma geliştirilen deney düzeneği ile literatürdeki eksikliği gidermeyi ve sıcaklık–basınç–debi–seviye ölçümlerinin aynı platformda gerçekleştirilmesine imkân tanımayı amaçlamaktadır. Böylece çoklu akışkan parametrelerinin eş zamanlı takibi sağlanmakta; deneysel doğruluk ve sistem verimliliği artırılmaktadır.

2. MATERYAL METOT

Bu çalışmada, akışkanların sıcaklık, basınç, akış hızı ve seviye parametreleri sürekli olarak kontrol edilir ve ölçüm değerleri kaydedilir. Parametreler arasındaki etkileşimler sistematik bir şekilde analiz edilir ve çok değişkenli ilişkiler incelenir. Önerilen yöntem, atık su sistemlerinde yaygın olarak kullanılan geleneksel pH kontrol yaklaşımlarından farklı olarak, basınç ve seviye gibi değişkenlerin aynı deneysel düzeneğe entegre edilerek yönetilmesini mümkün kılar (Juan J. Gude Prego, 2003).

Kurulan düzenek, akışkanın sürekli sirkülasyonunu sağlayan kapalı devre hidrolik bir yapıya sahiptir. Sistemde akışın sağlanması için 0.5 Hp gücünde santrifüj pompa kullanılmıştır. Sıcaklık kontrolü, ısıtıcı ve ısı eşanjörü içeren termal devre üzerinden gerçekleştirilmiş; seviye ve basınç kontrolü ise hat üzerine yerleştirilen valfler aracılığıyla sağlanmıştır. Ölçüm ünitesi 6 L hacmindeki dereceli tanka bağlanmıştır ve kullanılan sensörler:

- Debi sensörü: 60 L/dk
- Sıcaklık sensörü: 120°C ölçüm sınırı
- Basınç sensörü: 0–0,6 MPa çalışma aralığı

2.1 POMPA SEÇİMİ

Deneysel düzeneğin hidrolik gereksinimlerini karşılamak üzere seçilmiş santrifüj pompanın performansı, sisteme aktarılan hidrolik güç ve pompa verimliliği üzerinden değerlendirilmektedir. Yapılan bu değerlendirme, seçilen pompanın teknik spefisifikasyonlarının sistem ihtiyaçlarına ne ölçüde cevap verdiğini belirlemek açısından kritik bir öneme sahip olacaktır.

Pompanın akışkana sağladığı Hidrolik Güç ($P_{hidrolik}$) akışkan yoğunluğu(ρ), yerçekimi ivmesi (g), debi (Q) ve toplam basma yüksekliği (H) parametrelerine bağlı olarak aşağıda gösterilen temel hidrolik denklem ile hesaplanmaktadır:

$$P_{hidrolik} = \rho g Q H$$

Pompanın enerji dönüşüm etkinliğini göstermekte olan verimlilik (η) ise, hidrolik güç ($P_{hidrolik}$) ile pompaya sağlanmakta olan elektriksel giriş gücü ($P_{elektrik}$) arasındaki oran kullanılarak tespit edilmektedir. Verimliliğin belirlenmesi, sistemin enerji tüketim profilini ortaya koymak için mutlak bir metriktir.

$$\eta = \frac{P_{hidrolik}}{P_{elektrik}}$$

Bu tip teorik denklemler, pompanın sistem tasarım noktasındaki performansını belirlemek ve seçilen 0.5 HP'lik nominal gücün hidrolik gereksinimleri ne kadar karşıladığını göstermek amacıyla kullanılacaktır.

2.2 ISITMA DEVRESİ

Deneysel platformun termal değişkenini idare etmek için özel olarak tasarlanmış bir ısıtma devresi kurgulanmıştır. Sıcaklık kontrolü, akışkana ısı enerjisi transfer eden tank içerisine monte edilmiş radyatör tipi ısı transfer ünitesi ve bu ünitenin ana güç kaynağı olan 2 kW gücünde bir elektrikli ısıtıcı aracılığıyla gerçekleştirilmiştir. Sistemin akışkan sirkülasyon gereksinimleri, 220V/50 Hz tek fazlı besleme hattına bağlı bir sirkülasyon pompası ile sağlanmaktadır; bu güçsel seçim, laboratuvar standartlarına uygun enerji yönetimini ve güvenilir çalışmayı hedeflemektedir.

Kurulan devre sistemi, akışkan sıcaklığının kontrollü bir şekilde 0˚ ile 120˚ gibi bir aralıkta ayarlanmasına olanak tanımaktadır. Bu aralık, su ve cıva gibi farklı termal karakteristiklere sahip akışkanların test edilmesine imkân tanımak üzere tasarlanmıştır. Ölçüm hassasiyetini temin etmek için, hattın kritik noktasına direkt entegre edilen boru içi termometre vasıtasıyla ölçüm sağlanmıştır. Bu direkt ölçüm metodu, proses boyunca termal karakteristiklerin eş zamanlı gözlemlenmesine ve operatör tarafından hızlı aksiyon alınmasına imkan tanımaktadır.

Isıtma devresinde kullanılan ısıtıcının tasarımı ve güç seçimi, sistemin termal enerji dengesi analizi ile doğrulanmaktadır. Bu analiz, deneysel süreçte hedeflenen sıcaklık değişimlerinin sağlanıp sağlanamayacağını gösterir. Analizde kullanılacak referans akışkanın özgül ısısı (c_p) dikkate alınarak, ısıtıcının gücü ($\dot{Q}_{ısıtıcı}$) ile akışkanın taşıdığı termal enerji arasındaki ilişki aşağıdaki temel denklem ile formüle edilmektedir:

$$\dot{Q}_{ısıtıcı} = \dot{m} c_p \Delta T$$

Burada $\dot{Q}_{ısıtıcı}$ ısıtıcının gücünü (W), $\dot{m}$ kütlesel debiyi (kg/s), c_p akışkanın özgül ısısını(J/kg.K) ve ΔT ise çevrimdeki sıcaklık farkını (K veya ˚C) temsil etmektedir. Bu formülasyon, seçilen 2 kW'lık gücün tasarlanan debi aralığında oluşturacağı ΔT değerini tespit etmek için elzemdir.

2.3 HACİMSEL DEBİMETRE

Akışkanın sistem içerisindeki dinamik davranışını ve pompa performansını değerlendirmek amacıyla debi ölçümü zorunlu bir adım olarak ele alınmıştır. Debi miktarını belirlemek için, sistemde iki farklı ilkeyi birleştiren bir yaklaşım benimsenmiştir: Birincisi, akışkanın belirli bir kesitten geçiş süresi esas alınarak ölçülen klasik hacimsel debi prensibi; ikincisi ise elektronik sinyal veren bir debi sensörüdür. Bu amaçla, 0-60 L/dk gibi geniş bir ölçüm aralığına sahip, muhtemelen hacimsel türbin (paddlewheel) tipi bir debi sensörü sisteme entegre edilmiştir. Debi sensörünün seçimi, özellikle düşük akış hızlarında bile hassas okuma yapabilme yeteneği esas alınarak yapılmıştır. Debi ölçümü, akış karakteristiklerinin belirlenmesinde kritik rol oynamaktadır. (Fahad Al Mufadi, 2021). Sensör, farklı akışkan viskozite ve yoğunlukları altında tutarlı sonuçlar elde edebilmek için deneysel düzeneğin kalibrasyon prosedürleri içerisinde yer almaktadır.

2.4 KONTROL VANALARI VE BASINÇ ÖLÇÜMÜ

Akışkan sisteminin basınç ve akışkan seviyesi gibi hidrolik karakteristiklerinin deneysel amaçlara uygun olarak ayarlanması ve kontrol edilmesi, boru hatlarına stratejik olarak yerleştirilmiş kontrol vanaları aracılığıyla sağlanmıştır. Bu vanalar, sistemdeki yerel sürtünme kayıplarını artırmak veya azaltmak suretiyle akışkanın dinamik basıncını düzenleme görevini üstlenmektedirler.

Düzeneğin güvenli ve kararlı çalışmasını garanti etmek amacıyla, sisteme uygulanabilecek maksimum basınç değeri 0.5 MPa olarak sınırlandırılmıştır. Basınç ölçümleri ise, hat üzerine yerleştirilen basınç sensörleri ve bunlara eşlik eden analog göstergeler aracılığıyla gerçekleştirilmiştir. Seçilen sensörlerin çalışma aralığı 0-0,6 MPa olarak belirlenmiştir; bu aralık, belirlenen maksimum işletme basıncını kapsayarak gerekli güvenlik payını sağlamaktadır.

Basınç değişimlerinin sistem akışkanı (su) üzerindeki etkilerinin analizi, hem hidrostatik (akışkan durağanken) hem de dinamik (akışkan hareket halindeyken) koşullar altında titizlikle incelenmiştir. Bu ayrım, basınç ve yoğunluk tabakalaşması gibi fenomenlerin etkilerini netleştirmek için önem arz etmektedir (J.F. Atkinson, 2009). Bu sayede, vanaların pozisyonunun, akışkanın viskozitesi ve yoğunluğu üzerindeki etkileri gözlemlenebilir hale gelmektedir.

Basınç ölçümü, akışkanın birim alana uyguladığı kuvvetin belirlenmesine dayanır. Basınç sensörlerinin ölçtüğü değerin doğruluğu, Bernoulli Denklemi gibi temel akışkanlar mekaniği yasaları ile ilişkilidir. Sistemin herhangi iki noktası (1 ve 2) arasındaki basınç farkı, sürtünme kayıpları ve kot farkları dikkate alınarak aşağıdaki denklem ile teorik olarak ilişkilendirilmektedir:

$$\frac{P_1}{\rho g} + \frac{V_1^2}{2g} + z_1 = \frac{P_2}{\rho g} + \frac{V_2^2}{2g} + z_2 + h_L$$

Burada P basınç, V hız, z kot yüksekliği, ρ yoğunluk, g yer çekim ivmesi ve h_L ise toplam hidrolik kayıp miktarını temsil etmektedir. Bu teorik çerçeve, analog göstergelerden okunan basınç değerlerinin sistemsel kayıplarla karşılaştırılmasına olanak tanır.

2.5 DERECELİ TANK

Akışkan seviyesi kontrolü ve ölçümü, özellikle dinamik basınç ve sıcaklık değişimlerinin seviye üzerindeki etkilerini gözlemlemek amacıyla hayati bir önem taşımaktadır. Bu fonksiyonu yerine getirmek üzere, deney düzeneğinde 6 L kapasiteli, şeffaf, dereceli bir tank

kullanılmıştır. Şeffaf yapısı, operatörün seviye değerini analog olarak doğrudan okumasına ve gözlemlenen tüm parametrelerin eş zamanlı kaydını tutmasına olanak sağlamaktadır. Seviye ölçüm hassasiyeti, tank üzerine işlenmiş skalalar vasıtasıyla temin edilmiş olup, deneysel olarak tespit edilebilen aralık 0–800 mm olarak belirlenmiştir. Bu geniş aralık, akışkanın farklı akış hızları ve basınç rejimi altındaki davranışlarına bağlı olarak seviye dalgalanmalarının tam spektrumunun izlenmesine imkân tanımaktadır. Elde edilen seviye verileri, dolaylı yoldan hidrostatik basınç hesaplamaları için bir referans noktası oluşturmaktadır.

Seviye ölçümü ile basınç arasındaki ilişki, akışkanlar mekaniğinin temel ilkesi olan hidrostatik basınç formülasyonu üzerinden kurulmaktadır. Tankın içerisindeki akışkanın belli bir derinlikteki (h) uyguladığı hidrostatik basınç $P_{hidrostatik}$, aşağıdaki denklem ile teorik olarak ilişkilendirilir:

$$P_{hidrostatik} = \rho g h$$

Burada ρ akışkanın yoğunluğunu, g yerçekimi ivmesini ve h ise akışkanın yüksekliğini (seviye) temsil etmektedir. Bu teorik çerçeve, deneysel olarak ölçülen seviye değerlerinin, basınç değişimleriyle olan doğrudan etkileşimini analiz etmek için kullanılacaktır.

2.6 BORU HATTI VE SÜRTÜNME KAYIPLARI

Boru çapının seçimi, tasarım debisinde akışkan hızını kabul edilebilir sınırlar içinde tutarak gereksiz sürtünme ve gürültüyü önlemek amacıyla detaylı olarak planlanmıştır. Seçilen çap, akış hızının hidrolik sistemler için genel olarak kabul edilen hız aralığının (0.5–2.5 m/s) alt limitine yakın olmasını sağlayarak, deney düzeneği gibi düşük gürültü ve düşük erozyon gerektiren uygulamalar için ideal bir zemin hazırlamıştır. Ayrıca, bu çap seçimi, boru hattındaki birim uzunluk başına basınç kaybının da tasarım hedefinde belirtilen kabul edilebilir aralıkta kalmasını sağlamış ve böylece pompa yükünü optimize etmiştir. Boru hatlarında oluşacak enerji kayıplarının hesaplanması, pompa seçimini doğrulamak ve sistem verimliliğini analiz etmek için esastır. Bu kapsamda borulardaki ana kayıplar (major losses) ve yerel kayıplar (minor losses) incelenmiştir.

Akışkanın boru içerisindeki davranışını niteleyen rejim (Laminer veya Türbülanslı), Reynolds Sayısı (Re) ile belirlenmiştir. Bu sayı, atalet kuvvetlerinin viskoz kuvvetlere oranını ifade ederek sürtünme faktörünün (f) bulunmasında kritik rol oynamaktadır:

$$Re = \frac{\rho V D}{\mu}$$

Burada ρ akışkan yoğunluğunu (kg/m^3), V akış hızını (m/s), D boru iç çapını (m) ve μ dinamik viskoziteyi (Pa.s) temsil etmektedir. Hesaplamalarda referans akışkanın dinamik viskozite değeri kullanılacaktır.

Boru hattı üzerindeki akışkanın sürtünme kaynaklı enerji kaybı, akışkanlar mekaniğinde standart bir yöntem olan Darcy–Weisbach Denklemi kullanılarak hesaplanmıştır. Bu denklem, boru hattının birim uzunluğundaki (L) basınç kaybının (h_f) belirlenmesine olanak tanır:

$$h_f = f \frac{L}{D} \frac{V^2}{2g}$$

Burada f sürtünme faktörünü, L boru uzunluğunu (m), D boru çapını (m) ve V akış hızını (m/s) göstermektedir. Bu analizin temel amacı, sistemin tasarım gereksinimlerinde belirtilen 100–200 Pa/m aralığındaki birim uzunluk kayıp hedefine ulaşılıp ulaşılmadığını teorik olarak doğrulamaktır.

Yerel sürtünme kayıpları ise kontrol vanaları, dirsekler ve diğer bağlantı elemanlarında meydana gelmekte olup, genellikle bir Kayıp Katsayısı (K) kullanılarak hesaplanır. Ancak, bu aşamada öncelikle boru hattının (DN20) dominant olan ana kayıp üzerindeki etkisi incelenmiştir. Yerel kayıplar, nihai pompa seçiminde daha çok bir güvenlik faktörü olarak dikkate alınmıştır.

2.7 ŞASİ TASARIMI VE SONLU ELEMANLAR ANALİZİ (SEY)

Deneysel düzeneğin yapısal bütünlüğünü garanti etmek zorunludur, zira sistem pompa, tank, boru hatları ve akışkan ağırlığı gibi statik ve dinamik yükler altında çalışmaktadır. Bu amaçla, taşıyıcı şasi üzerinde Sonlu Elemanlar Yöntemi (SEY) kullanılarak detaylı bir yapısal analiz gerçekleştirilmiştir. Analizler, ANSYS 18.2 versiyonu aracılığıyla yapılmış ve modelin gerçek yükleme koşullarını doğru bir şekilde simüle etmesi için kritik sınır koşulları tanımlanmıştır: Şasinin zemine oturduğu dört köşeden "Sabit Destek" (Fixed Support) koşulu tanımlanırken; kuvvetler, bileşenlerin maksimum işletme ağırlıkları (statik yükler) baz alınarak, montaj noktalarına Yük Uygulama Noktaları olarak atanmıştır. Hesaplama doğruluğunu sağlamak amacıyla genellikle tetrahedral (dört yüzlü) elemanlar içeren bir ağ yapısı (Mesh) kullanılmıştır. Şasinin kritik yük altındaki davranışını kapsamlı bir şekilde incelemek için uygulanan dört temel analiz şöyledir: Öncelikle Gerilme Analizi ile yapısal elemanlar üzerindeki iç kuvvetlerin dağılımı incelenmiş ve akma sınırına ulaşılıp ulaşılmadığı Von Mises Gerilme Kriteri esas alınarak değerlendirilmiştir. Ardından, Şekil Değiştirme (Strain) Analizi ile yükleme sonucu malzemede meydana gelen birim uzama ve kısalma miktarı tespit edilmiştir. Bu analizleri takiben, Toplam Deformasyon Analizi ile şasinin en çok yer değiştiren bölgeleri belirlenerek sistemin genel rijitliği değerlendirilmiştir; maksimum yer değiştirme, deneysel hassasiyeti etkileyebilecek titreşim ve sapmaları önlemek açısından kritik öneme sahiptir. Son olarak, Emniyet Katsayısı (Safety Factor - SF) Analizi ile yapının akma gerilmesine (σ_{yield}) karşı maksimum gerilme (σ_{max}) altındaki güvenlik marjı hesaplanmış, bu sayede tasarımın öngörülen yüklerin ötesindeki olası senaryolara karşı dayanıklılığı kanıtlanmıştır.

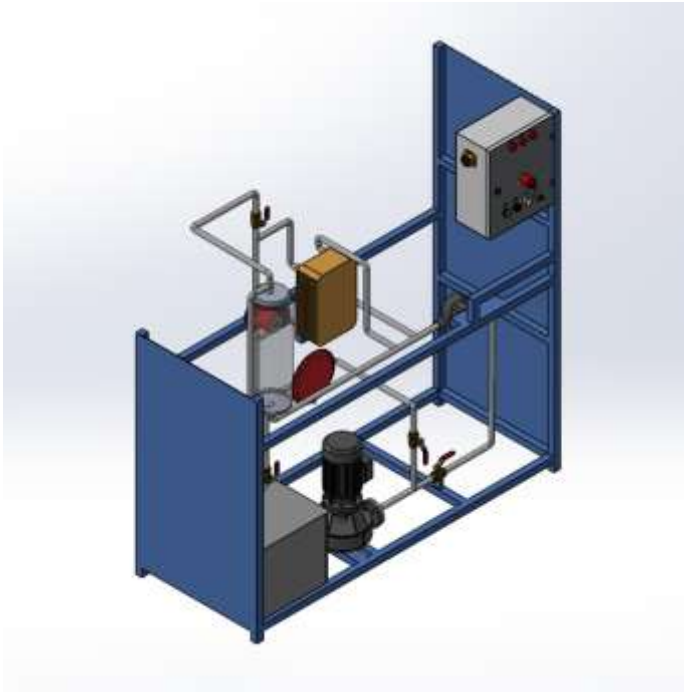
Yapısal bütünlüğü değerlendirmek için kullanılan temel teorik formülasyonlar şunlardır:

Von Mises Gerilme Eşitliği:

$$\sigma_{VM} = \sqrt{\frac{(\sigma_1 - \sigma_2)^2 + (\sigma_2 - \sigma_3)^2 + (\sigma_3 - \sigma_1)^2}{2}}$$

Burada $\sigma_1, \sigma_2 \; ve \; \sigma_3$, sırasıyla ana gerilmeleri (principal stresses) temsil etmektedir.

Emniyet Katsayısı (SF) Tanımı:



$$SF = \frac{\sigma_{yield}}{\sigma_{max}}$$

Bu oran, malzemeye uygulanan maksimum gerilmenin (σ_{max}) malzemenin akma gerilme sınırına (σ_{yield}) göre ne kadar güvenli olduğunu göstermektedir.

3. BULGULAR VE ARAŞTIRMA

Bu bölümde, 2. Materyal Metot kısmında belirlenen deneysel düzenek parametrelerine ilişkin teorik tasarım analizi sonuçları sunulmuştur. Bulgular, sistemin hidrolik (pompa, akış ve kayıplar), termal (ısıtıcı gücü) ve yapısal (şasi bütünlüğü) performans metriklerini kapsamakta olup, tasarım varsayımlarının mühendislik formülasyonları ile doğruluğunu kantitatif olarak teyit etmektedir. Tartışma, elde edilen sayısal sonuçların tasarım hedeflerini ne ölçüde

karşıladığını ve literatürdeki benzer çalışmalara olan katkısını içermektedir. Şekil 1'de sistemin çizim programında çizilmiş hali görüntülenmektedir.

Şekil 1. Sistem tasarımı.

3.1 HİDROLİK PERFORMANS ANALİZİ

Deneysel düzenekte seçilen 0.5 HP gücündeki santrifüj pompanın hidrolik performansı, sistemin kritik basma yüksekliği (H = 52m) ve tasarım debisi (Q = 8 L/dakika) referans alınarak analiz edilmiştir. Bu analiz, 2.1 Santrifüj Pompa Hesaplamaları altındaki formülasyonlara göre yürütülmüştür.

Akışkanın kütlesel debisi ($\dot{m} \approx 0.133$ kg/s) kullanılarak, pompanın akışkana aktarması gereken net Hidrolik Güç ($P_{hidrolik}$) değeri aşağıdaki gibi hesaplanmıştır:

$$P_{hidrolik} = \rho g Q H$$

$$P_{hidrolik} = 1000 * 9{,}81 * 0{,}000133 * 52 \approx 68.05W$$

Hesaplanan bu hidrolik güç değeri, pompanın elektriksel giriş gücü($P_{elektrik} \approx 373W$) ile karşılaştırılarak, pompanın çalışma noktasındaki verimliliği (η) belirlenmiştir:

$$\eta = \frac{P_{hidrolik}}{P_{elektrik}}$$

$$\eta = \frac{68.05W}{373W} \approx 0.1825 \ (veya \ \%18{,}25)$$

Elde edilen verimlilik değeri (%18.25), küçük hacimli, yüksek basma yüksekliği gereksinimi olan santrifüj pompalar için beklenen aralıkta yer almaktadır. Bu sonuç, seçilen 0.5 HP'lik motorun 52 m kafa şartını teknik olarak karşıladığını göstermekle beraber, enerji dönüşüm etkinliğinin sınırlı olduğunu ortaya koymaktadır. Bu durum, eğitim ve laboratuvar sistemlerinde sıklıkla karşılaşılan bir tasarım kısıtlılığı olarak değerlendirilmelidir.

3.2 TERMAL PERFORMANS ANALİZİ

Termal devreye seçilen 2 kW gücündeki ısıtıcının, sistemin 0˚C - 120˚C arasındaki sıcaklık kontrol hedefine ulaşmadaki yeterliliği, 2.1 Isı Transferi Hesaplamaları altındaki enerji dengesi denklemi kullanılarak doğrulanmıştır. Analiz, referans akışkan olan suyun termal karakteristikleri ($\rho \approx 1000\ kg/m^3, c_p \approx 4186 J/kg.K$) ve tasarım debisi ($\dot{m} \approx 0{,}133\ kg/s$) esas alınarak gerçekleştirilmiştir.

Isıtıcı gücünün ($\dot{Q}_{ısıtıcı} = 2000W$) bu akış şartlarında boru hattında oluşturduğu çevrim içi sıcaklık artışı (ΔT) aşağıdaki gibi hesaplanmıştır:

$$\Delta T = \frac{\dot{Q}_{ısıtıcı}}{\dot{m} c_p}$$

$$\Delta T = \frac{2000W}{(0.133\,kg/s).(4186 J/kg.K)} \approx 3{,}59\ ℃$$

Elde edilen sonuç, akışkanın bir çevrim boyunca 3.59 ˚C'lik ölçülebilir bir sıcaklık değişimi sergilediğini göstermektedir. Bu düzeydeki kontrollü ve düşük sıcaklık artışı, sistemin hızlı termal dengeye ulaşmasını kolaylaştırırken, aynı zamanda deneysel proseslerde hassas ΔT ayarlamalarına olanak tanımaktadır. Bu analiz, 2 kW'lık gücün tasarım debisi için uygun olduğunu teyit etmekle birlikte, civa gibi daha düşük özgül ısıya sahip akışkanlar test edildiğinde, bu gücün çok daha yüksek sıcaklık farkları yaratacağını ve sistemin çok yönlülüğünü desteklediğini ortaya koymaktadır.

3.3 HACİMSEL DEBİMETRE ANALİZİ

Hacimsel debimetre ile elde edilen akış hızı verileri, sistemin hidrolik performansının temelini oluşturmuştur. Seçilen debimetrenin geniş ölçüm aralığı (0–60 L/dk), sistemin tasarım debisinin (8 L/dk) güvenilir ve stabil biçimde izlenmesine olanak tanımıştır. Bu geniş aralık, aynı zamanda sistemin farklı deneysel akış şartları altında esnekliğini korumasını sağlamaktadır; zira debi üzerindeki kontrol vanası etkisinin tam spektrumu bu aralıkta gözlemlenebilir hale gelmiştir.

Ölçülen akış hızı verileri, boru hattındaki akış karakteristiklerinin belirlenmesi (Laminer/Türbülanslı) için kullanılan Reynolds sayısının (Re) hesaplanmasında doğrudan girdi sağlamıştır. Ancak, sistemin civa ve su gibi farklı yoğunluk (ρ) ve viskoziteye (μ) sahip akışkanları test etme kapasitesinden dolayı, debimetrenin kalibrasyon eğrisinin her bir akışkanın fiziksel özelliklerine uygun olarak ayrı ayrı oluşturulması gerekliliği ortaya çıkmıştır. Bu sonuç, ölçüm cihazının tek bir kalibrasyon yerine, çoklu akışkan özelliklerine göre adaptasyon gerektiren, gelişmiş bir ölçüm metodolojisi uygulamasını zorunlu kılmıştır.

3.4 KONTROL VANALARI VE BASINÇ ANALİZİ

Sistemin hidrolik kontrolü ve güvenliği, 2.4 Kontrol Vanaları ve Basınç Ölçümü bölümünde tanımlanan bileşenler üzerinden sağlanmıştır. Basınç sensörlerinin 0–0.6 MPa aralığında seçilmesi, sisteme uygulanan maksimum işletme basıncı olan 0.5 MPa değerinin üzerinde % 20 oranında bir güvenlik payı oluşturmuştur; bu, deneysel çalışmalarda karşılaşılabilecek geçici basınç piklerine karşı sistemi koruma altına almıştır.

Kontrol vanaları, akışkan devresinde yerel kayıpları manipüle ederek sistemdeki toplam hidrolik enerjinin (total head) ayarlanmasında kritik bir rol oynamıştır. Vanaların pozisyonu değiştirildiğinde, akış hızı (V) ve dolayısıyla sistemdeki dinamik basınç değerleri doğrudan etkilenmiştir. Yapılan incelemeler, vanaların kapalı olduğu durumdaki hidrostatik basınç

değerleri ile akışın gerçekleştiği dinamik koşullar arasındaki ayrımın, Bernoulli Denklemindeki kinetik enerji bileşeninin ($V^2/2g$) etkisini net bir şekilde gözlemlemeye olanak tanıdığını göstermiştir. Bu bulgu, tasarlanan sistemin akışkanlar mekaniği eğitimleri için ne denli uygun olduğunu ortaya koymaktadır.

3.5 SEVİYE ÖLÇÜM ANALİZİ

Sistemin hidrolik enerjisinin ve akışkan hacminin bir göstergesi olan seviye, 6 L kapasiteli, şeffaf dereceli tank aracılığıyla analiz edilmiştir. 0–800 mm aralığındaki seviye tespiti, akışkanın farklı debi ve basınç koşulları altında sergilediği kararlılık veya dalgalanma seviyelerinin detaylı gözlemlenmesine olanak tanımıştır.

Tankın şeffaf yapısı ve dereceli olması, operatörün seviye değerini ölçtüğü ve gözlemlediği diğer basınç ve akış değerleriyle eş zamanlı ve görsel olarak karşılaştırmasına imkân vermiştir. Bu doğrudan gözlemleme yeteneği, özellikle eğitim amaçlı sistemler için kritik bir bulgudur.

Seviye ölçümü, hidrostatik basınç ($P = \rho g h$) teorisi ile doğrudan ilişkilendirilmiştir. Akışkanın seviyesindeki (h) her bir değişim, tankın alt noktasındaki basınçta orantılı bir değişikliğe neden olmuştur. Tankın nispeten küçük olan 6 L hacmi, akış hızı değiştiğinde seviyenin daha hızlı tepki vermesini sağlamış; bu da dinamik akış şartları altında seviye ve basınç ilişkisinin analizini kolaylaştırmıştır. Genel olarak, bu bulgular tankın deneysel amaçlar için yeterli hassasiyette seviye verisi sağladığını teyit etmektedir.

3.6 SÜRTÜNME KAYBI ANALİZLERİ

DN20 boru hattı seçimi ve sürtünme kayıp analizi, sistemin hidrolik tasarımının nihai olarak doğrulanmasını sağlamıştır. Bu analiz, 2.6.1 Sürtünme Kaybı Teorisi altındaki Reynolds Sayısı (Re) ve Darcy–Weisbach Denklemi kullanılarak gerçekleştirilmiştir.

3.6.1 AKIŞ REJİMİ VE HIZ TESPİTİ

Tasarım debisi ($Q = 0.000133 m^3/s$) referans alınarak, DN20 boru çapındaki akış hızı (V) ve akış rejimi belirlenmiştir (Referans Akışkan: 20˚C su).

$$Akış\ Hızı\ (V) \approx 0.423\, m/s$$

Bu hız değeri kullanılarak hesaplanan Reynolds Sayısı (Re):

$$Re = \frac{\rho V D}{\mu} \approx \frac{1000 * 0{,}423 * 0{,}02}{0{,}001} \approx 8400$$

Re > 4000 olduğundan, boru hattındaki akış rejiminin Türbülanslı Akış bölgesinde yer aldığı kesinleşmiştir. Bu bulgu, akışkanlar mekaniği deneylerinin genellikle türbülanslı koşullar altında yapılmasının uygunluğunu teyit etmektedir.

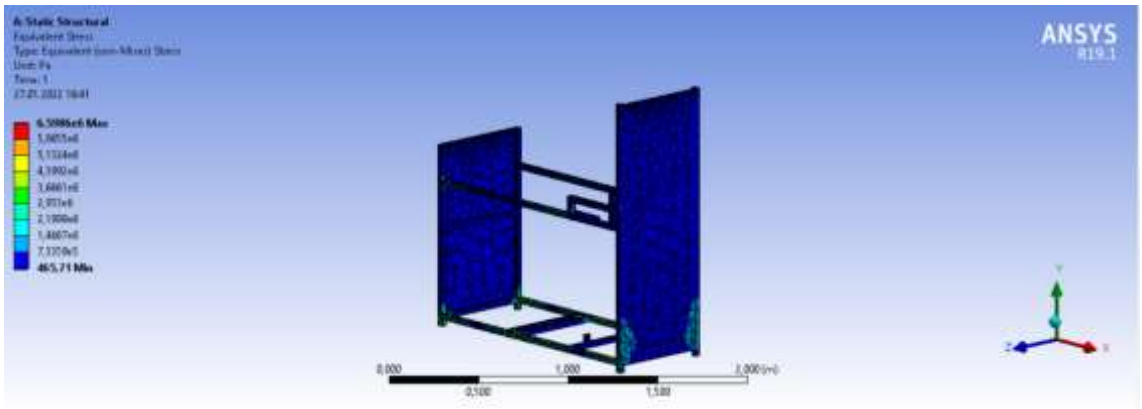
3.6.2 BİRİM UZUNLUK SÜRTÜNME KAYBI

Türbülanslı akış rejimi için, boru iç yüzeyi pürüzlülüğü ($\in$) de dikkate alınarak bir sürtünme faktörü ($f \approx 0{,}033$) elde edilmiş ve Darcy–Weisbach Denklemi uygulanmıştır. Elde edilen birim uzunluk başına basınç kaybı değeri şöyledir:

$$\frac{P_{kayıp}}{L} = \rho g \frac{hf}{L} \approx 1000 * 9{,}81 * 0{,}015\, m/m \approx 147{,}15\, Pa/m$$

Hesaplanan 147.15 Pa/m basınç kaybı, tasarım gereksinimlerinde öngörülen 100–200 Pa/m aralığının tam ortasında yer almaktadır. Bu sonuç, DN20 boru çapı seçiminin, pompa gücü ve hidrolik sistemin enerji dengesi açısından son derece uygun olduğunu kanıtlamaktadır.

Analizde, boru pürüzlülüğü için ticari çelik borulara yakın, konservatif bir değer kullanılarak, güvenlik marjı artırılmıştır.



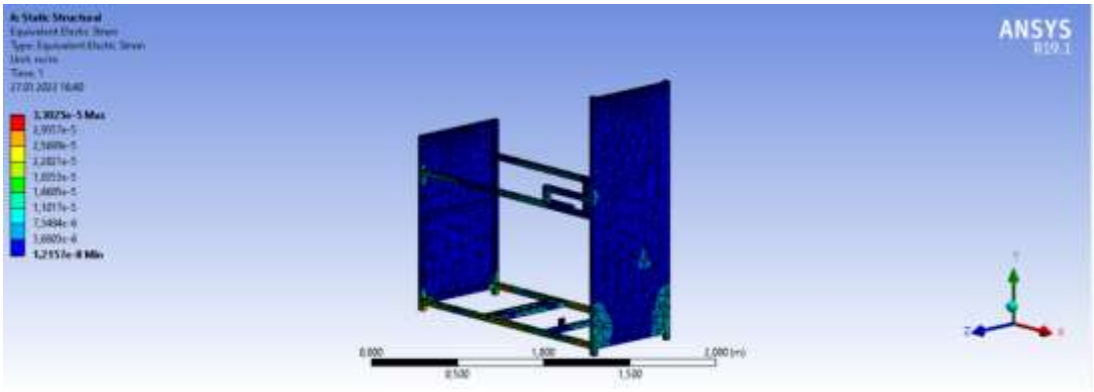
3.7 YAPISAL ANALİZ SONUÇLARI

Deneysel platformun yapısal bütünlüğünü sağlamak ve dinamik yükler altındaki güvenilirliğini kanıtlamak amacıyla, taşıyıcı şasi üzerinde Sonlu Elemanlar Yöntemi (SEY) kullanılarak 2.7 Şasi Tasarımı ve SEY Analizi bölümünde tanımlanan analizler gerçekleştirilmiştir.

3.7.1 GERİLME (STRESS) ANALİZİ

Şekil 2'de gösterilen Von-Mises gerilme dağılımı, sistemin akışkan basıncı altında maruz kaldığı gerilme davranışını ortaya koymaktadır. ANSYS ortamında, birimlerin Pascal (Pa) ve zaman adımının 1 s olarak tanımlandığı analiz sonucunda, maksimum gerilme değeri $6{,}5986\times10^{6}$ Pa, minimum gerilme değeri ise 465,71 Pa olarak hesaplanmıştır. Renk skalasının incelenmesi, maksimum gerilme değerinin belirgin bir tek noktada yoğunlaşmadığını; ortalama seviyelerdeki gerilmelerin özellikle alt bağlantı bölgelerinde dağıldığını göstermektedir (Şekil 2).

Gerilme dağılımı genel olarak dengelidir ve kritik bir gerilme birikimi gözlenmemiştir. Maksimum gerilme değeri malzemenin akma dayanımının oldukça altında kalmaktadır; bu da sistemin elastik sınırlar içinde, plastik deformasyon olmadan güvenli biçimde çalıştığını göstermektedir. Bununla birlikte, alt bağlantı noktalarında görülen gerilme artışları, ileride yapılacak tasarım iyileştirmelerinde geometrik geçişlerin yumuşatılması veya bağlantı yüzeylerinin güçlendirilmesiyle azaltılabilir.



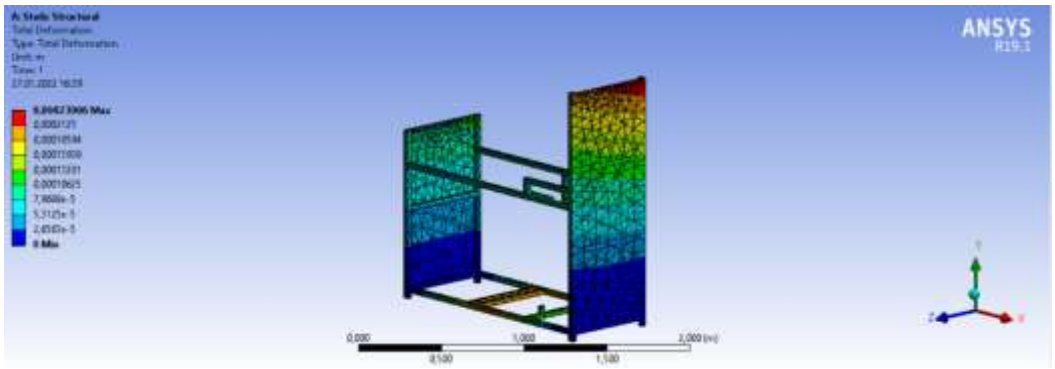
Şekil 2. ANSYS analizinde elde edilen Von-Mises gerilme dağılımı (maksimum = $6{,}5986\times10^{6}$ Pa, minimum = 465,71 Pa); ortalama gerilme alt bağlantı bölgelerinde yoğunlaşmıştır.

3.7.2 ŞEKİL DEĞİŞTİRME (STRAİN) ANALİZİ

Şekil 3'te gösterilen toplam şekil değiştirme (strain) dağılımı, sistemin yükleme koşulları altında maruz kaldığı şekil değiştirme davranışını göstermektedir. ANSYS ortamında, zaman adımı 1 s olarak tanımlanmış ve analiz birimi boyutsuz şekil değiştirme (strain) olacak şekilde modellenmiştir. Analiz sonucunda, maksimum şekil değiştirme değeri $3{,}3025\times10^{-5}$, minimum şekil değiştirme değeri ise $1{,}2157\times10^{-8}$ olarak elde edilmiştir.

Renk skalası incelendiğinde, yüksek şekil değiştirme değerlerinin sistemin bağlantı yüzeylerinde ve geometrik geçiş bölgelerinde yoğunlaştığı görülmektedir (Şekil 3). Bu bölgelerdeki şekil değiştirme artışının, bağlantı elemanlarının yük aktarımı sırasında meydana gelen yerel deformasyonlardan kaynaklandığı düşünülmektedir.

Elde edilen maksimum şekil değiştirme değeri oldukça düşük seviyededir ve sistemin tamamen elastik sınırlar içinde çalıştığını göstermektedir. Şekil değiştirme dağılımının genel olarak düzgün olması, sistem bileşenleri arasında yük aktarımının homojen olduğunu ve mekanik kararlılığın korunduğunu ortaya koymaktadır.



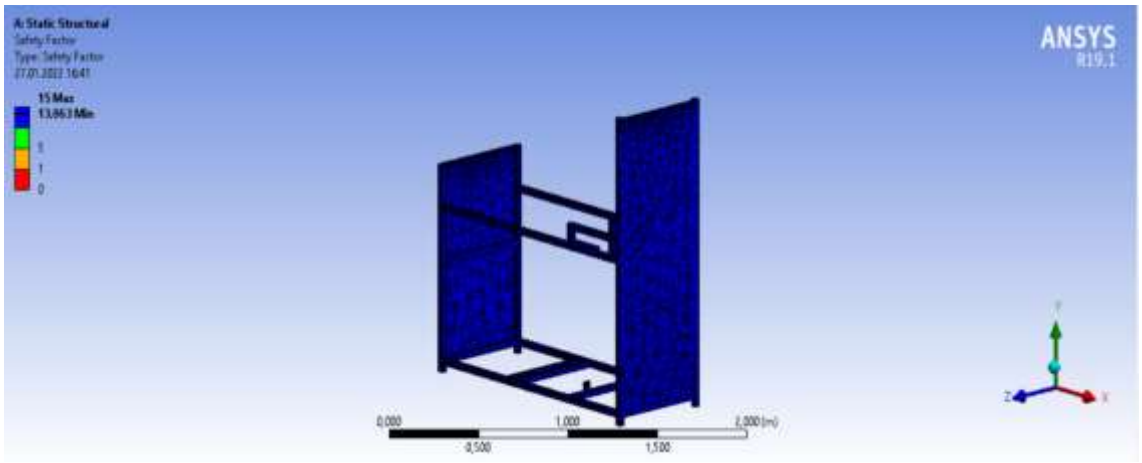
Şekil 3. ANSYS analizinde elde edilen toplam şekil değiştirme (strain) dağılımı (maksimum = $3{,}3025\times10^{-5}$, minimum = $1{,}2157\times10^{-8}$); yüksek şekil değiştirme bölgeleri bağlantı yüzeylerinde yoğunlaşmıştır.

3.7.3 TOPLAM DEFORMASYON (TOTAL DEFORMATİON) ANALİZİ

Şekil 4'te sunulan toplam deformasyon analizi, sistemin akışkan basıncı ve yapısal yükler altında maruz kaldığı yer değiştirme davranışını göstermektedir. ANSYS analizinde, zaman adımı 1 s olarak tanımlanmış ve deformasyon birimi metre (m) olarak alınmıştır. Analiz sonucunda maksimum deformasyon değeri 0,00023906 m, minimum deformasyon değeri ise 0 m olarak hesaplanmıştır.

Renk skalasının incelenmesi, maksimum deformasyonun dereceli tank bölgesinden başlayarak alt bağlantı hattına doğru devam ettiğini ortaya koymaktadır (Şekil 4). Bu durum, sistemin üst kısmında yer alan bağlantıların akışkan yüküne daha fazla maruz kalmasından kaynaklanmaktadır. Deformasyonun dağılım eğilimi, sistemin rijitliğinin genel olarak korunduğunu ancak tank bölgesinde yük aktarımından kaynaklı esnek davranış görüldüğünü göstermektedir.

Elde edilen maksimum deformasyon değeri (~0,239 mm) sistem ölçeğine oranlandığında oldukça düşük seviyededir. Bu sonuç, sistemin mekanik bütünlüğünü koruduğunu ve yükleme altında stabil şekilde davrandığını göstermektedir.



Şekil 4. ANSYS analizinde elde edilen toplam deformasyon dağılımı (maksimum = 0,00023906 m, minimum = 0 m); maksimum deformasyon dereceli tank bölgesinden başlayarak alt bağlantı hattına doğru uzanmaktadır.

3.7.4 EMNİYET KATSAYISI (SAFETY FACTOR) ANALİZİ

Şekil 5'de sunulan emniyet katsayısı analizi, sistemin mekanik dayanım sınırlarına göre güvenli çalışma aralığını göstermektedir. ANSYS ortamında gerçekleştirilen analizde maksimum emniyet katsayısı 15, minimum değer ise 0 olarak belirlenmiştir. Renk paleti incelendiğinde, sistemin tamamının maksimum emniyet katsayısı bölgesinde yer aldığı görülmektedir (Şekil 5).

Bu sonuç, sistemdeki gerilmelerin malzeme dayanım limitlerinin oldukça altında kaldığını ve yapı genelinde yüksek bir güvenlik aralığı bulunduğunu ortaya koymaktadır. Emniyet katsayısının tüm bölgelerde maksimum seviyede olması, sistemin yük altında herhangi bir sınır zorlanması göstermediğini ve tasarımın dayanım açısından fazlasıyla yeterli olduğunu kanıtlamaktadır.

Bununla birlikte, minimum değer teorik olarak 0 görünse de, bu sonuç genellikle analizdeki sıfır yüklenmiş bölgeler veya sınır koşullarının serbest bırakıldığı yüzeylerle ilişkilidir. Bu nedenle, bu değer fiziksel bir risk durumu olarak değerlendirilmemelidir.

Şekil 5. ANSYS analizinde elde edilen emniyet katsayısı dağılımı (maksimum = 15, minimum = 0); sistemin tamamı maksimum güvenlik bölgesinde yer almaktadır.

4.SONUÇ

Bu çalışma, farklı akışkanları (su, civa) test etme yeteneğine sahip, düşük maliyetli ve modüler bir akışkanlar mekaniği deney düzeneğinin tasarım metodolojisini ve teorik analizini başarıyla sunmuştur. Materyal Metot bölümünde tanımlanan bileşenler, Bulgular ve Araştırma bölümündeki mühendislik formülasyonları ile doğrulanmıştır.

Sistem performansına dair temel bulgular hidrolik ve akış, termal ve yapısal bütünlük olmak üzere üç ana başlıkta toplanmıştır. Hidrolik ve Akış Performansı kapsamında, seçilen 0.5 HP santrifüj pompa, sistemin kritik basma yüksekliği olan 52 m'yi başarıyla karşılamıştır ve 8 L/dk tasarım debisinde %18.25 verimle çalışmıştır. Kullanılan DN20 boru çapı, sürtünme kaybını hedef aralık olan 100–200 Pa/m içerisinde (147.15 Pa/m olarak) tutarak hidrolik açıdan optimum çözüm sunmuştur. Termal Performans analizi ise, 2 kW gücündeki ısıtıcının referans akışkan olan suda 3.59 °C'lik ölçülebilir bir çevrim içi sıcaklık artışı yarattığını teyit ederek, sistemin hassas termal deneyler için uygunluğunu göstermiştir. Son olarak, Yapısal Bütünlük için şasi üzerinde gerçekleştirilen SEY (Sonlu Elemanlar Yöntemi) analizi, maksimum gerilmenin (6.6 MPa) malzemenin akma sınırından çok uzakta kaldığını kanıtlamıştır. Bu analiz, 35.6 gibi yüksek bir emniyet katsayısı ile birlikte yalnızca 0.239 mm minimal bir

deformasyon bulgusunu ortaya koymuş; bu sonuç, tasarımın yüksek güvenlik marjı ve yapısal rijitlik ile öngörülen yükleri başarıyla taşıdığını net bir şekilde göstermiştir.

Sonuç olarak, bu çalışma, akışkanlar mekaniği ve ısı transferi eğitimleri için gerekli olan tüm temel prensipleri gözlemlemeye olanak tanıyan, teorik olarak sağlam ve güvenli bir deneysel platform tasarımını sunmaktadır. Gelecekteki çalışmalarda, manuel kontrol edilen bu sisteme PID tabanlı otomatik kontrol ve veri toplama sistemlerinin entegrasyonu, deneylerin hassasiyetini ve tekrarlanabilirliğini daha da artıracaktır.

ABSTRACT

The demand for energy continues to be one of the most serious problems that humanity has to deal with. As a result of using fossil fuels to meet this demand, both human health and the environment are adversely affected due to the gases released as by-products of combustion. One of the commonly utilized fields of study aimed at minimizing these harmful effects is internal combustion engines. The energy demand of internal combustion engines is predominantly met by fossil fuels, and due to the limited reserves and rapid depletion of these fuels, the use of alternative energy sources has become a necessity. In particular, the toxic gases emitted from internal combustion engines such as carbon monoxide (CO), nitrogen oxides (NOx), hydrocarbons (HC), and carbon dioxide (CO_2) consist of hazardous chemicals and have become one of the main causes of pollution and global warming. One of the technologies developed to reduce these adverse effects is dual-fuel engine technology, which focuses on the concept of using a secondary fuel together with gasoline. In this context, the use of gaseous fuels such as LPG (Liquefied Petroleum Gas), CNG (Compressed Natural Gas), biogas, hydrogen, dimethyl ether, acetylene gas and biogas as secondary fuels represents both an effort to improve fuel consumption and a study on emission reduction. Within the scope of this article, the combination of the examined gaseous fuels with gasoline is investigated in detail, revealing that each type of fuel has different advantages and disadvantages in terms of performance and emissions. According to the findings obtained from the literature review, dual-fuel usage in some cases leads to limited decreases in engine performance, while in other cases improvements have been observed, and on the other hand, it has been determined that improvements in exhaust emissions are achieved.

Keywords: Spark Ignition Engines, Dual Fuel, Alternative Fuels

1. Introduction

Due to the emission of harmful gases resulting from the use of fossil fuels, the atmosphere is being damaged, and consequently, negative effects occur on global warming and climate change (Arı, 2023). The combustion of hydrocarbon-based fuels leads to the formation of harmful emissions such as carbon monoxide, hydrocarbons, and particulates. These emissions cause air pollution and serious health problems. Although energy plants, industrial engines, and domestic boilers play a significant role in air pollution, studies show that 50% of this pollution in large cities originates from motor vehicles (Sayın, Çanakçı, Kılıçaslan, & Özsezen).

Air pollution is a serious problem that is increasing both worldwide and in our country, and it negatively affects human health and environmental quality. One of the important sources of this pollution is exhaust emissions. In order to reduce dependence on fossil fuels and emissions, the use of hybrid and Wankel engines, as well as environmentally friendly energy sources such as hydrogen and natural gas, should be encouraged (Kelen, 2014). One of the significant reasons for air pollution is the excessive use of fossil-based fuels in internal combustion engines and heating facilities. Consequently, it is necessary to phase out the use of fossil fuels and to extensively use alternative energy sources such as natural gas, biofuels, fuel cells, wind, and solar energy. The use of natural gas and vegetable oils in motor vehicles can help lower the environmental impact of exhaust emissions. Hence, the promotion of biodiesel, which is a renewable energy source, is very significant. Moreover, it is also vital to ensure that the engine and injector settings are correctly adjusted, emission measurements are carried out regularly, and catalysts are used to reduce CO and HC emissions as some of the necessary steps towards environmental sustainability. (İlkılıç & Behçet, 2006).

Components that are harmful to humans, such as hydrocarbons, carbon monoxide, and nitrogen oxides that are found in the exhaust gases of motor vehicles deteriorate the health of humans and natureThe reason for this is that these substances have a cancer-causing effect and are toxic in nature. In order to prevent this situation, legal regulations have been implemented in many countries and strategies have been developed to reduce fuel-based environmental damage. In recent years, studies aimed at increasing the use of alternative fuels instead of conventional fuels have gained importance (Koçtürk & Onurbaş, 2012).

Incomplete combustion in motor vehicles, imbalances in the air–fuel ratio, the chemical properties of the fuel, and different operating conditions of the engine cause the formation of exhaust emissions. These gases, which emerge as a result of inadequate combustion conditions, pose a significant threat to the environment and human health (Uyumaz, Boz, Yılmaz, Solmaz, & Polat, 2017). The use of internal combustion engines that meet energy needs through petroleum-based fuels leads to the rapid depletion of resources and the deterioration of ecological balance. This situation has led to research on environmentally friendly, economical, and safe alternative fuels (Batmaz, 2007).

Motor vehicle emissions play a major role in the formation of air pollution, and the most important of these gases are greenhouse gases. Therefore, emission control systems should be developed for motor vehicles and regulated by legal means. In addition, fuel savings should be achieved by reducing vehicle size for mass reduction during the design stage, improving tire performance, and enhancing aerodynamics to reduce wind resistance, thus also reducing exhaust emissions. Furthermore, interest in renewable energy sources such as hydrogen, natural gas, and biodiesel should be increased due to their lower exhaust emissions compared to petroleum-based fuels. As a result, a cleaner future and a cleaner environment can be achieved (Mutlu, Bayrakçeken, Yavuz, Çengelci, & Kunt, 2018).

The increase in petroleum consumption has made it necessary to investigate alternative energy sources due to rising prices and environmental negative effects (Yakın & Behçet, 2021). Especially for countries like Türkiye, which deeply feel the need for economic development, the importance of energy resources is quite significant. Petroleum, as one of the oldest energy resources, has been one of the fundamental determinants of economic growth and development in the past and today. At the same time, as concerns about the depletion of petroleum have increasingly been expressed, the necessity of considering alternative resources that can substitute petroleum for economic growth and development has emerged (Gökçe, 2015).

One of the main factors that lead to air pollution and climate change is the release of carbon monoxide (CO), hydrocarbons (HC), nitrogen oxides (NOx), and particulate matter as a result of the burning of fossil-based fuels. On the whole, the exhaust emissions from motor vehicles are the major contributors to air pollution in metropolitan areas, and as such, they pose a considerable threat to the human body.In addition, the increasing consumption of petroleum leads not only to environmental problems but also to economic fluctuations and energy supply security risks. In this context, it is important to expand the use of alternative and renewable energy sources such as hydrogen, natural gas, and biodiesel in order to reduce dependence on fossil fuels. Moreover, increasing engine efficiency, developing emission control technologies, and ensuring aerodynamic and weight optimizations in vehicle design will contribute to both the reduction of emissions and a sustainable energy transition.

Within the scope of this study, the aim is to contribute to reducing the environmental crisis, carbon emissions, greenhouse gas effects, and ensuring energy sustainability. In line with the global “Net Zero Carbon Emissions” target set for 2050 by many countries and major companies, the ecological and energetic aspects of different gaseous fuels as potential energy sources for internal combustion engines have been examined in depth as alternatives to fossil fuels. In this study, dual-fuel usage was investigated in order to reduce the environmental impacts of spark-ignition engines, and within this scope, gases such as LPG (Liquefied Petroleum Gas), CNG (Compressed Natural Gas), biogas, hydrogen, dimethyl ether, and acetylene were examined, and their environmental and human health effects were evaluated with the aim of reducing dependence on fossil fuels and minimizing the environmental footprint of internal combustion engines.

2. Material and Method

Within the scope of this study, gaseous fuels used as secondary fuels in spark-ignition engines were examined. Studies available in the literature on gaseous fuels such as LPG, CNG, biogas, hydrogen, dimethyl ether, acetylene gas, and methane were evaluated in detail.

2.1. Liquefied Petroleum Gas (LPG)

The history of LPG goes back to the 1900s. The short form LPG is derived from the English phrase "liquefied petroleum gas". In 1910, the American chemist Dr. Walter Snelling, during his studies on the volatile components of gasoline, determined that the main components of the vapor were propane and butane and succeeded in liquefying these gases under pressure. Thus, LPG was first separated and rendered usable. LPG mainly consists of a mixture of propane (C_3H_8) and butane (C_4H_{10}); additionally, smaller amounts of components such as ethane, isobutane, pentane, and olefinic hydrocarbons may also be present. LPG, which exists in gaseous form under normal temperature and pressure conditions, can be liquefied under low temperatures or specific pressure conditions. Industrial LPG is obtained both as a by-product or product during the processing of natural gas and the distillation of crude oil in refineries. In natural gas production, propane and butane are separated from condensed liquid fractions, while

refinery-based LPG is produced by collecting light hydrocarbons released during the heating of crude oil at certain temperatures (Saka, 2003).

2.2. Compressed Natural Gas (CNG)

Compressed Natural Gas is a clean fuel alternative that comes from the compression of natural gas, which is mainly methane (CH_4), to about 200-250 bar. Its combustion produces very little carbon monoxide since its principal methane content is almost one. This signifies that carbon monoxide, nitrogen oxides, and particulate matter are among the emission sources that are greatly reduced by this fuel source. Hence, it has an ecological advantage over fossil fuel energy sources.The natural gas for CNG may have different proportion of components such as ethane (C_2H_6), propane (C_3H_8), butane (C_4H_{10}), nitrogen (N_2), and carbon dioxide (CO_2). These compositional differences affect the energy density, combustion efficiency, and thermodynamic behavior of the gas. The development of CNG technology has been able to provide a solution to the needs of different sectors especially the transportation and public transit sectors, due to the ability to be stored under high pressure, ease of transportation, and low emission values. In addition, its lower price relative to diesel and gasoline has made it possible for CNG to play an important role in the implementation of sustainable energy policies(Özcan, 2025).

2.3. Hydrogen

Cavendish discovered Hydrogen in 1766. Later, Lavoisier essentially redefined its properties when he found out that it is the lightest, tasteless, and colorless element in nature. Its flammability limits are from 0.15 to 4.35 λ which makes it the most suitable fuel for Otto engines. Hydrogen is a cool, convertible energy source, so it can be stored either in a liquid or gaseous state and emits only water vapor when burned. The fact that it is around four times lighter than air both allows for safer operations and makes them more difficult when it comes to handling and storage. After all, hydrogen has a high energy density per unit of mass, but a low energy density per unit of volume, so special storage systems are needed for it. The large ignition range and the low ignition energy of hydrogen make the combustion process more flexible in engines. As no carbon compounds are generated in the burning of hydrogen, no pollutants like CO_2, CO, or SO_x find their way into the atmosphere. Because of these features hydrogen is regarded as a renewable energy source with far less environmental impact than fossil fuels and thus it is likely to become an integral part of the future energy systems(Kahraman, Akansu, & Albayrak, 2007).

2.4. Dimethyl Ether (DME)

Dimethyl ether (DME), with the chemical formula $CH_3–O–CH_3$, is a very light ether derivative and shows great similarity to LPG in terms of physical properties. Therefore, it can be used under infrastructure conditions similar to those of LPG for storage, transportation, and fuel systems. DME can be produced by either indirect or direct synthesis methods. In the indirect method, DME is obtained as a result of the dehydration reaction of methanol, while in the direct method, production is carried out directly from natural gas. When compared in terms of energy equivalence, the production cost of DME is lower than that of diesel or gasoline. Moreover, in large-scale plants, its cost is at a level similar to compressed or liquefied natural gas. DME is gaseous under normal temperature and pressure and is non-toxic; however, it must be stored under a pressure of approximately 0.5 MPa or higher to remain in liquid form. Under engine operating conditions, this pressure must be increased to the range of 1.7–2.0 MPa.

Its high cetane number indicates good ignition capability, while its high latent heat of vaporization contributes to a decrease in mixture temperature. The absence of C–C bonds in its structure and its oxygen content of approximately 35% ensure that the combustion process is

almost completely free of particulate matter (PM), reduce engine noise, and allow the use of higher EGR rates to reduce NOx emissions. However, its low viscosity and poor lubricating properties may cause leakage and wear problems in the fuel system; therefore, the use of suitable additives is required. Due to its high compressibility, DME requires more pumping power than diesel fuel. In addition, since it may chemically interact with some rubber materials and cause deformation, it is recommended to use DME-resistant materials in fuel systems. With all these characteristics, DME is considered an environmentally friendly, low-emission, and promising alternative fuel for diesel engines (Sezer, 2023).

2.5. Acetylene Gas

Acetylene gas holds an indispensable place especially in the manufacturing industry and is used for various purposes such as cutting and welding. The first use of acetylene in internal combustion engines can be associated with Gustave Whitehead's manned flight on December 17, 1903, at Kitty Hawk beach. The engine used in this historic experiment operated on acetylene gas. However, since sufficient power could not be obtained from the approximately 21-horsepower engine, the aircraft remained in the air for only about 50 meters before crashing. Acetylene (C_2H_2) is a colorless, garlic-odored, highly flammable gas that is lighter than air. Although it has low toxicity, it may cause asphyxiation by consuming the oxygen in the environment. In industry, it is generally produced by the reaction of carbide with water. The most distinctive feature of acetylene is its high flame temperature (approximately 3160 °C) and fast flame speed; therefore, it is widely preferred in welding and cutting applications together with oxygen. In gaseous form, it is highly unstable and may decompose explosively at pressures above 2 bar; thus, it is usually stored dissolved in acetone in special cylinders. Although acetylene has a high heating value and provides advantages in terms of energy yield, it requires careful handling in terms of storage and safety. Free acetylene gas is dangerous at pressures above 15 psig (approximately 1.013 bar), and as a safety measure, it is of vital importance that the temperature of acetylene cylinders does not exceed 50 °C. Commercially, acetylene is mostly obtained by adding water to carbide or vice versa. In the market, acetylene is available as a gas absorbed in a solvent (usually acetone) inside specially designed cylinders. To generate the welding flame, a combustible gas is required; in oxy-gas welding, the necessary heat is provided by burning the combustible and oxidizing gases mixed in specific ratios in the torch. With a flame power of 43 kW/cm² and a flame temperature of 3200 °C, acetylene has the highest flame power and temperature among all combustible gases, making it the most preferred industrial fuel gas (Vural & Özer, 2014).

2.6. Biogas

Biogas is a clean energy source obtained from the anaerobic digestion of organic wastes (for example agricultural residues, animal manure, and domestic waste) by bacteria. The chief constituent of biogas is CH_4, but there is also CO_2, very small quantities of hydrogen sulfide (H_2S), nitrogen (N_2), and some other non-combustible gases. The percentage of methane is usually between 50% and 70%, and this proportion is the key element that specifies the calorific value of biogas.. Oxygen- and sulfur-containing compounds such as CO_2 and H_2S reduce the heating value of biogas; therefore, biogas purification processes, in which these components are removed, are preferred to increase energy efficiency. As a simple hydrocarbon, CH_4 can be used safely and efficiently as a fuel in internal combustion engines due to its chemical stability. In addition, the combustion of biogas reduces the amount of methane released into the atmosphere, creating a positive effect in terms of global warming, since methane has a much higher global warming potential than carbon dioxide. The disadvantages of biogas are limited by the low flame propagation speed inside the cylinder due to its low heating value and the low

volumetric efficiency resulting from the unburned mixture. Nevertheless, due to its high combustion characteristics, ease of production from renewable sources, and strong potential as an energy storage technology, biogas is considered a highly important energy source in today's energy markets (Yılmaz, Yavuz, & Gümüş, 2020).

2.7. Methane

Both hydrogen and methane, as alternative fuels, can provide remarkable advantages in efficiency and performance of internal combustion engines. Hydrogen being the lightest and most abundant element in the universe, basically generates just water vapor as a combustion product, therefore, it is an environmentally friendly source with zero carbon-based emissions. Methane, however, is the major component of natural gas.As a matter of fact, hydrogen has spectacular advantages because of its high heating value and very wide ignition limits whereas, the low flame speed of methane can cause some combustion problems. One of the major problems of backfiring is the low ignition energy of hydrogen which together with storage limitations, constitutes the main technical barriers for its widespread application. Generally, these fuels are envisaged in dual or ternary fuel systems with a fuel such as methanol to increase thermal efficiency and decrease emissions (Akbıyık, 2025).

Methane is the major constituent of natural gas and it contributes to good knock resistance and low particulate matter (PM) emissions because of its high octane number and hydrogen-to-carbon ratio. Hence, it is regarded as a clean fuel in terms of the emission performance. On the other hand, the methane molecule has a very stable structure, which results in a slow combustion rate and causes ignition difficulties when a lean mixture is used. The slow combustion leads to increased cycle-to-cycle variations, reduced thermal efficiency, and increased exhaust gas temperatures in spark-ignition engines. Still, methane, because of its high hydrogen content, makes possible a more environmentally friendly combustion process, hence the release of carbon emissions is lowered. To enhance engine performance and keep the combustion stable condition even with a low energy density, several methods like changing the ignition energy, multi-point ignition, and generating turbulent mixture formation are utilized (Chen et al., 2019).

3. Results and Discussions

3.1 Use of Liquefied Petroleum Gas and Compressed Natural Gas as Dual Fuels in Spark-Ignition Engines

Doğu et al. (Doğu, Yontar, & Kantaroğlu, 2018) first conducted tests using single fuel operation with gasoline (G100), and then compared the results by adding supplementary fuels. They injected 10% CNG (CNG10) and 5% LPG (LPG5) into gasoline on a mass basis. In their experimental study, they examined the effects on engine performance and exhaust emissions. The results indicated that both fuels caused a reduction in torque and volumetric efficiency compared to gasoline. For CNG10, torque decreased by 17.4% and volumetric efficiency by 23.2%, whereas for LPG5, torque decreased by 8.5% and volumetric efficiency by 15.6%. In terms of specific fuel consumption, both mixtures showed improvement compared to gasoline. A reduction of 5% was achieved for CNG10 and 7.1% for LPG5. Emission analysis showed significant decreases in CO and HC emissions for both fuels. HC emissions decreased by 29% for CNG10 and 34% for LPG5. However, both mixtures caused NOx emissions to increase by 4 to 5 times compared to gasoline.

Sayın et al. (Sayın, Çanakçı, & Kılıçaslan, 2005) examined the effects of combined use of gasoline and LPG on the performance and emissions of a dual-fuel engine. The results showed that specific fuel consumption in dual-fuel operation was lower than in single-fuel operation.

This improvement was attributed to increased turbulence in the intake manifold caused by high-pressure LPG injection, which enhances combustion efficiency. Exhaust emissions were also found to be lower compared to single-fuel operation across all engine loads and speeds.

3.2 Use of Hydrogen as a Dual Fuel in Spark-Ignition Engines

In a study investigating hydrogen addition, Batmaz (Batmaz, 2007) experimentally analyzed the effects of using hydrogen as an auxiliary fuel on the performance and emission parameters of spark-ignition engines. In his experimental setup, a single-cylinder, four-stroke engine was operated with hydrogen-enriched fuel without any modifications. Hydrogen was added at rates of 4%, 8%, and 12%. The findings showed that hydrogen addition improved the combustion characteristics of the engine and significantly reduced CO and HC emissions. It also resulted in lower specific fuel consumption. However, due to hydrogen's low density and high displacement volume, volumetric efficiency, engine torque, and power output decreased. Therefore, while hydrogen addition provides environmentally favorable emission benefits, it presents limiting effects on engine performance.

3.3 Use of Dimethyl Ether as a Dual Fuel in Spark-Ignition Engines

In the study where dimethyl ether (DME) was added to gasoline as a secondary fuel, the effects of DME–gasoline mixtures on CO emissions in spark-ignition engines were examined. The findings showed that DME improves combustion due to its oxygenated structure and significantly reduces CO emissions, particularly under lean-burn conditions. During cold-start operation, CO levels decreased more rapidly than with gasoline, which was attributed to DME entering the engine in gaseous form and forming a more homogeneous mixture. However, while certain proportions of DME addition reduced emissions, higher addition rates caused an increase in CO formation. It was also determined that injection strategy and ignition timing significantly affect emission outcomes. Overall, the study concluded that DME has strong potential for reducing CO emissions in gasoline engines when used as a supplementary fuel, but optimal effects require careful selection of blending ratio, combustion conditions, and injection strategy (Sezer, 2025).

3.4 Use of Acetylene Gas as a Dual Fuel in Spark-Ignition Engines

The experiment added 20% and 30% acetylene gas to gasoline at variable engine speeds and constant throttle position to study the effects on exhaust gas temperature and emission levels. The outcomes displayed substantial decreases: exhaust gas temperature diminished by 8–21%; HC emissions by 40–56%; CO emissions by 30–60%; CO_2 emissions by 25–55%; and NOx emissions by 5–19%. Nevertheless, the occurrence of knocking due to acetylene self-ignition at 3 bar pressure was noticed, which led to reduced combustion efficiency (Vural & Özer, 2014).

3.5. Use of Biodiesel as a Dual Fuel in Spark-Ignition Engines

Fil (Fil, 2025) conducted a study investigating the effects of gasoline–biodiesel fuel blends under partial load conditions and examined their performance and emission characteristics. In the study, tests were performed on a four-cylinder, multi-point injection engine using 100% gasoline (B100), 95% gasoline + 5% biodiesel (B95BD5), and 90% gasoline + 10% biodiesel (B90BD10) blends at different excess air ratios (λ = 0.9, 1.0, 1.1). The results showed that 5% biodiesel addition reduced brake-specific fuel consumption, increased volumetric efficiency, and decreased unburned hydrocarbons and carbon monoxide emissions. However, due to the high oxygen content of biodiesel, an increasing trend was observed in carbon dioxide and nitrogen oxide emissions. Under lean-burn conditions (λ = 1.1), the highest brake thermal efficiency was achieved with the 10% biodiesel blend. Overall, the study indicated that

biodiesel use in gasoline engines can provide significant reductions in harmful emissions without causing substantial performance losses, highlighting its notable potential.

4.Conclusions and Recommendations

In this study, the effects of different gaseous secondary fuels used in spark-ignition engines on engine performance and exhaust emissions were investigated and examined using the available literature. When the studies presented in the literature are generally evaluated, it is observed that the use of various alternative fuels and fuel additives in spark-ignition engines creates significant effects on both performance and emissions. The gases examined focus on the use of LPG, CNG, hydrogen, dimethyl ether, acetylene, biogas, and methane as additives to gasoline. The findings obtained from the literature review are as follows:

- In general, dual-fuel applications lead to limited reductions in engine performance, while providing significant improvements in emissions.
- In spark-ignition engines with the addition of Compressed Natural Gas (CNG) and LPG:
  - o It has been determined that torque and volumetric efficiency decrease compared to gasoline.
  - o On the other hand, a 5–7% improvement in specific fuel consumption was achieved, and significant reductions in CO and HC emissions were observed.
  - o However, a 4–5-fold increase in NOx emissions was noted.
- When hydrogen is added, combustion characteristics improve, resulting in substantial reductions in CO and HC emissions and a decrease in specific fuel consumption. However, due to its low density, charging efficiency and engine torque also decrease.
- Dimethyl ether, being an oxygenated compound, increases combustion efficiency and particularly reduces CO emissions, providing a more homogeneous mixture under lean conditions. However, at high DME blending ratios, CO formation may increase again.
- In experiments with acetylene addition, significant reductions in HC, CO, CO_2, and NOx emissions were observed. However, due to its high flammability, the tendency for knocking increased, which adversely affected combustion efficiency.
- The addition of biodiesel, when used in small amounts, reduced brake-specific fuel consumption and lowered HC and CO emissions. However, due to its high oxygen content, an increasing tendency in CO_2 and NOx emissions was noted.

ABSTRACT

With the increasing efficiency of large language models (LLMs) and the expansion of their applications, research attention has shifted from basic LLMs to compound AI systems, and, more recently, to multi-agent architectures for more complex tasks. These systems demonstrate enhanced reasoning capabilities, autonomous decision-making, and improved task focus while mitigating the limitations of the context window length, one of the main constraints on large language models. Although there has been growing interest in this field, the current literature still lacks a sufficient number of experimental studies that systematically evaluate the performance of LLM-based AI agent systems. This is especially true since their efficiency depends on several factors, including collaboration among agents, the efficiency of the employed model, the nature of the tasks, the quality of the tools, and the structure of the system. This study aims to experimentally compare LLM-based single-agent and multi-agent structures for automating a procurement process. The experiment was conducted using the CrewAI framework in the Google Colab environment with Python, and performance was tracked via the AgentOps platform to measure metrics execution time, token consumption, and task success rate. The results showed that both systems successfully completed the task. Unexpectedly, the multi-agent system exhibited a shorter execution time and lower token consumption. These findings suggest that role distribution and collaboration among agents can improve overall efficiency, even for simple tasks, and reduce operational costs. Therefore, this study contributes to clarifying practical aspects of AI system design and provides a novel experimental comparison demonstrating the impact of agent structure and organization.

Keywords: Large language model (LLM), Single agent, Multi agent, Task automation

1. Introduction

In recent years, Multi-Agent Systems (MAS) have received considerable attention for their capability to handle complex problems. These systems comprise autonomous entities known as agents, which are designed to perceive their environment, remember past situations, make decisions, and take actions (Perera et al., 2025). Agents cooperate, leveraging their knowledge and tools to make informed decisions and solve assigned tasks. Despite the efficiency of agent systems, they have faced several challenges, including learning, fault detection, task allocation, and generalization to new cases (Dorri et al., 2018).

Recent advances in Large Language Models (LLMs) represent a significant turning point in the history of artificial intelligence. LLMs exhibit broad capabilities in knowledge acquisition, reasoning, and interaction. LLMs have led to the development of LLM-based agent systems, which some researchers view as a step toward Artificial General Intelligence (AGI) (Xi et al., 2023). Unlike traditional rule-based systems, these systems rely on LLMs, which enable them to reason more effectively and to use their knowledge to handle long contexts and extract information more effectively (Zhao et al., 2024). These systems follow the ReAct principle, which involves reasoning and action. They comprise three key components: brain, perception, and action. The brain represents LLM and memory, whereas action depends on tools that enable agents to perform tasks (Xi et al., 2025). Current research often focuses on employing these systems to improve efficiency.

The efficiency of LLM-based agent systems depends on several factors, making it difficult to identify a single approach that yields optimal performance. Some of the most important factors include collaboration among agents, model efficiency, task characteristics, tool quality, and system structure. The context window problem, considered one of the primary limitations of LLMs, has been a key driver of the shift toward the use of multi-agent systems (Zhao et al., 2024). Recent studies have shown that allocating tasks and tools to each agent and establishing a clear distribution of roles in a multi-agent system generally lead to improved performance and efficiency by reducing task complexity and guiding models toward more effective reasoning (Li et al., 2025; Mohammed & Kora, 2025). Although LLM-based multi-agent AI systems are highly efficient, they may be more costly due to higher communication overhead between agents and frequent calls to tools and LLMs. The balance between cost and efficiency, as well as the choice between single-agent and multi-agent systems, remains an area of ongoing research. With advances in LLMs, single-agent systems have achieved performance comparable to that of multi-agent systems in less complex tasks, thereby reducing the need for multi-agent systems in many cases. Our study is motivated by this observation, as there are currently insufficient comparisons between single-agent and multi-agent systems for low-complexity tasks.

This study aims to perform an experimental comparison between LLM-based single and multi-agent structures within the task of automating a procurement process. The results showed that both systems successfully completed the task; however, unexpectedly, the multi-agent system recorded a shorter execution time and lower token consumption. These findings suggest that the distribution of roles and collaboration between agents can improve overall efficiency, even in simple tasks, and reduce operational costs. Therefore, this study contributes to clarifying the practical aspects of designing AI systems and provides a new experimental comparison that helps demonstrate the impact of agent structure and organization.

2. Related work

LLM-based AI agent systems are considered a new technology that emerged around 2022. Therefore, the literature remains limited. However, the field continues to grow significantly. This section reviews the major studies that have contributed to this field, with a focus on key concepts and practical applications.

Zhao et al. (2024) discussed the capabilities of LLMs and how they contribute to the development of multi-agent systems. Xi et al. (2025) conducted a comprehensive study on LLM-based agents, covering configuration frameworks, application scenarios, and future directions of LLM-based agents. There is also research that provides an overview of various applications of LLM-based multi-agent systems across different fields (Wang et al., 2024). From a practical perspective, Zhong et al. (2024) applied LLM-based agent systems to develop a framework for information processing in Internet of Things (IoT) environments, whereas Jiang et al. (2025) proposed a framework to enhance decision making in autonomous driving systems. In the field of networking, Chatzistefanidis et al. (2024) presented a framework for automating shared 6G networks and optimizing resource allocation among users. From a different perspective, Park et al. (2023) conducted simulations of human behavior using LLM-based multi-agent systems to examine their ability to interact in everyday human-like scenarios, raising questions about how well these systems can perform under full autonomy. Li et al. (2025) conducted an experimental comparison between single-agent and multi-agent systems for predicting Alzheimer's disease, demonstrating that multi-agent systems are more effective than single-agent systems. A survey conducted by X. Li et al. (2024) provides an overview of the key concepts, trends, and challenges in the development of LLM-based agent systems.

Despite the growing interest in this field, studies and experiments in other fields remain necessary. Cooperation among agents and their design structures, evaluation metrics, interactions with humans, and the autonomy and security of these solutions remain important research gaps.

3. Method

This section aims to explain the implementation of the experiment, the architectures used, the evaluation of system performance, and the experimental results.

3.1 Use case

The procurement process was selected as the use case for this experiment to compare the performance of single-agent and multi-agent systems. The process involves several steps: it begins with a request for a specific product, followed by generating search keywords and conducting online research to collect and scrape information about the product and its alternatives regarding specifications and prices. It concludes by comparing the options and generating a summary report. This case was chosen because it follows a clear and structured workflow, making it suitable for comparison of the two systems. In addition, most applied studies focus on coding or scientific research tasks; therefore, incorporating this use case expands the applications of LLM-based agent systems.

3.2 Agents and Structures

The number of agents is the primary variable compared in this study. A single-agent system, as its name suggests, consists of one agent performing all tasks, while a multi-agent system consists of four agents; the query generator agent, which generates search keywords required to search for products; the web search agent, which searches Google for products using those keywords; the product scraper agent, which scrapes product information from the web for each

product; and finally, the report generation agent, which analyzes the results and generates the final report. Figure 1 provides an overview of the agents within each architecture.

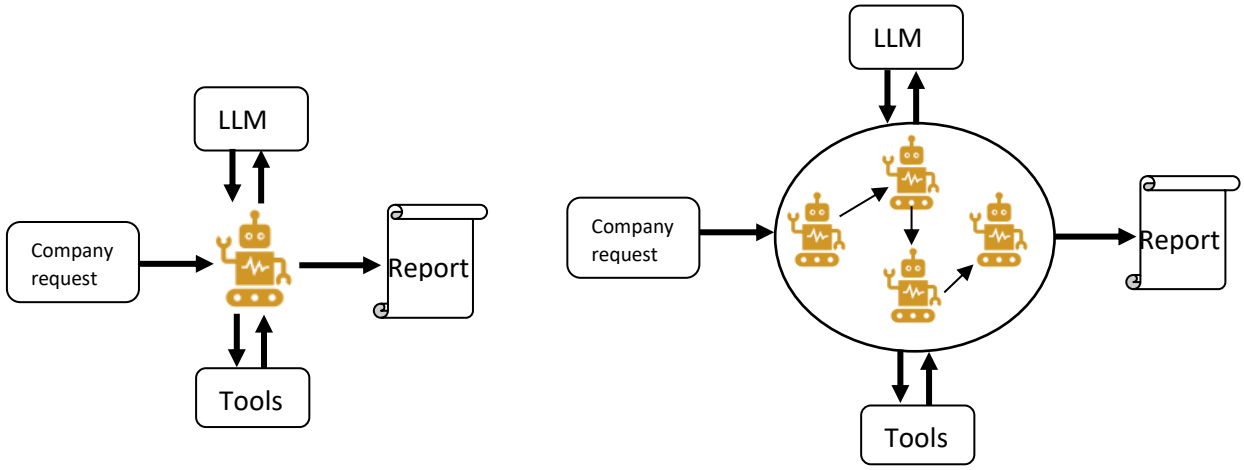

Figure 1. Overview of the single-agent (left) and multi-agent (right) system architectures.

3.3 Tasks and tools

The use case comprises four tasks, each assigned to a specific agent based on its role in the multi-agent system; in the single-agent system, a single agent performs all four tasks. The process is sequential, meaning tasks are performed in a specific order: generating search keywords, searching the internet using these keywords, scraping product information, comparing the results, and creating the final report. The agents leveraged the LLM's knowledge to generate search keywords and create the final report in HTML format, without the need for any additional tools or functions. For web searching and web scraping, two external tools were used: Tavily for searches and ScrapeGraph for web scraping, both of which were accessed via APIs. Figure 2 shows the sequence of tasks for the use case.

3.4 Experiment environment and conditions

The experiment was conducted using Google Colab and Python. CrewAI was selected as the framework for creating agent systems, and GPT 4.0 as the LLM. The processes were monitored using Agentops. The experimental conditions were designed to ensure fair results by keeping just one variable (agent counts) while all other conditions were kept the same. In other word the single-agent system included one agent, and the multi-agent system included four agents.

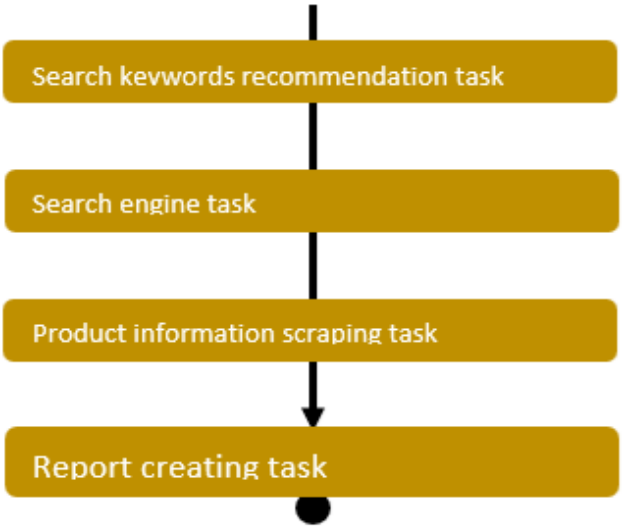

Figure 2. The order of tasks in the use case.

3.5 Evaluation metrics

The evaluation of LLM-based multi-agent systems remains a gap in current research. Currently, there is no general standard metric to evaluate the performance of these systems, as they rely on multiple components that work together. For this reason, evaluating only the system's outputs is insufficient; a deeper analysis of the agent's behavior is crucial to obtain a more reliable evaluation and to improve system efficiency. Most current studies focus on evaluating the system's final outputs, as in Mandal et al. (2025) and Wu et al. (2025). Common metrics include total token consumption and execution time, which are especially important for systems that require fast responses. Since many applications rely on performing automated tasks, the task success rate has become a key performance metric. Additional metrics can provide a deeper understanding of how the system works, such as the average task time or the rate of successful tool calls. In this study, execution time, total tokens, successful task rate, successful tool call rate, and average task time were used to evaluate system performance.

4. Results

The experiment was conducted twice on each system using two different product requests. The variation between the two systems affected execution time and token consumption; however, the overall performance trends of the two systems were similar. Unexpectedly, the results showed that the multi-agent system achieved better efficiency in terms of execution time and resource consumption. Both systems completed the tasks successfully. Table 1 and Figure 3 present the results of the comparison between the two experiments. With respect to output quality, both systems generated the final report correctly, exhibiting proper structure and complete content. However, the report generated by the multi-agent system exhibited a more professional design and more formal phrasing.

Table 1. Performance comparison table between the single and multi-agent systems.

Experiment no	System Type	exec time (sec)	total tokens	successful tasks rate	successful tool calls rate	avg task time (sec)
1	Single-agent	149.357	82648	100%	100%	36.582
	Multi-agent	**75.360**	**27861**	**100%**	**100%**	**18.823**
2	Single-agent	57.064	56069	100%	100%	14.09
	Multi-agent	**54.917**	**33411**	**100%**	**100%**	**13.71**

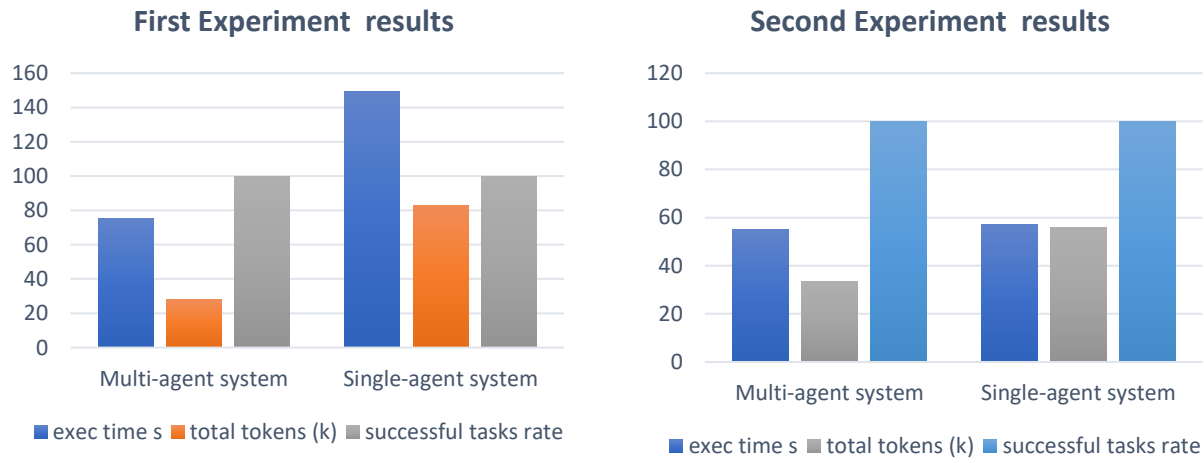

Figure 3. Performance comparison charts between the single and multi-agent systems.

5. Conclusion

This study experimentally compared LLM-based single-agent and multi-agent systems in the context of automating a procurement process. The results show that both systems successfully completed the task. However, the multi-agent system exhibits reduced token consumption and a shorter execution time. This suggests that task sharing and cooperation between agents can positively impact system efficiency. The results demonstrate that multi-agent systems can offer cost and quality advantages not only in complex tasks but also in simpler scenarios.

6. Discussion and Future work

The results of this study cannot be generalized, as the performance of multi-agent systems depends on numerous factors, including the nature of the task, the type of process, the system's design structure, and the selection of the LLM. In our experiment, the process was sequential, which reduced the need for delegation and communication between agents. This may partially explain why the multi-agent system exhibited better token efficiency than the single-agent system. This study contributes to clarifying practical aspects of designing LLM-based agent systems and suggests directions for future work. One important direction is exploring how different communication methods and organizational structures impact the performance of

agents. Another research topic is studying the level of autonomy at which these systems can operate safely and reliably. Human–agent interaction is also a key aspect that warrants study, alongside the development of more stable and fair evaluation metrics for assessing the performance of such systems across different tasks.

ÖZET

Bu çalışma, askerî taktik tekerlekli araçların hiyerarşik bakım yapısını incelemekte ve kullanıcı, birlik ve fabrika seviyelerindeki faaliyetlere odaklanmaktadır. Her bakım seviyesi; farklı teknik yetkinlikler, lojistik destek ihtiyaçları ve donanımlarla yürütülen, operasyonel sürekliliği ve araç göreve hazırlığını sağlayan bütünleşik bir sistemin parçasıdır. Bu çalışmada, bakım faaliyetlerinin yanı sıra, her seviyede yapılandırılmış teknik eğitimin rolü vurgulanmakta ve eğitim sonrası saha desteği ile kullanıcı geri bildirim mekanizmalarının sistem performansına olan katkısı analiz edilmektedir. Gerçek saha örnekleri üzerinden, uzaktan arıza tespiti ve geri bildirimle yapılan sistem iyileştirmeleri aracılığıyla, eğitimin yalnızca bir bilgi aktarımı değil; operasyonel sürdürülebilirliği destekleyen dinamik bir süreç olduğu ortaya konulmaktadır. Bulgular, teknik eğitim ile saha destek yapısının birlikte ele alınmasının, bakım sürecini statik bir işlem olmaktan çıkararak göreve uyumlu ve gelişime açık bir yapıya dönüştürdüğünü göstermektedir.

MAINTENANCE LEVELS AND TRAINING DYNAMICS IN MILITARY VEHICLES: ANALYSIS OF USER, UNIT, AND FACTORY-LEVEL APPROACHES

ABSTRACT

This study examines the hierarchical maintenance structure of military tactical wheeled vehicles, focusing on the user, unit, and factory-level operations. Each level involves distinct technical competencies, logistical support, and tools, forming an integrated framework to ensure operational continuity and vehicle readiness. Beyond maintenance tasks, this paper emphasizes the role of structured training at each level and analyzes how post-training support mechanisms and user feedback loops contribute to continuous improvement in system performance. Real-world examples, including remote troubleshooting and adaptation based on field experiences, illustrate how training evolves into a dynamic process influencing technical quality and operational sustainability. The findings highlight that technical training, coupled with active field support and systematic feedback evaluation, transforms maintenance from a static process into a responsive, evolving system aligned with mission requirements.

Keywords: Training and logistics support, Field support system, Integrated logistics support, Maintenance personnel training

1. Giriş

Zırhlı kara araçlarının yüksek teknolojiye sahip sistemlerinin operasyonel sürekliliği, planlı ve çok seviyeli bakım faaliyetlerine bağlıdır. Bu araçların bakım sistemleri, kullanıcı, birlik ve fabrika seviyeleri olmak üzere üç ana kategoriye ayrılmakta olup, her bir seviye farklı teknik bilgi, donanım ve lojistik altyapı gereksinimleri içermektedir. Bu makalede, bakım seviyelerinin teknik detayları, uygulama örnekleri ve kullanılan araç-gereçler kapsamlı şekilde incelenecek; çok katmanlı bakım sisteminin askerî operasyonlardaki önemi vurgulanacaktır.

2. Kullanıcı Seviyesi Bakım

2.1 Tanımı ve Kapsamı

Kullanıcı seviyesi bakım, askerî araçların günlük operasyonlarda kesintisiz ve güvenli şekilde görev yapabilmesi için, aracın doğrudan kullanıcı personel tarafından gerçekleştirilen temel bakım faaliyetlerini kapsar. Bu seviyedeki bakım işlemleri, rutin kontroller, temizlik, sıvı seviyelerinin izlenmesi ve küçük çaplı arızaların önlenmesi gibi basit fakat kritik görevlerden oluşur. Kullanıcı seviyesi bakım; görev öncesi, görev süresi ve görev sonrası olmak üzere periyodik olarak uygulanmakta olup, bakım zincirinin ilk halkasını oluşturur ve daha karmaşık tamirlerin önünü açar.
Örneğin, motor yağı, soğutma suyu, fren hidrolik seviyesi, lastik basıncı ve araç ışıklarının kontrolü kullanıcı seviyesi bakım kapsamındadır. Ayrıca görsel muayeneler aracın genel durumu hakkında ön bilgi sağlar ve sonraki bakım aşamalarına yönlendirme işlevi görür.

2.2 Uygulama Örnekleri

- Motor yağı ve soğutma suyu kontrolü: Sürücü, günlük göreve çıkmadan önce motor yağ ve soğutma suyu seviyelerini ölçer, eksiklik varsa tamamlar.
- Lastik basıncı ölçümü: Lastiklerin arazi şartlarına uygun hava basıncında tutulması, aracın güvenliği ve performansı için elzemdir. Basınç ölçümü manuel cihazlarla yapılır.
- Görsel muayene: Araç gövdesinde sızıntı, çatlak veya bağlantı gevşekliği gibi durumlar kontrol edilir.
- Fonksiyon testleri: Far, fren, sinyal ve haberleşme ekipmanlarının çalışırlığı test edilir.

2.3 Kullanılan Avadanlıklar

Kullanıcı seviyesinde kullanılan araç gereçler dayanıklı, portatif ve ergonomik olmalıdır:

- Tornavidalar (düz, yıldız), lokma anahtar setleri
- Lastik basınç ölçer ve el pompası
- Gres tabancası, yağlama fırçaları
- Basit elektrik test cihazları (kontrol lambası, voltmetre)
- Temizlik malzemeleri ve sıvı dolum hunisi

2.4 Personel Yeterliliği ve Eğitim

Bu seviyede bakım yapan personel temel teknik eğitim almakta, örneğin tank sürücüleri rutin bakım prosedürlerini öğrenip uygulamaktadır. Personel, bakım çizelgeleri doğrultusunda kontrol listelerini düzenli olarak tamamlamaktadır.

3. Birlik Seviyesi Bakım

3.1 Tanımı ve Kapsamı

Birlik seviyesi bakım, kullanıcı seviyesinde tespit edilen veya sahada ortaya çıkan daha karmaşık arızaların, birlik bünyesinde kurulan tamir atölyelerinde uzman personelce giderilmesini ifade eder. Bu bakım seviyesi, motor, şanzıman, elektronik kontrol üniteleri ve süspansiyon sistemleri gibi kritik bileşenlerde kapsamlı müdahaleler gerektirir. Birlik bakımının amacı, aracın operasyonel ortamdan çıkarılmaksızın, saha veya yakın lojistik merkezlerinde hızlı ve etkili onarımını sağlayarak operasyonel sürekliliği maksimize etmektir. Ayrıca, kritik parçaların performans ölçümleri, test ve ayarları da bu seviyede gerçekleştirilir.

3.2 Uygulama Örnekleri

- Motor onarımı: Performans düşüklüğü tespit edilen motor, atölyede sökülüp incelenir ve gerekli tamiratlar yapılır.
- Elektronik arıza teşhisi: Savaş yönetim sistemindeki sinyal kesintileri, bilgisayar destekli arıza teşhis cihazları ile analiz edilir.
- Şanzıman ve diferansiyel bakımı: Kritik hareket sistemleri sökülüp onarılır veya değiştirilir.
- Süspansiyon ve fren sistemi kontrolü: Ağır arazi koşullarına maruz kalan süspansiyon ve fren elemanları ayrıntılı olarak kontrol edilir.

3.3 Kullanılan Avadanlıklar

Birlik seviyesinde bakım için gelişmiş ekipmanlar kullanılır:

- Elektrikli ve pnömatik el aletleri (matkap, taşlama, vidalama)
- Hidrolik kaldırıcılar, krikolar
- Bilgisayar destekli arıza teşhis cihazları (multimetre, osiloskop, ECU programlayıcılar)
- Motor test ve kompresyon ölçüm cihazları
- Kaynak makineleri ve montaj ekipmanları

3.4 Personel Yeterliliği ve Organizasyon

Birlik seviyesi bakım personeli ileri teknik eğitimli teknisyenlerden oluşmakta, motor, elektronik ve mekanik alanlarda uzmanlaşmaktadır. Personel, bakım prosedürlerine uygun çalışmak ve lojistik destek ile koordinasyonu sağlamakla yükümlüdür.

4. Fabrika Seviyesi Bakım

4.1 Tanımı ve Kapsamı

Fabrika seviyesi bakım, askerî araçların yapısal ve fonksiyonel bütünlüğünü sağlamak üzere en kapsamlı ve ileri düzey bakım işlemlerini içermektedir. Genellikle üretim tesisleri veya yetkili bakım fabrikalarında gerçekleştirilir ve araçların kapsamlı revizyon, yenileme ve modernizasyon işlemlerini kapsar.
Bu seviyede motor ve şanzımanın komple revizyonu, elektronik sistemlerin yenilenmesi, gövde yapısının güçlendirilmesi ve zırh plakalarının değiştirilmesi gibi ileri teknoloji ve hassasiyet gerektiren işlemler yürütülür. Parçaların hassas ölçüm, test, kalibrasyon, kalite kontrol ve yazılım güncellemeleri de fabrika seviyesinde yapılır.

4.2 Uygulama Örnekleri

- Motor revizyonu: Motor tamamen sökülüp parçalar ölçülür, aşınan parçalar değiştirilir ve performans testlerine tabi tutulur.
- Elektronik sistem modernizasyonu: Yeni nesil yazılım ve donanımlar entegre edilir.
- Araç gövde yenileme: Zırh plakaları değiştirilir, korozyon önleyici kaplamalar uygulanır.
- Kapsamlı test ve sertifikasyon: Araçların hareket kabiliyeti, ateş gücü ve elektronik sistemleri fabrikada detaylıca test edilir.

4.3 Kullanılan Ekipmanlar

- Ağır kaldırma ve montaj makineleri
- CNC makineleri, hassas ölçüm cihazları
- Robotik kaynak sistemleri
- Gelişmiş elektronik test ve kalibrasyon cihazları
- Yazılım güncelleme ve simülasyon ortamları

4.4 Personel Yeterliliği ve Yönetim

Fabrika seviyesi bakım personeli mühendisler, yüksek eğitimli teknisyenler ve kalite kontrol uzmanlarından oluşur. Bu personel, ileri mühendislik bilgisi ile bakım süreçlerini uluslararası kalite standartlarına uygun şekilde yürütür.

5. Bakım Seviyeleri Arasındaki Entegrasyon ve Lojistik Önemi

Askerî araç bakım faaliyetlerinde bakım seviyeleri arasındaki entegrasyon, operasyonel etkinliği ve araçların görevde kalma süresini doğrudan etkileyen kritik bir unsurdur. Bakım süreçlerinin hiyerarşik yapısı, kullanıcı, birlik ve fabrika seviyelerinde yürütülen işlemlerin koordineli şekilde planlanmasını ve uygulanmasını gerektirir. Bu koordinasyonun sağlanması, bakım döngüsünün etkinliği, lojistik destek altyapısının yeterliliği ve personelin eğitim seviyesi ile yakından ilişkilidir.

5.1 Bakım Seviyeleri Arasındaki İlişki ve Süreç Yönetimi

Kullanıcı seviyesinde tespit edilen basit arızalar veya bakım ihtiyaçları, hızlı müdahaleyle giderilmediğinde veya teknik olarak aşılması gereken sorunlara dönüştüğünde, bu durum birlik seviyesine sevk edilir. Birlik seviyesi bakım merkezleri, kullanıcı seviyesinde çözülemeyen teknik problemleri çözerek, aracın operasyonel sürekliliğini sağlar ve fabrika seviyesine gitme ihtiyacını minimize eder. Ancak, birlik seviyesinde de giderilemeyen kapsamlı arızalar veya revizyon gereksinimleri fabrika seviyesine aktarılır.
Bu aşamalar arasındaki etkin bilgi akışı, bakım planlarının güncellenmesi ve operasyonel gereksinimlerin karşılanması bakımından önemlidir. Bakım kayıtları, arıza geçmişi ve performans verilerinin dijital ortamda paylaşılması, bakım kararlarının hızlı ve doğru verilmesini mümkün kılar.

5.2 Lojistik Zincirinin Rolü

Bakım faaliyetlerinin aksamaması için lojistik destek sisteminin sağlıklı işlemesi gerekmektedir. Her bakım seviyesi, ihtiyaç duyulan yedek parça, özel araç-gereç ve malzeme temininde farklı lojistik stratejileri gerektirir.

- Kullanıcı seviyesi bakımda, kritik olmayan ve standart yedek parçalar araç içinde veya birliklerin depolarında stoklanır. Bu sayede küçük bakım işlemleri hızlıca gerçekleştirilir.
- Birlik seviyesi bakımda, daha teknik ve kritik parçalar birliklerin bakım depolarından temin edilir. Ayrıca, uzman personel tarafından kullanılan özel ekipmanların da lojistiği koordineli şekilde yürütülür.
- Fabrika seviyesi bakımda, yüksek maliyetli ve hassas parçalar, üretici firmalardan veya merkezi depo ve lojistik merkezlerinden tedarik edilir. Bu aşamada lojistik, bakım sürelerinin uzamaması için etkin zaman yönetimi ve stok planlamasını zorunlu kılar.

Bu üç seviyede lojistik destek, bakım sürecinin zamanında ve etkin şekilde tamamlanmasını garanti eder ve operasyonel kesintilerin önüne geçer.

5.3 Bakım Planlaması ve Yönetimi

Bakım seviyeleri arasında entegrasyonu sağlayan en önemli unsur, kapsamlı bir bakım planlama ve yönetim sistemidir. Bu sistem, bakım faaliyetlerinin önceliklendirilmesini, kaynakların optimal kullanılmasını ve süreçlerin standardizasyonunu hedefler.
Modern bakım yönetimi yazılımları, araçların arıza verilerini gerçek zamanlı izleyerek, bakım ihtiyaçlarını öngörür ve planlamayı kolaylaştırır. Böylece, hem kullanıcı hem birlik hem de fabrika seviyesindeki bakım süreçleri senkronize edilir, gereksiz tamir veya parça değişimlerinin önüne geçilir.

5.4 Personel Eğitimi ve İletişimi

Bakım seviyeleri arasındaki koordinasyonun başarısı, sadece teknik altyapıya değil, aynı zamanda personelin eğitim ve iletişim becerilerine bağlıdır. Kullanıcı seviyesindeki personelin arızaları doğru tespit edip ilgili seviyelere bildirmesi, birlik ve fabrika bakım ekiplerinin etkili müdahalesinin ön koşuludur.
Düzenli eğitim programları ve bakım prosedürlerine yönelik seminerler, bakım zincirindeki tüm personelin bilgi ve becerilerinin güncel tutulmasını sağlar. Aynı zamanda dijital iletişim ve raporlama araçlarının kullanımı, bakım seviyeleri arasında zaman kaybını en aza indirir.

5.5 Operasyonel ve Ekonomik Kazanımlar

Bakım seviyeleri arasındaki etkin entegrasyon, sadece teknik başarı sağlamaz; aynı zamanda operasyonel etkinlik ve ekonomik açıdan da önemli kazanımlar yaratır. Bakım süresinin kısalması, aracın görev dışı kalma süresinin azalmasına ve dolayısıyla operasyonel gücün artmasına yol açar. Ayrıca, lojistik ve bakım maliyetleri düşürülür, parça ve işçilik kaynaklarının verimli kullanımı sağlanır.
Bu bağlamda, bakım sisteminin sürekli iyileştirilmesi, teknolojik gelişmelerin entegrasyonu ve veri analizlerine dayalı karar mekanizmaları kritik önem taşır.

6.1 Eğitim ve Personel Gelişimi: Bakım Sürekliliğinin Temel Unsuru

Askerî araç bakım sistemlerinin başarısı yalnızca ekipman temini ve süreç planlamasına değil, doğrudan bu sistemleri uygulayan personelin bilgi ve beceri düzeyine bağlıdır. Kullanıcı, birlik ve fabrika seviyelerindeki bakım faaliyetlerinin sürdürülebilirliği; her seviyede görev yapan personelin ihtiyaca uygun, sistematik ve teknik olarak güncel eğitimler almasını gerektirir. Bu nedenle eğitim süreçleri, bakım sisteminin ayrılmaz bir bileşeni olarak değerlendirilmelidir.

6.1.1 Kullanıcı Seviyesi Eğitimler

Kullanıcı seviyesi eğitimler, genellikle aracın operatörleri ve sürücüleri için düzenlenmektedir. Bu eğitimlerin temel amacı; aracın doğru ve güvenli şekilde kullanılmasını, basit arızaların

tanımlanmasını ve günlük bakım faaliyetlerinin eksiksiz şekilde yerine getirilmesini sağlamaktır. Eğitim içerikleri genellikle şunları kapsar:

Araca günlük bakım ve kontrol listesi uygulaması

Sıvı seviyeleri (yağ, soğutma suyu, fren hidroliği) kontrolü

Hava filtresi, lastik basınçları ve dış aksam kontrolleri

Uyarı lambalarının takibi ve ön tanı koyma becerileri

Kullanıcı el kitabı ve temel teknik doküman okuma yetkinliği

Bu eğitimler çoğunlukla saha ortamında, araca doğrudan uygulama yapılacak şekilde verilir. Pratik temelli olduğu için öğrenme kalıcılığı yüksektir.

6.1.2 Birlik Seviyesi Eğitimler

Birlik seviyesi bakım, daha teknik detaylara hâkim personel tarafından gerçekleştirilir. Bu nedenle eğitim içeriği de daha kapsamlıdır. Eğitilen personel genellikle bakım çavuşları, teknisyenler ve araç sorumlularıdır. Bu seviyedeki eğitimlerin ana başlıkları şunlardır:

Elektriksel sistemlerin temel ölçüm ve test yöntemleri

Motor ve şanzıman arıza teşhis teknikleri

Elektronik kontrol üniteleri (ECU) arıza kodlarının okunması ve yorumlanması

Hızlı parça değişimi (starter, alternatör, akü vb.)

Diagnostik cihaz ve test yazılımlarının kullanımı

Bu eğitimlerde katılımcılar, hem teorik derslere katılır hem de uygulama araçları üzerinde birebir arıza giderme faaliyetleri yürütür.

6.1.3 Fabrika Seviyesi Eğitimler

Fabrika seviyesinde bakım yapan personel, genellikle yüksek teknik yeterliliğe sahip mühendis ve teknisyenlerden oluşur. Eğitimler daha çok sistem mühendisliği ve kalite süreçlerine odaklanır. Fabrika seviyesi eğitimlerin içeriği şu başlıkları içerebilir:

Komple sistem sökme ve montaj prosedürleri

Yazılım güncelleme ve elektronik bileşen kalibrasyonu

Tahribatsız muayene ve test yöntemleri (X-Ray, ultrasonik vb.)

Ar-Ge destekli teknik güncellemeler ve modernizasyon bilgisi

Fabrika kabul testleri (FAT) ve raporlama metodolojisi

Bu eğitimlerin büyük kısmı teknik dokümantasyon, laboratuvar ortamı ve yüksek teknoloji test altyapıları ile desteklenir. Katılımcılar detaylı teknik analiz ve geribildirim süreçlerine dahil edilir.

6.1.4 Eğitim Sonrası Saha Desteği ve Uygulama Etkisi

Eğitim faaliyetlerinin etkisi yalnızca sınıf ortamında ya da simülasyon üzerinden ölçülemez. Gerçek başarı, personelin sahadaki görevlerinde eğitimin etkisini sürdürebilmesi ve ihtiyaç duyduğunda destek alabilmesiyle mümkün olur.

Eğitmen olarak görev yapan kişi, bu bilinçle yalnızca eğitim anlarında değil, sonrasında da kursiyerlerle iletişimini sürdürmektedir. Eğitim alan personelin sahadaki karşılaştığı

beklenmedik teknik sorunlar, hızlı müdahale ve yönlendirme sayesinde çözüme kavuşturulmaktadır. Bu yaklaşım, sadece teknik destek değil; aynı zamanda kullanıcı nezdinde kurumsal güvenin pekişmesini de sağlar.

Gerçek bir örnek olarak, yurt dışında görev yapan bir kursiyer, resmi tatil günü bir sistemin devreye alınamaması nedeniyle doğrudan eğitmeni aramıştır. Telefon görüşmesi sırasında yapılan teknik yönlendirmeyle sorun hızlıca tespit edilmiş, gerekli müdahale gerçekleştirilmiş ve personel görevine kesintisiz şekilde devam etmiştir. Bu olay, eğitimin sahaya yansıyan etkisini ve eğitmen–kursiyer arasındaki güçlü iletişimin kritik önemini açıkça ortaya koymaktadır.

Ayrıca, eğitim sonrasında kursiyerlerden gelen geri bildirimler düzenli olarak kayıt altına alınmakta ve ortaklaşan şikâyet veya talepler teknik toplantılara taşınmaktadır. Bu sayede, eğitim yalnızca bilgi aktarımı değil; aynı zamanda araçların saha performansını artırmaya yönelik bir iyileştirme mekanizmasına dönüşmektedir. Toplantı sonuçlarına göre gerekirse araç tasarımında değişiklik yapılmakta veya kalite kontrol süreçleri daha sıkı hale getirilmektedir.

Eğitmenin sahada sürdürdüğü bu ilişki yalnızca bireysel destekle sınırlı kalmamaktadır. Farklı birliklerden ve görev bölgelerinden gelen benzer sorunlar ve kullanıcı talepleri zaman içerisinde sınıflandırılarak teknik ekiplerle paylaşılmakta, bu doğrultuda araç tasarımında iyileştirmeye yönelik değişiklikler yapılabilmektedir. Aynı şekilde, kalite kontrol aşamalarında sıklık artırımı ya da test prosedürlerinde detaylandırma gibi adımlar da kullanıcı geri bildirimlerine bağlı olarak uygulanmaktadır. Böylece eğitim süreçleri, yalnızca bilgi aktarımı değil; aynı zamanda ürün geliştirme ve operasyonel mükemmellik için bir veri kaynağı işlevi görmektedir.

Tüm bakım seviyelerinin etkin işlemesi için eğitim kritik bir faktördür. Personelin görevini bilinçli ve doğru biçimde yerine getirebilmesi, bakım sürekliliğinin temelini oluşturur. Ayrıca sistematik eğitimler sayesinde arıza tespiti ve müdahale süresi azalır, yedek parça kullanımı optimize edilir. Sahada doğrudan verilen uygulamalı eğitimler, teorik bilginin pratiğe dönüşmesini sağlar. Bu kapsamda bugüne dek eğitim verilen yaklaşık 300 personelin hiçbirinin araçla ilgili bir kazaya karışmamış olması, eğitimin doğrudan güvenlik performansına etkisini net biçimde ortaya koymaktadır.

Sonuç olarak, askerî bakım sisteminin başarısı yalnızca lojistik zincire değil; bu zinciri işleten personelin bilgi altyapısına da bağlıdır. Eğitimlerin sistematik ve seviyelere göre yapılandırılması, bakım sürekliliğinin en önemli güvencesidir. Dolayısıyla, eğitim planlaması bakım yönetiminin ayrılmaz bir parçası olarak ele alınmalıdır.

Uluslararası literatür de, teknik eğitimlerin yalnızca bilgi aktarımıyla sınırlı kalmadığını; aynı zamanda iş güvenliği performansına doğrudan etki edebildiğini ortaya koymaktadır. Örneğin Robson ve arkadaşlarının yaptığı kapsamlı derlemede, iş sağlığı güvenliği eğitimlerinin çalışanların bilgi ve davranışlarını anlamlı şekilde geliştirdiği, buna paralel olarak kaza oranlarının da azaldığı rapor edilmiştir. Burke ve arkadaşları tarafından yürütülen bir meta-analiz, eğitim yoğunluğu ve uygulamalı öğrenme unsurlarının kazaları azaltma üzerinde doğrudan etkili olduğunu göstermektedir. Casteel'in genç işçiler üzerinde yaptığı araştırmada, hedeflenmiş eğitim programlarının iş kazası kaynaklı tazminat taleplerini %42'ye kadar azalttığı belirlenmiştir. Benzer şekilde, sürücü odaklı güvenlik eğitimlerine ilişkin uluslararası çalışmalar, özellikle askeri ve ağır vasıta alanında eğitim alan personelin kaza sıklığında kayda değer düşüşler sağlandığını göstermektedir. Bu bağlamda, sahada eğitim verilen yaklaşık 300 personelde bugüne dek kaza yaşanmamış olması, yalnızca yerel bir başarı göstergesi değil, aynı zamanda literatürle uyumlu küresel bir eğilimin pratik yansımasıdır.

6. Sonuç

Askerî araçların operasyonel sürekliliği ve yüksek görev hazır bulunuşluk seviyesinin sağlanması, çok katmanlı ve hiyerarşik bir bakım sistemine dayanmaktadır. Bu sistem içerisinde kullanıcı, birlik ve fabrika seviyeleri bakım faaliyetleri, farklı bilgi birikimi, teknik donanım ve lojistik destek gereksinimleriyle ayrışmakla birlikte, birbirini tamamlayan ve bütünleşik bir yapı arz etmektedir.

Kullanıcı seviyesi bakım, aracın günlük operasyonlara hazır hale getirilmesi için temel kontrollerin, rutin sıvı tamamlamalarının ve küçük müdahalelerin uygulandığı kritik bir aşamadır. Bu seviyede yapılan bakım işlemleri, görev öncesi arızaların tespit edilmesini ve önleyici tedbirlerin alınmasını mümkün kılarak, operasyonel kesintilerin minimize edilmesini sağlar. Zırhlı kara araçları bağlamında değerlendirildiğinde, sürücülerin gerçekleştirdiği lastik basıncı ölçümü, motor yağı ve soğutma suyu kontrolü gibi işlemler, aracın arazi koşullarında güvenli ve etkin kullanılabilirliğini doğrudan etkiler. Kullanıcı seviyesinde kullanılan el aletlerinin ergonomik, dayanıklı ve kolay taşınabilir olması, bakımın hızlı ve etkin yapılabilmesi açısından vazgeçilmezdir.

Birlik seviyesi bakım, teknik donanım ve uzman personel gerektiren ara müdahale seviyesi olup, motor, şanzıman ve elektronik sistemler gibi kritik bileşenlerin onarım ve teşhis faaliyetlerini kapsar. Bu bakım aşaması, araçların arazi dışına çıkarılmadan saha ortamında onarılmasına olanak vererek, operasyonel sürekliliği artırır. Örneğin, zırhlı araçların elektronik kontrol ünitelerinde meydana gelen arızaların bilgisayar destekli arıza tespiti ve tamiri, birlik seviyesi bakımın temel faaliyetlerindendir. Ayrıca, bu seviyede kullanılan gelişmiş el aletleri ve test cihazları, bakım kalitesini artırırken, personelin yüksek teknik bilgi ve deneyim gereksinimi, eğitim programlarının önemini vurgular.

Fabrika seviyesi bakım ise, araçların revizyon, modernizasyon ve kapsamlı onarım işlemlerinin yapıldığı en üst seviyedir. Bu seviyede gerçekleştirilen motor revizyonu, elektronik sistem yenileme ve gövde kaplama işlemleri, aracın uzun vadeli performans ve dayanıklılığını garanti altına alır. Zırhlı kara araçlarının teknoloji ve fonksiyonlarının güncel tutulması, bu bakım seviyesinin sorumluluk alanına girmektedir. Fabrika seviyesinde kullanılan ileri teknoloji ekipmanlar ve yüksek uzmanlık gerektiren personel, bakım faaliyetlerinin kalite standartlarına uygun biçimde yürütülmesini sağlar.

Sonuç olarak, askerî bakım sisteminin başarısı yalnızca lojistik zincire değil; bu zinciri işleten personelin bilgi altyapısına da bağlıdır. Eğitimlerin sistematik ve seviyelere göre yapılandırılması, bakım sürekliliğinin en önemli güvencesidir. Dolayısıyla, eğitim planlaması bakım yönetiminin ayrılmaz bir parçası olarak ele alınmalıdır. Buna ek olarak, eğitimlerin saha desteğiyle sürdürülebilir hâle getirilmesi ve kursiyerlerden gelen geri bildirimlerin sistematik biçimde değerlendirilerek araç tasarımına ya da kalite süreçlerine yansıtılması, askerî araç yönetiminde operasyonel etkinliği artıran önemli bir faktördür.

Eğitim yalnızca bilgi aktarımı değil; aynı zamanda kullanıcı deneyiminden beslenen dinamik bir geliştirme mekanizması olarak da değerlendirilmelidir. Eğitimlerin sistematik ve seviyelere göre yapılandırılması, bakım sürekliliğinin en önemli güvencesidir. Dolayısıyla, eğitim planlaması bakım yönetiminin ayrılmaz bir parçası olarak ele alınmalıdır.

EXPLORING MAGNETIC PROPERTIES of $GdCo_2$ THIN FILM

Gizem DURAK YÜZÜAK

Munzur University, Rare Earth Elements Application and Research Center, Tunceli/Turkey

Ercüment YÜZÜAK

Recep Tayyip Erdoğan University, Department of Energy Systems Engineering, Rize/Turkey

ABSTRACT

A large class of very desirable materials that have recently garnered considerable interest in cutting-edge technology are intermetallic complexes, which consist of transition metals and rare earth elements. Since these compounds are anisotropic and can have their particle size easily adjusted, they exhibit excellent electrical, magnetic, and magneto-optical characteristics. They find widespread application in the production of permanent magnets and magneto-optical storage systems due to their extraordinary properties. This keeps people interested in learning more about this field. At room temperature, an amorphous GdCo2 thin film was made on Si(100) substrates. This film had unique structural and magnetic properties that are common in amorphous rare-earth transition metal systems. At a thickness of 100 nm, a significant transition in magnetic anisotropy was observed, characterised by a pronounced deviation in the orientation of the easy axis from that of the hard axis, accompanied by corresponding changes in remanence and coercivity values. We used a vibrating sample magnetometer (VSM), the anomalous Hall effect (AHE) and magneto-optical Kerr effect measurements (MOKE) to look at the magnetic properties and find out the magnetic saturation, coercivity, and remanence. The magnetic characteristics suggest that GdCo2 systems have potential for spintronic and magneto-optical applications; nevertheless, thorough characterisation under various processing conditions is essential for technical implementation. According to the findings, when subjected to a perpendicular magnetic field, the 100 nm film's Hall resistivity was found to be 0.575 μΩ·cm/(μB/f.u.). This anisotropy is very important for technology because it controls the stability and tunability of magnetisation, which has a direct effect on how well materials work in spintronic devices and magnetic storage systems.

Keywords: $GdCo_2$, Vibrating Sample Magnetometer, Magnetic Properties, Rare Earth Elements

INTRODUCTION

Transition-metal intermetallic compounds incorporating rare-earth elements (REE) constitute an intriguing class of functional materials that have gained considerable interest for modern technological applications. Their exceptional electrical, magnetic, and magneto-optical behaviors originate from their strong anisotropy and tunable particle size, making them highly versatile. Owing to these superior features, such materials have been widely employed in the fabrication of high-performance permanent magnets and magneto-optical data storage devices, thereby sustaining strong research momentum in this area [1].

Within this group, $GdCo_2$ alloys stand out as particularly compelling due to their distinctive ferrimagnetic nature and high degree of spin polarization. This substantial spin polarization is a key enabler for spintronic technologies, which exploit both the electronic charge and spin for information transfer and processing. The rapid evolution of spintronics has transformed the landscape of electronic device engineering, enabling systems with enhanced functionality, improved energy efficiency, and reduced power consumption [2].

The strong inherent spin polarisation of $GdCo_2$-based systems is a major advantage for magnetic sensing devices, which rely on being sensitive to small changes in magnetic fields. The elevated magnetic susceptibility and enhanced magnetisation fluctuations in amorphous $GdCo_2$ films at low applied fields render them more advantageous than crystalline $GdCo_2$ films, hence augmenting their practical applications. Nevertheless, considerable challenges in characterising $GdCo_k$ come from its ferrimagnetic behaviour. Conventional magnetometry techniques may lack the sensitivity required to detect domain dynamics and minor magnetic transitions near the compensation temperature, at which point the net magnetisation approaches zero [3].

Fortunately, vibrating sample magnetometer (VSM) offer elegant solutions to magnetic characterization challenges. VSM provides a precise and efficient approach for the magnetic characterization of materials, offering high sensitivity, broad measurement ranges, and rapid data acquisition. Based on the principle of detecting the magnetic moment induced in a sample that is mechanically vibrated within a uniform magnetic field, VSM enables direct and accurate determination of key magnetic parameters such as saturation magnetization (M_S), coercivity (H_C), and remanent magnetization (M_R). It is well-suited for both bulk materials and thin films, and when equipped with temperature-controlled measurement capabilities, VSM becomes a powerful tool for studying magnetic phase transitions, thermal effects, and magnetization dynamics. Its fast measurement capability and high repeatability make it particularly valuable for correlating synthesis conditions with magnetic behavior, enabling efficient material optimization. With these advantages, VSM serves as an indispensable characterization technique for the development of advanced magnetic materials, especially in emerging fields such as spintronics, magnetic semiconductors, and neuromorphic magnonic devices.

However, $GdCo_2$ ferrimagnetic compounds present distinctive characterisation issues. When temperatures go over certain limits, magnetisation values drop to very low levels, making it hard to do normal magnetometry observations. This constraint necessitates the exploration of alternate characterisation approaches that demonstrate increased sensitivity to subtle magnetic fluctuations [3]. Fortunately, the anomalous Hall effect (AHE) and magneto-optical Kerr effect measurements (MOKE) provide advanced characterisation solutions. Unlike regular magnetometers, these methods can find differences in magnetisation without needing the whole magnetic moment. The AHE is affected by conduction band polarisation, while the Kerr effect is controlled by optical transitions between sub-bands. These two effects give us different ways to look at the material's magnetic characteristics.

The AHE is an essential physical phenomenon used to investigate charge transport properties in solid-state materials. The Hall coefficient (R_h) reveals whether electrons or holes dominate conduction, while the magnitude of the Hall voltage allows for the calculation of carrier concentration and mobility, making Hall measurements a standard technique for semiconductor analysis. Beyond conventional systems, the Hall effect also holds significant relevance in magnetic materials. In ferromagnetic or ferrimagnetic thin films, an additional contribution known as the Anomalous Hall Effect (AHE) arises due to spin–orbit coupling and magnetization. This effect provides valuable insight into magnetic ordering, spin-dependent transport, and electron–spin interactions, making Hall measurements a powerful tool for emerging spintronics research. Because of its ability to correlate electrical and magnetic properties, the Hall effect is widely used in the characterization of magnetic thin films, sensors, and next-generation spintronic materials. Its simplicity, sensitivity, and diagnostic value make it indispensable for understanding and optimizing materials for magnetic sensing, data storage, and neuromorphic computing technologies.

In this work, we conduct an in-depth investigation of the structural and magnetic characteristics of $GdCo_2$ thin films through state-of-the-art characterization techniques. Leveraging these advanced methods enables us to gain valuable insights into their potential for high-performance spintronic and magnetic applications, paving the way for future technological advancements.

EXPERIMENTAL

This research employed DC magnetron sputtering utilising a stoichiometric $GdCo_2$ alloy target to fabricate an amorphous $GdCo_2$ thin film on a Si(100) substrate, achieving a thickness of 100 nm. To make sure the plasma environment was ideal and to keep impurities from getting in, the sputtering medium was high-purity argon gas (6N) held at a working pressure of $2x10^{-3}$ mTorr. The substrate was spun at 10 rpm while the film was being deposited to make sure that it developed evenly and that the composition of the surface stayed the same. We used a VSM to measure the temperature dependent magnetic properties between 50-430 K range, the AHE measurements in plane and out-of-plane directions under +-50 Oe range and magneto-optical Kerr effect measurements (MOKE) up to +-9 T to look at the magnetic properties and find out the magnetic saturation, coercivity, and remanence.

RESULTS and DISCUSSION

Figure 1 illustrates the **temperature dependent magnetisation measurement (M-T)** of the $GdCo_2$ thin film deposited at a thickness of 100 nm on the Si(100) substrate under room-temperature conditions. The M–T curve measured in the 50–430 K range for the 100 nm-thick $GdCo_2$ thin film. The inset displays the dM/dT versus temperature plot, representing the derivative of magnetization with respect to temperature. The minimum point in this derivative curve was identified as the Curie temperature (T_C) of the film, which was determined to be 383 K. The obtained Curie temperature is consistent with the values reported in the literature [2] and aligns with the results. This result indicates that the magnetic structure of the produced thin films matches the expected parameters and exhibits the desired thermal magnetic stability for practical applications.

The deposited $GdCo_2$ thin film can be classified as amorphous, a structural feature commonly observed in rare-earth-transition-metal thin films grown at room temperature due to restricted surface diffusion and low adatom mobility, which suppress crystalline ordering. This amorphous nature is consistent with the magnetic behavior observed in the VSM measurements. The smooth and isotropic magnetic response reflected in the M-T curve, along with the well-defined Curie temperature of 383 K, indicates a uniform magnetic phase without crystalline

anisotropy-driven anomalies. Such structural homogeneity is particularly beneficial for magneto-optical and spintronic applications, as amorphous films typically provide isotropic magnetization, smoother interfaces, and minimized grain-boundary scattering, collectively contributing to enhanced device performance and operational stability.

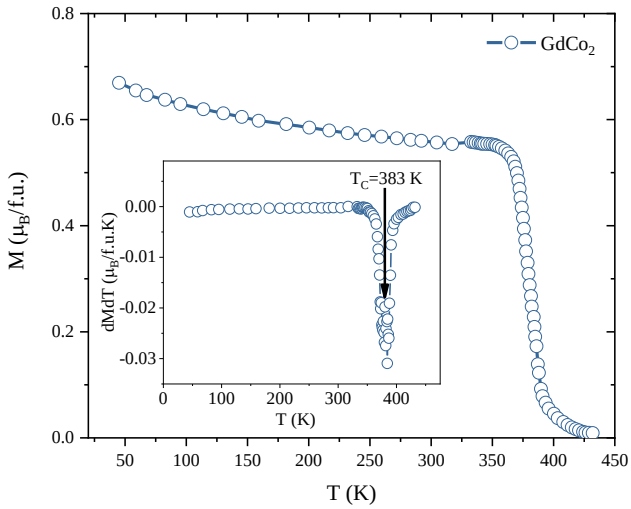

Figure 1. M-T measurement of $GdCo_2$

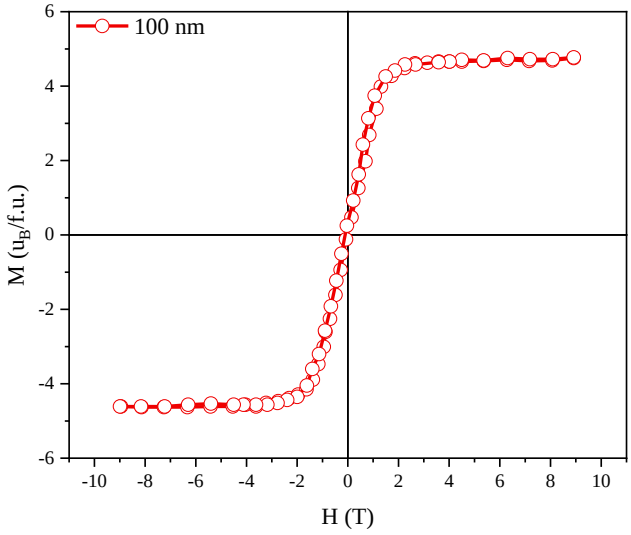

Figure 2. MOKE measurement of $GdCo_2$

According to the MOKE results in Figure 2, the measurements were conducted on the thin films produced at a sputtering pressure of 5 mTorr and a sputtering power of 50 W with thicknesses of 100, as this films exhibited superior soft magnetic behavior and lower coercivity. The saturation magnetization values of these soft magnetic films, which rapidly reach saturation, were found to be 4.5–5 μB/f.u. (850–950 emu/cc). These values are in good agreement with both the literature and the target values defined in the project proposal [1].

Therefore, to resolve the magnetic anisotropy behaviour of the system, the AHE measurements were carried out in Fig. 3(a) and (b). The measurements confirm the $GdCo_2$ thin film show good in-plane and out-of-plane magnetic anisotropy. Thin films were measured according to IP (0 °) and OOP (90 °) planes. Measurements performed for each axis are normalized within themselves to unveil the magnetic properties of thin films. Based on the obtained results, the Hall resistivity value for the 100 nm film was measured as 0.575 μΩ·cm/(μB/f.u.) under a

perpendicular magnetic field. This outcome is in good agreement with both the project's target values and the literature [3].

The magnetic response that relies on the axis reveals how the magnetoelastic effects, local atomic configurations, and exchange connections of amorphous rare-earth transition metal alloys are all fighting for attention. The transition from soft magnetic properties, marked by low coercivity and high permeability, to hard magnetic properties, indicated by increased HC along the hard axis, signifies a gradual transformation of the thin film when the direction of magnetisation reversal is less advantageous. This anisotropy has a direct effect on how well materials work in spintronic devices, magnetic storage technologies, and magnetic applications. This is important from a technological point of view because it affects the stability and tunability of magnetisation [4].

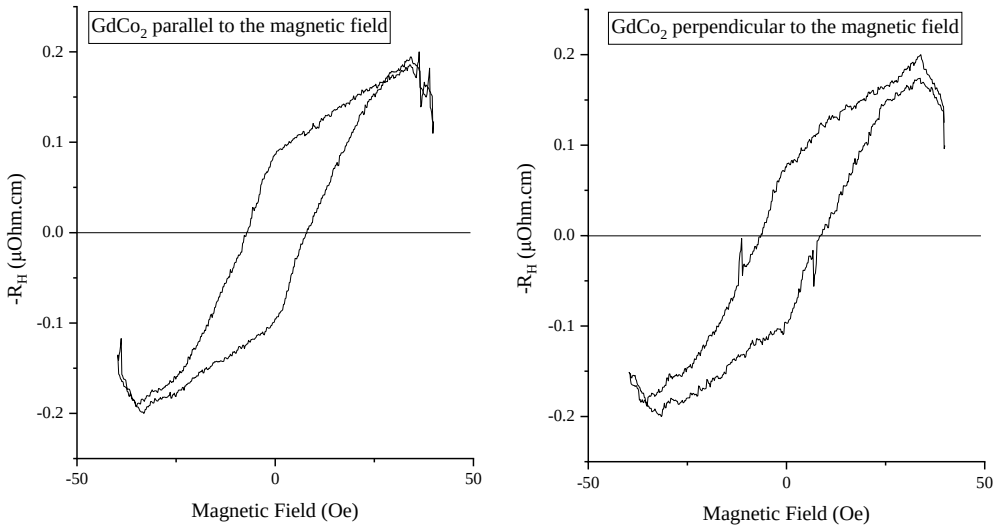

Figure 3. Hall effect measurement of $GdCo_2$ (a) 0 degree and (b) 90 degree

CONCLUSION

A thin layer of GdCo2 was generated at temperatures near room temperature using a Si(100) substrate for this discussion. Our sample exhibited all the characteristic magnetic and structural features of amorphous $GdCo_2$ systems. At a 100 nm thickness, there is a slight misalignment between the IP magnetic axis and the OOP axis in a thin layer. Sends resistivity signal only in out-of-phase direction. It is necessary to conduct research and categorise $GdCo_2$ systems before considering them as potentially highly beneficial magnetic materials with spintronic capabilities for the creation of novel optical media.

ÖZET

Savunma sanayii günümüzde en hızlı gelişen sektörlerden biridir ve zırhlı muharebe araçları bu alanda önemli bir yer tutmaktadır. Bu araçların üretiminde çelik, alüminyum, seramik ve kompozit malzemeler kullanılmakla birlikte, şekillendirilebilirlik, tedarik kolaylığı ve maliyet açısından en yaygın tercih edilen malzeme çeliktir. Zırh çelikleri, bu araçların tasarımlarına uygun geometrilerde kullanılmak üzere çoğunlukla lazer kesim yöntemi ile işlenmektedir. Ancak bu yöntemde malzeme yüzeyine aktarılan yüksek ısı girdisi, martensitik yapıya sahip yüksek sertlikteki çeliklerde mikroyapısal dönüşümlere ve buna bağlı olarak mekanik özelliklerde değişimlere yol açabilmektedir. Literatürde özellikle 600 HB sertlik seviyesindeki çeliklerde, lazer kesim sonrasında çekme dayanımı ve akma dayanımında belirgin düşüşler raporlanmıştır. Bu çalışmada, ortalama 600 HB sertlikte zırh çeliğinde 1700 mm/dk kesim hızında gerçekleştirilen lazer kesim işleminin mekanik özellikler ve yüzey pürüzlülüğü üzerindeki etkileri deneysel olarak incelenmiştir. Kesim işlemleri sabit 1900 W lazer gücü, belirli odak konumu ve sabit gaz basıncı altında gerçekleştirilmiştir. Kesim sonrasında hazırlanan numunelerde akma dayanımı ($Rp_{0.2}$), çekme dayanımı (Rm) ve kopma uzaması (A%) değerleri ölçülmüş; ayrıca kesim yüzeylerinden pürüzlülük (Ra) değerleri elde edilmiştir. Elde edilen sonuçlar, lazer kesim sonrası çekme ve akma dayanımlarında belirgin bir düşüş gözlenmediğini, ancak kopma uzamasında(süneklik) ve yüzey pürüzlülüğünde ısıl etkiden kaynaklı değişimlerin meydana geldiğini göstermiştir. Bu bulgular, literatürdeki benzer çalışmalarda raporlanan yüksek düşüş değerlerinden farklı olarak, kullanılan kesim parametrelerinin ısı girdisini sınırladığı ve dolayısıyla mekanik özelliklerdeki değişimin minimum düzeyde kaldığını ortaya koymaktadır.

Anahtar Kelimeler: Zırh çeliği, Lazer kesim, Mikroyapı, Isı tesiri altındaki bölge (ITAB)

THE MECHANICAL EFFECTS OF LASER CUTTING ON ARMOR STEELS

ABSTRACT

The defense industry is one of the fastest-developing sectors today, and armored combat vehicles constitute a significant part of this field. Although materials such as aluminum, ceramics, and composites are also used in their production, steel remains the most commonly preferred material due to its formability, availability, and cost efficiency. Armor steels, which generally possess a martensitic microstructure with hardness levels around 600 HB, are typically shaped by laser cutting to achieve the geometries required by vehicle designs. However, the high thermal energy transferred to the material during laser cutting may cause microstructural transformations in these ultra-high-hardness steels, leading to changes in mechanical properties. In the literature, particularly for steels with hardness values near 600 HB, several studies have reported a considerable decrease in tensile and yield strength after laser cutting. In the present study, the effect of the laser cutting process at a constant cutting speed of 1700 mm/min on the mechanical properties and surface quality of armor steel with an average hardness of 600 HB was experimentally investigated. The cutting operations were carried out using a constant laser power of 1900 W, a fixed focal position, and constant assist-gas pressure. Following the cutting process, yield strength ($Rp_{0.2}$), ultimate tensile strength (Rm), and elongation at fracture (A%) values were measured on prepared specimens, while surface roughness (Ra) values were also obtained from the cut edges. The experimental results indicated no significant reduction in tensile and yield strengths after laser cutting, while a slight change in elongation and surface roughness was observed due to the localized thermal effects. These findings differ from the higher degradation levels reported in previous studies and suggest that the applied cutting parameters in this work effectively limited the thermal input, resulting in minimal variation in the mechanical behavior of the 600 HB armor steel.

1. GİRİŞ

Günümüzde artan güvenlik tehditleri, askeri operasyonların çeşitlenmesi ve savunma sistemlerinin modernizasyonu, zırhlı muharebe araçlarının stratejik önemini giderek artırmaktadır. Bu araçlarda kullanılan malzemeler, yüksek mukavemet, düşük yoğunluk, darbe dayanımı ve maliyet etkinliği gibi kriterler doğrultusunda seçilmektedir. Zırh sistemlerinde kullanılan malzemeler arasında çelik, alüminyum, seramik ve kompozit esaslı malzemeler yer almakta; ancak şekillendirilebilirlik, kaynaklanabilirlik, üretim kolaylığı ve tedarik avantajı gibi nedenlerle zırh çelikleri en yaygın kullanılan malzeme türü olarak öne çıkmaktadır (Cimpoeru 2016). Zırh çeliklerinin üretim süreci, hedeflenen mekanik özelliklerin elde edilmesinde belirleyici rol oynamaktadır. Bu süreç genellikle yüksek alaşımlı çeliklerin dökümü ile başlamakta, ardından sıcak haddeleme işlemiyle devam etmektedir. Sıcak haddeleme, çeliğin yüksek sıcaklıklarda plastik deformasyona uğratılarak kalınlığının düşürülmesini ve homojen bir mikroyapı elde edilmesini sağlar. Elde edilen levhalar, daha sonra ısıl işlem basamaklarına tabi tutulur. Bu aşamada çelik, östenitleştirme sıcaklığına kadar ısıtılır, ardından su verme (quenching) işlemi ile hızla soğutularak martensitik yapı oluşturulur. Sonrasında uygulanan temperleme (tavlama) işlemi ise iç gerilmeleri azaltarak çeliğe tokluk kazandırır (ILSENBURGER Grobblech 2023). Bu işlem dizisi sonucunda, hem balistik dayanım hem de darbe tokluğu açısından yüksek performans gösteren, yaklaşık 600 HB sertlikte zırh çelikleri üretilmektedir.

Zırh çeliklerinin şekillendirilmesi ve montajında kullanılan işlemler arasında lazer kesim, plazma kesim, su jeti ve mekanik kesme yöntemleri yer almaktadır. Bu yöntemler arasında lazer kesim, sunduğu yüksek hassasiyet, dar kesim aralığı (kerf width), düşük deformasyon oranı ve seri üretim avantajları sayesinde tercih edilmektedir (Gao et al. 2020). Ancak lazer kesim işlemi sırasında malzeme yüzeyine aktarılan yüksek ısı girdisi, özellikle martensitik yapıya sahip yüksek sertlikteki çeliklerde mikroyapısal dönüşümlere neden olabilmektedir. Bu dönüşümler, kesim kenarına yakın bölgede temperlenmiş martensit, karbür çözünmesi veya ferritik dönüşüm şeklinde ortaya çıkar ve mekanik özelliklerde lokal değişimlere yol açabilir (Barényi et al. 2014). Lazer kesim parametreleri — özellikle kesim hızı, lazer gücü, odak konumu ve yardımcı gaz tipi — malzemenin ısı tesiri altındaki bölge (ITAB) genişliği ve yüzey kalitesi üzerinde doğrudan etkilidir (Nadkarni et al. 2021). Kesim hızı azaldığında, ışının malzeme üzerinde etki süresi artmakta ve ısı girdisi yükselmektedir; bu da ITAB genişlemesine ve mikroyapısal yumuşamaya yol açmaktadır. Tersine, kesim hızının artırılması, ısı girdisini sınırlayarak yapısal bozulmaların daha düşük seviyede kalmasını sağlar. Literatürde yapılan çalışmalar, düşük kesim hızlarında çekme ve akma dayanımlarında %10–20 arası azalma görülebileceğini, buna karşılık yüksek hızlarda yapılan kesimlerde bu etkinin minimuma indiğini göstermektedir (Khurshid et al. 2017; Gao et al. 2020). Zırh çelikleri üzerine yapılan çalışmalarda, özellikle 600 HB sertlik sınıfındaki malzemelerde, lazer kesim sonrası mekanik özelliklerde belirgin düşüşler raporlanmıştır (Barényi et al. 2014). Bunun temel nedeni, kesim sırasında açığa çıkan yüksek ısı enerjisinin yüzeye yakın bölgede martensitik dönüşümün kısmen tersine dönmesi ve lokal temperleme etkisi oluşturmasıdır. Ancak bazı araştırmalarda, kesim hızının artırılması veya uygun gaz kombinasyonlarının kullanılmasıyla bu etkinin sınırlanabildiği belirtilmiştir (Gao et al. 2020). Gerçekleştirilen bu çalışmada, yaklaşık 600 HB sertliğe sahip zırh çeliğinde farklı kesim hızlarında gerçekleştirilen lazer kesim işleminin mekanik özellikler (çekme ve akma dayanımı, kopma uzaması) ve yüzey pürüzlülüğü üzerindeki etkileri deneysel olarak incelenmiştir. Çalışmanın amacı, lazer kesim sırasında oluşan ısı girdisinin malzemenin mekanik bütünlüğünü ne ölçüde etkilediğini belirlemek ve literatürde bildirilen düşüş değerleriyle karşılaştırmalı bir değerlendirme sunmaktır.

2. MALZEME VE METOT

Deneysel çalışmada kullanılan zırh malzemesi kimyasal bileşim Tablo 1'de, mekanik özellikler ise Tablo 2'de verilmiştir.

Tablo 1. 600HB sertlikteki malzemeye ait kimyasal bileşim (% ağırlıkça)

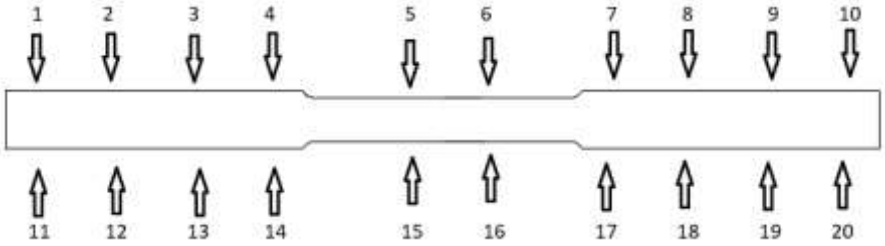
Malzeme	C	Si	Mn	P	S	Cr	Ni	Mo	B
600HB	0,45	0,7	0,8	0,015	0,004	0,5	3,0	0,6	0,003

Tablo 2. 600HB sertlikteki malzemeye ait mekanik özellikler.

Malzeme	Akma Dayanımı (N/mm^2)	Çekme Dayanımı (N/mm^2)	Uzama (%)	Darbe Dayanımı (J)
600HB	1400	1950-2150	6	14 (-40°C)

8.5mm kalınlığındaki çekme numuneleri bystronic lazer kesim tezgahında kesilmiştir. Kesim parametreleri tablo 3'de verilmiştir.

Şekil 1. Bystronic lazer kesim tezgahı



Tablo 3. 600HB sertlikteki malzemenin kesim parametreleri.

Malzeme	Lazer Gücü (W)	Kesme Hızı (mm/dk)	Gaz Basıncı (Bar)	Yardımcı Gaz
600HB	1900	1700	0.8	O_2

Kesilen numunelerin görüntüleri Şekil 2'de verilirken, yüzey pürüzlülük ölçümleri Tablo 5'de verilmiştir. Ölçümler, Mahr MarSurf PS1 pürüzlülük cihazı kullanılarak gerçekleştirilmiştir. Malzeme yüzeyinden 20 farklı noktadan ölçüm alınmış, alınan bölgeler Şekil 3'de gösterilmiştir. Elde edilen değerlerin ortalaması hesaplanmıştır. Ölçümler, DIN ISO 9013 standardı dikkate alınarak, malzeme kalınlığının 2/3 derinliğine kadar olan bölgeden gerçekleştirilmiştir.

Şekil 2. Kesilen Çekme Numuneleri

Şekil 3. Numune üzerindeki ölçüm noktaları

3. BULGULAR VE TARTIŞMA

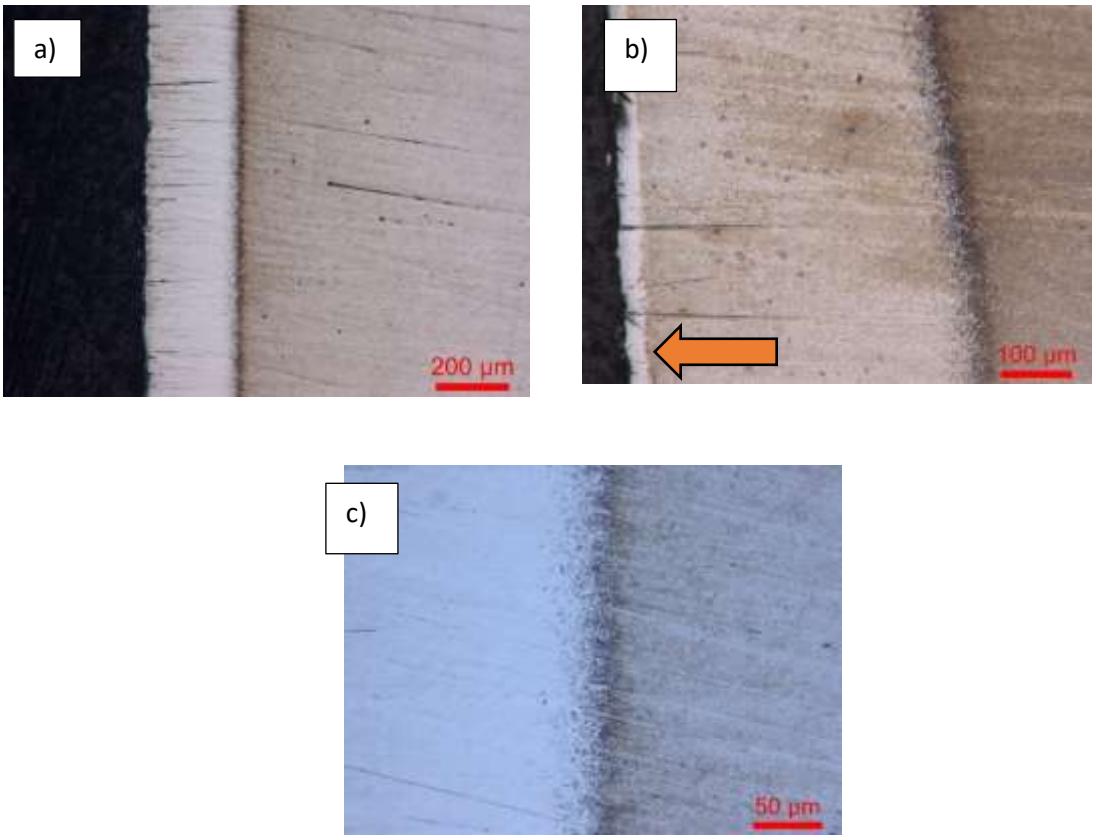
Belirlenen kesim hızında hazırlanan numunelere ait çekme test sonuçları Tablo 4'de verilmiştir. Belirlenen hız için kesilen 3 numunenin akma mukavemeti ($Rp_{0.2}$), çekme dayanımı (Rm) ve kopma uzaması (A%) değerleri hesaplanmıştır.

Tablo 4. 600HB sertlikteki malzemeye ait çekme testi sonuçları.

Numune Adı	Akma Mukavemeti	Çekme Mukavemeti	Yüzde Uzama
	MPa	MPa	%
A	1557,34	2090,62	4,30
B	1575,70	2120,84	5,40
C	1570,10	2108,57	5,10

Elde edilen sonuçlar, tüm numunelerde çekme dayanımlarının 2090–2120 MPa aralığında akma dayanımnın ise 1500-1600 arasında kaldığını göstermektedir. Bu değerler, üretici firma verileriyle oldukça uyumludur.

Kesim hızının belirlenmesiyle birlikte kopma uzamasında belirgin bir azalma eğilimi gözlenmiştir; kesilen numunelerde yüzde uzama yüzde 5 civarına düşmüştür. Bu durum, lazer kesim sırasında seçilen parametrelerin ITAB genişliğinin daralması ve lokal gevrekleşme oluşmuş olacağını işaret etmektedir. Öte yandan, $Rp_{0.2}$ ve Rm değerlerinde istatistiksel olarak anlamlı bir değişim tespit edilmemiştir. Bu da lazer kesim sürecinin çeliğin optimal parametreler seçildiği takdirde mukavemetini önemli ölçüde değiştirmediğini göstermektedir.



Kesilen ürünlerden alınan ölçümler Tablo 5'de verilmiştir.

Kesim yüzeylerinden alınan pürüzlülük ölçümleri, lazer kesimin yüzey kalitesini değerlendirmek amacıyla gerçekleştirilmiştir. Ölçümler DIN ISO 9013 standardına göre, malzeme kalınlığının 2/3 derinliğinden yapılmıştır.

Tablo 5. 600HB sertlikteki malzemeleye ait lazer kesim sonrası yüzey pürüzlülükleri

Sıra No	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**	
A	2,797	3,303	2,598	2,646	2,525	2,947	2,803	2,847	2,809	2,805	
B	3,106	2,369	3,127	2,503	3,141	2,978	2,871	3,353	2,834	2,720	
C	2,362	3,001	2,656	3,160	3,229	3,088	2,916	2,749	2,823	2,828	
Sıra No	**11**	**12**	**13**	**14**	**15**	**16**	**17**	**18**	**19**	**20**	**Ortalama**
A	3,353	2,852	2,808	2,825	2,835	2,771	2,821	3,303	3,229	2,777	**2,883**
B	2,785	3,206	2,819	2,822	3,229	2,773	2,784	2,873	2,828	2,810	**2,897**
C	2,700	2,854	2,802	2,745	2,821	2,825	2,826	2,759	2,795	2,832	**2,839**

Yüzey pürüzlülüğü değerleri, yüksek kesim hızının yüzey kalitesini iyileştirdiğini göstermektedir. Ra değerinin yaklaşık 2.8 µm seviyesinde olması, erime tabakasının minimum, yeniden katılaşma izlerinin sınırlı olduğunu göstermektedir. Bu bulgu, literatürde yüksek hızlarda ısı girdisinin azalmasıyla yüzey kalitesinin arttığını belirten çalışmalarla örtüşmektedir (Nadkarni et al. 2021).

Şekil 4. Kesilmiş zırh malzemesinin ITAB bölgesi mikroyapısı

(a)50x (b) 100x (c) 200x

Lazer kesim işlemi sonrasında elde edilen ve Şekil 4b'de verilen mikroyapı görüntüsü, ısı girdisinin malzeme üzerindeki etkisini net biçimde göstermektedir. Kesim yüzeyine en yakın bölgede, ergiyip katılaşma sonucu oluşan düzensiz, yönsüz ve mikroyapısal olarak homojen

olmayan bir tabaka gözlemlenmiştir. Literatürde bu bölge yeniden katılaşan tabaka (YKT) olarak tanımlanmakta olup, yüksek sıcaklık nedeniyle ergiyen malzemenin hızlı katılaşmasıyla oluştuğu belirtilmektedir (Saha et al., 2019). YKT tabakası, kesim işleminde en yüksek sıcaklıkla temas eden yüzeyidir.Şekil 4b'de okla gösterilmiştir. Yeniden katılaşan tabakanın hemen altında, kesim esnasında yüksek sıcaklıklara maruz kalmış ancak erimeye uğramamış bir bölge yer almaktadır. Bu bölge, yüksek sıcaklıkların etkisiyle martensitik yapının kısmen temperlenmiş martensite dönüştüğü ve iğnemsi morfolojide bozulmaların başladığı bir ısıdan etkilenmiş zon olarak değerlendirilmektedir. Nadkarni et al. (2021) bu bölgeyi, yüksek sıcaklıklı ısı tesiri altındaki bölge (YS-ITAB) olarak sınıflandırmakta ve özellikle temperlenme etkisiyle mikrosertlikte düşüş yaşanabileceğini belirtmektedir. YS-ITAB, lazer kesiminde oluşan en aktif dönüşüm zonlarından biridir. Bu yüksek sıcaklık etkisinin daha da az hissedildiği, kesim yüzeyinden uzaklaşan bölgelerde ise düşük sıcaklıklı ısı tesiri altındaki bölge (DS-ITAB) olarak adlandırılan, martensitik yapının büyük oranda korunduğu ancak ısının yine de mikro yapıda hafif düzenlenmelere neden olduğu bir zon tespit edilmiştir. Andrés et al. (2016), (DS-ITAB) bölgesinde iğnemsi martensitin daha net ayırt edilebildiğini ve mekanik özelliklerin bu bölgede büyük ölçüde korunduğunu ifade etmektedir. Bu zonlardan sonra gelen ana malzeme, herhangi bir ısı etkisine maruz kalmamış ve orijinal temperlenmiş martensitik yapısını koruyan alandır. Bu bölge, ısıl işlem sonrası kazanılmış olan nihai mekanik ve mikroyapısal özelliklerini muhafaza etmektedir. Bu morfolojik zon ayrımı, lazer kesim gibi yüksek enerji yoğunluklu işlemler sonrası oluşan termal etkileri anlamak açısından kritik önem taşımaktadır. Özellikle zırh çelikleri gibi sertleştirilmiş martensitik yapıya sahip malzemelerde bu geçişlerin net olarak analiz edilmesi, kesim parametrelerinin malzeme performansına olan etkilerinin değerlendirilmesine katkı sağlamaktadır.

4. SONUÇ

Bu çalışmada, yaklaşık 600 HB sertlik seviyesindeki zırh çeliğinin 1700 mm/dk kesim hızında lazerle kesilmesi sonrasında mekanik özelliklerinde ve yüzey kalitesinde meydana gelen değişimler kapsamlı biçimde değerlendirilmiştir. Çekme testi sonuçları, gerilme–şekil değiştirme davranışı ve yüzey pürüzlülüğü ölçümleri birlikte incelenerek lazer kesim sürecinin malzeme performansı üzerindeki etkisi ortaya konmuştur. 1700 mm/dk hızda kesilen numunelerde gerçekleştirilen çekme testleri, malzemenin akma dayanımı ($Rp_{0.2}$) ve çekme dayanımı (Rm) değerlerinde belirgin bir düşüş oluşmadığını göstermiştir. Ölçülen $Rp_{0.2}$ değeri yaklaşık 1600 MPa, Rm değeri ise 2130 MPa olarak bulunmuştur. Bu değerler, literatürde 600 HB sınıfı çelikler için verilen tipik dayanım aralıkları ($Rp_{0.2} \approx 1500–1700$ MPa, $Rm \approx 2000–2200$ MPa) ile tamamen uyumludur (Cimpoeru 2016). Bu sonuç, 1700 mm/dk kesim hızında lazerin malzeme üzerinde düşük bir ısı girdisi yaratması sayesinde, martensitik mikro yapının büyük ölçüde korunmuş olduğunu göstermektedir. Lazer kesim sonucunda oluşan ısı tesiri altındaki bölge (ITAB) dar kalmış, martensitten temperlenmiş martensite veya ferritik fazlara dönüşüm için gerekli süre sağlanmamıştır (Nadkarni et al., 2021; Saha et al., 2019; Andrés et al., 2016). Bu nedenle kesim sonrası mekanik bütünlüğün korunduğu söylenebilir. Yapılan mikroyapı analizleri, lazer kesim işleminin zırh çeliği üzerinde belirgin bir ısıdan etkilenmiş bölge (ITAB) oluşturduğunu göstermiştir. Kesim kenarına en yakın bölgede yeniden katılaşma tabakası (YKT), onun hemen altında ise sırasıyla yüksek ve düşük sıcaklık etkili ITAB bölgeleri tanımlanmıştır. Bu zonlar, mikroyapısal bozulma derecelerine göre ayrımlanmış ve temperlenmiş martensit yapıda kısmi dönüşümler gözlenmiştir. Ancak bu mikroyapısal değişimlere rağmen çekme testi sonuçlarında mekanik özelliklerde belirgin bir farklılık meydana gelmemiştir. Bu durum, doğru lazer parametreleri ile işlem yapıldığında lazer kesim yönteminin yüksek sertlikteki zırh çelikleri için uygulanabilir ve güvenilir olduğunu göstermektedir.

ÖZET

Fosil temelli kaynakların hızla tükenmesi ve artan çevresel kaygılar, geleneksel polimerik malzemelere karşı biyolojik olarak parçalanabilir ve sürdürülebilir alternatiflerin araştırılmasını hızlandırmıştır. Bu çalışmada, biyolojik olarak parçalanabilir kopolimer poli(3-hidroksibutirat-ko-4-hidroksibutirat) (P3HB4HB) matris malzemesi ve indirgenmiş grafen oksit (rGO) iletken nano dolgu maddesi kullanılarak çevre dostu ve tamamen biyo-bazlı kompozit polimerik membranlar geliştirilmiştir. Çalışmada amaç, potansiyel yakıt hücresi uygulamaları için P3HB4HB membranlarının mekanik, termal ve proton iletkenlik özelliklerini iyileştirmektir. Farklı rGO yüklemeleri (ağırlıkça %0,5, 1, 3 ve 5) içeren kompozit membranlar, elektroçekim yöntemi ile üretildi. Termogravimetrik analiz (TGA), rGO ilavesiyle membranların termal stabilitesinin arttığını, rGO'nun termal olarak kararlı yapısı nedeniyle ise kalıntı kütlenin arttığını göstermiştir. Mekanik testler, %1 ağırlıkça rGO kompozitinin maksimum yük ve çekme dayanımında en yüksek uzama gösterdiğini ortaya koymuş ve bu bileşimde optimum dolgu maddesi dağılımını gözlenmiştir. Ancak, daha yüksek rGO içeriği esnekliğin azalmasına ve kırılganlığın artmasına neden olmuştur. Sıcaklığa bağlı proton iletkenliği ölçümleri, hidrojen bağı ağlarının oluşumu ve iyileştirilmiş yük transfer yolları sayesinde rGO'nun membran yapısı içindeki proton taşınımının arttığını göstermiştir. Genel olarak, orta miktarda rGO ilavesi, P3HB4HB membranlarının termal ve mekanik kararlılığını artırmıştır. Bu bulgular, rGO/ P3HB4HB kompozit membranların, mikrobiyal yakıt hücresi uygulamalarında sürdürülebilir ve çevre dostu proton değişim membranları için umut verici adaylar olduğunu göstermektedir.

Anahtar Kelimeler: Biyobozunur polimer; poli(3-hidroksibutirat-ko-4-hidroksibutirat) (P3HB4HB); İndirgenmiş grafen oksit (rGO); Mikrobiyal yakıt hücresi, Proton değişim membranı

PRODUCTION AND CHARACTERIZATION OF BIODEGRADABLE RGO/P3HB4HB COMPOSITE MEMBRANES FOR FUEL CELL APPLICATIONS

ABSTRACT

The rapid depletion of fossil-based resources and growing environmental concerns have accelerated the search for biodegradable and sustainable alternatives to traditional polymeric materials. In this study, environmentally friendly and fully bio-based polymeric composites membranes were developed using a biodegradable copolymer poly(3-hydroxybutyrate-co-4-hydroxybutyrate) (P3HB4HB) matrix material and reduced graphene oxide (rGO) conductive nano filler. The objective of study was to improve the mechanical, thermal and proton conductivity properties of P3HB4HB membranes for potential fuel cell applications. Composite membranes containing different rGO loadings (0.5, 1, 3 and 5 wt%) were produced using the electrospinning method. Thermogravimetric analysis (TGA) showed that the addition of rGO increased the thermal stability of the membranes, while the residual mass increased due to the thermally stable structure of rGO. Mechanical tests revealed that the 1% weight rGO composite exhibited the highest elongation at maximum load and tensile strength, indicating optimal distribution of the filler at this concentration. However, a higher rGO content has led to a decrease in flexibility and an increase in brittleness. Temperature-dependent proton conductivity measurements have shown that rGO enhances proton transport within the membrane structure due to the formation of hydrogen bond networks and improved charge transfer pathways. Generally, the addition of moderate amounts of rGO increased the thermal and mechanical stability of P3HB4HB membranes while maintaining their biodegradability. These findings indicate that rGO/P3HB4HB composite membranes are promising candidates for sustainable and environmentally friendly proton exchange membranes in microbial fuel cell applications.

GİRİŞ

Küresel nüfusun ve teknolojik gelişimin hızlı artışı, geleneksel olarak fosil yakıtlarla karşılanan enerji talebinin artmasına neden olmuştur. Ancak, fosil kaynaklardan enerji üretimi, sera gazı emisyonları ve çevre kirliliği ile ilişkilidir. Ayrıca, fosil kaynakların sınırlı olması, petrol ihraç eden ülkelere bağımlılığı artırmaktadır (Martins, Felgueiras, and Smitková 2018). Sonuç olarak, yenilenebilir, sürdürülebilir ve karbon nötr enerji teknolojilerinin geliştirilmesi küresel bir öncelik haline gelmiştir (Ananthi et al. 2021). Maliyet etkin ve çevreye uyumlu yeşil teknolojilerin geliştirilmesi, kirliliği azaltırken gelecekteki enerji taleplerini karşılamak için gereklidir (M. Kumar et al. 2021). Bunlar arasında, mikrobiyal yakıt hücreleri (MYH'ler), organik bileşiklerin mikrobiyal oksidasyonu yoluyla aynı anda elektrik üretebilen ve atık suyu arıtabilen umut verici biyo-bazlı enerji sistemleri olarak ortaya çıkmıştır (Chauhan et al. 2022; Holder et al. 2016).

MYH'lerin temel bileşenlerinden biri, anot ve katot arasındaki proton transferini düzenleyen ve hücrenin genel verimliliğini doğrudan etkileyen proton değişim membranıdır (PEM). Ticari bir perflorosülfonik asit membran olan Nafion, yüksek maliyeti ve çevresel dezavantajlarına rağmen bu amaçla yaygın olarak kullanılmaktadır. Nafion, toplam sistem maliyetinin yaklaşık %38'ini oluşturduğu ve geri dönüştürülebilirlik sorunları yarattığı için, düşük maliyetli ve biyolojik olarak parçalanabilir membran alternatiflerinin geliştirilmesi büyük ilgi görmüştür (Ghasemi et al. 2013). Poli(eter eter keton) (PEEK), poli(eter sülfon) (PES), polisülfon (PSU), polibenzimidazol (PBI), poliimid (PI), poliamid (PA) ve polistiren (PS) gibi çeşitli sülfonlanmış sentetik polimerler alternatifler olarak incelenmiştir (Diaz, Abuin, and Corti 2012; Neves et al. 2010; Yang et al. 2009; Zhang and Shen 2012). Ancak, biyolojik olarak parçalanamayan yapıları uzun vadeli çevre sorunları yaratmakta ve sürdürülebilir MYH uygulamaları için biyo-bazlı ve çevre dostu membranlara olan ihtiyacı güçlendirmektedir. Petrol bazlı plastikler, dayanıklılıkları, korozyon dirençleri ve düşük ısı iletkenlikleri nedeniyle değerlidir, ancak ekosistemlerde kontrolsüz birikimlerinden dolayı "beyaz kirlilik" gibi ciddi çevre sorunlarına neden olmaktadır (Xanthos and Walker 2017; Frias and Nash 2019). Bu sorunu çözmek için biyolojik olarak parçalanabilir alternatiflerin geliştirilmesi zorunlu hale gelmiştir. Bunlar arasında, mikroorganizmalar tarafından hücre içi karbon ve enerji depolama malzemesi olarak sentezlenen çevre dostu ve biyouyumlu polimerler olan polihidroksialkanoatlar (PHA'lar) öne çıkmaktadır. PHA'lar hem karasal hem de deniz ortamlarında tamamen biyolojik olarak parçalanabilir ve CO_2 ve su gibi toksik olmayan yan ürünlere ayrışır (G. Q. Chen and Patel 2012; Sudesh, Abe, and Doi 2000; Park et al. 2024).

Bu çalışmada bir tür PHA kopolimeri olan poli(3-hidroksibutirat-ko-4-hidroksibutirat) (P3HB4HB), yakıt hücresi uygulamaları için potansiyel bir biyolojik olarak parçalanabilir membran malzemesi olarak seçilmiştir ve rGO destekli kompozit membranlar üretilmiştir. Grafen oksitin (GO) kısmi indirgenmesiyle elde edilen indirgenmiş grafen oksit (rGO), geniş bir yüzey alanına ve Grotthuss mekanizması yoluyla proton taşınmasını kolaylaştıran kalıntı oksijenli fonksiyonel gruplara sahiptir. (Karim et al. 2013; R. Kumar, Mamlouk, and Scott 2011; Pandey, Reifenberger, and Piner 2008). Bu bağlamda, mevcut çalışma, mikrobiyal yakıt hücrelerinde proton değişim membranı uygulamaları için uygunluklarını değerlendirmek üzere, rGO/P3HB4HB kompozit membranların geliştirilmesi ve karakterizasyonuna odaklanmaktadır.

MALZEMELER VE YÖNTEMLER

Malzemeler

P3HB4HB, PHABuilder (Shunyi County, China) firmasından TPTRPB3420-P34HB (10%) kodlu (Mw ≈ 700,000), 1,23 g/cm^3 yoğunluğa sahip, eriyik akış indeksi 2 gr/dk (180 °C, 2,16 kg) ve erime noktası 170 °C olan ürünü satın alınmıştır. Katkı maddesi olarak %99 saflıkta, 15,62 m^2/gr özgül yüzey alanına ve 4,5 µm boyuta sahip indirgenmiş grafen oksit (rGO) (Nanografi, Türkiye) takviye olarak kullanılmıştır. N, N-dimetilformamid (DMF), Kloroform (CF) (Sigma- Aldrich), satın alınmıştır.

Elektroçekim ile rGO/P3HB4HB Nanolif Membranların Hazırlanması

Deneysel çalışmalara başlamadan önce P3HB4HB polimeri, nem içeriğinin giderilmesi amacıyla vakumlu etüvde 80 °C'de 6 saat boyunca kurutulmuştur. Daha sonra, ağırlıkça %10 derişiminde P3HB4HB çözeltisi, 95/5 (v/v) oranındaki kloroform/DMF karışımında hazırlanarak manyetik karıştırıcıda 750 rpm hızında 18 saat karıştırılmıştır. Karıştırma işlemi tamamlandıktan sonra bekletilmeden elektroçekim işlemine geçilmiş; bu işlem 3 mL/saat besleme hızı, 15 cm iğne-toplayıcı mesafesi ve 10 kV uygulanan voltaj koşullarında gerçekleştirilmiştir. Elde edilen nanolif membranlar, test aşamasına kadar oda sıcaklığında desikatör içerisinde muhafaza edilmiştir. Nanoliflerin ortalama kalınlığı 130 ± 5 µm olarak belirlenmiştir. Üretilen membranlar, içerdiği rGO oranı esas alınarak adlandırılmıştır (örneğin, 1 rGO numunesi %1 rGO içeren nanolifi ifade etmektedir).

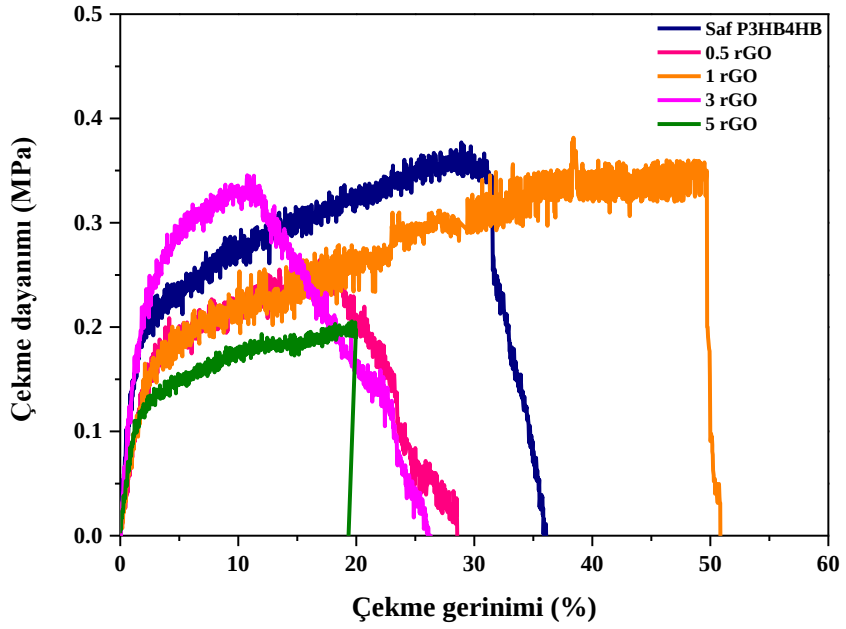
Karakterizasyon

Kompozit membranların mekanik özelliklerinin belirlenmesi amacı ile çekme testi Instron marka Universal Tester cihazı kullanılarak 10 mm/dk çekme hızında ASTM D882 standardına göre gerçekleştirilmiştir. Her bir bileşimden en az 5 numune oda sıcaklığında test edilmiştir. Test sonucunda elde edilen gerilme-gerinim grafiklerinden çekme dayanımı ve kopma uzaması değerleri elde edilmiş olup bu değerlerin ortalamaları raporlanmıştır.

Kompozit membranların termal bozunma ve ayrışma sıcaklıklarını analiz etmek için termogravimetrik analiz (TGA) kullanılmıştır. Ölçümler için Mettler Toledo TGA 1 cihazı kullanılmıştır. TGA, azot atmosferinde 10 °C/dk ısıtma hızında 25-600°C aralığında gerçekleştirilmiştir.

Proton iletkenlik ölçümleri, Gamry Reference 3000 Potansiyostat/Galvanostat kullanılarak, dört noktalı prob empedans spektroskopisi yöntemi ile gerçekleştirilmiştir. Düzlem içi proton iletkenliği ölçümleri için, membran örneği ile iki plaka elektrot, membranın bir yüzeyine yerleştirilen iki paralel platin elektrot aracılığıyla bir Teflon hücreye monte edilmiştir. Membran, platin elektrotlar arasında sıkıştırılmış ve hücre, %100 bağıl nemi korumak amacıyla deiyonize su ile doldurulmuş sıcaklık kontrollü bir ortamda konumlandırılmıştır. İletkenlik ölçümleri, 30 °C - 80 °C sıcaklık aralığında gerçekleştirilmiştir. Empedans ölçümleri sırasında 100 kHz–1 Hz frekans aralığında 10 mV AC sinyal genliği uygulanmıştır. Membran direnci (R), empedans eğrisinin yüksek frekans bölgesinin gerçek eksenle kesişim noktası kullanılarak belirlenmiştir.

Membranların su alım kapasitesi, deiyonize suya daldırılmadan önce ve sonra ölçülen ağırlık değişimleri esas alınarak belirlenmiştir. Kurutulmuş membranlar hassas terazi ile tartıldıktan sonra, 24 saat deiyonize suya daldırılmış, yüzeydeki fazla su filtre kağıdı ile giderildikten sonra son ağırlıkları ölçülmüş ve su alımı hesaplanmıştır.



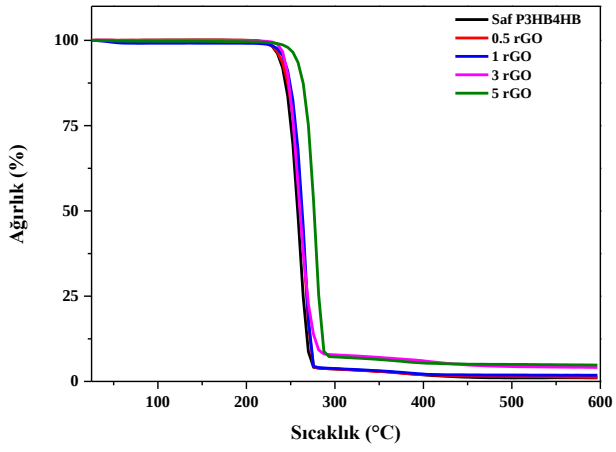
Membranların iyon değişim kapasitesi (IEC), asit-baz titrasyonu yöntemi kullanılarak belirlenmiştir. Kurutulmuş membranlar tartıldıktan sonra, H^+ iyonlarının çözeltideki Na^+

iyonları ile yer değiştirmesi için oda sıcaklığında 24 saat boyunca 1 M NaCl çözeltisine daldırılmıştır. Ardından, membrandan salınan H^+ iyonlarını tespit etmek amacıyla, asidik pH indikatörü fenolftalein kullanılarak 0,01 M NaOH çözeltisi ile titrasyon yapılmıştır. Membrandan salınan H^+ iyonlarının miktarı, IEC değerine dönüştürülmüştür.

BULGULAR VE TARTIŞMA

Mekanik Özellikler

P3HB4HB ve rGO bazlı kompozit nanolif membranlarının gerilme davranışı Şekil 1 ve Tablo 1'de gösterilmektedir. Saf P3HB4HB, maksimum yükte yaklaşık %36,8 uzama ile en yüksek gerilme dayanımı (0,37 MPa) sergilemiş ve sünek bir yapıya sahip olduğunu göstermiştir. Ağırlıkça %0,5 rGO ilavesi, gerilme mukavemetinin 0,25 MPa'ya düşmesine ve uzamanın %28,7'ye azalmasına neden olmuştur, bu da az miktarda rGO'nun polimer zinciri hareketliliğini hafifçe kısıtladığını göstermektedir. Bununla birlikte, %1 ağırlıkça rGO ilavesi uzamanın önemli ölçüde artmasına (%50,1) yol açarak, rGO nano tabakalarının homojen dağılımı sayesinde esneklik ve tokluğun arttığını gösterdi; bu da dolgu maddesi ile polimer matrisi arasındaki gerilim transferinin iyileştirmiştir. rGO içeriği ağırlıkça %3 ve %5 oranına arttıkça hem çekme dayanımı hem de uzama değerleri tekrar azalmıştır (sırasıyla 0,33 MPa ve 0,18 MPa; %26,9 ve %18,7). Bu eğilim, daha yüksek konsantrasyonlarda rGO'nun aglemerasyonu ile açıklanabilir; bu durum, gerilme yoğunlaştırıcıları olarak hareket etmiş ve arayüzey bağlarını zayıflatmış olabilir. Genel olarak, orta düzeyde rGO ilavesi (yaklaşık ağırlıkça %1) P3HB4HB'nin mekanik performansını artırırken, aşırı yükleme kırılganlığa ve sünekliğin azalmasına neden olmuştur.

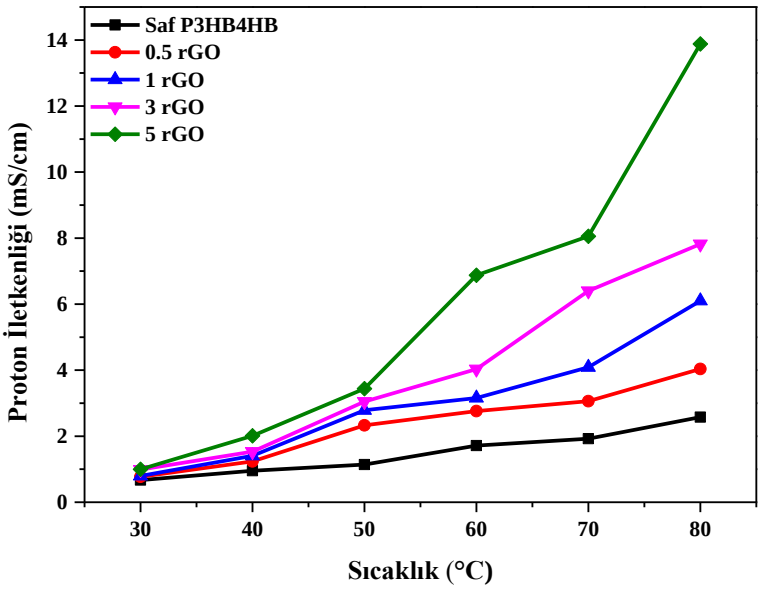


Şekil 1. Kompozit membranların çekme dayanımına karşı gerinim değerleri

Tablo 1. rGO/ P3HB4HB kompozit membranların mekanik özellikleri

Numune	Maksimum Yükte Çekme Dayanımı (MPa)	Young Modulu's (MPa)	Maksimum Yükte Uzama (%)
Saf P3HB4HB	0.37±0.05	17.9±0.76	36.8±2.61
0.5 rGO	0.25±0.01	11.1±1.10	28.7±2.37
1 rGO	0.37±0.05	13.4±0.67	**50.1**±6.97
3 rGO	0.33±0.03	12.1±1.30	26.9±0.29
5 rGO	0.18±0.01	10.3±0.87	18.7±0.11

Termogravimetrik özellikler



Saf P3HB4HB ve rGO/ P3HB4HB kompozit nanolif membranların ısıl bozunma davranışı TGA ile değerlendirilmiş ve ilgili termogramlar Şekil 2'de sunulmuştur. Saf P3HB4HB, maksimum bozunma sıcaklığı (T_{max}) 259,45 °C olan tek aşamalı ısıl bozunma sergilemiştir. rGO'nun eklenmesiyle, 0,5 rGO ve 1 rGO kompozitlerinde sırasıyla 264,90 °C ve 265,32 °C T_{max} değerleri ile ısıl karalılıkda hafif bir iyileşme gözlemlenmiştir. Bu iyileşme, polimer matris içindeki rGO tabakalarının iyi dağılımına atfedilebilir; bu da muhtemelen polimer zincirlerinin ısıl hareketini engellemiş ve ayrışmalarını geciktirmiştir. Bununla birlikte, 3 rGO numunesi, muhtemelen ısıl bariyer etkisini bozan rGO'nun bölgesel aglomerasyonu nedeniyle T_{max}'ta (259,03 °C) küçük bir düşüş gösterdi. İlginç bir şekilde, 5 rGO kompoziti en yüksek T_{max}'ı (277,90 °C) sergiledi, bu da daha yüksek miktarda rGO'nun, uygun şekilde dağıtıldığında daha güçlü arayüzey etkileşimlerini ve iyileştirilmiş ısı direncini teşvik edebileceğini düşündürmektedir. Ayrıca, 600 °C'de kalıntı miktarları değerlendirildiğinde, saf P3HB4HB için kalıntı değeri %1,05'ten 5 rGO kompozit için %4,79'a yükseldi, bu da rGO'nun yüksek ısıl karalılığını ve uçucu olmayan doğasını göstermektedir. Genel olarak, bu sonuçlar rGO'nun dahil edilmesinin, özellikle daha yüksek dolgu yüklemelerinde P3HB4HB'nin ısıl kararlılığını ve kalıntı içeriğini artırdığını göstermektedir.

Şekil 2. rGO destekli membranların TGA eğrileri

Proton İletkenliği

İletkenlik, tüm yakıt hücresi elektrolitleri için çok önemli bir faktördür ve proton iletkenliği, yakıt hücresi uygulamaları için membranları değerlendirmek için kullanılan temel özelliktir (Kim and Pivovar 2007). İyonların bir membrandan geçme yeteneği, iyonik veya proton iletkenliği olarak bilinir ve membranın protonları ne kadar etkili bir şekilde iletebileceğini belirler (Dharmalingam, Kugarajah, and Elumalai 2021). İçsel kütle iletkenliği ve membran kalınlığına bağlı olan hedef iletkenlik değeri, genellikle 0,05–0,1 S/cm aralığındadır. Çoğu proton ileten polimer için iletkenlik, membranın su içeriğine büyük ölçüde bağlıdır (de Bruijn et al. 2007). P3HB4HB'nin kendisi iyonik bir yapıya sahip olmasa da rGO'nun eklenmesinin iletkenlik yollarını geliştirerek proton taşınmasını kolaylaştırması beklenmektedir. Bununla birlikte, bu varsayımı doğrulamak için proton iletkenliğinin ölçülmüştür. Proton iletkenliği, yakıt hücrelerindeki proton değişim membranlarının performansında belirleyici bir rol oynadığından, membran seçiminde değerlendirilmesi kritik bir adımdır. Bu nedenle, bu çalışmada hazırlanan kompozit membranların sıcaklığa bağlı proton iletkenliği belirlenmiş ve Şekil 3'te sunulmuştur.

Şekil 3. Kompozit membranların proton iletkenlik değerleri

Genel olarak, tüm numunelerde sıcaklık artışıyla birlikte proton iletkenlik değerlerinin yükseldiği gözlenmiştir. Bu durum, sıcaklığın iyon hareketliliğini artırarak proton taşınımını hızlandırdığı yaygın olarak bilinen bir mekanizma ile açıklanabilir. Saf P3HB4HB membranı, test edilen sıcaklık aralığında en düşük proton iletkenliği sergilemiştir, bu da P3HB4HB'nin hidrofobik ve iletken olmayan doğası nedeniyle iyonik hareketi destekleme yeteneğinin sınırlı olmasının bir sonucudur. Ancak rGO katkısı ve katkı oranının artması ile proton iletkenliğinde belirgin bir iyileşme gözlemlenmiştir. Düşük katkı seviyelerinde (0,5 ve 1 rGO) iletkenlikte düşük artışlar sağlarken, 3 rGO ilavesinde bu eğilim daha belirgin hale gelmiştir. 5 rGO katkı içeren kompozit membranda iletkenlikte dikkate değer bir artış sağlanmıştır.

Su Alımı ve İyon Değişim Kapasitesi

Üretilen kompozit membranların su emme ve iyon değişim kapasitesi (IEC) değerleri Tablo 2'de özetlenmiştir. Proton değişim membranlarında proton taşınımı, protonların genellikle hidrojen bağına sahip su ağları veya iyon değişim grupları aracılığıyla hareket etmesinden dolayı su moleküllerine büyük ölçüde bağlıdır (X. Chen et al. 2010). Bu nedenle, proton iletkenliği su alımıyla artar, ancak aşırı şişme membran yapısını zayıflatabilir. P3HB4HB ve rGO gibi hidrofobik malzemelerin kullanılması bu sorunun önlenmesine yardımcı olur. Bu membranların nem içermediği, TGA analizinde 100 °C civarında nem kaybının olmaması ile doğrulanmıştır. İyon değişim kapasitesi (IEC), muhtemelen –COOH veya –SO_3H gibi güçlü asidik fonksiyonel grupların bulunmaması nedeniyle, rGO ilavesiyle önemli bir iyileşme göstermemiştir. rGO, iyon değişimi için daha az etkili olan –OH ve epoksi gruplarını içerir. Morfolojik gözlemler, saf P3HB4HB membranının ince, gözenekli nanofiberlere sahip olduğunu ve hidrofobik olmasına rağmen yüksek su emilimine yol açtığını göstermiştir. rGO ilavesiyle lifler daha kalın ve daha kompakt hale gelerek, özellikle %3 rGO'da gözenekliliği ve su emilimini azalttı. Ancak, daha yüksek rGO içeriklerinde (%5), lif yapısı tekrar daha düzenli ve gözenekli hale gelerek, biraz daha yüksek su emilimi sağladı. Bu sonuçlar, kontrollü rGO ilavesinin yapısal stabiliteyi iyileştirebileceğini ve proton taşınması için daha uygun bir morfoloji sağlayabileceğini göstermektedir.

Tablo 2. Kompozit membranların su emme ve iyon değişim kapasitesi

Membran	Membran Kalınlığı (cm)	Su Alımı (%)	IEC (meq/g)
Saf P3HB4HB	0,0130 ± 0,01	157	0,168
0.5 rGO	0,0130 ± 0,01	149	0,142
1 rGO	0,0130 ± 0,03	113	0,053
3 rGO	0,0130 ± 0,02	71	0,069
5 rGO	0,0130 ± 0,01	91	0,045

SONUÇLAR

Bu çalışma kapsamında, P3HB4HB membranlar, mekanik, termal ve proton iletkenlik özelliklerini iyileştirmek için çeşitli rGO yüklemeleriyle güçlendirildi. TGA sonuçları, rGO ilavesiyle membranların ısıl kararlılığını hafifçe arttığını, rGO'nun ısıl olarak kararlı yapısı nedeniyle ise kalıntı kütlesinin arttığını gösterdi. Mekanik analiz, %1 ağırlıkça rGO'nun gerilme dayanımı ve esneklik arasında en iyi dengeyi sağladığını, daha yüksek rGO içeriklerinin ise uzama oranının azalmasına ve kırılganlığın artmasına neden olduğunu ortaya koydu. Genel olarak, rGO'nun orta düzeyde eklenmesi, P3HB4HB membranların ısıl kararlılığını ve mekanik bütünlüğünü artırarak, yakıt hücresi uygulamalarında proton değişim membranı olarak kullanılabileceğini göstermiştir.

TEŞEKKÜRLER

Bu çalışma, Türkiye Bilimsel ve Teknolojik Araştırma Kurumu (TÜBİTAK) tarafından desteklenmiştir (Proje 124C192-TÜBİTAK 2218). Yazarlar, TÜBİTAK'a mali desteklerinden dolayı teşekkür eder.

ABSTRACT

The growing demand for sustainable, high-performance materials has intensified research on bio-based polymer nanocomposites with multifunctional properties. This study reports the development of biodegradable nanocomposites by incorporating zinc oxide (ZnO) nanoparticles into a poly(lactic acid) (PLA)/poly(butylene succinate) (PBS) matrix. The blend, composed of 80% PLA and 20% PBS, provides renewability, biodegradability, and good processability, while ZnO nanoparticles (0–10 wt%) were introduced as functional fillers to enhance mechanical and thermal behavior. ZnO is a cost-effective, thermally stable, and environmentally benign metal oxide with semiconductive and photocatalytic properties. The composites were fabricated via melt extrusion followed by hot-press molding, suitable for scalable processing. Tensile testing revealed a significant decline in flexibility with increasing ZnO content: tensile strain dropped from 23% for the neat PLA/PBS blend to 5% with 1 wt% ZnO and below 1% at higher loadings, primarily due to filler aggregation. In contrast, tensile strength increased from ~15 MPa for the neat blend to ~45 MPa with 1 wt% ZnO, then decreased below 1 MPa at higher concentrations due to embrittlement. Thermogravimetric analysis (TGA) showed an ~80 °C reduction in onset degradation temperature with ZnO incorporation, while final mass correlated with filler content. Fourier-transform infrared spectroscopy (FTIR) revealed an intensified peak near 1600 cm^{-1} (O–H stretching) with increasing ZnO, without the appearance of new peaks. This work contributes to sustainable polymer development by elucidating the structural, thermal, and mechanical effects of ZnO nanoparticle incorporation in bio-based PLA/PBS composites.

INTRODUCTION

The global production of petroleum-based plastics has surpassed 460 million tonnes annually, with inadequate end-of-life management leading to pervasive environmental pollution. Mismanaged plastic waste contributes approximately 1–2 million tonnes entering aquatic ecosystems each year, exacerbating biodiversity loss, microplastic infiltration into food chains, and greenhouse gas emissions throughout the plastic lifecycle [1, 2] . This escalating crisis has spurred extensive research into fully bio-based and biodegradable polymers that offer comparable or enhanced performance while facilitating circularity through industrial or home composting[3]. Poly(lactic acid) (PLA) stands as the most commercially viable bio-based polyester, sourced from renewable feedstocks like corn or sugarcane, and characterized by excellent transparency, high modulus, and scalable production[4]. Nonetheless, pristine PLA exhibits inherent brittleness (elongation at break typically <10%), low impact strength, sluggish crystallization kinetics, and a limited heat distortion temperature (~55–65 °C), which curtail its applicability in flexible or semi-durable products[5, 6]. Blending PLA with poly(butylene succinate) (PBS)—a ductile, biodegradable aliphatic polyester boasting elongation >300% and robust thermal stability—emerges as a premier strategy to enhance PLA's toughness while preserving renewability and compostability[7, 8]. PLA/PBS blends with 20–30 wt% PBS commonly display markedly improved ductility and processability, alongside satisfactory strength and complete biodegradability, positioning them as viable candidates for packaging, agricultural films, and biomedical devices [7]. To augment multifunctionality and performance, integrating nanofillers into biodegradable polymer blends represents a pivotal advancement for crafting next-generation sustainable materials endowed with attributes such as mechanical reinforcement, UV shielding, antimicrobial efficacy, and oxygen barrier capabilities[9]. Zinc oxide (ZnO) nanoparticles emerge as an exemplary nanofiller owing to their affordability, thermal resilience, GRAS (generally recognized as safe) designation, semiconducting nature, potent UV absorption, and substantiated antimicrobial/photocatalytic attributes, rendering them more eco-friendly than alternatives like silver or TiO_2 nanoparticles [10, 11]. Investigations into PLA/ZnO nanocomposites have underscored gains in tensile strength, modulus, and bioactive functionality at modest loadings (≤3 wt%), albeit with elevated concentrations prone to aggregation-driven embrittlement and hastened thermal degradation [11, 12]. Although progress in standalone PLA/ZnO and PLA/PBS systems is notable, the ternary PLA/PBS/ZnO configuration remains underexplored, especially concerning the delicate equilibrium of reinforcement, toughness preservation, filler dispersion, and thermal integrity across broad loading spectra (0–10 wt%). This study bridges this void by engineering melt-processable PLA/PBS (80/20) nanocomposites incorporating 0–10 wt% ZnO nanoparticles, and rigorously dissecting the attendant morphological, mechanical, and thermal trade-offs, thereby advancing the deliberate engineering of high-performance, wholly biodegradable, multifunctional materials for sustainable packaging and allied domains.

MATERIALS AND METHODS

Materials

PLA was acquired from NatureWorks under the trade name Ingeo2003D, with a density of 1.24 g/cm^3 and a melting point of 155 °C. PBS was procured from PTT MCC Biochem Co., Ltd. under the trade name BioPBS™ FZ71 PM, with a density of 1.26 g/cm^3 and a melting point of 115 °C.

Sample preparation

Firstly, the materials were dried in a vacuum oven at 80 ºC to remove the moisture. A laboratory-scale twin-screw Xplore brand mini-blender (extruder) was employed for blending. The extrusion was performed at 180 °C, 100 rpm, and 3 min. At the end of the melting process, the molten blend was transferred to the injection molding machine (Explore MI-12). The composites were molded at 8 bar with melt and mold temperatures of 180 °C and 25 °C, respectively.

Characterization

Structural properties were determined with Fourier transform infrared spectroscopy (FTIR) by using Perkin Elmer Spectrum 100. Measurements were performed at the range of 650-4000 cm^{-1} wavelength.

The mechanical properties of samples were determined by tensile test. The tests were performed using dog-bone specimens at a tensile speed of 5 mm/min according to ISO 527 5 A standard.

Thermogravimetric Analysis (TGA) was used to analyze the thermal strength and decomposition temperatures of the samples. Mettler Toledo TGA 1 device was employed for measurement and the analysis was carried out in the range of 25-600 °C with a heating rate of 10 °C/min.

RESULTS AND DISCUSSION

Fourier-transform infrared (FTIR)

Figure 1 presents the Fourier-transform infrared (FTIR) spectra of the neat PLA/PBS (80/20) blend and its nanocomposites containing 1, 3, 5, and 10 wt% ZnO nanoparticles in the wavenumber range of 3500–600 cm^{-1}. All spectra exhibit the characteristic absorption bands of the PLA/PBS matrix, including the strong C=O stretching vibration at 1748 cm^{-1}, symmetric and asymmetric C–O–C stretching at 1180, 1082, and 1042 cm^{-1}, and $–CH_3$ asymmetric and symmetric deformation at 1452 and 1386 cm^{-1}, and –CH stretching at 2960 cm^{-1}, with no significant shifts in peak position observed upon ZnO incorporation. No new absorption peaks appeared across the entire ZnO loading range (0–10 wt%), confirming the absence of chemical reactions or formation of new covalent bonds between the ZnO nanoparticles and the polymer chains during melt processing. The most prominent change is a progressive intensification and slight broadening of the broad band centered near 1600 cm^{-1}, which is assigned to O–H stretching vibrations of adsorbed water molecules and hydroxyl groups present on the ZnO nanoparticle surface. The intensity of this band increases systematically with ZnO content, being barely detectable in the neat PLA/PBS blend and becoming markedly pronounced at 10 wt% loading, reflecting the increasing availability of surface oxygen and hydroxyl groups contributed by the hydrophilic ZnO filler. A concomitant weak enhancement of the broad O–H band in the 3500–3200 cm^{-1} region further supports the incorporation of moisture-attracting ZnO surfaces within the composite. These observations indicate that the interaction between ZnO nanoparticles and the PLA/PBS matrix is predominantly physical in nature, with no evidence of chemical functionalization or grafting, while the increased hydroxyl-related absorbance highlights the growing contribution of the inorganic filler's surface chemistry to the overall spectral profile of the nanocomposites.

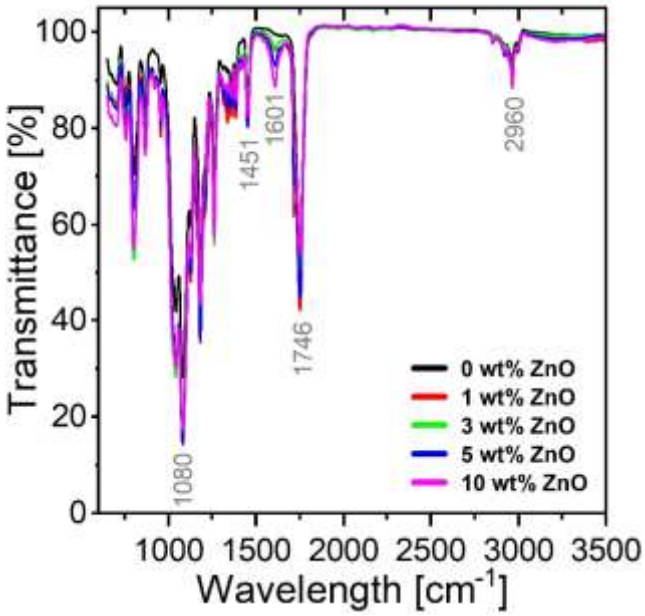

Figure 1. FTIR spectra of the neat PLA/PBS (80/20) blend and PLA/PBS/ZnO nanocomposites containing 1, 3, 5, and 10 wt% ZnO nanoparticles.

Thermogravimetric Analysis (TGA)

Figure 2 presents the thermogravimetric analysis (TGA) curves of the neat PLA/PBS (80/20) blend and PLA/PBS/ZnO nanocomposites containing 1, 3, 5, and 10 wt% ZnO nanoparticles, recorded under nitrogen atmosphere from 30 to 600 °C at a heating rate of 10 °C min^{-1}. The neat blend exhibits a single-step degradation profile with an onset temperature (defined as 5 % mass loss, T_5%) of approximately 300 °C and complete decomposition by ~400 °C, leaving virtually no residue (< 1%) at 600 °C. In contrast, incorporation of ZnO nanoparticles dramatically reduces thermal stability: the onset of degradation shifts to ~225–235 °C (a decrease of nearly 80 °C even at the lowest loading of 1 wt%), and the degradation proceeds through a distinct two-step process. The first major mass-loss step, occurring between ~220 and ~310 °C, accounts for approximately 70–80 wt% of the total mass and corresponds closely to the nominal PLA fraction in the blend matrix, indicating that ZnO selectively accelerates the thermal decomposition of the PLA phase, most likely via catalytic action of Zn^{2+} Lewis acid sites [13]. The second, smaller step between ~310 and ~400 °C corresponds to decomposition of the PBS-rich phase and follows a profile similar to that of the neat blend. Above 500 °C, the remaining mass plateau increases systematically with ZnO content, yielding final residues at 600 °C of approximately 3, 4, 6, and 11 wt% for the 1, 3, 5, and 10 wt% ZnO composites, respectively—values that align closely with the targeted filler loadings and thereby confirm successful incorporation of the inorganic nanoparticles throughout the series. These results underscore the strong catalytic influence of ZnO on the thermal degradation pathway of the PLA/PBS matrix, particularly its pronounced destabilizing effect on the PLA component.

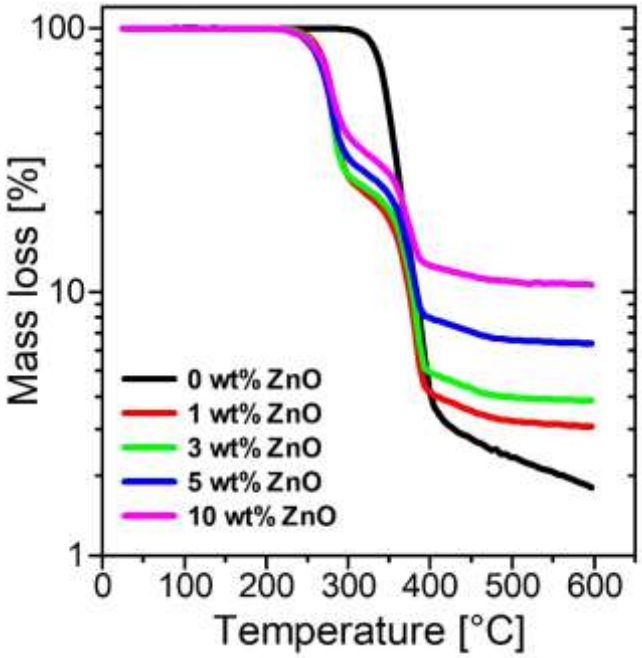

Figure 2: Thermogravimetric analysis curves of the neat PLA/PBS (80/20) blend and PLA/PBS/ZnO nanocomposites containing 1, 3, 5, and 10 wt% ZnO nanoparticles.

Tensile test

Figure 3 illustrates the tensile mechanical properties of the neat PLA/PBS (80/20) blend and its ZnO-loaded nanocomposites, with elongation at break presented in Figure 3a and the corresponding tensile strength (stress at break) summarized in Figure 3b (error bars represent the standard error of the mean calculated from five independent specimens per formulation). The unfilled PLA/PBS blend exhibits a ductile response typical of well-compatibilized systems, yielding a tensile strength of ~ 15 MPa and a remarkably high elongation at break of ~ 23 %, reflecting the effective toughening contribution of the 20 wt% PBS phase. Incorporation of only 1 wt% ZnO produces a pronounced reinforcing effect: tensile strength increases sharply to a maximum of ~ 44.8 Mpa at 1 wt% ZnO (an almost threefold improvement), while elongation at break simultaneously drops to ~ 5 %. This simultaneous gain in strength and loss of ductility indicates that low ZnO loadings act as efficient stress-transfer nanofillers that restrict chain mobility and promote stiffening of the matrix. At higher ZnO concentrations (≥3 wt%), however, both properties deteriorate catastrophically: tensile strength falls progressively to below 1 Mpa, while elongation at break collapses to <1 % across the entire high-loading regime. The drastic embrittlement and strength loss are directly attributable to severe nanoparticle aggregation, which creates stress-concentrating defect clusters, promotes premature crack initiation, and transforms the material from tough and deformable to extremely brittle. These results highlight a narrow processing window—centered around 1 wt% ZnO—where significant reinforcement can be achieved without complete sacrifice of ductility, whereas excessive filler content induces percolation of agglomerates and renders the nanocomposites mechanically unsuitable for most practical applications.

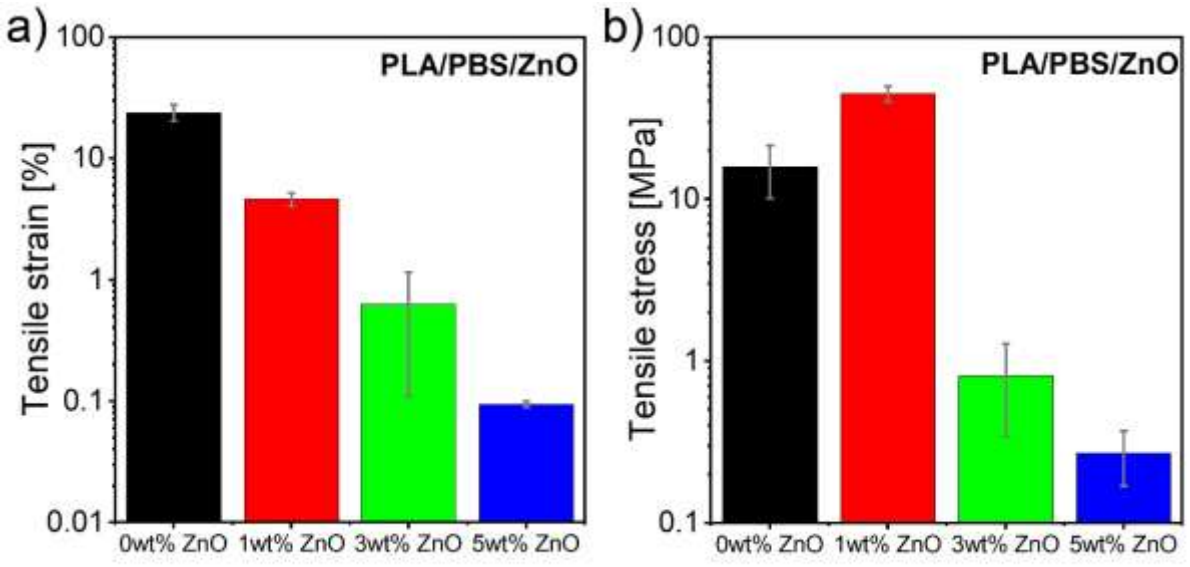

Figure 3: Tensile strain and tensile stress at break point of the neat PLA/PBS (80/20) blend and PLA/PBS/ZnO nanocomposites containing 1, 3, and 5 wt% ZnO nanoparticles.

CONCLUSION

Fully biodegradable PLA/PBS (80/20)/ZnO nanocomposites (0–10 wt%) were successfully prepared by melt extrusion and hot pressing. FTIR confirmed physical interactions only, with increasing O–H intensity due to ZnO surface hydroxyls and no new chemical bonds. TGA revealed a dramatic ~80 °C drop in onset degradation temperature and a shift to two-step decomposition, driven by selective catalytic acceleration of PLA degradation via Zn^{2+} Lewis acid sites, while residual mass accurately reflected ZnO content. Mechanical properties showed strong loading dependence: 1 wt% ZnO tripled tensile strength (~15 to ~45 MPa) but reduced elongation from 23 % to ~5 %. Higher loadings (≥3 wt%) caused severe aggregation, leading to extreme brittleness (elongation <1 %) and near-complete loss of strength (<1 MPa). Although low ZnO loadings offer significant reinforcement and potential multifunctionality, the accompanying loss of ductility and thermal stability limits practical utility. Future work should focus on improvement of dispersion through surface modification of fillers or use of compatibilizers to improve dispersion, thereby enabling the design of high-performance, multifunctional, biodegradable nanocomposites.

ÖZET

Geleneksel yöntemlerle yapılan tarımsal üretim modellerinde birim alandan maksimum verim elde etmek amacıyla kimyasal girdilerin aşırı ve yoğun bir şekilde kullanılması çevresel sürdürülebilirliği olumsuz etkilemekte ve insan sağlığı açısından riskler doğurmaktadır. Bu nedenle, düşük maliyetli, çevre dostu ve uygulanması kolay fiziksel biyostimülasyon tekniklerine yönelik ilgi son yıllarda hızla artmıştır. Statik ve alternatif manyetik alanlar, elektromanyetik alanlar (EMF), manyetize su, soğuk plazma ve nanoteknoloji destekli magnetopriming uygulamaları; tohum çimlenmesi, fide gelişimi, fotosentetik kapasite, mineral alımı ve abiyotik stres dayanımı üzerinde olumlu etkiler gösterebilen yenilikçi yaklaşımlardır. Bu çalışmada, 2020–2025 yılları arasında yayımlanan güncel araştırmalar temel alınarak farklı manyetik/EMF uygulamalarının tohum fizyolojisi, erken büyüme performansı, fotosentez, biyokimyasal düzenlemeler ve moleküler yanıtlar üzerindeki etkileri değerlendirilmiştir. Yapılan araştırmalarda, manyetik/EMF uygulamalarının; doza, frekansa, maruz kalma süresine, manyetik akı yoğunluğuna, tohum türüne ve çevresel koşullara yüksek derecede duyarlı olduğu belirtilmiştir. Çoğu çalışma, EMF'nin uyarıcı- inhibitör olarak iki fazlı bir doz–tepki dinamiği sergilediğini vurgulamaktadır. Çalışmaların birçoğunda manyetik/EMF uyarımı; su alımı ve imbibisyon hızını artırmış, amilaz aktivitesine ve protein sentezine katkıda bulunmuş, metabolik süreçleri hızlandırmak suretiyle çimlenme oranını ve fide vigorunu yükselttiği bildirilmiştir. Bu çalışmalarda manyetik/EMF uygulamasının fotosentetik pigmentler ve klorofil içeriği üzerinde iyileştirici etkilere yol açtığı, ışık kullanım etkinliğini ve karbon asimilasyonunu artırdığı beyan edilmiştir. Ayrıca; manyetik/EMF uygulamalarının besin elementi alımını optimize ettiği, kök gelişimini güçlendirdiği ve nanoparçacık taşınımının kolaylaşmasına yardımcı olduğu belirtilmiştir. Araştırmada manyetik/EMF uygulamalarının biyokimyasal düzeyde etkilerinin incelendiği çalışmalara da yer verilmiştir. Bu çalışmalarda manyetik/EMF uygulamalarının ROS–antioksidan dengesini optimum düzeye getirerek oksidatif stresin azaltılmasında etkili rol aldığı belirtilmiştir. Buna ilaveten; bazı araştırmalarda manyetik/EMF uygulamasının; ABA, GA ve IAA gibi fitohormonların sentez ve dağılımında değişimlere neden olduğu ve bu sayede bitkilerde kuraklığa karşı dayanaklılık, tuz ve ağır metal streslerine karşı tolerans geliştirdiği belirlenmiştir. Ancak konu ile ilgili çalışmalar bütün olarak ele alındığında bazılarının birbiri ile çelişkili sonuçlar beyan ettiği gözlenmiştir. Bu farklı yaklaşımlardan yola çıkılarak manyetik/EMF uygulamalarının bitkisel materyal üzerindeki etki mekanizmalarının tam anlamıyla çözülmediği sonucuna varılabilir. Bu çalışmada, EMF tabanlı biyostimülasyonun tarımsal kullanım potansiyeli, sınırlarını ve gelecekteki araştırma konuları kapsamlı biçimde tartışılmıştır.

EFFECTS OF ELECTROMAGNETIC AND MAGNETIC FIELDS ON GERMINATION AND STRESS PHYSIOLOGY IN PLANT BIOSYSTEMS

ABSTRACT

In traditional agricultural production models, the excessive and intensive use of chemical inputs to maximize yield per unit area can harm environmental sustainability and pose risks to human health. As a result, interest in low-cost, environmentally friendly, and easy-to-implement physical bio-stimulation techniques has grown rapidly in recent years. Innovative approaches such as static and alternating magnetic fields, electromagnetic fields (EMF), magnetized water, cold plasma, and nanotechnology-supported magnetopriming have shown potential to positively influence seed germination, seedling development, photosynthetic capacity, mineral uptake, and abiotic stress tolerance. This study, based on recent research published between 2020 and 2025, examines the effects of various magnetic/EMF applications on seed physiology, early growth, photosynthesis, biochemical regulation, and molecular responses. The studies highlight that magnetic/EMF effects depend heavily on dose, frequency, exposure duration, magnetic flux density, seed type, and environmental conditions. Most research indicates that EMF shows a two-phase dose–response relationship, acting as both a stimulant and an inhibitor. Many studies report that magnetic/EMF stimulation improves water uptake and imbibition rates, increases amylase activity and protein synthesis, and enhances germination and seedling vigor by speeding up metabolic processes. These studies also note positive effects on photosynthetic pigments and chlorophyll content, which improve light utilization efficiency and carbon fixation. Moreover, magnetic/EMF treatments help optimize nutrient absorption, strengthen root development, and facilitate nanoparticle transport. Some research has explored the biochemical impacts of magnetic/EMF applications, revealing their role in reducing oxidative stress by balancing ROS and antioxidants. Additionally, certain studies have observed that magnetic/EMF exposure influences the synthesis and distribution of phytohormones, such as ABA, GA, and IAA, thus improving drought resistance and tolerance to salt and heavy metal stress. However, a review of the overall body of research shows conflicting results in some cases. Due to these varied findings, the mechanisms through which magnetic/EMF applications affect plant material are not yet fully understood. This study offers a comprehensive discussion of the potential, limitations, and future research directions for EMF-based bio-stimulation in agriculture.

1. GİRİŞ

Bitkisel biyosistemler, moleküler etkileşimlerden hücresel metabolizmaya, hücre/doku/organ büyümesi ve gelişimi ile çevresel tepkilere kadar çeşitli ölçeklerde biyolojik süreçleri içeren karmaşık, çok hücreli organizmalar olarak tanımlanmaktadır (Yang et al., 2020). Bu sistemlerin tasarımı, bitki sistemlerinin yapısının grafiksel bir görünümünü sağlayan çizge teorisi, genleri fenotipik özelliklere bağlayan mekanik modeller ve genetik olarak değiştirilmiş veya de novo bitki sistemlerinin genetik stabilitesi ile evrimleşe bilirliğini tahmin etmeyi sağlayan evrimsel dinamik teorisi gibi çeşitli teorik yaklaşımları içermektedir (Yang et al., 2020). Bitkiler ve çevresindeki biyolojik sistemler, gezegenin ve sakinlerinin gelecekteki sağlığı için merkezi bir öneme sahiptir (Henkhaus et al., 2020). Bitki sistemleri biyolojisi, genlerin, proteinlerin ve metabolitlerin belirli koşullar altında bu plastisiteyi gerçekleştirmek için nasıl birlikte çalıştığını ortaya koyan karmaşık moleküler etkileşimleri bütünsel bir yaklaşımla incelemektedir (Gechev & Petrov, 2022).

Elektromanyetik alanlar, elektrik yüklü nesneler tarafından üretilen ve biyolojik sistemlerle etkileşime giren hem elektrik hem de manyetik bileşenleri içeren fiziksel alanlardır (Murugan et al., 2023). Manyetik alanlar ise, EMF'nin hareketli elektrik yükleri tarafından oluşturulan ve elektrik alanından ayrı olarak ele alınan bir bileşenidir (Murugan et al., 2023). Doğal ve antropojenik kaynaklı elektromanyetik alanlar çevrede yaygın olarak bulunur ve bitkiler de dahil olmak üzere tüm biyolojik organizmalarla etkileşime girer (Schmidtpott et al., 2022). Özellikle yeni teknolojilerin uygulanmasıyla antropojenik kaynaklardan gelen alternatif EMF'lerin kalitesi ve niceliği artmaktadır (Schmidtpott et al., 2022). Elektrik ve manyetik alanlar, biyolojik sistemlerle etkileşime girebilen ortak bir elektromanyetik modalitenin ayrı bileşenleridir (Murugan et al., 2023). Canlı organizmalar elektriksel olarak nötr olsalar da elektromanyetizma ve termodinamik yasalarına uyan yüklü iyonlar, polarize moleküller ve elektrik alanlar içerirler (Romanenko et al., 2017).

EMF'lerin bitki gelişimi üzerindeki potansiyel etkileri hem olumsuz hem de faydalı sonuçlar doğurabilmektedir (Ayesha et al., 2023). Mevcut araştırmalar, radyo frekanslı EMF radyasyonunun bitki büyüme ve gelişimini, gen ekspresyonunu ve çeşitli metabolik aktiviteleri etkileyebileceğini göstermiştir (Czerwiński et al., 2023). Örneğin, marul bitkilerinde RF-EMF maruziyeti, fotosentetik verimlilikte önemli ve sistemik bir azalmaya ve çiçeklenme zamanının hızlanmasına yol açmıştır (Tran et al., 2023). Diğer taraftan, EMF'lerin tohum çimlenmesini, bitki beslenmesini, hassas tarımı, su kullanım verimliliğini, kök hidrolik iletkenliğini, bitki suyu alımını, anti-oksidatif savunmayı, zararlı önlemeyi, stres sinyallemesini ve hormonal yolları iyileştirerek mahsul verimliliğini artırabileceğine dair belirtiler de bulunmaktadır (Ayesha et al., 2023). Statik manyetik alanlar bitki hücrelerinin yapısını, biyokimyasal aktivitesini ve gen ekspresyonunu düzenleyebilir (Saletnik et al., 2022). SMF'lerin bitkiler üzerinde, fotosentetik verimlilik ve canlılık birikim indeksleri üzerinde önemli etkileri olduğu rapor edilmiştir (Saletnik et al., 2022). Ayrıca, SMF'lerin bitki fonksiyonlarını, büyümesini düzenlediği ve çevresel streslere karşı toleransı artırdığı da belirtilmiştir (Radhakrishnan, 2019). Yönlü bir elektromanyetik alanın, turp ve şeker kamışı bitkilerinin erken büyüme aşamalarında filizlerin ortaya çıkışını, filiz uzamasını, kök çoğalmasını ve bitki büyüme hormonlarını teşvik ettiği gözlemlenmiştir (Jo et al., 2024).

Bu çalışmanın amacı, elektromanyetik alanların belirli frekans ve şiddetlerde bitkisel biyosistemler üzerindeki etkilerini deneysel olarak incelemektir. Kapsam dahilinde, bitki büyüme indeksleri (çimlenme indeksleri gibi), fizyolojik stres göstergeleri ve moleküler düzeydeki değişimler analiz edilecektir. Bu araştırma, EMF'lerin bitkiler üzerindeki etkileşim

mekanizmalarını daha iyi anlamayı ve potansiyel tarımsal uygulamalar için bilgi sağlamayı hedeflemektedir.

2. ELEKTROMANYETİK ALANLARIN TEMEL PRENSİPLERİ

Elektromanyetik alanlar, frekans, şiddet ve dalga boyu gibi temel özelliklerle karakterize edilir (Suzuki et al., 2024). Frekans, birim zamanda dalga döngüsü sayısını (örneğin Hertz cinsinden) ifade eder ve biyolojik etkileşimlerin belirlenmesinde kritik bir parametredir (Suzuki et al., 2024). Şiddet veya alan gücü, elektrik alanlar için V/m, manyetik alanlar için ise Tesla (T) veya Gauss (G) birimleriyle ölçülerek, alanın bitkisel biyosistemler üzerindeki potansiyel etkisinin doz-tepki ilişkilerini anlamak için önem taşır (Czerwiński et al., 2019). Dalga boyu ise, dalganın bir tam döngüsünü tamamlamak için katettiği mesafeyi belirtir ve frekans ile ters orantılıdır (Suzuki et al., 2024). Bu parametreler, EMF'nin bitki hücreleri ile etkileşim biçimini ve sonuçlarını doğrudan etkilemektedir (Ayesha et al., 2023).

EMF'ler, bitki hücreleri ile çeşitli mekanizmalar aracılığıyla etkileşime girer (Schmidtpott et al., 2022). Doğal ve antropojenik kaynaklı EMF'ler çevrede yaygın olarak bulunur ve bitkiler de dahil olmak üzere tüm biyolojik organizmalarla etkileşime girer (Schmidtpott et al., 2022). Yüksek frekanslı iyonize olmayan elektromanyetik alanlar, bitkilerde stres koşulları altında gözlemlenenlere benzer spesifik yanıtlar uyandırabilen gerçek bir çevresel uyaran oluşturur (Vian et al., 2016). Bu etkileşimler, bitki büyümesi, gelişimi, gen ekspresyonu ve çeşitli metabolik aktiviteler üzerinde hem olumlu hem de olumsuz sonuçlar doğurabilir (Czerwiński et al., 2023). Statik manyetik alanlar, bitki hücrelerinin yapısını, biyokimyasal aktivitesini ve gen ekspresyonunu düzenleyebilir (Saletnik et al., 2022). SMF'lerin hücre şekli ve hücre zarı yapısı üzerinde güçlü bir etki göstererek, geçirgenliklerini artırdığı ve çeşitli metabolik yol aktivitelerini etkilediği belirtilmiştir (Saletnik et al., 2022).

İyon taşınımı ve membran potansiyeli, EMF'nin bitki hücreleri üzerindeki biyofiziksel etkileşimlerinin merkezinde yer almaktadır (Bajagić et al., 2023). Canlı organizmalar elektriksel olarak nötr olsalar da elektromanyetizma ve termodinamik yasalarına uyan yüklü iyonlar, polarize moleküller ve elektrik alanlar içerirler (Romanenko et al., 2017). Darbeli elektromanyetik alanların etki mekanizmasının, bitki hücrelerindeki membran elektro potansiyeli ve protein ve enzim aktiviteleri gibi çeşitli biyokimyasal süreçleri etkilediği belirtilmiştir (Bajagić et al., 2023). Bu, yüklü parçacıkların hücre zarı boyunca hareketini etkileyerek su ve besin maddelerinin daha hızlı emilimini sağlayabilir, bu da bitkilerin daha hızlı büyümesine ve iklim koşullarına karşı daha dirençli olmasına katkıda bulunabilir (Bajagić et al., 2023). Aşırı yüksek frekanslı elektromanyetik alanlara maruz kalma, yapay bir akson modelinde transmembran potasyum akışını artırarak elektriksel sinyal yayılımını kolaylaştırmaktadır (D'Agostino et al., 2018). Ayrıca, elektrik sinyallerinin yayılımının, iyon kanallarının ve plazma zarındaki H+-ATPaz aktivitesinin faaliyetleri ile ilişkili olabileceği de düşünülmektedir (Sukhova & Sukhov, 2021).

EMF'nin biyofiziksel rolü, esasen fiziksel alanların biyolojik moleküller ve yapılarla doğrudan etkileşimine dayanır (Romanenko et al., 2017). Elektrik ve manyetik alanlar, biyolojik sistemlerle etkileşime girebilen ortak bir elektromanyetik modalitenin ayrı bileşenleridir (Murugan et al., 2023). EMF'ler, biyolojik sistemlerdeki yüklü iyonlar, polarize moleküller ve elektrik alanlar üzerinde kuvvet uygulayarak hücresel süreçleri etkileyebilir (Romanenko et al., 2017). Bu etkileşimler sonucunda, gen ekspresyonu, fitohormon sentezi, fotosentez, solunum, floem kütle akışı ve ATP içeriği gibi çok sayıda fizyolojik süreç etkilenebilir (Sukhova & Sukhov, 2021). Bu değişikliklerin, bitkilerin stres faktörlerine karşı toleransını artırdığı ve belirli moleküler yapıların hasarlarının uyarılmasıyla ilişkili olabileceği düşünülmektedir (Sukhova & Sukhov, 2021).

3. MANYETİK ALANLARIN BİYOFİZİKSEL ETKİLERİ

3.1 Statik Manyetik Alan Tanımı

Statik manyetik alanlar, biyolojik sistemler üzerindeki etkileri nedeniyle uzun yıllardır bilimsel ilgi odağı olmuştur (Saletnik et al., 2022). Dünya'nın manyetik alanı (jeomanyetik alan, GMF) tüm canlı organizmalar için kaçınılmaz bir çevresel faktör olup, yeryüzünde 25 ila 65 μT arasında değişen bir yoğunluğa sahiptir ve bir statik manyetik alan olarak kabul edilir (Bellino et al., 2023). Araştırmacılar, bitki türleri üzerindeki GMF etkilerini taklit etmek veya güçlendirmek amacıyla farklı parametrelerde SMF'ler kullanmaktadır (Zhou et al., 2024). Magnetopriming çalışmalarında, zayıf statik homojen manyetik alanlar (0–100 μT dahil GMF) ve güçlü homojen manyetik alanlar (milliTesla ila Tesla) gibi çeşitli manyetik alan türleri incelenmiştir (Sarraf et al., 2020).

3.2 Paramanyetik İyonlar Üzerindeki Etkiler

Manyetik alanlar, bitki hücrelerindeki iyon kanallarının geçirgenliğini etkileyerek maddelerin hücre içine taşınımını değiştirebilmektedir (Kornarzyński et al., 2020). Ayrıca hormon ve enzim konsantrasyonlarında değişikliklere yol açabilirler (Kornarzyński et al., 2020). Manyetik alanın etkisi altında, su moleküllerinin ve çözünmüş iyonların dış elektron kabukları polarize olarak iyon hidrasyon koşullarında değişimlere neden olabilir (Kornarzyński et al., 2020). Jeomanyetik alanın azaltılması (sıfıra yakın manyetik alan, NNMF) bitki dokularındaki metallerin, özellikle demir ve çinko birikimini etkilemektedir (Islam et al., 2020). SMF, bitkilerin demir homeostazisini sürdürmelerine yardımcı olmakta ve demir metabolizmasıyla ilgili genlerin aşağı regüle olmasına rağmen bitki dokularındaki demir içeriğinin nispeten değişmeden kalmasını sağlayabilir (Zhou et al., 2024). Radikal çift mekanizması, manyetik alanın redoks reaksiyon hızları üzerindeki etkileri ve dolayısıyla serbest radikaller ile reaktif oksijen türleri konsantrasyonlarındaki değişimlerle açıklanmaktadır (Parmagnani et al., 2022).

3.3 Su Yapısının Değişimi ve İmbibisyon Üzerindeki Etkiler

Manyetik alanlar, suyun yapısal özelliklerini ve bitkilerdeki imbibisyon süreçlerini önemli ölçüde etkilemektedir (Dobránszki, 2023). Bir manyetik alanın etkisi altında, su moleküllerinin ve çözünmüş iyonların dış elektron kabuklarının polarize olması, iyon hidrasyon koşullarında değişikliklere ve kristalleşme çekirdeklerinin oluşumuna yol açabilmektedir (Kornarzyński et al., 2020). Bitki materyalindeki su ile manyetik alan etkileşimi, suyun elektriksel iletkenliğinde bir artışa ve yüzey geriliminde bir azalmaya neden olabilir (Kornarzyński et al., 2020). Bu durum, sudaki yüklü parçacıklar (iyonlar) üzerindeki Lorentz kuvvetinin, dış manyetik alana karşılık gelen geçici polarizasyona yol açmasından kaynaklanmaktadır (Kornarzyński et al., 2020). Manyetize su, moleküllerini kompleksler halinde daha kolay bağlayabilir ve stres altındaki dokularda daha iyi tutabilir (Ergashova et al., 2023). Zayıf bir manyetik alana maruz bırakılan su, dielektrik sabitini değiştirebilir, bu da fiziksel özelliklerini etkileyebilir (Abu-Saied et al., 2023). Manyetik işlem, suyun fiziksel, kimyasal, biyofiziksel ve fiziko-kimyasal özelliklerini değiştirebilir; bu değişiklikler arasında hidrojen bağı oluşumu, iletkenlik, aktivasyon enerjisi, yüzey gerilimi, su moleküllerinin boyutu ve yapısal düzenlilik bulunmaktadır (Alattar et al., 2022).

3.4 Fotosentetik ve Metabolik Etkiler

Manyetik alanlar, bitkilerin fotosentetik verimliliği ve metabolik süreçleri üzerinde belirgin etkiler yaratmaktadır (Schmidtpott et al., 2022). Manyetik alanlar, biyokütle fotosentez verimliliği ve canlılık birikim indeksleri üzerinde önemli bir etkiye sahiptir (Saletnik et al., 2022). SMF uygulaması, reaktif oksijen türlerinin oluşumunu ve birikimini hızlandırsa da aynı zamanda antioksidan enzimlerin yüksek aktivitesine yol açarak oksidatif stresi azaltmaktadır

(Saletnik et al., 2022). SMF'ler, hücre şekli ve hücre zarı yapısı üzerinde güçlü bir etki göstererek geçirgenliklerini artırır ve çeşitli metabolik yolları etkileyebilir (Saletnik et al., 2022). SMF'ye maruz kalma, bitkilerin ROS seviyelerini düşürmesine ve antioksidan enzim aktivitesini ve nikotinamid birikimini artırarak oksidan dengesini sinerjik olarak sürdürmesine yardımcı olmaktadır (Zhou et al., 2024). Manyetik alan uyarımı, protein ve minerallerin gruplanmasını artırabilir veya fotosentezi iyileştirebilir (Kornarzyński et al., 2018). Karşılaştırmalı transkriptomik analizler, oksin sentezi ve sinyal iletimi genlerinin SMF maruziyetiyle yukarı regüle olduğunu göstermiştir (Zhou et al., 2024). Jeomanyetik alanın azaltılması, ROS temizleyici enzimlerin ve H_2O_2 üretiminin metabolomik ve transkriptomik modülasyonuna yol açar (Parmagnani et al., 2022). Yüksek jeomanyetik değişkenlik altında Elodea bitkilerinde günlük oksijen üretiminde azalma gözlemlenmesi, jeomanyetik bozulmanın fotosentez gibi metabolik süreçleri etkileyebileceğini düşündürmektedir (Thoradit et al., 2023). Transkriptom analizi, EMF maruziyeti sonrası transkript miktarlarında değişiklikler ve fotosentetik ile merkezi enerji metabolizmasındaki varyasyonlarla birlikte metabolit havuz boyutlarında yeniden düzenlemeler olduğunu ortaya koymuştur (Schmidtpott et al., 2022).

3.5.ÇİMLENME PARAMETRELERİNE ETKİLER

Elektromanyetik alanlar ve manyetik alanlar, bitki tohumlarının çimlenme süreçleri üzerinde çeşitli etkilere sahiptir. Bu etkiler, çimlenme indeksleri, enzimatik aktivite, tohum kabuğu geçirgenliği, fide gelişimi ve kök mimarisi gibi parametreler üzerinden incelenmektedir.

Çimlenme İndeksleri

Manyetik alan uyarımlarının tohum çimlenme hızı üzerinde belirgin etkileri gözlemlenmektedir (Dziwulska-Hunek et al., 2023). Tohumların manyetik alanlara maruz bırakılması, çimlenme yüzdesi, çimlenme hızı indeksi ve çimlenme hızı katsayısı gibi çimlenme parametrelerinde önemli artışlar sağlayabilmektedir (El-Sayed, 2023). Örneğin, soya fasulyesi tohumlarında statik manyetik alanın, daha hızlı çimlenme ve artan çimlenme oranı sağladığı bildirilmiştir (Bezerra et al., 2023). Bir çalışmada, belirli manyetik alan yoğunluklarının (0.1 mT) optimum çimlenme süresi, gövde büyümesi ve klorofil içeriği gibi parametrelerde en iyi sonuçları verdiği belirtilmiştir (Tirono, 2022). Manyetik olarak işlenmiş suyun kullanımı, çimlenme ve fide parametreleri, büyüme ve verim üzerinde faydalar sağlayabilmektedir (Selim et al., 2022).

3.6 EMF'nin Enzimatik Aktiviteye Etkisi

Manyetik alanların, tohumlarda meydana gelen biyokimyasal süreçlerdeki protein ve enzim aktivitelerini uyararak çimlenmeyi etkilediği literatürde yer almaktadır (Dziwulska-Hunek et al., 2023). Bitkilerde kriptokrom adı verilen mavi ışık reseptörleri, uyarıldığında radikal çiftleri oluşturarak proteinlerin radikal tabanlı manyetik sensörler olarak işlev görmesini sağlamaktadır (Dziwulska-Hunek et al., 2023). Bu mekanizma, manyetik alanların enzimatik süreçler üzerindeki etkisinin temelini oluşturabilir. Elektromanyetik alanlara maruz kalan ürün tohumlarında, fotosentez ve enzimatik kimyasal reaksiyonlarda önemli bir artış kaydedilmiş, bu da bitki büyümesini hızlandırmıştır (El-Sayed, 2023). Ayrıca, manyetik alan, iyon kanallarının geçirgenliğini etkileyerek hücrelere madde taşınımını değiştirebilir, hormon ve enzim konsantrasyonlarında değişikliklere yol açabilir (Kornarzyński et al., 2020).

3.7 Manyetik Alanın Kabuk Geçirgenliğini Artırması

Manyetik alanın etkisi altında, su moleküllerinin ve çözünmüş iyonların dış elektron kabukları polarize olabilir, bu da iyon hidrasyon koşullarında değişikliklere neden olabilir (Kornarzyński et al., 2020). Tohumların manyetik alanlara maruz bırakılmasıyla tohum kabuğunun geçirgenliğinin iyileştiği gözlemlenmiştir (Tomeková et al., 2023). Bu durum, suyun elektriksel iletkenliğinde bir artışa ve yüzey geriliminde bir azalmaya yol açarak tohumların su alımını

(imbibisyon) kolaylaştırabilir (Kornarzyński et al., 2020). Tohum kabuğunun sertliği ve suya geçirimsizliği gibi nedenlerle zayıf veya engelli çimlenme yaşayan tohumlarda, manyetik alan uygulamaları çimlenmeyi teşvik edebilir (Dziwulska-Hunek et al., 2023).

3.8 Fide Gelişimi ve Kök Mimarisi Üzerindeki Etkiler

Manyetik alanların fide gelişimi ve kök mimarisi üzerinde belirgin etkileri bulunmaktadır (Bernard, 2024). Statik manyetik alanların kök büyümesini teşvik ettiği ve Arabidopsis bitkilerinde kökün manyetik alan etkilerini doğrulamak için ideal bir sistem olabileceği belirtilmiştir (Zhou et al., 2024). Manyetize su kullanımı hem sert buğday hem de mercimek genotiplerinde kök uzamasını artırmıştır (Sestili et al., 2023). Manyetik alanların kök ucundaki iyon kanallarının geçirgenliğini etkileyerek, besin ve su alımını optimize edebileceği düşünülmektedir (Islam et al., 2020). GMF'nin kök ve sürgünlerdeki genleri düzenlediği, ancak genlerin %49'unun bu organlarda ters yönde düzenlendiği, yani yerleşik sinyal ağlarının spesifik genlerin yukarı veya aşağı regülasyonunu belirlediği belirtilmiştir (Paponov et al., 2021). Bu da manyetik alanların bitki gelişimindeki karmaşık rolünü vurgulamaktadır.

4. FİZYOLOJİK VE BİYOKİMYASAL STRES YANITLARI

4.1 Oksidatif Stres Göstergeleri (MDA, PRO, H_2O_2, ROS)

Elektromanyetik alanlara ve manyetik alanlara maruz kalmak, bitkilerde reaktif oksijen türleri metabolizması ve sitozolik kalsiyumda artışa yol açarak hücresel tepkileri tetikleyebilir (Kaur et al., 2021). Bu durum, gen ekspresyonu ve/veya enzimatik aktivitelerde değişikliklere yol açarak hücrelerde hemen veya gecikmeli olarak bitki büyüme değişiklikleri meydana getirebilir (Kaur et al., 2021). Düşük frekanslı elektromanyetik alanların, hücreler arası serbest radikal homeostazını değiştirdiği ve stres tepkileriyle ilgili genlerin ekspresyonunu etkilediği öne sürülmektedir (Kostyń et al., 2023). Özellikle radyo frekanslı maruziyet, ROS oluşumunu etkileyen iki önemli homeostatik sistem olan kalsiyum hareketini ve ROS oluşumunu etkilemektedir (Tran et al., 2023). Örneğin, 900 MHz radyasyona maruz kalan domates bitkilerinde calmodulin (calm-n6) ve kalsiyum bağımlı protein kinaz (lecdpk1) seviyelerinde artış gözlemlenmiştir (Tran et al., 2023). Ayrıca, 900 MHz radyasyona maruz kaldıktan sonra, mung fasulyesinde H_2O_2 birikiminde artış ve ROS temizleme enzim aktivitelerinde önemli bir yukarı regülasyon tespit edilmiştir (Tran et al., 2023).

Jeomanyetik alanın azaltılması (near-null magnetic field, NNMF), Arabidopsis thaliana'da ROS temizleyici enzimlerin metabolomik ve transkriptomik modülasyonuna ve H_2O_2 üretimine yol açmaktadır (Parmagnani et al., 2022). Statik manyetik alan uygulaması, reaktif oksijen türlerinin oluşumunu ve birikimini hızlandırsa da aynı zamanda antioksidan enzimlerin yüksek aktivitesine yol açarak oksidatif stresi azaltmaktadır (Saletnik et al., 2022). SMF'ye maruz kalma, bitkilerin ROS seviyesini düşürmesine ve antioksidan enzim aktivitesini ve nikotinamid birikimini artırarak oksidan dengesini sinerjik olarak sürdürmesine yardımcı olmaktadır (Zhou et al., 2024). Şuman rezonans aralığındaki manyetik alanların buğday ve bezelye bitkilerinin redoks metabolizması üzerindeki etkileri incelendiğinde, katalaz ve süperoksit dismutaz aktiviteleri ile malondialdehit içeriği gibi parametrelerde değişiklikler gözlemlenmiştir (Mshenskaya et al., 2022). MDA, lipid peroksidasyonunun bir ürünü olup, oksidatif stresin önemli bir göstergesidir. Başka bir çalışmada, statik manyetik alana maruz kalan marul fidelerinde hidrojen peroksit, süperoksit radikali ve lipid peroksidasyonu gibi oksidatif hasar kriterlerinin kontrol gruplarına göre düşük seviyelerde tutulduğu belirtilmiştir (Latef et al., 2020).

4.2 Antioksidan Enzim Aktiviteleri

Manyetik alanların bitkilerdeki antioksidan enzim aktiviteleri üzerinde düzenleyici etkileri bulunmaktadır (Saletnik et al., 2022). Statik manyetik alanlar reaktif oksijen türlerinin oluşumunu ve birikimini artırırken, aynı zamanda antioksidan enzimlerin yüksek aktivitesine neden olarak oksidatif stresi azaltmaktadır (Saletnik et al., 2022). Bu durum, bitkilerin oksidatif hasara karşı savunma mekanizmalarını güçlendirmektedir (Saletnik et al., 2022). Örneğin, Arabidopsis bitkilerinde SMF maruziyetinin köklerde H_2O_2 içeriğini önemli ölçüde azalttığı ve süperoksit dismutaz, katalaz ve peroksidaz gibi çeşitli antioksidan enzimlerin aktivitelerini artırdığı gözlemlenmiştir (Zhou et al., 2024). Bu artışların doku-spesifik olduğu ve bitkinin oksidatif strese karşı yanıtında önemli rol oynadığı belirlenmiştir (Zhou et al., 2024).

Şuman rezonans aralığındaki elektromanyetik alanlara maruz kalan buğday ve bezelye bitkilerinde katalaz ve süperoksit dismutaz aktiviteleri incelenmiş ve bu enzimlerin bitki redoks metabolizmasında önemli bir rol oynadığı gösterilmiştir (Mshenskaya et al., 2022). Düşük frekanslı manyetik alanlara dört saat boyunca 3 mT ve 10 mT şiddetinde maruz bırakılan bitkilerde katalaz ve askorbik peroksidaz aktivitesinin kök ve sürgün dokularında önemli ölçüde arttığı rapor edilmiştir (Tirono, 2022). Jeomanyetik alanın azaltılması da Arabidopsis thaliana'da ROS temizleyici enzimlerin metabolomik ve transkriptomik modülasyonuna yol açmaktadır (Parmagnani et al., 2022).

4.3 Fotosentetik Pigmentlerde Meydana Gelen Değişimler

Elektromanyetik alanlar ve manyetik alanlar, bitkilerin fotosentetik pigment içeriklerini ve dolayısıyla fotosentetik verimliliğini etkileyebilir (Schmidtpott et al., 2022). RF-EMF'ye maruz kalan marul bitkilerinde, fotosentetik verimlilikte önemli ve sistemik bir azalma gözlemlenmiştir (Tran et al., 2023). Alternatif elektromanyetik alanlara maruz kalan Arabidopsis thaliana'da yapılan bir çalışmada, fotosentetik parametrelerde belirgin farklılıklar kaydedilmiştir; bu durum ya düşük fotokimyasal sönümleme ya da plastokinon havuzunun daha yüksek indirgenmesi veya her ikisiyle ilişkilendirilmiştir (Schmidtpott et al., 2022). Transkriptom analizleri, EMF maruziyeti sonrasında transkript miktarlarında değişiklikler ve fotosentetik ile merkezi enerji metabolizmasındaki varyasyonlarla birlikte metabolit havuz boyutlarında yeniden düzenlemeler olduğunu göstermiştir (Schmidtpott et al., 2022).

Elektrik alan stimülasyonunun soya bitkilerinde klorofil içeriğini önemli ölçüde artırdığı, benzer bir etkinin fasulye bitkilerinde de gözlemlendiği belirtilmiştir (Dziwulska-Hunek et al., 2023). Ancak, yonca yapraklarında yapılan bazı çalışmalarda, elektromanyetik stimülasyonun klorofil a ve b konsantrasyonlarında azalmaya neden olduğu da rapor edilmiştir (Dziwulska-Hunek et al., 2022). Bu durum, pigment değişimlerinin tür ve uygulama koşullarına bağlı olarak farklılık gösterebileceğini düşündürmektedir. Statik manyetik alanlara maruz kalan marul fidelerinde tüm fotosentetik pigmentlerin, özellikle klorofil a'nın belirgin şekilde arttığı belirtilmiştir (Latef et al., 2020).

4.4 EMF ve Manyetik Alanların Stres Azaltıcı Rolleri

EMF ve manyetik alanların bitkilerdeki stres azaltıcı rolleri, antioksidan savunma sistemlerinin uyarılması ve hücresel adaptasyon mekanizmalarının etkinleştirilmesiyle ilişkilidir (Ayesha et al., 2023). SMF'lerin bitki fonksiyonlarını, büyümesini düzenlediği ve çevresel streslere karşı toleransı artırdığı belirtilmiştir (Radhakrishnan, 2019). SMF uygulaması, ROS oluşumunu hızlandırsa da antioksidan enzimlerin aktivitesini artırarak oksidatif stresi azaltmaktadır (Saletnik et al., 2022). Bu durum, bitkilerin stres altında hücre hasarını sınırlamasına yardımcı olur (Saletnik et al., 2022).

Manyetik alanların, bitki beslenmesini, su kullanım verimliliğini ve antioksidatif savunmayı iyileştirerek mahsul verimliliğini artırabileceğine dair bulgular mevcuttur (Ayesha et al., 2023). SMF'ye maruz kalma, bitkilerin ROS seviyesini düşürmesine ve antioksidan enzim aktivitesini ve nikotinamid birikimini artırarak oksidan dengesini sinerjik olarak sürdürmesine yardımcı olmaktadır (Zhou et al., 2024). Bu veriler, SMF'nin Arabidopsis thaliana'nın büyüme ve gelişimini, demir homeostazisini sürdürerek ve oksidatif stresi dengeleyerek düzenlediğini, bunun da bitki sağkalımı ve büyümesi için faydalı olabileceğini düşündürmektedir (Zhou et al., 2024). EMF'lerin fizyolojik süreçler üzerindeki etkileşimlerini anlamak, bitki verimliliğini artırmak ve çevresel streslere karşı direncini güçlendirmek için yeni stratejiler geliştirmeye olanak tanır (Schmidtpott et al., 2022). Manyetik alan uygulamaları, bitki büyümesini sürdürülebilir bir şekilde artırmak için modern tarımda giderek daha fazla kullanılmaktadır (Bellino et al., 2023).

5. STRES TOLERANS MEKANİZMALARI

Bitkiler, çevresel stres faktörlerine karşı çeşitli mekanizmalar geliştirmiştir ve elektromanyetik alanlar ile manyetik alanlar bu mekanizmaları etkileyerek stres toleransını değiştirebilmektedir.

5.1 Ca^{2+}, MAPK, CDPK Temelli Sinyal Yolları

Bitkilerde kalsiyum iyonları, çeşitli çevresel uyarılara verilen ilk yanıtlardan biri olan hızlı değişikliklerle stres sinyalizasyonunda önemli bir ikincil haberci görevi görür (Patra et al., 2021). Ca^{+2} sinyalleri, kalsiyum bağımlı protein kinazlar ve mitojenle aktive olan protein kinazlar gibi farklı protein kinazlar tarafından çözümlenir (Wurzinger et al., 2011). CDPK'ler, bitkilerdeki temel Ca^{+2} sensör gruplarını temsil eder ve çeşitli abiyotik ve biyotik streslere karşı adaptif yanıtları tetiklemek için özel Ca^{+2} imzalarını fosforilasyon olaylarına dönüştürür (Deepika et al., 2020). MAPK ve CDPK yolları, bitki hücrelerinde strese karşı hücresel metabolizmayı uyarlamak için birlikte çalışan iki ana yoldur (Wurzinger et al., 2011). Radyo frekanslı EMF maruziyeti, sitozolik kalsiyum hareketini ve reaktif oksijen türleri oluşumunu etkileyerek hücresel yanıtları tetikleyebilir (Tran et al., 2023). Örneğin, 900 MHz radyasyona maruz kalan domates bitkilerinde calmodulin ve kalsiyum bağımlı protein kinaz seviyelerinde artış gözlemlenmiştir (Tran et al., 2023). Bu durum, EMF maruziyetinin Ca^{+2} sinyal yollarını etkilediğini ve bitkilerin stres tepkilerini modüle edebileceğini göstermektedir (Kaur et al., 2021). CDPK genlerinin ekspresyon seviyeleri ve kinaz aktiviteleri, çeşitli abiyotik stresler, patojen saldırısı ve gelişimsel ipuçlarından etkilenir (Kiselev & Dubrovina, 2025).

5.2 Stomatal Düzenleme

Stomalar, bitkilerin CO_2 alımını fotosentez için dengelemek ve yapraklardan su kaybını düzenlemek için çevresel uyaranlara karşı açılıp kapanarak önemli bir rol oynar (Zhang et al., 2024). Bu stomatal hareketler, kuraklık gibi abiyotik stres faktörlerinin etkilerini hafifletmede kritik bir öneme sahiptir (Matkowski & Daszkowska-Golec, 2023). Aşırı düşük frekanslı manyetik alanların, bitkilerin olumsuz faktörlere, özellikle de kuraklığa karşı direncini modüle edebileceği düşünülmektedir (Mshenskaya et al., 2023). Buğday bitkilerinde 14.3 Hz. frekanslı bir manyetik alanın transpirasyon ve fotosentez üzerindeki etkisi incelenmiş ve kuraklık yoğunlaşması sırasında fotosentez süreçlerinin aktivitesi, mahsul su stresi indeksi ve yaprak alanı gibi parametrelerde değişiklikler belirlenmiştir (Mshenskaya et al., 2023). Bu, manyetik alanların stomatal düzenlemeyi dolaylı yollarla etkileyerek bitkilerin su dengesini ve stres toleransını optimize etmeye yardımcı olabileceğini düşündürmektedir.

5.3 Pigment Stabilizasyonu

Fotosentetik pigmentler, bitkilerin ışık enerjisini toplama ve dönüştürme yeteneği için esastır ve stres koşulları altında bunların stabilitesi, bitkinin hayatta kalması için kritik öneme sahiptir.

Elektromanyetik stimülasyonun fotosentetik pigment sentezinde bozulmaya neden olabileceği belirtilmektedir (Dziwulska-Hunek et al., 2023). Bununla birlikte, elektrik alan stimülasyonunun soya fasulyesinde klorofil içeriğini önemli ölçüde artırdığı gözlemlenmiştir (Dziwulska-Hunek et al., 2023). Benzer şekilde, statik manyetik alanlara maruz kalan marul fidelerinde tüm fotosentetik pigmentlerin, özellikle klorofil a'nın belirgin şekilde arttığı bildirilmiştir (Latef et al., 2020). Ancak, yonca yapraklarında yapılan bazı çalışmalarda, elektromanyetik stimülasyonun klorofil a ve b konsantrasyonlarında azalmaya yol açtığı da rapor edilmiştir (Dziwulska-Hunek et al., 2022). Alternatif elektromanyetik alanlara maruz kalan *Arabidopsis thaliana*'da fotosentetik parametrelerde belirgin farklılıklar kaydedilmiştir; bu durum, ya düşük fotokimyasal sönümleme ya da plastokinon havuzunun daha yüksek indirgenmesi veya her ikisiyle ilişkilendirilmiştir (Schmidtpott et al., 2022). Bu sonuçlar, pigment stabilizasyonunun bitki türüne, EMF/MF'nin özelliklerine ve uygulama koşullarına bağlı olarak değişebileceğini göstermektedir.

5.4 Metabolik Adaptasyon Süreçleri

EMF ve manyetik alanlar, bitkilerin metabolik süreçlerini etkileyerek stres koşullarına adaptasyon yeteneklerini geliştirebilir. Statik manyetik alan uygulaması, reaktif oksijen türlerinin oluşumunu hızlandırsa da, antioksidan enzimlerin yüksek aktivitesine yol açarak oksidatif stresi azaltmaktadır (Saletnik et al., 2022). SMF'ye maruz kalma, bitkilerin ROS seviyesini düşürmesine ve antioksidan enzim aktivitesini ile nikotinamid birikimini artırarak oksidan dengesini sinerjik olarak sürdürmesine yardımcı olmaktadır (Zhou et al., 2024). Jeomanyetik alanın azaltılması, *Arabidopsis thaliana*'da ROS temizleyici enzimlerin metabolomik ve transkriptomik modülasyonuna ve H_2O_2 üretimine yol açmaktadır (Parmagnani et al., 2022). Transkriptom analizleri, EMF maruziyeti sonrasında transkript miktarlarında değişiklikler ve fotosentetik ile merkezi enerji metabolizmasındaki varyasyonlarla birlikte metabolit havuz boyutlarında yeniden düzenlemeler olduğunu göstermiştir (Schmidtpott et al., 2022). Bu adaptif değişiklikler, bitkilerin çevresel stres faktörlerine karşı direncini artırmak için metabolik yollarını yeniden programlamasını sağlamaktadır.

6. SONUÇLAR

Bu çalışma, elektromanyetik alanların ve manyetik alanların bitkisel biyosistemler üzerindeki karmaşık ve çok yönlü etkilerini inceleyerek, bu fiziksel faktörlerin bitki gelişimi ve stres toleransı üzerindeki düzenleyici rollerini ortaya koymaktadır.

Manyetik alanların tohum çimlenme süreçleri üzerinde belirgin düzenleyici etkileri olduğu gözlemlenmiştir. Özellikle manyetik alan uyarımı, tohum çimlenme hızı ve yüzdesi gibi çimlenme indekslerinde önemli artışlara yol açabilmektedir (El-Sayed, 2023). Bu etkiler, manyetik alanların tohumlardaki biyokimyasal süreçleri ve protein/enzim aktivitelerini uyarmasıyla ilişkilendirilmektedir (Dziwulska-Hunek et al., 2023). Ayrıca, manyetik alanlar tohum kabuğunun geçirgenliğini artırarak su alımını kolaylaştırabilir (Tomeková et al., 2023), bu da çimlenmeyi teşvik eden önemli bir mekanizmadır (Kornarzyński et al., 2020). Fide gelişimi ve kök mimarisi üzerindeki olumlu etkiler, statik manyetik alanların kök büyümesini teşvik etmesi ve iyon kanallarının geçirgenliğini optimize etmesiyle açıklanmaktadır (Islam et al., 2020; Zhou et al., 2024).

EMF ve manyetik alanlar, bitkilerin abiyotik stres faktörlerine karşı geliştirdiği fizyolojik ve biyokimyasal yanıtları modüle ederek stres tolerans mekanizmalarına önemli katkılar sağlamaktadır. Bu alanlara maruz kalma, bitkilerde reaktif oksijen türleri metabolizmasını ve sitozolik Ca^{+2} seviyelerini etkileyerek hücresel tepkileri tetikleyebilir (Kaur et al., 2021). Statik

manyetik alanlar, ROS birikimini hızlandırsa da, antioksidan enzimlerin (katalaz, süperoksit dismutaz, peroksidaz gibi) aktivitesini artırarak oksidatif stresi azaltmaktadır (Saletnik et al., 2022; Zhou et al., 2024). Bu durum, bitkilerin hücresel hasarı sınırlamasına ve strese karşı direncini güçlendirmesine yardımcı olmaktadır (Saletnik et al., 2022). Fotosentetik pigmentlerde (klorofil a, b) meydana gelen değişimler, EMF maruziyetinin fotosentetik verimliliği etkileyebileceğini göstermekle birlikte (Schmidtpott et al., 2022), statik manyetik alanların klorofil içeriğini artırarak fotosentetik kapasiteyi iyileştirebileceği de belirtilmiştir (Latef et al., 2020). Ca^{+2}, MAPK ve CDPK temelli sinyal yollarının aktivasyonu, bitkilerin stres sinyallerini algılaması ve bunlara yanıt vermesinde kilit rol oynamakta olup, EMF'lerin bu yolları etkileyerek stres adaptasyonunu modüle edebileceği düşünülmektedir (Tran et al., 2023; Wurzinger et al., 2011).

EMF ve manyetik alanların bitki fizyolojisi üzerindeki bu düzenleyici etkileri, biyosistem tabanlı üretimde önemli potansiyel uygulamalar sunmaktadır. Manyetik olarak işlenmiş suyun kullanımı, çimlenme ve fide parametrelerini, büyüme ve verimi iyileştirerek tarımsal verimliliği artırabilmektedir (Selim et al., 2022). Manyetik alanların tohum çimlenmesi, bitki beslenmesi, su kullanım verimliliği ve antioksidatif savunmayı iyileştirerek mahsul verimliliğini artırabileceği bulguları (Ayesha et al., 2023), bu teknolojilerin sürdürülebilir tarım uygulamalarında değerlendirilebileceğini göstermektedir (Bellino et al., 2023). Özellikle, çevresel stres faktörlerine karşı bitki toleransını artıran bu mekanizmalar, iklim değişikliği ve azalan tarım alanları gibi küresel zorluklara karşı mücadelede yeni stratejiler sunabilir.

Gelecek Araştırmalar İçin Öneriler

EMF ve manyetik alanların bitkiler üzerindeki etkileri konusunda daha derinlemesine bilgi edinmek için gelecekteki araştırmalar aşağıdaki alanlara odaklanabilir:

- **Moleküler Mekanizmaların Detaylı İncelenmesi**: Alanların iyon kanalları, membran potansiyelleri, gen ekspresyonu ve protein sentezi üzerindeki spesifik moleküler mekanizmalarının ileri düzeyde araştırılması gerekmektedir (Kornarzyński et al., 2020).
- **Doz-Tepki İlişkilerinin Optimizasyonu**: Farklı bitki türleri için optimum frekans, şiddet ve maruz kalma süresi gibi parametrelerin belirlenmesi, tarımsal uygulamalarda etkinliği artıracaktır (Jo et al., 2024).
- **Uzun Vadeli Etkilerin Değerlendirilmesi**: EMF/MF maruziyetinin bitkilerin tüm yaşam döngüsü boyunca ve sonraki nesiller üzerindeki uzun vadeli etkilerinin incelenmesi önemlidir.
- **Çoklu Stres Faktörleri ile Etkileşimler**: Tek başına EMF/MF etkileri yerine, kuraklık, tuzluluk, ağır metal stresi gibi diğer abiyotik stres faktörleri ile birleştiğinde ortaya çıkan sinerjik veya antagonistik etkilerin araştırılması gerekmektedir (Radhakrishnan, 2019).
- **Gelişmiş Alan Uygulama Teknolojileri**: Tarımsal uygulamalar için daha verimli, ölçeklenebilir ve enerji açısından optimize edilmiş elektromanyetik alan uygulama sistemlerinin geliştirilmesi ve test edilmesi.

Bu öneriler, elektromanyetik alanların bitkisel biyosistemler üzerindeki potansiyelini tam olarak anlamak ve sürdürülebilir tarımda yenilikçi çözümler geliştirmek için bir yol haritası sunmaktadır.

ÖZET

Tohumların fiziko-mekanik özellikleri ekimden hasat dönemine, ürün işlemeden depolamaya kadar uzanan üretim periyodunun sağlıklı bir şekilde yürütülmesi için bilinmesi gereken en temel konulardan biridir. Tohumların fiziksel ve mekanik özelliklerini dikkate alarak ekim makinalarında kullanılan farklı ekici düzenler tasarlanmaktadır. Ayrıca özellikle biçerdöverlerin sarsak ve batör-kontrbatör aralıklarının dizayn edilmesinde tohumların fiziksel ve mekanik özelliklerden yararlanılmaktadır. Buna ilaveten hasat işleminden sonra sınıflandırma amacıyla kullanılan elek tasarımlarında da tohumların hem boyut hem de geometrik yapıları dikkate alınmaktadır. Bu sayede hasat sonrası kalite sınıflandırılması da hassas ve doğru bir şekilde yapılabilmektedir. Ürün depolama aşamasında da tohumların bu özelliklerinden yararlanılmaktadır. Depolama işleminde, tohumları hacim ağırlıkları ve nem düzeyleri bu parametreler arasında ön sırada yer almaktadır. Buna ilaveten kırılma, ezilme gibi mekanik özellikler de farklı makina tasarımlarında dikkate alınan temel bileşenler arasındadır. Son yıllarda tohumların bu özelliklerini dikkate alınarak yapılan çalışmalarda özellikle görüntü işleme tabanlı algoritmalar ve farklı yapay zekâ tahmin yöntemlerinden yararlanılmaktadır. Bu sayede zor ve zaman alıcı birçok işlem saniyeler içinde tamamlanmakta ve bu esnada insan faktörlü yanlışlarında önüne geçilmektedir. Bu amaç doğrultusunda yapılan araştırmaların çoğunda tohumların boyut özellikleri ve nem içeriklerinden yola çıkılarak kırılma direnci gibi mekanik özellikleri yüksek doğrulukla modellenebilmektedir. Ayrıca tohumlarının fiziksel ve mekanik özelliklerine dayalı olarak geliştirilen karar destek sistemleri; hassas ekim, enerji verimliliği yüksek kurutma teknolojileri, kontrollü depolama ve ileri kalite sınıflandırma uygulamaları içinde kullanılmaktadır. Bu modeller ıslah çalışmalarında etkin bir şekilde kullanılmaktadır. Bu bütüncül yaklaşım, sürdürülebilir tarımsal üretimin ve endüstriyel gıda güvenliğinin gelecekteki anahtar bileşenlerinden biri olacaktır. Bu çalışmada tohumların boyut, şekil, yoğunluk, sertlik ve kırılma dirençleri gibi fiziksel ve mekanik özelliklerin tarımsal üretim sürecindeki etkileri incelenmiştir. Ayrıca hasat sonrası yapılacak iş ve işlemlerde bu özelliklerden nasıl yararlanıldığı detaylıca analiz edilmiştir.

Anahtar Kelimeler: Tohum, fiziksel özellikler, mekanik dayanım, hasat sonrası işleme, kalite

THE EFFECT OF PHYSICAL-MECHANICAL AGRICULTURAL PRODUCTION, PROCESSING TECHNOLOGIES, AND QUALITY STANDARDS ON SEEDS

ABSTRACT

The physical and mechanical properties of seeds are essential factors to understand for smooth operation throughout the entire production process, from planting to harvest, processing, and storage. Different seeding arrangements used in planting equipment are designed considering these properties. Additionally, the physical and mechanical characteristics of seeds are taken into account when designing the spacing of concaves and counter-concaves in combine harvesters. Moreover, seed size and geometric structure are important for designing sieves used in classification after harvesting to ensure accurate and reliable quality assessment. These seed traits also influence storage, where parameters like volume weight and moisture content are critical. Mechanical properties, such as resistance to breakage and crushing, are fundamental in designing various machinery. In recent years, research on these seed characteristics has often utilized image processing algorithms and artificial intelligence prediction methods, enabling many complex and time-consuming tasks to be completed in seconds and reducing human error. Most studies indicate that properties like resistance to breakage can be accurately modeled based on seed size and moisture levels. Furthermore, decision support systems based on these properties are used in precision planting, energy-efficient drying, controlled storage, and advanced quality grading. These models are also valuable in breeding programs. This comprehensive approach will be vital for sustainable agriculture and food safety in the future. This study examines how seed physical and mechanical properties—such as size, shape, density, hardness, and fracture resistance—affect the agricultural production process. It also provides a detailed analysis of how these properties are applied during post-harvest operations and procedures.

Keywords: Seed, physical properties, mechanical strength, post-harvest processing, quality

1. GİRİŞ

Tohumlar, küresel gıda güvenliği ve sürdürülebilir tarımsal sistemlerin temelini oluşturan önemli bir tarımsal girdi olarak kabul edilmektedir (Sundareswaran et al., 2023). Dünya nüfusunun artışıyla birlikte gıda ihtiyacının karşılanması noktasında, yüksek kaliteli tohum kullanımı tarımsal üretimin artırılmasında vazgeçilmez bir unsurdur. Nitekim, bitkisel üretimin temelini oluşturan tohum kalitesi, herhangi bir başarılı tarım programının köşe taşını teşkil etmektedir. Tohum sektörü, çiftçilere kaliteli tohumlar sağlayarak gıda güvenliği açısından önemli bir role sahiptir. Kaliteli tohum kullanımı, standart uygulamalarla birleştiğinde, ürün verimini %15-20 oranında artırma potansiyeline sahiptir (Kumar et al., 2023). Bu bağlamda, tohumların genetik, fiziksel ve sağlık standartlarını karşılaması, arzu edilen ürün kalitesini ve verimliliğini belirleyen önemli faktörlerdendir (Tiwari & Park, 2024).

Tohumların fiziksel ve mekanik özellikleri; çimlenme, fide çıkışı ve genel fide canlılığı üzerinde doğrudan etkilere sahiptir (Blalogoe et al., 2020). Tohum boyutu, şekli ve iç yapısı; çimlenme performansını, canlılığı ve fide gelişimini önemli ölçüde etkiler. Örneğin, daha büyük tohumlar genellikle daha iyi tarla performansı ve fizyolojik kalite sergilemektedir. Tohum kabuğunun rengi, kalınlığı ve anatomik yapısındaki farklılıklar gibi fiziksel özellikler, su alımını ve tohum kabuğunun geçirgenliğini düzenleyerek çimlenme ve büyüme üzerinde belirleyici bir rol oynar (Upretee et al., 2024).

Mekanik özellikler ise tarım makinelerinin tasarımı ve işletilmesi açısından büyük önem taşımaktadır. Tohumların işlenmesi, ekim hassasiyeti ve hasat sonrası süreçlerde maruz kaldıkları mekanik stresler, tohum kalitesini ve ekim performansını doğrudan etkiler (Xue et al., 2019). Hasat ve işleme sırasındaki mekanik hasarlar, tohum canlılığını ve kalitesini olumsuz yönde etkileyebilir. Bu nedenle, tohumların fiziksel ve mekanik özelliklerinin anlaşılması, ekim teknolojilerinin geliştirilmesi ve tarımsal verimliliğin artırılması için önemlidir.

Tohum kalitesi ile tarımsal verimlilik arasında güçlü ve doğrudan bir ilişki bulunmaktadır. Tohum canlılığı, tarla koşullarında bitki gelişimi ve ürün verimliliği ile ilişkilendirilen temel bir fizyolojik özelliktir. Yüksek tohum canlılığı, tohumların çeşitli çevresel koşullar altında hızlı, homojen ve güçlü bir şekilde çimlenmesini ve fide oluşturmasını sağlayarak, ürün verimini ve kaynak kullanım verimliliğini doğrudan etkiler. Yüksek tohum canlılığı, zorlu çevre koşullarında hayatta kalmayı mümkün kılarak ekilebilir arazilerin verimliliğini artırır (Qiao et al., 2023).

Genel anlamda tohum kalitesi kavramı canlılık ve sağlık parametrelerini içermekte olup, yüksek verim elde etmenin ön koşuludur (Misra et al., 2023). Düşük tohum kalitesi, çimlenme oranını ve fide çıkışını azaltarak zayıf bitki gelişimi ve nihayetinde verim kaybına yol açabilir. Kaliteli tohum kullanımı; daha hızlı büyüme oranları, daha yüksek ekonomik getiriler ve daha değerli ürünler elde etmenin ilk adımıdır. Hasat ve kurutma tekniklerinin optimizasyonu da dahil olmak üzere tohum kalitesinin geliştirilmesi, tarımsal üretkenliği artırma potansiyeline sahiptir (Pedrosa et al., 2024).

Bu çalışma, tohumların tarımsal üretimdeki vazgeçilmez rolünü, fiziksel ve mekanik özelliklerinin bitki gelişimi ve ekim teknolojileri üzerindeki önemli etkilerini, ayrıca tohum kalitesi ile tarımsal verimlilik arasındaki doğrudan ilişkiyi mevcut literatür ışığında değerlendirmeyi amaçlamaktadır. Elde edilen bulgular, tohum bilimi ve teknolojisindeki güncel gelişmeleri gözden geçirerek, gelecekteki araştırma ve uygulamalar için bir çerçeve sunmaktadır.

2. TOHUMLARDA FİZİKSEL ÖZELLİKLER

Tohumların fiziksel özellikleri, bitki gelişimi, ürün verimi ve tarımsal işlemlerin verimliliği üzerinde önemli etkilere sahiptir. Bu özellikler, tohum kalitesinin değerlendirilmesinde ve tarımsal uygulamaların optimize edilmesinde kullanılabilecek parametreler sunar.

2.1 Boyut, Şekil ve Geometrik İndeksler

Tohum boyutu ve şekli, bitki gelişiminin ve ürün veriminin önemli belirleyicileri arasında yer almaktadır. Tohumun olgunluktaki boyutu, vejetatif büyüme üzerinde etkili olan önemli bir fiziksel kalite göstergesidir ve sıklıkla verimle ilişkilendirilir (Blalogoe et al., 2020). Büyük tohumlar, genellikle daha fazla karbonhidrat depoladıkları için fidelerin daha iyi bir başlangıç yapmasını ve tarlada daha iyi performans göstermesini sağlar. Örneğin, bazı çalışmalarda büyük tohumların daha yüksek çimlenme oranı ve çimlenme hızı sergilediği belirlenmiştir (Blalogoe et al., 2020). Ayrıca yapılan bazı araştırmalarda tohum boyutunun ve ağırlığının; bitki adaptasyonu, çevresel stres toleransı, verim ve kalite üzerinde önemli agronomik özellikler olduğu ifade edilmektedir (Boccaccini et al., 2024).

Tohumun uzunluğu, genişliği, alanı, çevresi ve ağırlığı gibi morfolojik ölçümler, tohum boyutunu ve şeklini belirlemek için kullanılan önemli parametrelerdir . Tohum şekli ve boyutu, su alımını (imbibisyon), tohum nem içeriğini ve dolayısıyla tohum çimlenmesini ve kalitesini etkileyebilir (Blalogoe et al., 2020). Tohumun dairesellik, yuvarlaklık gibi geometrik indeksleri, türlerin tanımlanması ve sınıflandırılması için önemli özelliklerdir (Cervantés et al., 2016). Dijital görüntü işleme sistemleri, tohum boyutu ve şeklinin otomatik olarak belirlenmesinde temel bir araç haline gelmiştir (Cervantés et al., 2016). Bu sistemler, tohumların geometrik figürlerle (daire, kardiyoit, elips vb.) karşılaştırılması yoluyla şeklinin hassas bir şekilde nicelleştirilmesine olanak tanır. Ayrıca, genotipler arasındaki farklılıkları veya gelişim evreleri boyunca meydana gelen değişimleri karşılaştırmak için kullanılabilirler.

2.2. Yüzey Alanı ve Özgül Alan

Tohumların yüzey alanı ve özgül yüzey alanı, su alımı ve gaz değişimi gibi fizyolojik süreçlerde önemli bir rol oynar (Mahajan et al., 2023). Su alımı, tohum çimlenmesinin başlangıcını işaret eden temel bir süreçtir ve tohumun hidrasyon durumu, metabolik aktivitenin yeniden başlaması için gereklidir. Tohum kabuğunun geçirgenliği, su alımını düzenleyen önemli bir faktördür ve tohumun yüzey özellikleri bu geçirgenliği etkiler (Upretee et al., 2024). Tohum iç kabuğunun porozite ağı, suyun tohum içine hareketini sağlayan önemli bir yapısal özelliktir (Mahajan et al., 2023).

2.3. Renk, Optik Özellikler ve Kalite İlişkisi

Tohum rengi ve optik özellikleri, tohum kalitesinin tahribatsız bir şekilde değerlendirilmesi için potansiyel bilgiler sunmaktadır (Nehoshtan et al., 2021). Tohum kabuğu rengi; tohum canlılığı, çimlenme, depolama ömrü ve streslere karşı direnç gibi fizyolojik süreçlerle ilişkilendirilmiştir. Örneğin, pigmentli tohumların, pigment içermeyen tohumlara göre daha yüksek çimlenme oranları ve canlılık gösterdiği ve depolama sırasında bozulmaya karşı daha dirençli olduğu bulunmuştur. Koyu renkli tohum kabukları, genellikle daha yüksek tohum sertliği ve fenolik bileşik içeriği ile ilişkilendirilir, bu da tohumu bozulmaya karşı korur ve canlılığını uzun süreli depolama boyunca sürdürmesine yardımcı olur (Jiamtae et al., 2022).

Optik teknolojiler ve yapay zekâ, yer fıstığı tohumlarının kalitesini belirlemede etkili yeni bilgiler sunmaktadır. RGB görüntüleme, renk, boyut, şekil ve yüzey dokusu gibi morfolojik verileri toplamak için kullanılmaktadır. Bunlara ilaveten hiper spektral görüntüleme, tohum

kalitesi ve güvenliğinin tahribatsız ve hızlı bir şekilde değerlendirilmesinde kullanılan yöntemler arasına girmiştir (Feng et al., 2019).

2.4. Nem İçeriğinin Fiziksel Özelliklere Etkisi

Tohumların nem içeriği, tohumun fiziksel ve mühendislik özelliklerini etkileyen en önemli parametrelerden biridir. Hasat ve hasat sonrası işlemler, depolama ve tohum işleme ekipmanlarının tasarımında nem içeriğinin kontrolü esastır (Hay et al., 2023). Nem içeriğindeki artış, tohum boyutunu artırabilir ve şeklini değiştirebilir.

Nem içeriği, tohumun mekanik hasara karşı direncini de belirler (Shahbazi et al., 2023). Yüksek nem içeriği, genellikle tohumun esnekliğini artırarak mekanik hasara karşı direncini azaltırken, çok düşük nem içeriği de kırılganlığı artırabilir. Ayrıca, nem içeriği, tohumun yoğunluğu, hacimsel ağırlığı gibi diğer fiziksel özelliklerini de etkiler (Moret-Fernández et al., 2023).

3. TOHUMLARDA MEKANİK ÖZELLİKLER

Tohumların mekanik özellikleri, tarımsal üretim süreçlerinde, özellikle hasat, işleme, taşıma ve ekim makinelerinin tasarımında büyük önem taşımaktadır. Bu özellikler, tohumun dış etkilere karşı direncini, hasar görme eğilimini ve genel performansını doğrudan etkiler.

3.1 Sertlik, Kırılma Direnci ve Elastikiyet

Tohumların sertliği, kırılma direnci ve elastikiyeti, hasat sonrası işlemler sırasında tohum bütünlüğünün korunması için önemli parametrelerdir. Bu özellikler, bir malzemenin kuvvet uygulaması sonucunda gösterdiği fiziksel özellikler olup, elastikiyet modülü, çekme mukavemeti ve sertlik gibi parametreleri içerir. Tohum kabuklarının sertliği, tohumu yırtıcılara karşı korur ve yüksek dayanıklılık, darbe direnci ve hiyerarşik çok işlevli yapılar gibi istenen mekanik özellikleri sergileyebilir (Flores-Johnson et al., 2018).

Kırılma direnci, tohumun işleme ve taşıma sırasında maruz kaldığı mekanik streslere dayanma kabiliyetini ifade eder. Bu direnç, tohumun nem içeriği, boyutu ve yönelimi gibi faktörlerden etkilenir. Pamuk tohumlarında yapılan çalışmalar, dikey olarak yönlendirilen tohumların yatay olanlara göre daha fazla basma kuvvetine dayandığını ve daha kuru tohumların daha yüksek kırılma direncine sahip olduğunu göstermiştir (Dowd et al., 2019).

3.2. Sürtünme Katsayısı ve Kayma Davranışı

Tohumların sürtünme katsayısı ve kayma davranışı, tarım makinelerinin tasarımı ve etkin çalışması için önemli mühendislik parametreleridir. Bu özellikler, tohumların ekim makineleri, taşıma sistemleri ve depolama tanklarındaki akışını, yığılma açısını ve genel hareketini etkiler. Örneğin, bir ekim makinesinden tohum akışı, tohumların fiziksel ve sürtünme özelliklerine bağlıdır (Harshavardhan et al., 2020).

3.3. Mekanik Özelliklerin Nem ve Sıcaklıkla Değişimi

Tohumların nem içeriği, hasat ve hasat sonrası işlemlerin mekanik özelliklerini etkileyen en önemli parametrelerden biridir. Mısır, pirinç ve soya fasulyesi üzerinde yapılan çalışmalar, nem içeriğindeki artışın tohum boyutunu artırdığını, şeklini değiştirdiğini ve kırılma kuvvetini etkilediğini göstermiştir.

Mısır tohumlarının basınç dayanımı ve gerinim özellikleri, nem içeriği ile doğrudan ilişkilidir. Yüksek nem içeriği, genellikle tohumu daha esnek hale getirerek mekanik hasara karşı direncini azaltabilirken, çok düşük nem içeriği de tohumu daha kırılgan hale getirebilir (Kruszelnicka et al., 2022). Yapılan bir araştırmada bambara çekirdeklerinin mukavemet özellikleri, nem içeriğine ve dane boyutuna bağlı olarak değiştiği; nem içeriği arttıkça kırılma mukavemetinin

azaldığı bildirilmiştir (Nwakuba et al., 2022). Kuru koşullarda, tohumlar daha yüksek kırılma direncine sahip olabilir (Dowd et al., 2019). Çevresel sıcaklık da tohumların mekanik hasar görme yüzdesini etkileyen bir faktördür (Shahbazi et al., 2023). Bu nedenle, tohum işleme ekipmanlarının tasarımı ve işletilmesi sırasında bu çevresel faktörlerin dikkate alınması, tohum kalitesinin korunması ve mekanik hasarın en aza indirilmesi için kritik öneme sahiptir.

4. FİZİKO-MEKANİK ÖZELLİKLERİN TARIMSAL ÜRETİME ETKİSİ

Tohumların fiziko-mekanik özellikleri, tarımsal üretim zincirinin çeşitli aşamalarında önemli bir rol oynamaktadır. Bu özellikler, ekimden çimlenmeye, kalite kontrolünden depolamaya kadar birçok süreci doğrudan etkileyerek tarımsal verimlilik ve sürdürülebilirlik üzerinde belirleyici bir etki yaratır.

4.1. Ekim Makinalarında Akışkanlık

Ekim makinelerinde tohum akışkanlığı ve tohum borularındaki davranışı, hassas ekimin başarısı için temel teşkil eder. Tohumların boyutu, şekli, yüzey pürüzlülüğü, yoğunluğu ve sürtünme katsayısı gibi fiziko-mekanik özellikleri, ekim mekanizmalarının tasarımını ve performansını doğrudan etkiler (Harshavardhan et al., 2020). Örneğin, tohumun sürtünme katsayısı ve kayma davranışı, ekim sırasında tohumların düşme hızını ve dağılımını belirler (Kaliniewicz et al., 2016). Düşük sürtünme katsayısına sahip, pürüzsüz yüzeyli tohumlar ekim borularında daha düzenli akış sergileyebilirken, yüksek sürtünme veya düzensiz şekle sahip tohumlar tıkanmalara ve düzensiz ekime yol açabilir.

Hassas ekicilerin geliştirilmesinde, tohumların geometrik ve sürtünme özelliklerinin anlaşılması büyük önem taşımaktadır (Guru et al., 2023). Özellikle mısır gibi düzensiz şekilli tohumlar için tasarlanan mekanik ekicilerde, tohum morfolojisinin ekim performansı üzerindeki etkisi dikkate alınmalıdır (Mao et al., 2024). Ayrık elemanlar yöntemi gibi simülasyon teknikleri, tohumların ekim makinesi içindeki hareketini modelleyerek, tohum yataklarına yerleşim performansını optimize etmek için kullanılmaktadır. Bu tür analizler, farklı tohum çeşitlerinin ekim makineleriyle uyumluluğunu değerlendirmek ve ekim hassasiyetini artırmak için mühendislik tasarımlarına ışık tutar.

4.2. Tohum Yatağında Yerleşim ve Çimlenme Performansı

Tohum yatağında optimum yerleşim, başarılı çimlenme ve fide gelişiminin ön koşuludur. Tohumun fiziksel özellikleri, tohum-toprak teması, su alımı ve gaz değişimi gibi çimlenmeyi etkileyen temel süreçlerde merkezi bir rol oynar. Tohumun boyutu ve yoğunluğu, ekim derinliği ve toprak partikülleriyle etkileşimi üzerinde etkilidir. Yeterli tohum-toprak teması, tohumun topraktan gerekli su ve oksijeni alabilmesi için hayati öneme sahiptir. Kötü yerleşim, hava boşluklarının oluşmasına neden olarak su alımını engelleyebilir ve çimlenmeyi geciktirebilir veya tamamen önleyebilir (Moret-Fernández et al., 2023).

Tohum yatağının nem içeriği, sıcaklığı ve toprak yapısı gibi çevresel faktörler, tohumun fiziksel özellikleri ile etkileşime girerek çimlenme performansını etkiler (Lamichhane et al., 2019). Örneğin, homojen boyutlara sahip bir tohum yatağı, tahıllarda hızlı ve tekdüze fide çıkışı için önemlidir (Balsari et al., 2020). Toprak parçacıkları arasındaki temas alanı ve toprak hidrolik iletkenliği gibi faktörler, tohumun su alım oranını doğrudan etkiler. Bu nedenle, tohum yatağının fiziksel özelliklerinin iyi yönetilmesi, homojen fide çıkışı ve yüksek verim için kritik öneme sahiptir (Lal et al., 2020).

4.3. Tohum Kabuk Sertliğinin İmbibisyon Üzerindeki Rolü

Tohum kabuğunun sertliği, tohumun su alımı (imbibisyon) üzerinde önemli bir etkiye sahiptir ve özellikle fiziksel uyku halinde olan tohumlarda çimlenmeyi kısıtlayıcı bir faktör olabilir (Mandizvo & Odindo, 2019). Sert tohum kabukları, suyun tohum içine nüfuz etmesini fiziksel olarak engelleyerek, tohumun çimlenme potansiyelini uzun süre korumasına neden olabilir (Pompelli et al., 2023). Bu durum, doğal ortamda tohumun olumsuz koşullardan korunmasına yardımcı olurken, tarımsal üretimde homojen çimlenmeyi engelleyebilir.

Tohum kabuğunun yapısı ve bileşimi, su alım hızını ve miktarını belirleyen önemli özelliklerdir . Örneğin, *Gleditsia sinensis* tohumlarında su geçirmez tohum kabuğu, çevresel adaptasyon için faydalı olsa da, çimlenmeyi engeller (Zhu et al., 2021). Benzer şekilde, bazı türlerde tohum kabuğu rengi ile tohum kalitesi (canlılık ve vigor) arasında ilişki olduğu belirtilmiştir (Mandizvo & Odindo, 2019). Koyu renkli tohum kabukları genellikle daha sert ve daha az geçirgen olup, bu da su alımını yavaşlatarak çimlenmeyi geciktirir. Bu durum, tohumun depolama ömrünü uzatsa da, ekim sonrası hızlı ve eşzamanlı fide çıkışını zorlaştırabilir.

5. Sonuçlar

Bu çalışma, tohumların fiziko-mekanik özelliklerinin tarımsal üretimdeki temel önemini ve bu özelliklerin modern tarım teknolojileriyle nasıl entegre edilebileceğini vurgulamıştır.

Tohumların boyut, şekil, yoğunluk ve nem içeriği gibi fiziksel özellikleri, çimlenme ve fide gelişimini doğrudan etkileyen kritik parametrelerdir. İri tohumlar, genellikle daha yüksek çimlenme oranları ve güçlü fide gelişimi sergileyerek tarımsal verimlilik için bir temel oluşturur. Mekanik özellikler ise hasat, ürün işleme ve ekim süreçlerinde tohumun bütünlüğünü korumak için bilinmesi gereken parametrelerdir. Bu özellikler, ekim makinelerinin hassasiyetini, depolama sırasında kalite kaybını ve hasat sonrası mekanik hasarı belirler. Çevresel stres koşulları altında tohumların fiziko-mekanik özelliklerindeki değişimler, çimlenme performansını olumsuz etkileyebilir ve bu nedenle dayanıklı çeşitlerin geliştirilmesi için bu etkileşimlerin anlaşılması büyük önem taşır.

Tohumların fiziko-mekanik özellikleri, temizleme, sınıflandırma, depolama ve değirmencilik gibi hasat sonrası işleme teknolojilerinin tasarımında ve optimizasyonunda temel girdiler sağlar. Boyut ve yoğunluk bazlı ayırma sistemleri, tohum partilerinin kalitesini artırmak için tohumların fiziksel farklılıklarından yararlanır. Ekim makineleri, tohumların akışkanlık ve sürtünme özelliklerine göre tasarlanarak hassas bir ekimin yapılması sağlanır. Modern işleme tesislerinde, mekanik hasarı en aza indirmek ve tohum kalitesini korumak için tohumların darbe dayanımı ve kırılma limitleri gibi mekanik özellikleri de dikkate alınmalıdır.

ÖZET

E-ticaret sektöründe teslimat süresinin doğru ve güvenilir biçimde tahmin edilmesi, müşteri memnuniyetinin artırılması, operasyonel kaynakların etkin yönetilmesi ve işletmelerin rekabet gücünün korunması açısından stratejik bir önem taşımaktadır. Artan sipariş hacmi ve değişken operasyonel koşullar, geleneksel tahmin yöntemlerinin yetersiz kalmasına neden olmakta; bu durum yapay zekâ ve özellikle yapay sinir ağlarına dayalı modellerin kullanımını gerekli kılmaktadır. Bu çalışma, Multilayer Perceptron (MLP), Long Short-Term Memory (LSTM) ve Convolutional Neural Network (CNN) olmak üzere üç farklı yapay sinir ağı mimarisinin e-ticaret teslimat süresi tahminindeki performansını karşılaştırmalı olarak analiz etmektedir. Modelleme sürecinde hazırlık süresi, teslimat mesafesi, trafik yoğunluğu, hava durumu, araç türü ve sipariş zamanı gibi operasyonel değişkenleri içeren gerçek bir lojistik veri seti kullanılmıştır. Python ortamında TensorFlow, Keras ve scikit-learn kütüphaneleri ile eğitilen modeller, %80 eğitim ve %20 test veri ayrımıyla değerlendirilmiştir. Performans analizinde Ortalama Mutlak Hata (MAE), Kök Ortalama Kare Hata (RMSE) ve R^2 katsayısı temel alınmıştır. Bulgular, MLP modelinin MAE=4,11 dakika, RMSE=5,17 dakika ve R^2=0,85 değerleriyle en başarılı modeli oluşturduğunu göstermektedir. LSTM modeli R^2=0,83, CNN modeli ise R^2=0,74 değeriyle daha düşük performans sergilemiştir. Korelasyon analizine göre teslimat süresini en fazla etkileyen değişkenler hazırlık süresi ve mesafedir. Sonuç olarak çalışma, MLP mimarisinin zaman bağımlılığı sınırlı veri yapılarında daha tutarlı çıktılar ürettiğini ve e-ticaret lojistiğinde karar destek süreçlerinde etkin bir araç olarak kullanılabileceğini ortaya koymaktadır.

Anahtar Kelimeler: Teslimat Süresi Tahmini, Yapay Sinir Ağı, Makine Öğrenmesi, E-Ticaret, Akıllı Lojistik Sistemleri.

COMPARATIVE ANALYSIS OF DEEP LEARNING APPROACHES IN E-COMMERCE DELIVERY TIME PREDICTION: AN APPLICATION OF MLP, LSTM, AND CNN MODELS

ABSTRACT

This study aims to improve inventory management in retail supply chains through data-driven decision support approaches. In the research, the K-Means clustering algorithm—an unsupervised machine learning method—was used to identify the relationships among product sales performance, inventory level, and order frequency. By grouping stock items based on their similar characteristics, the model enables businesses to maintain inventory balance and base their decision-making processes on quantitative data. The analysis was conducted using the Python 3.10 programming language within the Spyder IDE of the Anaconda distribution. Data loading, cleaning, and transformation processes were carried out with the Pandas and NumPy libraries, while modeling and performance evaluations were performed using the scikit-learn library. To determine the optimal number of clusters, the Elbow Method, Silhouette Coefficient, Davies–Bouldin Index (DBI), and Calinski–Harabasz Score (CH) were employed. According to the results obtained, k = 3 was identified as the most appropriate number of clusters. The model outputs revealed that the products were grouped into three main categories: Overstock, Balanced, and Understock. The model's Silhouette score of 0.3141, Inertia value of 101,751.79, low DBI, and high CH scores indicate that the clusters have a strong separation structure. The findings show that products in the balanced stock cluster can serve as a reference for replenishment policies, while the overstock group poses a capital-holding burden and the understock group carries a risk of lost sales. Overall, the K-Means algorithm stands out as an effective and applicable analytical method for inventory optimization, cost reduction, and the development of decision support systems in the retail sector.

Keywords: Delivery Time Prediction, Artificial Neural Network, Machine Learning, E-Commerce, Smart Logistics Systems.

1.GİRİŞ

Günümüzde teknoloji, insan yaşamının hemen her alanında etkisini giderek artırmakta; bireylerin alışkanlıklarını, işletmelerin iş yapış biçimlerini ve toplumsal dinamikleri köklü biçimde dönüştürmektedir. Bu dönüşümün en belirgin biçimde gözlemlendiği alanlardan biri de e-ticaret sektörüdür. Dijital dönüşümle birlikte çevrimiçi alışveriş süreçlerinin hız, erişilebilirlik ve güven unsurları etrafında yeniden şekillenmesi, e-ticaret işletmelerine yenilikçi çözümler geliştirmeyi zorunlu kılmıştır. Özellikle dijital işlemlerin hızlı ilerlemesi, müşterilerin sipariş oluşturma anından teslimat sürecinin tamamlanmasına kadar geçen zamanda anlık bilgi ve hızlı hizmet beklentilerini artırmaktadır. Bu nedenle, çevrimiçi platformlardan verilen siparişlerin kısa sürede, doğru ve güvenilir biçimde ulaştırılması, firmalar açısından hem müşteri memnuniyetini sağlamada hem de rekabet üstünlüğü elde etmede kritik bir faktör hâline gelmiştir.

Bu bağlamda, teslimat süresinin doğru biçimde tahmin edilmesi yalnızca bir lojistik optimizasyon problemi olarak değil; aynı zamanda müşteri deneyimi yönetimi, stok planlama, rota optimizasyonu ve iş gücü dağılımı gibi birçok süreci doğrudan etkileyen çok boyutlu bir analiz alanı olarak öne çıkmaktadır. Örneğin, bir yemek siparişinin teslimat süresinin doğru tahmin edilmesi, hem müşterilerin memnuniyetini artırmakta hem de tedarik zinciri üzerindeki operasyonel yükü azaltmaktadır.

İnsanlar karar verme süreçlerinde geçmiş deneyimlerinden ve çevresel ipuçlarından yararlanırken, teknolojik sistemler de benzer şekilde veri analizine dayalı öğrenme mekanizmaları geliştirmektedir. Bu noktada yapay zekâ sistemleri, insanın karar verme süreçlerini modelleyen bir yapı olarak ortaya çıkmakta ve karmaşık problemlerin çözümünde güçlü bir araç sunmaktadır. Özellikle yapay sinir ağları (YSA), çok değişkenli ve dinamik veri ortamlarında öğrenme yeteneği sayesinde karmaşık ilişkileri modelleyebilmekte ve geleceğe yönelik yüksek doğrulukta tahminler üretebilmektedir.

Bu çalışmada, teslimat odaklı sektörlerde yapay sinir ağı tabanlı bir tahmin modelinin e-ticaret teslimat süresi üzerindeki öngörü gücü analiz edilmektedir. Modelleme sürecinde geçmiş teslimat kayıtları, hava durumu, ulaşım mesafesi, teslimat aracı bilgisi ve trafik yoğunluğu gibi değişkenler dikkate alınmış; Python programlama dili ve ilgili makine öğrenmesi kütüphaneleri kullanılarak eğitim ve test süreçleri yürütülmüştür. Çalışmanın temel amacı, geliştirilen modelin gerçek dünyadaki teslimat sistemleriyle uyum düzeyini incelemek ve elde edilen bulgular doğrultusunda sektörel uygulamalara katkı sunmaktır.

Araştırma Sorusu: E-ticaret teslimat süresinin tahmininde farklı yapay sinir ağı mimarileri (MLP, LSTM ve CNN) arasında doğruluk, kararlılık ve genellenebilirlik açısından anlamlı bir performans farkı var mıdır?

Araştırma Hipotezi (H_1): Multilayer Perceptron (MLP) mimarisi, zaman bağımlılığı sınırlı veri setlerinde LSTM ve CNN mimarilerine kıyasla daha yüksek doğruluk ve istikrarlı tahmin performansı göstermektedir. (H_0): MLP, LSTM ve CNN modelleri arasında e-ticaret teslimat süresi tahmini doğruluğu açısından anlamlı bir fark yoktur.

Mevcut literatür, e-ticaret teslimat süresi tahmini üzerine yoğunlaşsa da çalışmaların büyük bir kısmı ya tek bir makine öğrenmesi modeline odaklanmakta ya da zaman serisi tabanlı tahminler üzerinde sınırlı kalmaktadır. Derin öğrenme mimarilerinin (MLP, LSTM, CNN) aynı veri seti üzerinde sistematik biçimde karşılaştırıldığı kapsamlı çalışmalar oldukça sınırlıdır. Ayrıca, çevrimiçi teslimat süreçlerinde operasyonel faktörlerin (hazırlık süresi, trafik, mesafe, hava durumu vb.) etkisini bütüncül biçimde ele alan modelleme yaklaşımlarının azlığı dikkat çekmektedir. Bu çalışma, söz konusu boşluğu doldurarak farklı derin öğrenme mimarilerinin e-

ticaret teslimat süresi tahminindeki göreli başarımını karşılaştırmalı olarak ortaya koymayı amaçlamaktadır.

2. LİTERATÜR ARAŞTIRMASI

Son yıllarda e-ticaret ve lojistik sektörlerinde tahminleme süreçlerinde yapay zekâ ve makine öğrenmesi tabanlı yöntemlerin kullanımı hızla artmıştır. Bu yaklaşımlar, yalnızca operasyonel süreçleri optimize etmekle kalmayıp, müşteri deneyimini iyileştiren karar destek sistemlerinin geliştirilmesine de önemli katkılar sunmaktadır.

Liu, Wang, Li, Payne, Yue ve Man (2024), e-ticaret platformlarında doğru ürün seçimini desteklemek amacıyla satış tahmini ve ürün seçimini entegre eden bir model geliştirmiş; altı farklı makine öğrenmesi yöntemini birleştirerek daha yüksek doğruluk elde etmiştir. Abed (2024) ise 47 çevrimiçi mağazadan 413 günlük veriyle yürüttüğü çalışmada, talep tahmininde hibrit modellerin e-ticaretin dinamik veri yapılarıyla başa çıkmada etkili olduğunu göstermiştir. Benzer şekilde Küp, Küp, Koçak, Yücekaya ve Hekimoğlu (2023), teslimat gecikmelerini gerçek zamanlı olarak öngören makine öğrenmesi modelleriyle operasyonel verimliliği ve müşteri memnuniyetini artırmıştır.

Teslimat süresi tahmini konusunda Salari, Liu ve Shen (2020), çevrimiçi perakendecilikte sipariş zamanı, ürün tipi, müşteri profili ve dağıtım merkezi yoğunluğu gibi değişkenlerle doğruluğu %40 oranında artıran maliyet duyarlı kuantil regresyon ormanları (CQRF) yaklaşımını önermiştir. Rokoss, Syberg, Tomidei, Hülsing, Deuse ve Schmidt (2024) ise küçük parti üretim yapan firmalarda teslimat süresini tahmin etmek için ANN, XGBoost ve SVM modellerini karşılaştırmış ve %50'ye varan doğruluk artışı elde etmiştir.

Atak, Kaya ve Arslanoğlu (2023) hava koşullarının konteyner terminal operasyonlarındaki yük elleçleme süresine etkisini analiz etmiş, çevresel değişkenlerin lojistik performans üzerindeki etkisini ortaya koymuştur. Nnaji, Collins, Omoraiyewa ve Joshua (2022), e-ticaret teslimat yönetiminde makine öğrenmesiyle gecikme risklerini önceden tahmin ederek müşteri memnuniyetini artırabilecek bir çerçeve sunmuştur. Yalçınkaya ve Hızıroğlu (2024), online yemek teslimatında sipariş zamanı, hava durumu ve trafik yoğunluğu gibi faktörleri dikkate alarak teslimat süresi tahmini için yüksek doğrulukta bir model geliştirmiştir. Karl (2022) tüketici iadelerinin tahmininde istatistiksel ve makine öğrenmesi tabanlı yöntemleri karşılaştırarak farklı tahmin senaryolarını değerlendirmiştir. Eichenseer, Hans ve Winkler (2025) ise iş gücü planlamasında teslimat pozisyonlarını beş gün önceden tahmin eden bir model geliştirerek aşırı veya yetersiz personel kullanımını azaltmıştır.

Bu çalışmalar genel olarak, derin öğrenme ve makine öğrenmesi temelli modellerin teslimat süresi tahmininde klasik istatistiksel yöntemlere göre daha başarılı sonuçlar ürettiğini göstermektedir. Özellikle özellik mühendisliği, hiperparametre optimizasyonu ve gerçek zamanlı veri entegrasyonu gibi gelişmiş tekniklerin, tahmin doğruluğunu anlamlı ölçüde artırdığı vurgulanmaktadır. Dolayısıyla yapay sinir ağı tabanlı modeller, akıllı lojistik sistemlerinde zaman planlaması ve kaynak yönetimi için stratejik bir karar destek aracı olarak değerlendirilmektedir.

3. MATERYAL VE METOT

3.1. Araştırma Yaklaşımı

Bu çalışma, e-ticaret sektöründe teslimat süresini etkileyen operasyonel değişkenleri dikkate alarak, farklı yapay sinir ağı mimarilerinin (MLP, LSTM, CNN) tahmin performanslarını karşılaştırmalı biçimde değerlendirmeyi amaçlayan nicel bir araştırma tasarımına sahiptir.

Çalışmada, deneysel modelleme yaklaşımı benimsenmiş ve farklı derin öğrenme modellerinin aynı veri seti üzerinde eğitim–test analizleri gerçekleştirilmiştir.

3.2. Veri Seti ve Değişkenler

Modelleme sürecinde kullanılan veri seti, gerçek lojistik operasyonlarını temsil edecek şekilde oluşturulmuştur. Veri setinde her bir gözlem, bir teslimat işlemine karşılık gelmektedir. Teslimat süresini (dakika cinsinden) etkilediği düşünülen altı bağımsız değişken belirlenmiştir:

Hazırlık Süresi (Prep_Time)

Mesafe (Distance_km)

Trafik Yoğunluğu (Traffic_Level)

Hava Durumu (Weather)

Araç Türü (Vehicle_Type)

Sipariş Saati (Order_Time)

Bağımlı değişken, teslimatın tamamlanma süresini ifade eden Teslimat Süresi (Delivery_Time)'dir. Veri seti, Excel formatında düzenlenmiş ve Python ortamına aktarılmıştır.

3.3. Veri Ön İşleme Süreci

Modelin başarımını olumsuz etkileyebilecek eksik, hatalı veya uç değerler temizlenmiş; veri bütünlüğü sağlanmıştır. Kategorik değişkenler (hava durumu, trafik yoğunluğu, araç türü) Label Encoding yöntemiyle sayısallaştırılmış, sayısal değişkenler ise farklı ölçeklerin etkisini ortadan kaldırmak için MinMaxScaler tekniğiyle [0,1] aralığında normalize edilmiştir. Veri seti, rastgele seçim yöntemiyle %80 eğitim ve %20 test olarak ikiye ayrılmış; modelin genellenebilirliğini test etmek amacıyla bu işlem 10 farklı tekrar (random seed varyasyonu) ile yürütülmüştür.

3.4. Model Mimarileri

Teslimat süresi tahmini için üç farklı yapay sinir ağı mimarisi kullanılmıştır:

Multilayer Perceptron (MLP): Tam bağlantılı katmanlardan oluşan klasik bir ileri beslemeli ağ yapısıdır. İki gizli katman (32 ve 16 nöron) içermekte olup, aktivasyon fonksiyonu olarak ReLU (Rectified Linear Unit) kullanılmıştır. Çıktı katmanı, doğrusal regresyon tahmini üreten tek nöronludur.

Long Short-Term Memory (LSTM): Zaman serisi veya ardışık veri yapılarındaki bağımlılıkları yakalamak amacıyla geliştirilmiş tekrarlayan sinir ağı (RNN) tabanlı bir modeldir. Bu çalışmada, veri setindeki sınırlı ardışıklık yapısına rağmen LSTM'nin performansı karşılaştırmalı olarak incelenmiştir.

Convolutional Neural Network (CNN): Genellikle uzamsal veri analizinde kullanılan bu model, girdi değişkenleri arasındaki lokal ilişkileri öğrenme yeteneği nedeniyle değerlendirmeye alınmıştır. Modelde bir konvolüsyon katmanı, bir "flatten" katmanı ve tam bağlantılı katmanlar kullanılmıştır.

Tüm modellerde Adam optimizasyon algoritması, Mean Squared Error (MSE) kayıp fonksiyonu ve Epoch=200 değerleri kullanılmıştır.

3.5. Performans Ölçütleri

Model performanslarının karşılaştırılmasında üç temel ölçüt kullanılmıştır:

Ortalama Mutlak Hata (MAE): Tahmin edilen ve gerçek değerler arasındaki mutlak farkın ortalaması, modelin genel hata düzeyini gösterir.

Kök Ortalama Kare Hata (RMSE): Hataların karelerinin ortalamasının karekökü alınarak büyük hataların etkisini daha güçlü biçimde yansıtır.

Açıklama Katsayısı (R^2): Modelin bağımlı değişken varyansını açıklama oranını ifade eder.

Elde edilen sonuçlar, her modelin 10 tekrarı üzerinden ortalama alınarak karşılaştırılmış ve en düşük hata değerini, en yüksek açıklama katsayısını sağlayan mimari en başarılı model olarak değerlendirilmiştir.

3.6. Analiz Ortamı

Tüm analizler Python 3.10 sürümü kullanılarak, Anaconda dağıtımı altında çalışan Spyder IDE ortamında gerçekleştirilmiştir. Kullanılan temel kütüphaneler arasında NumPy, Pandas, Matplotlib, scikit-learn, TensorFlow ve Keras yer almaktadır.

4. ANALİZ VE BULGULAR

Bu çalışmada, akıllı lojistik sistemlerinde teslimat süresinin tahminine yönelik bir yapay sinir ağı modeli geliştirilmiştir. Model, gerçek dünyadaki bir lojistik senaryosunu temsil eden veri seti kullanılarak oluşturulmuş ve teslimat süresi üzerinde etkili olduğu düşünülen operasyonel değişkenler (hazırlık süresi, mesafe, trafik durumu, hava koşulları, araç türü ve sipariş zamanı) dikkate alınmıştır. Çalışmanın temel amacı, bu değişkenlere dayalı olarak teslimat süresini dakikalık bazda tahmin eden bir derin öğrenme modelinin performansını değerlendirmektir.

Modelleme süreci Python programlama dili kullanılarak gerçekleştirilmiş; Pandas, NumPy, scikit-learn, TensorFlow/Keras ve matplotlib kütüphanelerinden yararlanılmıştır. Geliştirme ortamı olarak Anaconda ve Spyder IDE tercih edilmiştir. Veri seti Excel formatında hazırlanmış, ardından veri ön işleme aşamasına geçilmiştir. Bu aşamada kategorik değişkenler (hava durumu, trafik yoğunluğu, araç türü) Label Encoding yöntemiyle sayısallaştırılmış; sayısal değişkenler ise MinMaxScaler tekniğiyle normalize edilmiştir. Veriler, modelin öğrenme başarımını değerlendirmek amacıyla %80 eğitim ve %20 test olarak ikiye ayrılmıştır. Rastgele seçim yöntemiyle oluşturulan bu bölünme, modelin genellenebilirliğini test etmek üzere 10 kez tekrarlanmış ve her çalıştırmadan elde edilen sonuçlar raporlanmıştır.

Modelleme sürecinde üç farklı yapay sinir ağı mimarisi karşılaştırılmıştır: Multilayer Perceptron (MLP), Long Short-Term Memory (LSTM) ve Convolutional Neural Network (CNN). Her modelin giriş katmanını izleyen iki gizli katman (32 ve 16 nöron) kullanılmış, bu katmanlarda ReLU aktivasyon fonksiyonu tercih edilmiştir. Çıktı katmanı tek nöronlu olup, doğrusal regresyon çıktısı verecek şekilde yapılandırılmıştır. Tüm modellerde kayıp fonksiyonu olarak Mean Squared Error (MSE), optimizasyon algoritması olarak ise Adam kullanılmıştır.

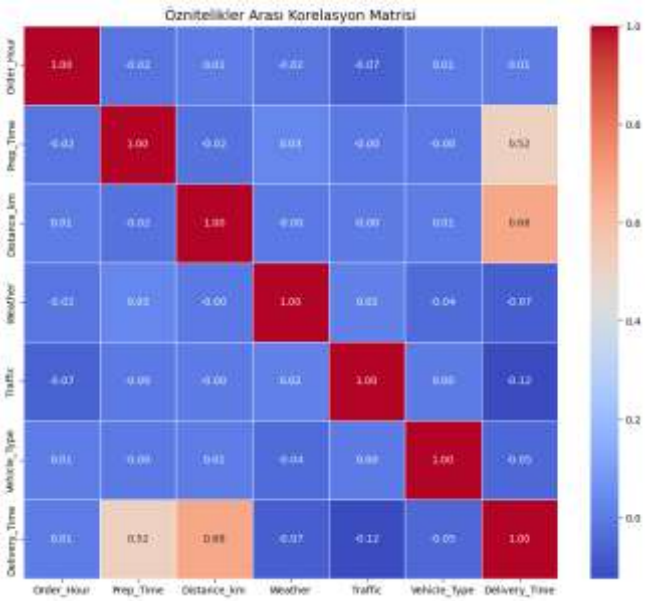
Eğitim süreci tamamlandıktan sonra modeller test verisi üzerinde değerlendirilmiş ve performans göstergeleri olarak Ortalama Mutlak Hata (MAE), Kök Ortalama Kare Hata (RMSE) ve R^2 (açıklama katsayısı) değerleri hesaplanmıştır. Elde edilen sonuçlar Tablo 1, Tablo 2 ve Tablo 3'te sunulmuştur.

Değişkenler arasındaki ilişkileri görsel olarak analiz etmek amacıyla oluşturulan korelasyon matrisi Şekil 1'de verilmiştir. Sonuçlara göre "Prep_Time" (hazırlık süresi) ile "Delivery_Time" (teslimat süresi) arasında 0,52, "Distance_km" (mesafe) ile "Delivery_Time" arasında ise 0,68 düzeyinde pozitif korelasyon gözlemlenmiştir. Bu bulgular, teslimat süresinin özellikle hazırlık süresi ve mesafe değişkenlerinden güçlü biçimde etkilendiğini ortaya koymaktadır. Diğer değişkenlerin (hava durumu, trafik yoğunluğu ve araç türü) düşük

korelasyon değerlerine sahip olması, bu faktörlerin sınırlı etkiye sahip olduğunu göstermektedir.

Modellerin karşılaştırmalı performans analizine göre, MLP modeli hem hata metrikleri hem de açıklama gücü açısından en başarılı sonuçları vermiştir. MLP modelinin ortalama MAE değeri 4,11 dakika, RMSE değeri 5,17 dakika ve R^2 değeri 0,85 olarak ölçülmüştür. LSTM modeli %83 doğruluk (R^2=0,83) düzeyinde kalırken, CNN modeli en düşük performansı göstermiştir (R^2=0,74; RMSE=6,71). Bu farklılık, veri setinin zaman bağımlılığının sınırlı olmasından kaynaklanmaktadır. Ayrıca CNN modelinde gözlemlenen yüksek varyans, modelin karmaşık veriyi aşırı öğrenmeye eğilimli olduğunu göstermektedir.

Tablo 1. Modellerin MAE – Ortalama Mutlak Hata Değerlerinin Test Sonuçları



Model	**MAE - Ortalama Mutlak Hata**					**MAE -Mean Absolute Error**					
	1	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**	**Ortalama**
MLP	4,172	4,08	4,295	3,985	4,109	4,133	4,139	4,237	4,075	3,897	4,1122
LSTM	4,489	4,041	4,147	4,334	4,52	4,507	4,642	4,317	4,353	4,527	4,3877
CNN	6,557	6,907	5,803	4,658	4,895	4,516	5,028	6,739	4,468	4,33	5,3901

Tablo 2. Modellerin R^2 – Skor Belirleme Katsayısı Değerlerinin Test Sonuçları

Model	**R^2 Skor Belirleme Katsayısı**				**R-squared - Coefficient of Determination**						
	1	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**	**Ortalama**
MLP	0,85	0,852	0,842	0,861	0,851	0,85	0,856	0,849	0,853	0,861	0,8525
LSTM	0,823	0,858	0,849	0,834	0,824	0,829	0,813	0,844	0,846	0,825	0,8345
CNN	0,628	0,603	0,702	0,804	0,781	0,825	0,77	0,624	0,817	0,832	0,7386

Tablo 3. Modellerin RMSE - Kök Ortalama Kare Hata Değerlerinin Test Sonuçları

Model	**RMSE - Kök Ortalama Kare Hata**				**RMSE - Root Mean Squared Error**						
	1	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**	**Ortalama**
MLP	5,179	5,167	5,338	5,016	5,166	5,254	5,156	5,295	5,141	4,977	5,1689
LSTM	5,62	5,055	5,205	5,399	5,656	5,595	5,762	5,43	5,406	5,612	5,474
CNN	8,078	8,442	7,286	5,916	6,221	5,598	6,366	8,242	5,594	5,338	6,7081

Şekil 1. Öznitelikler Arası İlişki Matrisi

E-ticaret teslimat süresi tahmininde MLP mimarisi, doğruluk, kararlılık ve genellenebilirlik açısından en uygun model olarak öne çıkmıştır. Bu bulgular, yapay sinir ağı tabanlı modellerin lojistik süreçlerdeki teslimat süresi tahmininde etkili, uygulanabilir ve güvenilir bir karar destek mekanizması sunduğunu göstermektedir.

5. TARTIŞMA

Bu çalışmada elde edilen bulgular, literatürdeki önceki araştırmalarla büyük ölçüde uyum göstermekte ve e-ticaret teslimat süresi tahmininde yapay sinir ağı tabanlı modellerin yüksek doğruluk sağladığını desteklemektedir. Çalışmanın sonuçları, özellikle Multilayer Perceptron (MLP) mimarisinin, doğrusal olmayan ilişkileri etkin biçimde öğrenebilmesi sayesinde, klasik makine öğrenmesi algoritmalarına kıyasla daha istikrarlı tahminler üretebildiğini ortaya koymuştur. Bu durum, Liu ve ark. (2024) ile Abed (2024)'in çalışmalarında vurgulanan, hibrit ve ensembel öğrenme yaklaşımlarının e-ticaret süreçlerindeki karmaşık veri yapılarında daha yüksek tahmin başarısı sağladığı yönündeki bulgularla örtüşmektedir.

Elde edilen sonuçlar ayrıca, teslimat süresini etkileyen temel faktörlerin hazırlık süresi ve mesafe olduğunu göstermektedir. Bu bulgu, Yalçınkaya ve Hızıroğlu (2024)'nun çevrimiçi yemek teslimat sistemlerinde sipariş zamanı, trafik yoğunluğu ve mesafe gibi değişkenlerin teslimat tahmini doğruluğunda kritik rol oynadığı sonucuyla paraleldir. Benzer biçimde, Salari, Liu ve Shen (2020) tarafından önerilen maliyet duyarlı kuantil regresyon ormanları (CQRF) modeli de operasyonel değişkenlerin doğru biçimde modellenmesinin tahmin performansını önemli ölçüde artırdığını göstermiştir.

Bu çalışmada kullanılan veri setinde ardışık zaman bağımlılığının sınırlı olması, LSTM mimarisinin beklenenden düşük performans sergilemesine neden olmuştur. Bu durum, zaman serisi niteliği güçlü olan veri kümelerinde LSTM veya GRU gibi sıralı modellerin daha avantajlı olabileceğini gösteren literatürle (örneğin Rokoss ve ark., 2024) uyumludur. CNN modelinin düşük performansı ise, veri setinin uzamsal paternler içermemesiyle ilişkilendirilebilir. Benzer şekilde, Karl (2022) ve Eichenseer, Hans ve Winkler (2025) tarafından yürütülen çalışmalar da, model seçiminde veri yapısının belirleyici olduğunu vurgulamaktadır.

Çalışmanın bulguları, makine öğrenmesi tabanlı tahmin modellerinin lojistik operasyonlarda yalnızca teslimat süresini öngörmekle kalmayıp, operasyonel kaynak planlaması, rota

optimizasyonu ve müşteri bilgilendirme süreçlerine de doğrudan katkı sunabileceğini göstermektedir. Bu yönüyle araştırma, Küp ve ark. (2023) ile Nnaji ve ark. (2022)'nin lojistik süreçlerde gecikme öngörüsü ve müşteri memnuniyeti üzerine yaptığı çalışmalarla da örtüşmektedir.

Genel olarak bu çalışma, e-ticaret sektöründe MLP mimarisinin, hem doğruluk hem de genellenebilirlik açısından uygulanabilir bir tahmin aracı olduğunu ortaya koyarak literatüre özgün bir katkı sağlamaktadır. MLP modelinin basit yapısına rağmen yüksek açıklama gücü göstermesi, yapay sinir ağlarının karmaşık optimizasyon gerektiren lojistik süreçlerde güvenilir ve düşük maliyetli çözümler sunabileceğini göstermektedir. Ayrıca bu bulgular, gelecekte yapılacak araştırmalarda gerçek zamanlı veri akışlarının ve hibrit model kombinasyonlarının kullanılması durumunda tahmin başarısının daha da artırılabileceğine işaret etmektedir.

6. SONUÇ VE ÖNERİLER

Bu çalışmada, e-ticaret teslimat süresinin tahminine yönelik olarak geliştirilen üç farklı yapay sinir ağı mimarisi — Multilayer Perceptron (MLP), Long Short-Term Memory (LSTM) ve Convolutional Neural Network (CNN) — karşılaştırmalı olarak değerlendirilmiştir. Modellerin performansları, Ortalama Mutlak Hata (MAE), Kök Ortalama Kare Hata (RMSE) ve R^2 (açıklama katsayısı) metrikleri üzerinden analiz edilmiştir. Elde edilen sonuçlara göre, MLP modeli 4,11 dk MAE, 5,17 dk RMSE ve 0,85 R^2 değeriyle en yüksek doğruluk ve kararlılığı göstermiştir. LSTM modeli 0,83, CNN modeli ise 0,74 R^2 değeriyle daha düşük performans sergilemiştir. Bu bulgular, MLP mimarisinin zaman hassasiyetinin yüksek olduğu lojistik operasyonlarda güvenilir bir tahmin aracı olduğunu ortaya koymaktadır. Korelasyon analizi bulguları, teslimat süresini en çok etkileyen değişkenlerin hazırlık süresi (Prep_Time) ve mesafe (Distance_km) olduğunu göstermektedir. Bu değişkenlerin hedef değişkenle yüksek pozitif korelasyonu, MLP modelinin açıklayıcılık gücünü desteklemiştir. Diğer değişkenlerin etkisi sınırlı olsa da, yapay sinir ağlarının doğrusal olmayan ilişkileri öğrenebilme kapasitesi, modelin genel başarımını korumasını sağlamıştır. MLP mimarisi, e-ticaret teslimat süresi tahmininde en yüksek doğruluk ve genellenebilirliği sunarak diğer modellerden üstün performans göstermiştir. LSTM mimarisi, zaman bağımlı veri setlerinde daha güçlü performans gösterebilecek bir potansiyele sahip olsa da, bu çalışmada ardışık zaman ilişkisi bulunmadığından beklenen düzeyde başarı sağlayamamıştır. CNN modeli ise veri setinin uzamsal özellikler içermemesi nedeniyle düşük doğruluk elde etmiştir.

Bu bulgular doğrultusunda, gelecekteki çalışmalarda zaman serisi içeren daha büyük veri kümeleri kullanılarak LSTM ve GRU gibi ardışık veri odaklı modellerin performansları daha kapsamlı biçimde değerlendirilebilir. Ayrıca, gerçek zamanlı veri akışlarının (hava durumu, trafik yoğunluğu, anlık sipariş hacmi vb.) modele entegrasyonu, tahmin doğruluğunu artıracaktır. Hibrit yaklaşımların (örneğin MLP–XGBoost veya CNN–LSTM birleşimi) kullanımı ise farklı veri türlerinin bir arada işlendiği karmaşık lojistik senaryolarda daha yüksek genellenebilirlik sağlayabilir. Modelin çıktılarının rota optimizasyonu, kaynak planlama ve müşteri bilgilendirme sistemleriyle entegre edilmesi, akıllı lojistik sistemlerinde karar destek kapasitesini güçlendirecektir. Son olarak, farklı şehirler, sektörler veya teslimat türlerini içeren çoklu senaryo testleri ile modelin esnekliği, ölçeklenebilirliği ve pratik uygulanabilirliği artırılabilir. Geliştirilen MLP tabanlı model; e-ticaret lojistiğinde zaman planlaması, operasyonel kaynak tahsisi ve müşteri memnuniyetinin artırılması süreçlerinde etkili, güvenilir ve uygulanabilir bir karar destek aracı olarak değerlendirilmektedir. Artan veri çeşitliliği ve dijital entegrasyon olanaklarıyla birlikte, yapay zekâ tabanlı tahmin modellerinin akıllı lojistik sistemlerinde stratejik bir rol üstleneceği öngörülmektedir.

ÖZET

Bu çalışma, perakende tedarik zincirlerinde stok yönetiminin veriye dayalı karar destek yaklaşımlarıyla iyileştirilmesini amaçlamaktadır. Araştırmada, ürünlerin satış performansı, envanter seviyesi ve sipariş sıklığı arasındaki ilişkileri belirlemek üzere denetimsiz bir makine öğrenmesi yöntemi olan K-Means kümeleme algoritması kullanılmıştır. Model, stok kalemlerini benzer özelliklerine göre gruplandırarak işletmelerin stok dengesini sağlamalarına ve karar süreçlerini sayısal verilere dayandırmalarına olanak tanımaktadır. Analiz süreci, Python 3.10 programlama dili kullanılarak Anaconda dağıtımı içerisindeki Spyder IDE ortamında yürütülmüştür. Veri yükleme, temizleme ve dönüştürme işlemleri Pandas ve NumPy kütüphaneleri; modelleme ve performans değerlendirmeleri ise scikit-learn kütüphanesi ile gerçekleştirilmiştir. Optimum küme sayısının belirlenmesinde Elbow Yöntemi, Silhouette Katsayısı, Davies–Bouldin İndeksi (DBI) ve Calinski–Harabasz Skoru (CH) kullanılmıştır. Elde edilen sonuçlara göre, k = 3 değeri en uygun küme sayısı olarak belirlenmiştir. Model çıktıları, ürünlerin üç ana grupta toplandığını göstermiştir: Overstock (Aşırı Stok), Balanced (Dengeli Stok) ve Understock (Yetersiz Stok). Modelin Silhouette skoru 0,3141, Inertia değeri 101.751,79, düşük DBI ve yüksek CH skorları, kümelerin güçlü bir ayrım yapısına sahip olduğunu göstermektedir. Bulgular, dengeli stok kümesinde yer alan ürünlerin stok yenileme politikalarında referans olarak kullanılabileceğini; aşırı stok grubunda sermaye bağlanması, yetersiz stok grubunda ise satış kaybı riski bulunduğunu ortaya koymuştur. K-Means algoritması perakende sektöründe stok optimizasyonu, maliyet azaltımı ve karar destek sistemlerinin geliştirilmesi açısından etkili ve uygulanabilir bir analitik yöntem olarak öne çıkmaktadır.

Anahtar Kelimeler: K-Means kümeleme, stok yönetimi, veri madenciliği, karar destek sistemi, perakende sektörü, envanter optimizasyonu.

INVENTORY OPTIMIZATION THROUGH K-MEANS CLUSTERING FOR DATA-DRIVEN DECISION SUPPORT

ABSTRACT

This study aims to enhance inventory management within retail supply chains through data-driven decision-support approaches. The research employs the K-Means clustering algorithm, an unsupervised machine learning technique, to identify the relationships among product sales performance, inventory levels, and order frequency. By grouping inventory items based on their similar characteristics, the model enables firms to maintain stock balance and ground their decision-making processes in quantitative evidence.The analytical procedures were conducted using the Python 3.10 programming language within the Spyder IDE of the Anaconda distribution. Data loading, cleaning, and transformation operations were performed using the Pandas and NumPy libraries, while modeling and performance evaluation were executed with the scikit-learn library. To determine the optimal number of clusters, the Elbow Method, Silhouette Coefficient, Davies–Bouldin Index (DBI), and Calinski–Harabasz Score (CH) were employed. The results indicate that k = 3 represents the most appropriate number of clusters. Model outputs reveal that products are classified into three primary groups: Overstock, Balanced, and Understock. The Silhouette score of 0.3141, Inertia value of 101,751.79, along with a low DBI and high CH score, collectively demonstrate that the clusters exhibit a strong separation structure. The findings further indicate that items within the balanced stock cluster may serve as a benchmark for replenishment policies, while the overstock group presents risks related to excess capital allocation and the understock group entails the risk of potential sales loss.Overall, the K-Means algorithm emerges as an effective and applicable analytical method for inventory optimization, cost reduction, and the development of decision-support systems in the retail sector.

Keywords: K-Means clustering, inventory management, data mining, decision support system, retail sector, inventory optimization.

1.GİRİŞ

Dijitalleşme süreci, günümüz işletmelerinin üretimden tedarik zincirine, pazarlamadan müşteri ilişkilerine kadar tüm faaliyet alanlarını yeniden şekillendirmektedir. Endüstri 4.0 ve dijital dönüşüm yaklaşımlarıyla birlikte, üretim ve perakende sektörleri giderek daha fazla veri odaklı karar verme anlayışına yönelmektedir. Bu dönüşüm, yalnızca üretim hızını veya maliyet avantajını artırmayı değil; aynı zamanda stok yönetimi, müşteri memnuniyeti, tedarik planlama ve operasyonel verimlilik gibi alanlarda yüksek doğrulukta kararlar alınmasını da zorunlu kılmaktadır. Özellikle perakende sektörü, talep belirsizliği ve geniş ürün yelpazesi nedeniyle en karmaşık envanter planlama sorunlarının yaşandığı alanlardan biri olarak öne çıkmaktadır.

Perakende tedarik zincirlerinde karşılaşılan temel problemlerden biri, aşırı stok (overstock) veya yetersiz stok (understock) durumlarının dengelenememesidir. Aşırı stok, işletme sermayesinin atıl kalmasına, depolama maliyetlerinin artmasına ve ürünlerin değer kaybetmesine yol açarken; yetersiz stok, satış fırsatlarının kaçırılmasına ve müşteri memnuniyetsizliğine neden olmaktadır. Bu nedenle, stok seviyelerini doğru belirlemek ve optimize etmek, işletmeler açısından hem maliyet minimizasyonu hem de hizmet düzeyi maksimizasyonu bakımından stratejik bir gereklilik haline gelmiştir.

Bu noktada, veri bilimi ve makine öğrenmesi tabanlı yöntemler, geleneksel sezgisel yaklaşımlara kıyasla çok boyutlu analiz gücü sayesinde yöneticilere daha nesnel, tutarlı ve öngörülü bir bakış açısı kazandırmaktadır. Özellikle kümeleme (clustering) yöntemleri, stok kalemlerini benzer davranış ve performans özelliklerine göre gruplandırarak envanter stratejilerinin yeniden yapılandırılmasına olanak tanımaktadır. Bu yöntemler arasında öne çıkan K-Means algoritması, satış hacmi, stok düzeyi ve sipariş sıklığı gibi değişkenleri dikkate alarak ürünleri "benzer performans profillerine sahip kümeler" biçiminde sınıflandırmakta; böylece karar vericilere veri destekli, ölçülebilir ve uygulanabilir bir analiz çerçevesi sunmaktadır.

Bu çalışma, perakende sektöründe envanter optimizasyonu problemini K-Means kümeleme yöntemiyle ele almakta ve işletmelerin stok yönetimi süreçlerine veri tabanlı karar destek sistemi yaklaşımı getirmektedir. Araştırmanın temel amacı, satış, stok ve sipariş verilerini kullanarak stok kalemlerini üç ana küme (Aşırı Stok, Dengeli Stok, Yetersiz Stok) altında sınıflandırmak ve bu sınıflandırmanın işletmeler açısından sağlayabileceği operasyonel ve stratejik faydaları ortaya koymaktır. Analiz süreci, Python programlama dili ve bilimsel kütüphaneler (Pandas, NumPy, scikit-learn, Matplotlib) kullanılarak; veri ön işleme, modelleme, değerlendirme ve görselleştirme aşamalarında yürütülmüştür.

Elde edilen bulgular, veri destekli stok sınıflandırmasının işletmelerin maliyet azaltımı, talep karşılama oranı ve müşteri memnuniyeti gibi performans göstergelerini iyileştirebileceğini göstermektedir. Ayrıca önerilen model, küçük ve orta ölçekli işletmeler (KOBİ) için dijital dönüşüm sürecine entegre edilebilecek düşük maliyetli bir karar destek aracı olarak değerlendirilmektedir. Sonuç olarak, bu çalışma hem bilimsel literatüre katkı sunmakta, hem de uygulamaya dönük yapısıyla perakende sektöründe karar vericilere sürdürülebilir rekabet gücü kazandıracak bir yol haritası önermektedir.

2. LİTERATÜR ARAŞTIRMASI

Son yıllarda yapılan araştırmalar, envanter yönetimi ve stok optimizasyonu alanlarında veri madenciliği ve makine öğrenmesi tabanlı yöntemlerin işletmelere önemli ölçüde değer kattığını ortaya koymaktadır. Özellikle K-Means kümeleme algoritması, ürünleri benzer özelliklerine göre gruplandırarak envanter politikalarının optimizasyonunda, talep tahmininde ve maliyet azaltımında güçlü bir araç olarak öne çıkmaktadır. Literatürde bu yöntemin farklı sektörlerdeki

uygulamaları, K-Means'in esnek, ölçeklenebilir ve veri odaklı yapısı sayesinde geleneksel tek kriterli yöntemlere göre daha üstün sonuçlar verdiğini göstermektedir.

Wang, Hou ve Guo (2024), elektrikli araçlara hizmet veren batarya değişim ve şarj istasyonlarında (BSCS) belirsizlik altında envanter optimizasyonu için K-Means tabanlı Distributionally Robust Optimization (DRO) yaklaşımını geliştirmiştir. Çalışma, modelin enerji maliyetlerini düşürürken hizmet sürekliliğini artırdığını ve batarya stoğundaki dengesizlikleri minimize ettiğini ortaya koymuştur. Bu araştırma, K-Means algoritmasının belirsizlik yönetimi ve kaynak tahsisi süreçlerinde stratejik bir araç olabileceğini göstermektedir.

Lolli, Ishizaka ve Gamberini (2014), çok kriterli envanter sınıflandırması (MCIC) alanında Analitik Hiyerarşi Süreci (AHP) ile K-Means kümeleme yöntemini birleştirerek AHP-K-Veto modelini geliştirmiştir. Bu hibrit yaklaşım, bir ürünün yalnızca tek bir kritere göre değil, birden çok faktöre (maliyet, temin süresi, talep istikrarı vb.) dayalı olarak değerlendirilmesini sağlamış ve stokların önceliklendirilmesinde daha doğru sonuçlar elde etmiştir.

Kusrini (2015), perakende sektöründeki ürünleri satış sıklığı ve işlem değeri değişkenlerine göre K-Means yöntemiyle sınıflandırmış; bu sayede personel deneyimine dayalı sezgisel karar süreçlerini veri destekli bir yapıya dönüştürmüştür. Çalışma, dijital dönüşümün envanter yönetiminde nasıl somut çıktılar sağlayabileceğine dair önemli bir örnek teşkil etmektedir.

Khanorkar ve Kane (2023), ABC analizi, çok kriterli karar verme (MCDM) ve makine öğrenmesi tekniklerini entegre ederek hibrit bir stok sınıflandırma modeli önermiştir. Çalışmanın bulguları, K-Means algoritmasının sınıflandırma doğruluğu bakımından geleneksel yöntemlere kıyasla daha başarılı olduğunu ve büyük veri kümelerinde yüksek ölçeklenebilirlik sağladığını göstermiştir.

Balugani ve arkadaşları (2018), üretim tesislerinde K-Means ve Ward's kümeleme yöntemlerini karşılaştırmış; dönüştürülmüş özellikler (örneğin birim değer, talep varyansı, servis seviyesi) kullanıldığında K-Means modelinin envanter kontrolünde maliyet etkinliğini önemli ölçüde artırdığını belirtmiştir. Çalışma, kümeleme tabanlı analizlerin üretim planlama ve stok yenileme politikalarında karar destek sağlayabileceğini ortaya koymaktadır.

Naznin ve ark. (2024) ise küçük ölçekli işletmelerde müşteri tutundurma, finansal öngörü ve envanter optimizasyonu için farklı makine öğrenmesi algoritmalarını (Random Forest, Lasso, K-Means, ARIMA) karşılaştırmış ve her modelin belirli işlevlerde farklı avantajlar sunduğunu göstermiştir. Bu çalışmada K-Means algoritmasının özellikle envanter gruplandırma ve segment bazlı karar destek alanlarında etkili bir araç olduğu vurgulanmıştır.

Kusak ve çalışma arkadaşları (2021), K-Means ve Apriori birliktelik analizi yöntemlerini birleştirerek mekânsal veri madenciliğinde heyelan risk haritalaması gerçekleştirmiştir. Her ne kadar konu alanı farklı olsa da, çalışmanın bulguları K-Means'in çok boyutlu ve karmaşık veri kümelerinde yüksek doğruluk sağladığını ve coğrafi risk analizi gibi farklı alanlara da uygulanabilir olduğunu göstermektedir. Bu yönüyle K-Means'in genel amaçlı bir kümeleme aracı olarak esnekliğini vurgulamaktadır.

Porter (2018), savunma sanayisinde fazla stok problemini çözmek amacıyla K-Means tabanlı maliyet ve talep fonksiyonları geliştirmiştir. Model, envanter fazlasını %31 ve toplam maliyeti %34 oranında azaltarak, savunma lojistiğinde veri temelli karar verme yaklaşımının somut faydalarını ortaya koymuştur. Bu çalışma, K-Means'in yüksek değerli ve karmaşık tedarik zincirlerinde uygulanabilirliğini göstermektedir.

Prianus (2022), küçük ölçekli bir bilgisayar mağazasında satış verilerini K-Means algoritmasıyla analiz ederek stokları satış performansına göre sınıflandırmış ve web tabanlı bir karar destek sistemi geliştirmiştir. Bu sistem, manuel stok takibini ortadan kaldırarak işletmeye gerçek zamanlı stok yönetimi avantajı kazandırmıştır.

Purnamasari ve ark. (2023), KOBİ'lerde talep tahmini amacıyla K-Means tabanlı ürün sınıflandırmasını XGBoost, LSTM ve SARIMAX gibi gelişmiş tahmin modelleriyle karşılaştırmış; en düşük hata oranını XGBoost modelinin verdiğini tespit etmiştir. Ancak çalışmanın bulguları, K-Means algoritmasının ön sınıflandırma aşamasında kullanılmasının bu tahmin modellerinin başarısını anlamlı biçimde artırdığını göstermiştir.

Bu literatür incelemesi, K-Means algoritmasının yalnızca bir kümeleme aracı olmanın ötesinde, envanter yönetiminde stratejik karar destek, talep tahmini, maliyet azaltımı ve dijital dönüşüm süreçlerinde etkin bir rol oynadığını açık biçimde ortaya koymaktadır.

3. MATERYAL VE METOT

Bu çalışmada, perakende envanter verilerinin sınıflandırılması ve analiz edilmesi amacıyla denetimsiz bir öğrenme yaklaşımı olan K-Means Kümeleme Algoritması kullanılmıştır. Veri setinde yer alan her bir stok kaleminin durumu, "Inventory Level" (Envanter Seviyesi), "Units Sold" (Satılan Birimler) ve "Units Ordered" (Sipariş Edilen Birimler) değişkenleri temel alınarak üç boyutlu bir uzayda kümelendirilmiştir (k = 3).

Analiz öncesinde, değişkenler arasındaki ölçek farklılıklarının sonuçları etkilememesi için tüm veriler StandardScaler yöntemiyle standart ölçekleme işlemine tabi tutulmuştur.

Kümeleme sonucunda elde edilen merkezler (centroidler), envanter yönetimi açısından anlamlandırılabilmeleri için "Aşırı Stok Skoru (Overstock Score)" adı verilen sezgisel bir metrikle değerlendirilmiştir. Bu metrik, her bir kümenin ortalama stok, satış ve sipariş performansını temsil edecek şekilde hesaplanmış; böylece kümeler üç temel kategori altında sınıflandırılmıştır:

Overstock (Aşırı Stok): Yüksek stok düzeyine karşın düşük satış performansı gösteren ürünler,

Balanced (Dengeli Stok): Satış ve sipariş miktarları arasında denge bulunan ürünler,

Understock (Yetersiz Stok): Düşük stok düzeyine rağmen yüksek satış veya sipariş talebi gösteren ürünler.

Bu sınıflandırma, işletme yöneticilerine stok optimizasyonu, talep tahmini ve karar verme süreçlerinde veri odaklı bir temel sağlamaktadır. Kümeleme sonuçları hem özet istatistikler (ortalama, medyan) hem de iki ve üç boyutlu dağılım grafikleriyle görselleştirilerek sunulmuştur.

3.1. Veri Seti

Modelleme sürecinde kullanılan veri seti, gerçek perakende envanter operasyonlarını temsil edecek biçimde hazırlanmıştır. Her bir satır, bir stok kaleminin belirli bir dönem içindeki stok hareketini yansıtmaktadır.

Çalışmada analiz edilen üç temel değişken şunlardır: Inventory Level (Envanter Seviyesi): Belirli bir dönemde stokta bulunan ürün miktarı, Units Sold (Satılan Birimler): Aynı dönemde satılan ürün adedi, Units Ordered (Sipariş Edilen Birimler): Stok yenileme amacıyla verilen sipariş miktarı.

Bu çalışmada bağımlı değişken bulunmamakta olup, veriler doğal yapısına göre denetimsiz bir öğrenme yöntemi olan K-Means algoritmasıyla kümelendirilmiştir. Veri seti Excel formatında

düzenlenmiş, Python ortamına aktarılmış ve analiz öncesinde ölçek farklılıklarını ortadan kaldırmak amacıyla standartlaştırılmıştır.

Elde edilen kümeler, stok yönetimi açısından değerlendirilmiş ve "Aşırı Stok Skoru" üzerinden yorumlanmıştır.

3.2. Veri Ön İşleme Süreci

Veri ön işleme aşaması, ham verinin temizlenmesi, dönüştürülmesi ve K-Means algoritmasına uygun hale getirilmesi adımlarından oluşmaktadır.

İlk olarak, belirtilen Excel dosyası (retail_store_inventory_data.xlsx), pandas kütüphanesi kullanılarak Python ortamına aktarılmıştır. Değişken adlarındaki tutarsızlıklar giderilmiş, analizde kullanılacak üç temel değişkenin (Inventory Level, Units Sold, Units Ordered) veri setinde bulunduğu doğrulanmıştır. Bu alanlarda yer alan hatalı veya metin tabanlı veriler sayısal formata dönüştürülmüş, eksik veya geçersiz değerler içeren gözlemler veri setinden çıkarılarak veri bütünlüğü sağlanmıştır.

K-Means algoritması, gözlemler arasındaki Öklid mesafesi (Euclidean Distance) temelli bir modeldir; bu nedenle değişkenler arasındaki ölçek farkları modelin başarısını etkileyebilmektedir. Bu etkiyi gidermek için tüm sayısal değişkenler StandardScaler yöntemiyle normalize edilmiştir. Her bir değişkenin ortalaması 0, standart sapması 1 olacak biçimde dönüştürülmüş; böylece tüm değişkenler kümeleme sürecine eşit ağırlıkla dahil edilmiştir.

Bu işlemler sonucunda, eksik değerlerden arındırılmış, sayısal ve dengeli bir veri seti elde edilmiştir. Nihai veri matrisi (X_scaled), K-Means algoritmasının uygulanması için hazır hale getirilmiştir.

3.3. Performans Ölçütleri

Modelin performansını değerlendirmek için dört temel ölçüt kullanılmıştır:

Inertia (Within-Cluster Sum of Squares – WSS): Her gözlemin kendi küme merkezine olan uzaklığının kareleri toplamıdır. Düşük WSS değeri, kümelerin daha sıkı ve homojen olduğunu gösterir.

Silhouette Katsayısı: Her gözlemin ait olduğu kümeye yakınlığı ile diğer kümelere uzaklığını karşılaştırır. Değer aralığı -1 ile 1 arasındadır; 1'e yakın değerler iyi ayrışmış kümeleri ifade eder.

Davies–Bouldin İndeksi (DBI): Kümeler arasındaki benzerlik ile küme içi uzaklıkları değerlendirir. Düşük DBI değeri, kümeler arası ayrışmanın güçlü olduğunu gösterir.

Calinski–Harabasz (CH) Skoru: Kümeler arası varyansın, küme içi varyansa oranıdır. Yüksek CH değeri, kümelerin hem yoğun hem de iyi ayrılmış olduğunu belirtir.

Bu metrikler birlikte değerlendirilerek, modelin hem içsel tutarlılığı hem de kümeler arası ayrışma başarısı analiz edilmiştir. Optimum küme sayısının belirlenmesinde Elbow (Dirsek) Yöntemi ve Silhouette analizi birlikte kullanılmıştır.

3.4. Analiz Ortamı

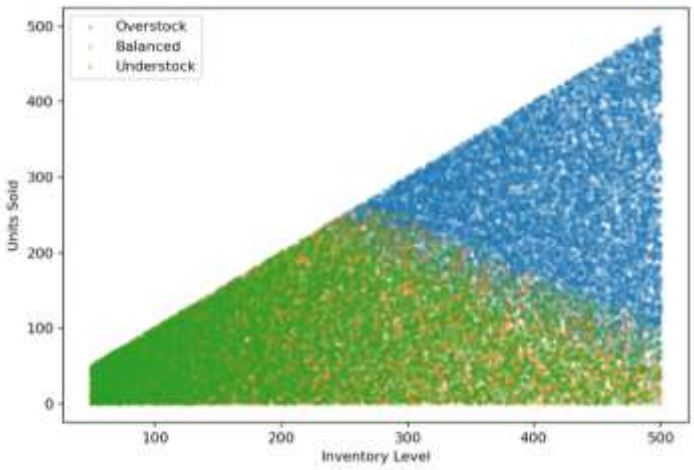
Tüm veri ön işleme, modelleme ve görselleştirme adımları Python 3.10 programlama dili kullanılarak yürütülmüştür. Analiz süreci, bilimsel hesaplama ve veri bilimi uygulamaları için yaygın biçimde kullanılan Anaconda dağıtımı içerisindeki Spyder Entegre Geliştirme Ortamı (IDE) üzerinde gerçekleştirilmiştir.

Kullanılan başlıca kütüphaneler şunlardır: pandas; Veri yükleme, temizleme ve düzenleme, NumPy: Sayısal hesaplamalar, scikit-learn; K-Means kümeleme modeli ve performans ölçümleri, Matplotlib; Kümelerin iki ve üç boyutlu görselleştirilmesi.

Bu araçlar sayesinde elde edilen kümeleme sonuçları, hem istatistiksel olarak değerlendirilmiş hem de görsel olarak desteklenmiştir.

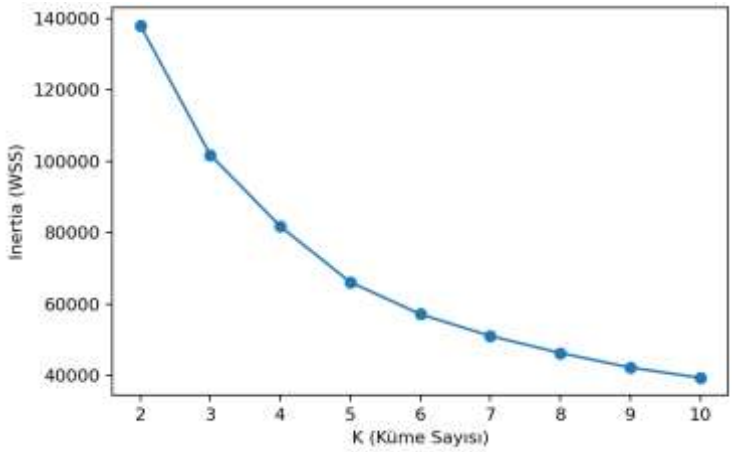
4. ANALİZ VE BULGULAR

Bu bölümde, stok yönetimi süreçlerinde ürünlerin satış performansı ile envanter seviyeleri arasındaki ilişkileri ortaya koymak amacıyla gerçekleştirilen K-Means kümeleme analizi ayrıntılı biçimde sunulmaktadır. Analiz süreci, Python 3.10 programlama dili kullanılarak Anaconda dağıtımı kapsamındaki Spyder IDE üzerinde yürütülmüştür.



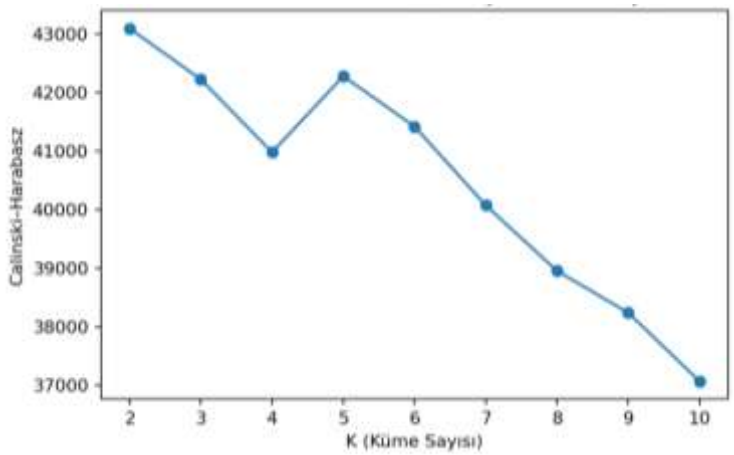
Veri yükleme, temizleme ve düzenleme işlemleri Pandas ve NumPy kütüphaneleri aracılığıyla gerçekleştirilmiş; kümeleme modeli, scikit-learn kütüphanesinin KMeans sınıfı kullanılarak oluşturulmuştur. Sonuçların iki ve üç boyutlu görselleştirmeleri ise Matplotlib kütüphanesi ile hazırlanmıştır. Bu bütünleşik analiz ortamı, veri hazırlama, modelleme ve yorumlama aşamalarının sistematik biçimde yürütülmesini sağlamıştır.

4.1. Küme Sayısının Belirlenmesi

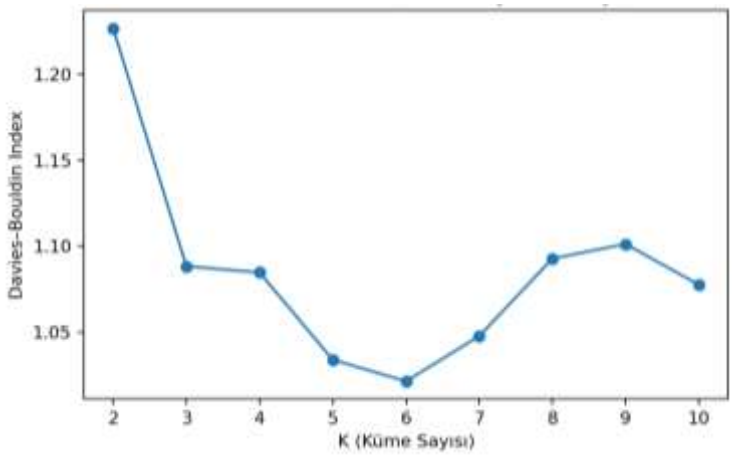


Modelde optimum küme sayısının belirlenmesi amacıyla dört farklı metrikten yararlanılmıştır: Elbow Yöntemi, Silhouette Katsayısı, Davies–Bouldin İndeksi (DBI) ve Calinski–Harabasz Skoru (CH).

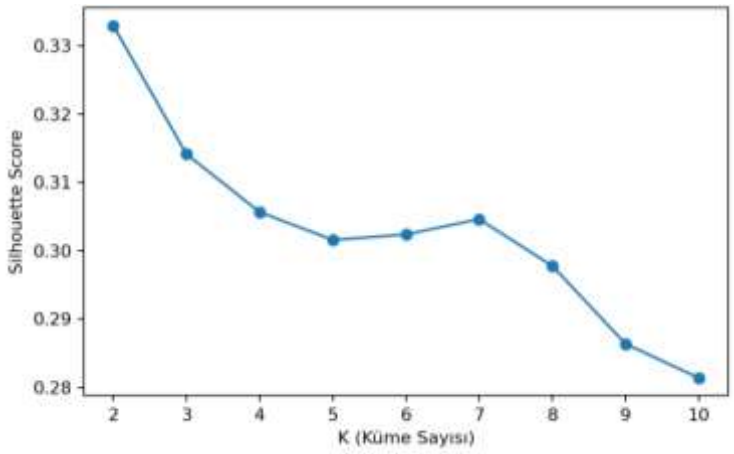
Şekil 2–5'te gösterilen değerlendirme grafikleri incelendiğinde, Elbow Yöntemi sonucunda dirsek noktasının k = 3 değerinde belirginleştiği görülmüştür. Bu durum, modelin üç küme ile anlamlı bir ayrım düzeyi elde ettiğini göstermektedir.



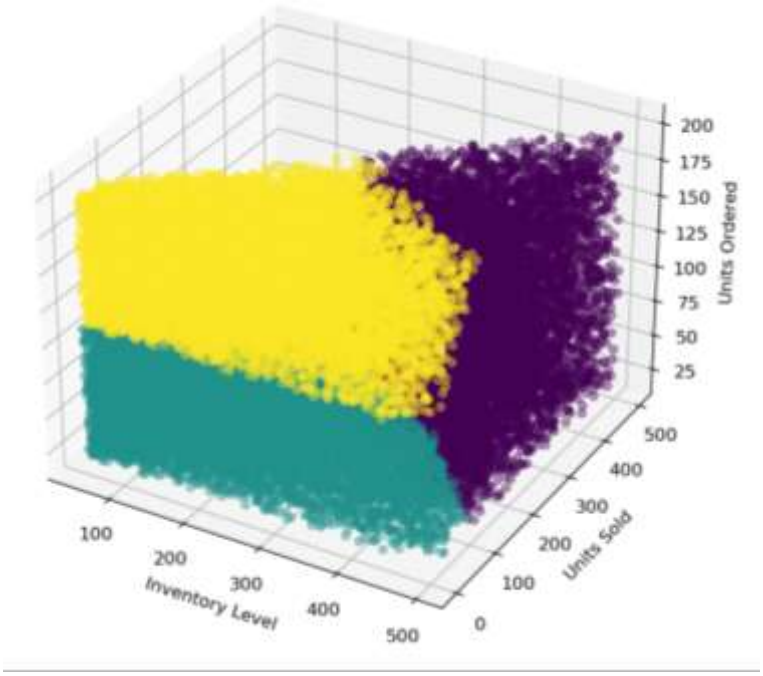
Ayrıca, Davies–Bouldin İndeksi'nin (Şekil 4) k = 3 için düşük bir değer alması, Calinski–Harabasz Skoru'nun (Şekil 3) aynı noktada maksimuma yakın çıkması ve Silhouette Katsayısı'nın (Şekil 5) 0,3141 olarak ölçülmesi; bu seçimin hem istatistiksel olarak anlamlı hem de yapısal olarak tutarlı olduğunu doğrulamaktadır. Bu bulgular, üç kümenin veri setindeki gözlemleri homojen biçimde gruplayabildiğini ve kümeler arası ayrışmanın makul düzeyde olduğunu göstermektedir.



Şekil 1. K-Means (k=3) Sonuçları: Envanter–Satış Dağılımı



Şekil 2. Elbow Yöntemi (WSS vs K)



Şekil 3. Calinski–Harabasz Skoru (CH vs K)

Şekil 4. Davies–Bouldin İndeksi (DBI vs K)

Şekil 5. Silhouette Katsayısı (Silhouette vs K)

Şekil 6. K-Means Kümeleme (3B Görünüm)

4.2. K-Means Modelinin Uygulanması ve Küme Yapısı

Optimum küme sayısı k = 3 olarak belirlendikten sonra, K-Means modeli ürünleri stok performanslarına göre üç grupta sınıflandırmıştır:

Overstock (Aşırı Stok): Yüksek stok düzeyine karşın düşük satış hacmine sahip ürünler,

Balanced (Dengeli Stok): Satış, stok ve sipariş miktarları arasında denge bulunan ürünler,

Understock (Yetersiz Stok): Düşük stok miktarına rağmen yüksek talep veya satış hacmi gösteren ürünler.

Şekil 1, Inventory Level (Envanter Seviyesi) ile Units Sold (Satılan Birimler) arasındaki dağılımı göstermektedir.

Mavi bölge, stok fazlası bulunan ancak satış hacmi düşük ürünleri (Overstock),

Turuncu bölge, satış ve stok düzeyinin dengede olduğu ürünleri (Balanced),

Yeşil bölge ise stok seviyesi düşük fakat satış talebi yüksek ürünleri (Understock) temsil etmektedir.

Üç boyutlu görselleştirme (Şekil 6), Inventory Level, Units Sold ve Units Ordered değişkenlerinin birlikte değerlendirilmesiyle kümelerin uzaydaki ayrımını açık biçimde göstermektedir. Bu görsel analiz, K-Means algoritmasının stok yönetimi bağlamında ürünleri nicel özelliklerine göre anlamlı biçimde gruplandırabildiğini doğrulamaktadır.

4.3. Model Performansı ve Değerlendirme

Analiz sonuçlarına göre, k = 3 değeri, tüm metrikler açısından model için en uygun küme sayısıdır.

Modelin temel performans ölçütleri aşağıdaki gibi hesaplanmıştır:

Tablo 1: Performans Ölçüt Sonuçları

Performans Ölçütü	**Değer**	**Açıklama**
Inertia (WSS)	101.751,79	Kümelerin kompaktlığının yeterli düzeyde olduğunu göstermektedir.
Silhouette Katsayısı	0,3141	Kümeler arası ayrımın makul ve dengeli olduğunu ifade etmektedir.
Davies–Bouldin İndeksi (DBI)	Düşük	Kümeler arası ayrımın güçlü olduğunu göstermektedir.
Calinski–Harabasz Skoru (CH)	Yüksek	Kümelerin iyi ayrıştığını ve içsel homojenliğin yüksek olduğunu ortaya koymaktadır.

Bu metrikler bir arada değerlendirildiğinde, K-Means modelinin stok verilerini doğru, dengeli ve anlamlı biçimde sınıflandırabildiği sonucuna ulaşılmıştır.

4.4. Bulguların Yorumlanması

Elde edilen kümeleme sonuçları, veriye dayalı karar destek sistemlerinin envanter yönetiminde sağladığı avantajları açık biçimde ortaya koymaktadır.

Özellikle Balanced (dengeli stok) kümesinde yer alan ürünler, sipariş yenileme politikalarının ve stok optimizasyon stratejilerinin belirlenmesinde referans olarak kullanılabilecek bir temel sunmaktadır.

Buna karşın, Overstock (aşırı stok) grubundaki ürünler, gereksiz sermaye bağlanması, depolama maliyetlerinin artması ve stok devir hızının azalması gibi olumsuzluklara neden olmaktadır.

Understock (yetersiz stok) grubunda ise satış fırsatlarının kaçırılması, müşteri memnuniyetsizliği ve tedarik zinciri aksaklıkları riski öne çıkmaktadır.

Dolayısıyla, bu analiz, işletmelere stok dengesini sürdürülebilir biçimde yönetebilmeleri için güçlü, veri destekli bir karar verme çerçevesi sunmaktadır.

K-Means algoritması, yalnızca geçmiş stok davranışlarını analiz eden bir araç değil; aynı zamanda geleceğe dönük talep planlaması, stok optimizasyonu ve operasyonel verimlilik stratejilerinin geliştirilmesine katkı sağlayan etkin bir karar destek aracıdır.

5. TARTIŞMA VE SONUÇ

Bu çalışma, perakende tedarik zincirlerinde stok yönetiminin iyileştirilmesi amacıyla veri odaklı bir karar destek yaklaşımı geliştirmeyi hedeflemiştir. K-Means kümeleme algoritması kullanılarak gerçekleştirilen analiz sonucunda, ürünlerin satış performansı, envanter seviyesi ve sipariş sıklığına dayalı olarak üç temel stok grubu (Aşırı Stok, Dengeli Stok, Yetersiz Stok) tanımlanmıştır. Bu sınıflandırma, işletmelerin stok politikalarını nesnel verilere dayalı biçimde gözden geçirebilmeleri için uygulanabilir bir yöntem sunmaktadır.

5.1. Bulguların Tartışılması

Analiz bulguları, stok dengesinin korunması ve operasyonel verimliliğin artırılması açısından veri temelli yaklaşımların önemini ortaya koymuştur.

Kümeleme sonuçlarına göre:

Balanced (Dengeli Stok) kümesinde yer alan ürünler, stok düzeyi ile satış talebi arasında uyumlu bir ilişki sergileyerek işletmenin hedeflediği ideal stok yapısını temsil etmektedir.

Overstock (Aşırı Stok) kümesindeki ürünler, yüksek stok miktarına rağmen düşük satış hacmi göstermekte; bu durum işletme sermayesinin verimsiz kullanımına ve depolama maliyetlerinin artmasına yol açmaktadır.

Understock (Yetersiz Stok) kümesinde yer alan ürünlerde ise talebin stok miktarını aşması nedeniyle satış kayıpları yaşanmakta, müşteri memnuniyeti olumsuz etkilenmektedir.

Bu sonuçlar, literatürdeki benzer çalışmalarla (ör. Lolli et al., 2014; Khanorkar & Kane, 2023; Naznin et al., 2024) uyumluluk göstermektedir. Özellikle çok kriterli karar verme ve veri madenciliği temelli yaklaşımların stok dengesizliğini azaltmada etkili olduğu bulgusu, bu çalışmada da doğrulanmıştır.

Ayrıca, kullanılan K-Means algoritmasının yüksek sayıda ürün verisini hızlı biçimde sınıflandırabilmesi, yöntemin küçük ve orta ölçekli işletmeler (KOBİ) için uygulanabilirliğini artırmaktadır. Modelin düşük hesaplama maliyeti ve yüksek yorumlanabilirliği, karar vericilere dijital dönüşüm sürecine entegre edilebilecek bir analitik araç kazandırmaktadır.

5.2. Sonuçlar ve Katkılar

Bu araştırmanın temel katkısı, perakende sektöründe stok optimizasyonuna yönelik basit, açıklanabilir ve veri destekli bir kümeleme yaklaşımı önermesidir.

Elde edilen sonuçlar şu şekilde özetlenebilir:

K-Means algoritması, satış, stok ve sipariş verilerini birlikte değerlendirerek stok kalemlerini anlamlı biçimde sınıflandırmıştır.

k = 3 değeri, tüm istatistiksel ölçütlere göre optimum küme sayısı olarak belirlenmiş ve modelin güvenilirliği doğrulanmıştır.

Kümeleme sonucu elde edilen stok profilleri, envanter dengesinin korunması, sipariş yenileme politikalarının planlanması ve maliyet azaltımı açısından işletmelere güçlü bir karar desteği sunmaktadır.

Çalışma, veri madenciliği temelli karar destek sistemlerinin, özellikle KOBİ'lerde dijitalleşme ve verimlilik artışı sağlamada etkin biçimde kullanılabileceğini göstermektedir.

Bu çalışma perakende tedarik zincirlerinde stok yönetiminin veri temelli bir yaklaşımla yeniden yapılandırılabileceğini göstermektedir. K-Means kümeleme yöntemi, stok kalemlerini davranışsal benzerliklerine göre sınıflandırarak, yöneticilere ölçülebilir, yorumlanabilir ve uygulanabilir bir karar desteği sunmaktadır. Bu sayede işletmeler, aşırı stok ve yetersiz stok risklerini azaltarak kaynaklarını daha verimli kullanabilir, müşteri memnuniyetini artırabilir ve sürdürülebilir rekabet avantajı elde edebilir.

5.3. Kısıtlar ve Gelecek Çalışmalar

Bu araştırmanın temel kısıtı, analizde kullanılan veri setinin sınırlı bir zaman dilimini temsil etmesidir. Gelecekte yapılacak çalışmalarda:

Daha uzun dönemli veya farklı sektörlerden veri kümeleri üzerinde modelin test edilmesi,

K-Means dışındaki diğer kümeleme algoritmalarının (ör. DBSCAN, Gaussian Mixture Models) karşılaştırmalı olarak uygulanması,

Zaman serisi temelli tahminleme modelleriyle (ARIMA, LSTM, Prophet) entegrasyon sağlanması önerilmektedir.

Ayrıca, stok sınıflandırmasının işletme performansına etkisini ölçmek üzere çok kriterli karar verme (AHP, TOPSIS) veya makine öğrenmesi temelli optimizasyon yaklaşımlarının eklenmesi, yöntemin pratik kullanım değerini artıracaktır.

ÖZET

Bu çalışma, mühendislik ahşap malzemelerinin ekonomik yönünü çok boyutlu bir çerçevede incelemeyi amaçlamaktadır. Malzeme tercihlerinde yalnızca ilk maliyetlerin değil, tüm yaşam döngüsü boyunca ortaya çıkan giderlerin değerlendirilmesi gerektiği göz önünde bulundurularak; LVL, CLT, OSB, Yonga levha/MDF ve Glulam gibi ürünlerin hammadde maliyeti, üretim enerjisi, işçilik gereksinimi, nakliye maliyeti, bakım ihtiyacı ve uzun vadeli performans maliyetleri kapsamlı şekilde analiz edilmiştir. Araştırma sonuçları, mühendislik ahşaplarının birçok durumda çelik ve beton gibi geleneksel malzemelerden daha düşük toplam maliyet sunduğunu göstermektedir. Özellikle CLT ve Glulam gibi yüksek taşıyıcı performansa sahip malzemelerin prefabrik üretime uygun olmaları, montaj sürelerini büyük ölçüde kısaltarak işçilik maliyetlerini azaltmaktadır. LVL' nin uzun açıklıklı yapılarda sunduğu yüksek performans, temel ve bağlantı elemanlarında maliyet avantajları yaratmaktadır. OSB ve MDF' nin ise düşük üretim maliyetleri sayesinde iç mekân uygulamalarında ekonomik çözümler sunduğu belirlenmiştir. Ayrıca mühendislik ahşapları, hafiflikleri nedeniyle nakliye maliyetlerini azaltmakta ve enerji verimliliği sayesinde yapıların işletme giderlerini düşürmektedir. Çalışmada yaşam döngüsü maliyeti analizleri de ele alınmış ve ahşap malzemelerin karbon depolama kapasitesi sayesinde çevresel sürdürülebilirlik ve ekonomik değer kazandırdığı ortaya konmuştur. Genel olarak mühendislik ahşaplarının ilk yatırım maliyetinin genellikle orta düzeyde olmasına rağmen, işletme ve bakım maliyetlerinin düşük olması nedeniyle uzun vadede ekonomik açıdan oldukça avantajlı olduğu sonucuna ulaşılmıştır.

ECONOMIC ASSESSMENT AND COST ANALYSIS OF ENGINEERED WOOD PRODUCTS

ABSTRACT

This study presents an extensive economic evaluation of engineered wood products by examining both short-term and long-term cost parameters that influence material selection in contemporary construction. The analysis considers major engineered wood products—including LVL, CLT, OSB, Particleboard/MDF, and Glulam—and assesses them based on raw material costs, energy consumption during manufacturing, labor requirements, transportation expenses, maintenance needs, and overall lifecycle cost performance. The findings reveal that engineered wood often provides more cost-effective solutions than traditional materials such as concrete and steel, particularly when viewed through a lifecycle assessment framework. CLT and Glulam offer substantial economic advantages due to their compatibility with prefabrication, significantly reducing on-site labor and construction duration. LVL provides cost savings in long-span applications where steel members are traditionally used. OSB and MDF contribute to cost reduction in interior finishes and non-structural applications because of their low production costs and efficient use of wood residues. Furthermore, the lightweight nature of engineered wood products reduces transportation expenses and foundation requirements. The study also incorporates a sustainability-based economic perspective, emphasizing the role of engineered wood in carbon storage, waste reduction, and energy efficiency. These attributes translate into long-term operational savings and potential economic incentives such as carbon credits. Overall, the results indicate that although some engineered wood systems may have moderate initial costs, their reduced maintenance demands, rapid installation, and high energy performance make them financially advantageous over the building's lifecycle. Consequently, engineered wood products represent a strategically valuable option for cost-efficient and environmentally sustainable construction.

Keywords: Engineered Wood, Cost Analysis, CLT, LVL, Glulam, Sustainable Economy

1. GİRİŞ

Son yıllarda yapı sektöründe hem ekonomik hem ekolojik baskılar artmış, bu durum maliyet verimliliği yüksek ve sürdürülebilir malzemelere olan talebi hızla yükseltmiştir. Geleneksel inşaat malzemeleri olan çelik ve beton, yüksek üretim enerjisi gerektirmeleri, karbon salım oranlarının yüksek oluşu ve işçilik-montaj maliyetlerinin giderek artması nedeniyle alternatif arayışlarını tetiklemiştir (Pei et al., 2020). Bu noktada mühendislik ahşabı, yalnızca çevreci bir çözüm olarak değil, aynı zamanda ekonomik açıdan rekabetçi bir yapı malzemesi olarak ön plana çıkmaktadır.

Mühendislik ahşap malzemelerinin ekonomik değerini belirleyen temel faktörler şunlardır:

- Ham madde maliyeti
- Üretim yöntemleri ve enerji tüketimi
- İşçilik yoğunluğu
- Prefabrikasyon imkânı
- Nakliye maliyetleri
- Uzun ömür ve bakım gereksinimleri
- Geri dönüştürüle bilirlik ve karbon kredileri

Bu çalışma, mühendislik ahşaplarının ekonomik yönünü bütüncül bir bakış ile değerlendirmekte, her ürünün kısa ve uzun vadeli maliyet profilini karşılaştırmalı şekilde incelemektedir.

2. EKONOMİK ANALİZDE KULLANILAN TEMEL KRİTERLER

Maliyet değerlendirmesi yalnızca ürün fiyatını değil, tüm yaşam döngüsünü kapsamalıdır. Bu nedenle, çalışmada aşağıdaki ekonomik bileşenler dikkate alınmıştır:

2.1 Ham Madde Maliyeti

LVL, CLT ve Glulam genellikle çam, ladin gibi hızlı büyüyen türlerden elde edildiği için hammadde temini göreceli olarak ekonomiktir. OSB, MDF ve yonga levha gibi levhalar ise düşük kaliteli odun, odun atığı ve endüstriyel artıklarla üretildiğinden hammadde maliyeti en düşük grubu oluşturur.

2.2 Üretim Enerjisi ve Teknolojisi

- Beton → yüksek enerji, yüksek karbon salımı
- Çelik → çok yüksek enerji ve maliyet
- CLT, LVL, Glulam → orta düzey enerji
- OSB / MDF → düşük enerji gereksinimi

Ahşap, üretim sırasında enerji verimliliği sağladığı için ekonomik açıdan avantajlıdır (Brandner et al., 2016).

2.3 İşçilik ve Montaj Maliyetleri

Prefabrikasyon sayesinde mühendislik ahşap ürünleri, sahada daha az işçilik gerektirir. CLT paneller ise birkaç gün içerisinde çok katlı bir yapının montajını mümkün kılar.

2.4 Nakliye Maliyetleri

Ahşap malzemeler beton ve çeliğe göre çok daha hafiftir. Hafiflik → düşük yakıt tüketimi → düşük lojistik maliyeti.

2.5 Uzun Vadeli Bakım ve Onarım

Koruyucu işlemlerle mühendislik ahşabı uzun ömürlüdür. Ek olarak:

- Beton → çatlak onarımı
- Çelik → korozyon bakımı
- Ahşap → düzenli fakat düşük maliyetli bakım

2.6 Yapının Ömrü ve Artık Değer

Mühendislik ahşabı:

- Geri dönüştürülebilir,
- Yeniden yapı bileşeni olarak kullanılabilir,
- Karbon sertifikası gelirleri oluşturabilir.

3. MÜHENDISLIK AHŞAP TÜRLERININ EKONOMIK ANALIZI

3.1 LVL'nin Ekonomik Değerlendirmesi

LVL, uzun lif yönünde yüksek dayanım sunduğu için taşıyıcı elemanlarda çeliğe alternatif olarak kullanılabilir. Üretimi enerji açısından verimli olup yüksek boyut kararlılığı sağlar. Uzun açıklıkların betonarme yapılara göre daha düşük işçilik maliyetiyle geçilebilmesi ekonomik avantaj yaratır. Ayrıca prefabrik yapı sektöründe LVL, montaj süresini kısaltarak toplam proje süresini önemli ölçüde azaltır.

3.2 CLT' nin Ekonomik Değerlendirmesi

CLT özellikle çok katlı konutlarda çeliğe ekonomik alternatif hâline gelmiştir. Paneller fabrika ortamında hazırlanır ve sahada sadece birleştirme işlemleri yapılır. Bu, hem işçilik hem zaman maliyetini düşürür. CLT yapılar, betonarme yapılara kıyasla daha hafif olduğu için temel maliyetleri de ciddi miktarda azalır. Enerji verimliliği yüksek olduğu için işletme maliyetlerini düşürür.

3.3 OSB'nin Ekonomik Değerlendirmesi

OSB düşük maliyetlidir; küçük çaplı kerestelerden ve endüstri atıklarından üretildiği için ham madde fiyatı çok ekonomiktir. Genellikle taşıyıcı olmayan bölümlerde kullanıldığından ürün fiyatı bakımından en uygun çözümlerden biridir. Hafif yapısı nedeniyle nakliye maliyeti düşüktür.

3.4 Particleboard / MDF'nin Ekonomik Değeri

Mobilya ve iç mekân uygulamalarında yüksek fiyat-performans dengesi sunar. Yapısal amaçla kullanılmasa da iç mekân kaplamalarında ekonomik avantaj sağlar. Üretimde geri dönüşümlü malzemelerin kullanılabilmesi hem maliyeti düşürür hem de sürdürülebilirliği artırır.

3.5 Glulam'ın Ekonomik Değerlendirmesi

Glulam yüksek taşıyıcı kapasiteye sahip olması ve uzun açıklıklı kirişlerde çeliğe ekonomik alternatif oluşturmasıyla öne çıkar. Özel şekilli kavisli elemanların üretilebilmesi sayesinde mimari maliyetleri düşürür. İşçilik gereksinimi düşüktür ve üretimi rasyonel enerji tüketir. Ayrıca bakım maliyetleri çeliğe göre daha düşüktür.

4. YAŞAM DÖNGÜSÜ MALIYETI (LCC) AÇISINDAN KARŞILAŞTIRMA

Yaşam döngüsü maliyeti, bir malzemenin:

- Üretim,
- Nakliye,
- Montaj,
- İşletme,
- Bakım,
- Söküm ve yeniden kullanım

gibi tüm aşamalarının parasal değeridir. Sonuç olarak;

- Beton → İlk maliyet düşük, uzun vadeli bakım ve enerji kaybı yüksek.
- Çelik → İlk maliyet yüksek, bakım maliyeti yüksek.
- Ahşap → İlk maliyeti orta, bakım maliyeti düşük, işletme maliyeti düşük.

Araştırmalar, CLT binaların ömür boyu maliyetinin betonarme binalara göre **%10–25** daha düşük olabileceğini göstermektedir (Espinoza et al., 2019).

5. SÜRDÜRÜLEBILIRLIK VE EKOLOJIK EKONOMI

Mühendislik ahşabı ekonomik değerlendirmenin yanında çevresel ekonomide de önemli bir rol oynar.

5.1 Karbon Depolama

1 m^3 ahşap yaklaşık **1 ton CO_2** depolar. Bu, karbon kredisi potansiyeli anlamına gelir → maliyet avantajı.

5.2 Enerji Tasarrufu

Ahşap yapılarda ısı yalıtımı yüksek olduğu için işletme maliyetleri düşüktür.

5.3 Atık Yönetimi

Çelik ve betonun tersine:

- Ahşap artıklar tekrar değerlendirilebilir,
- OSB/MDF üretiminde endüstri atıkları kullanılır,
- Malzemenin çevresel maliyeti düşüktür.

Bu faktörler ekonomik sürdürülebilirlik açısından mühendislik ahşaplarını avantajlı hâle getirir.

6. GENEL MALIYET KARŞILAŞTIRMASI: ÜRÜNLERE GÖRE EKONOMIK PROFIL

Aşağıda ürünlerin özet ekonomik profili yer almaktadır:

Tablo 6.1. Ahşap Malzeme Türlerinin Karşılaştırılması

MALZEME	BAŞLANGIÇ MALİYET	İŞCİLİK MALİYETİ	NAKLİYE	BAKIM	UZUN VADELİ EKONOMİ
LVL	ORTA	DÜŞÜK	DÜŞÜK	DÜŞÜK	YÜKSEK VERİM
CLT	ORTA-YÜKSEK	ÇOK DÜŞÜK	DÜŞÜK	DÜŞÜK	EN EKONOMİK LCC
OSB	ÇOK DÜŞÜK	DÜŞÜK	DÜŞÜK	ORTA	İÇ MEKÂNDA EKONOMİK
MDF/PB	DÜŞÜK	DÜŞÜK	DÜŞÜK	ORTA	MOBİLYA İÇİN UYGUN
GLULAM	ORTA	DÜŞÜK	DÜŞÜK	DÜŞÜK	ÇELİĞE EKONOMİK ALTERNATİF

7. SONUÇ

Bu çalışma, mühendislik ahşap malzemelerinin ekonomik değerini kapsamlı şekilde analiz etmiş ve her ürünün kısa ve uzun vadeli maliyet profilini ortaya koymuştur. Çalışmanın bulgularına göre:

- **CLT** çok katlı yapılarda betonarmeye göre daha düşük toplam maliyet sunmaktadır.
- **LVL** ve **Glulam**, çeliğe kıyasla daha ekonomik taşıyıcı seçeneklerdir.
- **OSB** ve **MDF**, iç mekân ve kaplama işlerinde düşük maliyetli çözümler oluşturur.
- Prefabrik üretim, montaj süresini kısaltarak toplam proje maliyetini belirgin düzeyde düşürür.
- Karbon depolama ve düşük enerji tüketimi sayesinde mühendislik ahşabı, sadece ekonomik değil, çevresel açıdan da önemli avantajlar sunmaktadır.

Sonuç olarak, mühendislik ahşapları hem ekonomik hem ekolojik sürdürülebilirlik açısından giderek daha cazip bir yapı malzemesi hâline gelmektedir. Gelecekte, karbon nötr inşa tekniklerinin yaygınlaşmasıyla bu malzemelerin kullanımının daha da artacağı öngörülmektedir.

ÖZET

Bu çalışma, mühendislik ahşap malzemelerinin modern inşaat sektöründeki rolünü, bu malzemelerin yapısal performanslarını ve uygulama alanlarını kapsamlı biçimde incelemektedir. Doğal ahşabın fiziksel ve mekanik zayıflıklarını geliştirmek amacıyla üretilen mühendislik ahşapları, günümüzde sürdürülebilirlik, hafiflik, yüksek dayanım ve prefabrikasyon imkânı gibi avantajlarıyla geleneksel malzemelere alternatif oluşturmaktadır. Çalışmada ele alınan Laminated Veneer Lumber (LVL), Cross-Laminated Timber (CLT), Oriented Strand Board (OSB), Particleboard/MDF ve Glue Laminated Timber (Glulam) gibi ürünlerin üretim teknikleri, malzeme bileşimleri ve dayanım özellikleri ayrıntılı olarak açıklanmıştır. LVL ve Glulam gibi yüksek taşıma kapasitesine sahip ürünlerin özellikle kiriş ve kolonlarda çeliğe alternatif oluşturduğu; CLT'nin ise çok katlı yapılarda betonarme sistemlere benzer bir taşıyıcı performans sunduğu belirlenmiştir. OSB ve MDF gibi levha ürünleri ise iç mekân uygulamalarında, kaplamalarda ve duvar elemanlarında ekonomik ve pratik çözümler sağlamaktadır. Çalışma, mühendislik ahşaplarının boyutsal kararlılık, rijitlik, yangın davranışı, sismik dayanım ve çevresel performans açısından sahip olduğu avantajları geniş bir çerçevede değerlendirmektedir. Sonuç olarak, mühendislik ahşap malzemelerin inşaat sektöründe artan şekilde tercih edilmesinin nedeninin yalnızca yapısal faydaları değil, aynı zamanda sürdürülebilirlik ve düşük karbon odaklı tasarım ilkelerine uyum sağlama kapasitesi olduğu vurgulanmaktadır. Bu bulgular, mühendislik ahşaplarının geleceğin yapı teknolojilerinde önemli bir konumda olacağını göstermektedir.

STRUCTURAL CHARACTERISTICS AND CONSTRUCTION APPLICATIONS OF ENGINEERED WOOD MATERIALS

ABSTRACT

This study provides a comprehensive examination of engineered wood materials and their application in the modern construction industry, focusing on their structural performance, physical behavior, and functional advantages. Engineered wood products—such as Laminated Veneer Lumber (LVL), Cross-Laminated Timber (CLT), Oriented Strand Board (OSB), Particleboard/MDF, and Glue Laminated Timber (Glulam)—have emerged as advanced alternatives to traditional building materials due to their enhanced strength, dimensional stability, and sustainability features. These materials are produced by reorganizing wood fibers, veneers, strands, or particles through controlled industrial processes, resulting in improved mechanical consistency and reduced defects compared to natural solid wood. The study discusses the manufacturing principles, structural properties, and functional capabilities of each engineered wood type. LVL and Glulam demonstrate high load-bearing capacity, making them suitable for beams, columns, and long-span structural elements, often replacing steel members. CLT functions as a mass timber panel system capable of serving as walls, floors, and multi-story load-bearing structures, offering high stiffness and excellent seismic performance. OSB and MDF, while not primarily used as structural components, are widely utilized in interior applications and sheathing due to their cost-efficiency and ease of processing. The article further highlights the fire performance, thermal behavior, and environmental contributions of engineered wood products. Their renewable nature, carbon storage capacity, and compatibility with sustainable design principles make them integral to low-carbon construction strategies. Ultimately, the study concludes that engineered wood materials represent an innovative, efficient, and environmentally responsible class of building materials poised to play an increasingly significant role in future construction technologies.

Keywords: Engineered wood materials, LVL, CLT, OSB, Glulam, Sustainable construction materials

1. GİRİŞ

Ahşap, insanlık tarihinin en eski yapı malzemelerinden biridir. Doğal yapısı, kolay işlenebilirliği ve yenilenebilir olması nedeniyle yüzyıllar boyunca hem geleneksel hem de modern mimaride önemli bir rol oynamıştır. Ancak son yüzyılda sanayileşmenin etkisiyle beton ve çelik gibi malzemelerin yaygınlaşması, ahşabın yapı sektöründeki kullanım oranını azaltmıştır. Bununla birlikte, son yıllarda artan çevre bilinci, karbon ayak izinin azaltılmasına yönelik politikalar ve sürdürülebilir malzeme arayışları, ahşabın yeniden popülerlik kazanmasına neden olmuştur (Yıldız & Akbaş, 2020).

Bu süreçte geliştirilen mühendislik ahşap malzemeleri, doğal ahşabın zayıf yönlerini (örneğin düzensiz lif yapısı, düşük dayanım ve boyutsal kararsızlık) ortadan kaldırarak üstün mekanik ve fiziksel özellikler sunmaktadır. Mühendislik ahşapları, ahşap liflerinin, kaplamaların veya parçacıkların endüstriyel yöntemlerle yeniden birleştirilmesiyle elde edilir. Bu yöntem, hem daha yüksek mukavemet hem de malzeme homojenliği sağlar (Blaß et al., 2019).

Bu çalışmada; Laminated Veneer Lumber (LVL), Cross-Laminated Timber (CLT), Oriented Strand Board (OSB), Particleboard / MDF ve Glue Laminated Timber (Glulam) olmak üzere beş temel mühendislik ahşap türü teknik açıdan incelenmiştir. Her bir malzemenin üretim yöntemi, dayanım karakteristiği, kullanım alanı ve çevresel performansı değerlendirilmiş; ayrıca bu malzemelerin yapı sektörüne sunduğu yenilikçi katkılar tartışılmıştır.

Mühendislik ahşap ürünlerinin incelenmesi, yalnızca malzeme bilimi açısından değil, aynı zamanda sürdürülebilir mimari ve yeşil bina uygulamaları açısından da önemlidir. Zira bu malzemeler, karbon salımını azaltmakta, enerji verimliliğini artırmakta ve döngüsel ekonomiye katkı sağlamaktadır.

2. MÜHENDİSLİK AHŞAP MALZEMELERİN TÜRLERİ VE ÖZELLİKLERİ

2.1 Laminated Veneer Lumber (LVL)

Laminated Veneer Lumber (LVL), ince ahşap kaplamaların lif yönü boyunca fenol-formaldehit gibi reçinelerle yapıştırılması sonucu elde edilen yüksek mukavemetli bir mühendislik ahşap türüdür. LVL üretiminde genellikle çam, ladin veya kavak gibi hızlı büyüyen ağaç türleri tercih edilir. Bu malzeme, lif yönünde yüksek dayanım göstermesi sayesinde özellikle kiriş, kolon, çatı ve döşeme gibi taşıyıcı elemanlarda kullanılmaktadır (Barber, 2021).

LVL'in homojen yapısı, doğal ahşapta görülen lif düzensizliklerini ortadan kaldırarak öngörülebilir mekanik performans sağlar. Ayrıca, büyük boyutlu elemanların üretimine olanak tanıdığı için uzun açıklıklı yapılar için uygun bir alternatiftir. Yüksek yoğunluklu yapısı sayesinde eğilme, burkulma ve kesme dayanımları oldukça yüksektir (Kurt & Çolak, 2020).

Şekil 2.1.1. Çok Katmanlı Yapısıyla Lamine Kaplama Kereste (LVL) Kiriş ve Kolon Detayları.

2.2 Cross-Laminated Timber (CLT)

Cross-Laminated Timber (CLT), birbiriyle dik yönde yerleştirilmiş ahşap tabakaların preslenerek birbirine yapıştırılmasıyla üretilir. Katmanların çapraz yerleştirilmesi, malzemenin hem boyutsal kararlılığını hem de yük taşıma kapasitesini artırır. CLT paneller, özellikle duvar, döşeme ve çatı elemanlarında yaygın olarak kullanılmaktadır (Brandner et al., 2016).

CLT'nin en önemli avantajı, çok katlı ahşap yapıların inşa edilmesine olanak tanımasıdır. Prefabrik olarak üretilen panellerin montaj süresi kısa olup, inşaat sahasında işçilik maliyetini azaltır. Ayrıca CLT, yangına karşı dayanıklı yapısı ve enerji verimliliği ile sürdürülebilir yapı projelerinde sıkça tercih edilmektedir (Espinoza et al., 2019).

Şekil 2.2.1. Amasya İlinde İnşası Yapılan Otelde Dış Duvarların ve Döşemelerin CLT Malzemesi ile İmal Edilmesi. (Ulusal Ahşap Birliği, 2020.)

2.3 Oriented Strand Board (OSB)

OSB, belirli yönlerde hizalanmış ince odun yongalarının suya dayanıklı reçinelerle preslenmesiyle oluşturulan levha tipi bir mühendislik ahşap malzemedir. OSB paneller, lif yönü kontrollü şekilde düzenlendiği için geleneksel kontrplaklara kıyasla daha yüksek rijitlik ve boyutsal kararlılık sunar (Rammer & Zelinka, 2020).

OSB, zemin alt yapısı, duvar kaplaması, çatı döşemesi ve taşıyıcı yüzeylerde kullanılmaktadır. Ayrıca düşük maliyetli, dayanıklı ve kolay işlenebilir yapısı nedeniyle hem konut hem endüstriyel yapılarda tercih edilir. OSB'nin üretiminde küçük çaplı ağaçların ve yan ürünlerin kullanılması, kaynak verimliliğini artıran önemli bir sürdürülebilirlik avantajı sağlar.

Şekil 2.3.1. Çift Taraflı OSB Üzerine Yapılan Alçıpan Kaplama Çalışması

2.4 Particleboard / MDF

Particleboard ve MDF (Medium Density Fiberboard), ahşap talaşı veya liflerin sentetik reçinelerle birleştirilip yüksek basınç altında sıkıştırılmasıyla üretilen malzemelerdir. Bu malzemeler, homojen yüzeyleri ve düzgün dokuları sayesinde özellikle iç mekân uygulamalarında tercih edilir (Çolak & Erdinler, 2018).

Yapısal dayanımı sınırlı olmasına karşın, işlenebilirlik ve yüzey kalitesi açısından önemli avantajlar sunar. Dolap, raf, duvar paneli ve mobilya üretiminde yaygın olarak kullanılır. Üretim sürecinde geri dönüştürülmüş ahşap atıklarının kullanılabilmesi, çevresel açıdan önemli bir kazanımdır.

Şekil 2.4.1. Mutfak Mobilyası İmalatında Kullanılan MDF Gövde ve Raf Sistemi Uygulaması.

2.5 Glue Laminated Timber (Glulam)

Glulam, ince ahşap lamellerin birbirine paralel şekilde yapıştırılmasıyla elde edilen yüksek dayanımlı bir yapı malzemesidir. Genellikle taşıyıcı kiriş, kolon, kemer ve köprü elemanlarında kullanılır. Lamellerin seçici şekilde birleştirilmesi, hem malzeme israfını azaltır hem de yüksek mekanik performans sağlar (Forest Products Laboratory, 2010).

Glulam'ın en önemli avantajlarından biri, büyük açıklıkları geçebilme kapasitesidir. Aynı zamanda doğal ahşap görünümünü koruyarak estetik bir görünüm sunar. Yangın dayanımı açısından da güvenli bir malzeme olarak kabul edilir; çünkü yüzeydeki karbonlaşma tabakası iç katmanları koruyarak mukavemetin düşmesini geciktirir.

3. MÜHENDİSLİK AHŞAP MALZEMELERİN İNŞAATTA KULLANIMI

Mühendislik ahşap malzemeler, modern inşaat uygulamalarında taşıyıcı sistemlerden kaplama elemanlarına kadar geniş bir kullanım yelpazesi sunar. LVL ve Glulam, özellikle çatı kirişleri, kolonlar ve köprü elemanlarında tercih edilirken; CLT, çok katlı yapıların duvar ve döşeme sistemlerinde kullanılır. OSB ve MDF ise genellikle zemin kaplamaları, duvar panelleri ve iç mekân tasarımlarında görev alır (Harte, 2017).

Bu malzemelerin tercih edilmesinde sadece dayanım değil, aynı zamanda montaj kolaylığı, hafiflik ve prefabrikasyona uygunluk gibi özellikler de etkilidir. Örneğin, CLT panelleri fabrika ortamında hazırlanıp sahaya taşındığında montaj süresi önemli ölçüde kısalır. LVL ve Glulam gibi yüksek dayanımlı malzemeler ise çelik ve betona alternatif taşıyıcı çözümler sunarak karbon ayak izini azaltır.

4. YAPISAL PERFORMANS, SÜRDÜRÜLEBİLİRLİK VE UYGULAMA BOYUTLARI

Mühendislik ahşap ürünlerinin yapısal performansı, kullanılan ahşap türü, reçine kalitesi ve üretim yöntemi ile doğrudan ilişkilidir. LVL ve Glulam, uzun ömürlü ve yüksek dayanımlı taşıyıcı sistemlerde kullanılırken; CLT paneller, hem yatay hem dikey yükleri güvenle taşıyabilme özelliğine sahiptir. OSB ve MDF ise taşıyıcı özellikten ziyade tamamlayıcı görevler üstlenir.

Bu malzemelerin en önemli katkılarından biri de sürdürülebilirliktir. Yenilenebilir kaynaklardan üretildikleri için karbon depolama kapasitesine sahiptirler. Ayrıca, prefabrik üretim süreçleri sayesinde atık miktarı azalır, enerji verimliliği artar (Pei et al., 2020). Üstelik mühendislik ahşap malzemelerin geri dönüştürülebilir olması, döngüsel ekonomiye katkı sunmaktadır.

Mühendislik ahşaplarının hafif yapısı, nakliye ve montaj sırasında enerji tasarrufu sağlar. Yangın dayanımı, ses yalıtımı ve ısı performansı açısından da modern yönetmeliklerle uyumlu hale getirilmiştir. Bu yönüyle, mühendislik ahşapları hem çevresel hem teknik açıdan sürdürülebilir yapı sistemleri için güçlü bir alternatiftir.

5. SONUÇ VE DEĞERLENDİRME

Bu çalışma, mühendislik ahşap malzemelerin üretim teknikleri, yapısal özellikleri ve inşaat sektöründeki kullanım alanlarını kapsamlı biçimde değerlendirmiştir. Elde edilen sonuçlar göstermektedir ki, LVL, CLT ve Glulam gibi yüksek dayanımlı mühendislik ahşap türleri, taşıyıcı sistemlerde güvenle kullanılabilecek düzeyde performans sergilemektedir. OSB, MDF ve Particleboard ise yapısal olmayan alanlarda estetik ve işlevsel katkı sağlamaktadır.

Mühendislik ahşap ürünleri, yenilenebilir kaynaklardan üretildikleri için çevresel sürdürülebilirlik açısından büyük önem taşır. Hafiflik, enerji verimliliği ve karbon depolama özellikleri sayesinde geleceğin çevre dostu yapı teknolojilerinde önemli bir rol üstleneceklerdir. Sonuç olarak, bu malzemelerin inşaat sektöründeki etkin kullanımının artması, yalnızca teknik performansı değil, aynı zamanda ekolojik dengeyi de olumlu yönde etkileyecektir.

ÖZET

Tarımsal üretimde kalite sınıflandırması, verim yönetimi ve hasat zamanlamasının optimize edilmesi için meyve-sebze boyutlarının doğrulukla belirlenmesi büyük önem taşır. Bu nedenle boyut ölçümünün hızlı, temassız ve güvenilir biçimde yapılması günümüzde giderek zorunlu hale gelmektedir. Salatalık (Cucumis sativus L.) gibi ince ve eğrisel morfolojiye sahip ürünlerde yapılan manuel ölçüm işlemleri zaman kaybına neden olmakta ve hataya açık bir süreç oluşturmaktadır. Çalışmada, tek bir RGB kamera kullanarak gerçek zamanlı uzunluk ve ağırlık tahmini yapabilen, derin öğrenme tabanlı ve düşük maliyetli bir sistem geliştirilmiştir. Nesne tespiti için hız, doğruluk ve donanım verimliliği arasında optimum denge sağlayan YOLOv8n mimarisi kullanılmıştır. YOLOv8n'nin anchor-free yapısı, çok ölçekli özellik birleştirme yeteneği ve parçalı tahmin başlığı, salatalığın farklı aydınlatma, örtüşme ve şekil varyasyonlarında yüksek algılama duyarlılığı sağlamıştır. Toplam 999 görüntüden oluşan veri seti ile model eğitilmiş, tespit edilen meyvelerin piksel boyutları kamera kalibrasyonu yardımıyla santimetre cinsine dönüştürülmüş ve silindirik hacim modeli ile kütle değerleri tahmin edilmiştir. Sistemin kararlılığı, Bland–Altman uyum analizi ve ablation çalışmaları ile istatistiksel olarak doğrulanmıştır. Uzunluk ölçümleri için ortalama fark +0,40 cm (SD: 0,35 cm), ağırlık tahmini için −2,35 g (SD: 3,10 g) elde edilmiş, yöntemler arasında %95 güven aralığında güçlü bir uyum saptanmıştır. En iyi performans gösteren ablation modeli R^2 = 0,994, RMSE = 2,76 g ve MAE = 1,95 g değerlerine ulaşarak yüksek tahmin doğruluğu sergilemiştir. YOLOv8n tabanlı sistem yalnızca salatalık için değil, kabak ve patlıcan gibi benzer morfolojiye sahip ürünlerde de otomatik boyutlandırma ve ağırlık tahmini için kullanılabilir. Bu durum, modelin farklı ürün türlerinde yüksek genelleme kapasitesine sahip olduğunu göstermektedir. Sistem, akıllı tarım teknolojilerinde kalite kontrol, otonom hasat ve karar destek süreçlerine uygulanabilirliği sayesinde, sürdürülebilir ve dijital tarımsal üretimin geliştirilmesine önemli katkı sunmaktadır.

Anahtar kelimeler: Salatalık, YOLOv8n, Uzunluk ve ağırlık tahmini, Bilgisayar tabanlı ölçüm ,Tarımsal otomasyon

COMPUTER-BASED APPROACH FOR MEASURING THE LENGTH AND WEİGHT OF CUCUMBERS (CUCUMIS SATIVUS L.) USING YOLOV8N

ABSTRACT

Accurate determination of fruit and vegetable sizes is essential for optimising quality classification, yield management, and harvest timing in agricultural production. Consequently, fast, contactless, and reliable size measurement is increasingly important. Manual measurement of products with thin and curved morphologies, such as cucumbers (Cucumis sativus L.), results in time loss and introduces errors. In this study, a low-cost, deep learning-based system capable of real-time length and weight estimation using a single RGB camera was developed. The YOLOv8n architecture, which offers an optimal balance of speed, accuracy, and hardware efficiency for object detection, was employed. YOLOv8n's anchor-free structure, multi-scale feature fusion capability, and segmented prediction header provided high detection sensitivity for cucumbers under varying lighting conditions, overlap, and shape variations. The model was trained on a dataset of 999 images. The pixel dimensions of the detected fruits were converted to centimetres using camera calibration, and mass values were estimated using a cylindrical volume model. The stability of the system was statistically validated using Bland–Altman agreement analysis and ablation studies. For length measurements, the mean difference was +0.40 cm (SD: 0.35 cm), and for weight estimation, −2.35 g (SD: 3.10 g), indicating strong agreement between methods within a 95% confidence interval. The best-performing ablation model achieved $R^2 = 0.994$, RMSE = 2.76 g, and MAE = 1.95 g, demonstrating high prediction accuracy. The YOLOv8n-based system can be used for automatic sizing and weight estimation not only for cucumbers but also for products with similar morphology, such as courgettes and aubergines. This demonstrates the model's high generalisation capacity across different product types. The system contributes significantly to the development of sustainable and digital agricultural production through its applicability in quality control, autonomous harvesting, and decision support processes in smart farming technologies.

Keywords:Cucumber, YOLOv8n, length and weight estimation, computer-based measurement, agricultural automation

1.Giriş

Tarımda verimlilik, kalite kontrolü, artan gıda telebi ve otomasyon gereksinimlerinin artışı meyve-sebze üretiminde fenotipik özelliklerin hızlı ve temassız olarak ölçülmesini zorunlu kılmaktadır.Özellikle seralarda ve tarlada ticari öneme sahip olan salatalık (Cucumis sativus L.), uzun, ince ve zaman zaman eğrisel bir morfolojiye sahiptir. Bu nedenle, uzunluk gibi boyutsal özellikler hem sınıflandırma ve ambalajlama stratejileri hem de hasat zamanlaması açısından karar vericiler için kritik bir rol oynamaktadır. Son yıllarda makine görüşü ve derin öğrenme tabanlı yaklaşımlar, meyve ve sebzelerin boyutlandırma ve derecelendirme süreçlerinde sahada uygulanabilir çözümler sunmaktadır. Bu çözümler, klasik mekanik ve manuel ölçüm tekniklerine kıyasla sistemlere daha fazla esneklik, hız ve ölçeklenebilirlik kazandırmıştır. Derin öğrenmenin en yaygın uygulama alanlarından biri, görüntü tanıma ve sınıflandırmadır. Hasat sırasındaki toplama sürecinde tespit edilen salatalıkların boyutları, klasik yöntemlere kıyasla daha yüksek doğruluk oranlarıyla ölçülebilmektedir. Özellikle konvolüsyonel sinir ağları, bitkilerin çeşitli boyutlarının doğru bir şekilde sınıflandırılması ve bu bilgilerin analiz edilmesi için sıklıkla kullanılmaktadır (Ökten ve Yüzgeç, 2022). Bu yöntemlerin uygulanabilirliği, özellikle büyük veri setlerinde, özellik çıkarımı ve model eğitimi aşamalarındaki gelişmelerle doğrudan ilişkilidir (Akdere ve ark., 2023).Özellikle, derin öğrenme süreçlerinde kullanılan veri ön işleme ve model geliştirme teknikleri, salatalıkların boyutunu algılayacak sistemlerin etkinliğini artırmaktadır Makine öğrenmesi ve derin öğrenme algoritmalarındaki bu yenilikler, tarımda akıllı sistemlerin entegrasyonunu hızlandırmakta ve işleme, analiz ve karar verme süreçlerini optimize etmektedir (Erol ve İnkaya, 2023). Bununla birlikte, derin öğrenme uygulamalarının daha sağlıklı ve güvenilir sonuçlar verebilmesi için, uygun eğitim veri setlerinin ve model parametrelerinin belirlenmesi büyük önem taşımaktadır (Demiryege ve Ulukavak, 2022).Bu nedenle görüntü tabanlı otomatik boyut tahmini, tarımsal süreçlerin dijitalleştirilmesi ve maliyet-etkin uygulanabilirliği açısından önemli bir araştırma alanıdır (Neupane ve ark.,2023). Özellikle görüntü işleme tekniklerinin kullanımı, bitkilerin büyüme aşamalarının ve boyutlarının belirlenmesinde etkili bir yöntem sunmaktadır (Yaman ve Tuncer, 2022). Bu eğilim; tarlada ve serada karmaşık arka plan, değişken aydınlatma, kısmi örtüşme ve şekil eğriliği gibi zorlu koşullarda dahi tespit–segmentasyon–boyut çıkarımı zincirini baştan sona öğrenebilen uçtan uca modellerin yaygınlaşmasıyla hız kazanmıştır (Miranda ve ark.,2023) . Endüstriyel üretim hatlarında kütle veya boyut tahmini amacıyla geliştirilen makine görüşü ve derin öğrenme tabanlı entegre sistemler başarılı sonuçlar vermiştir. Bu tür yaklaşımlar, uzunluk ve çap gibi morfolojik öznitelikleri kütle ile ilişkilendirerek bu parametrelerin doğrudan ya da dolaylı biçimde ölçülebilir hale gelmesini sağlamaktadır (Liu ve ark.,2024). Benzer biçimde, tarımsal araştırmalarda da bu tür derin öğrenme tabanlı görsel sistemler, meyve ve sebzelerin boyut, kütle ve olgunluk düzeylerinin temassız biçimde tahmin edilmesinde önemli bir potansiyel ortaya koymaktadır. Salatalık (Cucumis sativus L.) , meyvenin eksenel eğriliği, yaprak-gövde ile renk/tekstür benzerliği, perspektif ve ölçek değişimleri, tek görüntüden güvenilir uzunluk kestirimini güçleştirir. Yapılan araştırmalarda, meyve boyutlandırma amacıyla stereo veya derinlik sensörleri, çok-görüşlü sistemler ve referans ölçekleyiciler kullanılmıştır. Bununla birlikte, yalnızca RGB görüntülerle çalışan derin öğrenme tabanlı modellerin de başarılı sonuçlar elde ettiği gösterilmiştir. Uzunluk tahmininde öne çıkan üç temel metodolojik kategori; tespit tabanlı (Faster/Mask R-CNN, YOLO ailesi), segmentasyon tabanlı ve anahtar nokta tabanlı ölçüm yaklaşımlarıdır (Mirbod ve ark,2023).CucumberAI gibi araçlar; kontur tabanlı meyve segmentasyonu, şekil sınıflaması ve (çeşitler arası) biçimsel farkların otomatik ayrımında doğruluk sağlamıştır.Uzunluk/çap ölçümlerine temel teşkil etmiştir (Xue ve ark.,2024).Boğum (node) tespiti, boğum arası mesafe ve gövde geometri hesapları; 2D görüntüler ve 3D nokta bulutu (PointNet++ tabanlı) yöntemlerle başarıyla yapılmıştır. Bu hat, meyve-gövde ayrımını

iyileştirip meyve ekseninin güvenli çıkarımına destek vererek daha doğru uzunluk kestirimine zemin hazırlar(Boograad ve ark.,2023).

Derin öğrenmenin kullanıldığı bazı çalışmalarda, cep telefonlarıyla çekilen salatalık fotoğraflarından boyut tespitine yönelik prototipler geliştirmiştir. Bu sistemler, derin öğrenme algoritmaları aracılığıyla önceden eğitilmiş modeller kullanarak, resimler üzerinden mekanik çözümler sunmaktadır (Fırat ve Hanbay, 2022). Bu yaklaşımlar yardımıyla derin öğrenme yöntemleri hem doğruluk hem de hız açısından geleneksel ölçüm tekniklerine göre avantajlar sağlamaktadır.

Derin öğrenme, son on yıl içinde meyve tespiti, segmentasyonu ve nicel özellik çıkarımında hızlı ilerleme sağlamıştır.Özellikle nesne algılama (YOLO, Faster R-CNN vb.), örnek-tabanlı segmentasyon (Mask R-CNN, DeepLab) ve uçtan-uça regresyon ağları meyve morfolojisinin otomatik analizinde kullanılmıştır. Bu yaklaşımlar, hem paketleme hattı gibi kontrollü ortamlarda hem de saha/sera koşullarında uygulanmıştır. Kontrollü hatlarda top-view RGB kullanılarak kütle ve kalite tahmini yapan sistemler geliştirilmiştir.

Son yıllardaki derin öğrenme tabanlı çalışmalarda, tarımsal nesne tespiti ve hastalık sınıflandırması alanında önemli ilerlemeler sağlamıştır. Bao ve ark. (2023), Mask R-CNN ve çift yönlü sektör arama algoritmasını entegre ederek karmaşık bahçe koşullarında tutkulu meyve dallarının yüksek doğrulukla tespit ve yeniden inşasını gerçekleştirmiştir . Huu ve ark. (2023), Hard-sample Re-mining (HSReM) stratejisiyle salatalık ve domates hastalık verilerinde yanlış sınıflandırılan örnekleri yeniden değerlendirerek YOLO tabanlı modellerin doğruluğunu artırmıştır. Ahmed ve ark. (2022), MobileNetV2 tabanlı hafif bir model geliştirerek, domates yaprak hastalıklarını düşük maliyetli cihazlarda %99,3 doğrulukla sınıflandırmıştır. Mousse ve ark. (2023), karmaşık sahnelerde domates olgunluk evrelerini beş sınıfta ayıran bir derin sinir ağı modeli önermiş ve yüksek sınıflandırma başarısı elde etmiştir. Lim ve ark. (2020), Faster R-CNN ve SSD tabanlı ağlarla gerçek zamanlı kivi çiçeği tespitinde sırasıyla 0.919, 0.874 ve 0.889 Precision, Recall ve F1 değerlerine ulaşmıştır . Roy ve ark. (2022), DenseNet ve Hard-Swish aktivasyon fonksiyonlarını YOLOv4 mimarisine entegre ederek dört farklı domates hastalığını %96,29 mAP ile tespit etmiştir . Mishra ve ark. (2023), yakın kızılötesi görüntüleme ve derin öğrenme tekniklerini birleştirerek kivi meyvesinin kuru madde ve çözünebilir katı içeriğini doğrusal olmayan yöntemlerle tahmin etmiştir. Dolatabadian ve ark. (2024), makine öğrenmesi temelli bitki hastalığı tespiti çalışmalarını derleyerek sensör teknolojilerinin ve yapay zekâ algoritmalarının etkinliğini vurgulamıştır. Kang ve Chen (2020), LedNet adlı hafif mimarisiyle elma tespitinde %85,3 doğruluk ve 28 ms çıkarım süresiyle gerçek zamanlı performans göstermiştir. Benzer biçimde, YOLOv5 tabanlı tek aşamalı dedektör kullanan Cardellicchio ve ark. (2024), domates bitkilerinin fenotipik özelliklerini yüksek doğrulukla analiz etmiş ve gerçek zamanlı tespit hızı elde etmiştir. Chen ve ark. (2021), U-Net, DeepLabv3 ve Pix2Pix mimarilerini karşılaştırarak kısmen örtülü elma dallarının segmentasyonunda DeepLabv3'ün doğruluk, U-Net'in ise örtülü bölgelerde daha üstün performans sağladığını göstermiştir .Yang ve ark. (2024), S-YOLOv4-tiny modeline SENet dikkat modülü ekleyerek kivi tespitinde %93,96 doğruluk ve %7 performans artışı sağlamıştır. Xiao ve ark. (2023), derin öğrenme tabanlı meyve tespiti sistemlerini inceleyerek küçük nesne tespiti, örtüşme ve çoklu ölçek sorunlarına çözüm önerileri sunmuştur. Afonso ve ark. (2020), Mask-RCNN algoritmasıyla sera ortamında domateslerin tespit ve sayımını başarıyla gerçekleştirmiştir. Wang ve Liu (2021), YOLO-Dense modeliyle karmaşık sera koşullarında domates anomalilerini %96,41 mAP ve 20,28 ms tespit süresiyle belirlemiştir. Maheswari ve ark. (2021), semantik segmentasyon tekniklerinin meyve verim tahmininde kullanılabilirliğini derleyerek, örtüşme ve aydınlatma değişimi gibi sorunlara çözüm önermiştir. Saleem ve ark. (2019), CNN tabanlı bitki hastalık tanı modellerini inceleyerek görselleştirme tabanlı yaklaşımların doğruluk

üzerindeki etkilerini ortaya koymuştur . Hasan ve ark. (2020), son yıllarda geliştirilen derin ağ mimarilerini analiz ederek veri artırma stratejilerinin sınıflandırma doğruluğuna katkısını değerlendirmiştir. Biffi ve ark. (2021), ATSS tabanlı yöntemle elma meyvesinin yalnızca merkez koordinat etiketleriyle yüksek doğrulukla tespitini sağlamıştır .Tong ve ark. (2022), Cascade Mask R-CNN Swin-T mimarisiyle elma ağaçlarının gövde ve dallarını yüksek doğrulukla segment etmiş ve robotik budama sistemleri için referans veri üretmiştir .Liu ve ark. (2025), YOLOv11n tabanlı YOLO-Cucumber modelinde deformable convolution, target-aware loss ve channel pruning bileşenlerini birleştirerek salatalık hastalıklarını %93,8 mAP@50 doğrulukla tespit etmiştir. Bilal ve ark. (2025), fuzzy derin evrişimli sinir ağı ve kaotik parçacık sürüsü optimizasyonu kullanarak salatalık hastalıklarını %98 doğrulukla sınıflandırmıştır .Yang ve ark. (2024), ELD adı verilen hafif YOLOv5 tabanlı modelle elma tespitinde %87,4 doğruluk ve 156 FPS hız elde etmiş, düşük kaynak tüketimiyle dikkat çekmiştir . Magalhães ve ark. (2021), SSD MobileNet v2 modelinin sera koşullarında yeşil ve olgun domates tespitinde %66,15 F1 skoru ve 16,44 ms çıkarım süresiyle en yüksek performansı sağladığını rapor etmiştir . Ukwuoma ve ark. (2022), aynı dergide yayımladıkları incelemede CNN ve transfer öğrenme yaklaşımlarının tarımsal üretimdeki etkinliğini göstermiştir. Melnychenko ve ark. (2024), çoklu UAV (multi-UAV) görüntüleme ve YOLOv5-v1 mimarisini birleştirerek meyve tespitinde %86,8 mAP doğruluk ve düşük hata oranı ile gerçek zamanlı izleme başarısı elde etmiştir .

Yapılan çalışmada, tarımsal ürünlerin boyutlandırılmasında kullanılan geleneksel ve çoğunlukla manuel yöntemlerin derin öğrenme yardımıyla bulunması yapılmıştır. Aynı zamanda derin öğrenme tabanlı bütünleşik yaklaşımların saha koşullarında uygulanabilirliğini açık biçimde ortaya konmuştur. YOLOv8n derin öğrenmen, yalnızca tek bir RGB kamera üzerinden uzunluk ve ağırlık tahminini mümkün kılmakla kalmamaktadır. Ayrıca segmentasyon, ölçekleme ve iskelet çıkarımı gibi alt süreçleri birlikte optimize ederek ölçüm hatalarının sistematik biçimde azaltılmasını sağlanmıştır. Sistem, 2D görüntü tabanlı çözümlerin düşük maliyet ve kolay erişilebilirlik avantajını korumaktadır. Farklı ışık ve arka plan değişkenlerinin bulunduğu test koşullarında doğrulanan güçlü genellemeye sahiptir. Bu durum, sera ve açık tarla gibi değişken üretim ortamlarında ölçeklenebilir, temassız ve otonom bir boyut tahmin altyapısının geliştirilmesine bilimsel zemin sunacaktır. Derin öğrenmenin tarımda kullanımı, özellikle morfolojik olarak karmaşık yapıya sahip sebzelerden biri olan salatalığın büyüme takibi, kalite sınıflandırması ve hasat planlamasında önemli bir rol oynayacaktır. Bu entegrasyon, sürdürülebilir tarım uygulamaları ve akıllı üretim sistemlerinin gelişimini destekleyerek verimliliği ve kaynak kullanım etkinliğini artıracaktır. Derin öğrenme teknikleri, görsel veri analizi ve sınıflandırma görevlerinde yüksek performans göstermesi nedeniyle, tarımsal üretkenliği artırmak için potansiyel sunmaktadır (Gan ve ark., 2022). Salatalık gibi ürünlerin morfolojik çeşitliliği, doğru ve zamanında analiz gereksinimini artırmaktadır. Gelişmiş sinyal işleme ve derin öğrenme algoritmaları, kaliteli ürünlerin seçimi ve hasat planlamasında büyük bir rol oynamaktadır (Anand et al., 2023). Sürdürülebilir tarım uygulamalarında teknolojinin entegrasyonu, akıllı tarım sistemlerinin oluşturulmasına olanak sağlayacaktır. IoT cihazlarının sağladığı sürekli izleme ve veri toplama, toprağın nemi ve sıcaklığı gibi çevresel koşulları takip ederek çiftçilerin bilinçli kararlar almasına yardımcı olacaktır (Islam ve ark., 2021;Jadhav ve ark., 2023). Derin öğrenme teknolojilerinin salatalık gibi karmaşık morfolojik sebzelerde kullanımı, sürdürülebilir tarım uygulamalarını güçlendirecek ve akıllı üretim sistemlerinde daha bilinçli kararlar alınmasını sağlayacaktır. Tarımsal üretkenliği artırmayı, kaynakları daha verimli kullanmayı ve çevresel etkileri azaltmayı hedefleyen stratejik bir yaklaşım olarak değerlendirilmektedir.

2.Materyal ve yöntemler

2.1.1.Salatalık

Salatalık bitkisi (*Cucumis sativus L.*), Cucurbitaceae familyasına aittir.Dünya genelinde yaygın olarak yetiştirilen önemli bir sebze türüdür. Ilıman iklim koşullarında yüksek adaptasyon yeteneğine sahip olan bitkidir.Ayrıca sera ve açık tarla koşullarında yıl boyunca üretilebilmektedir. Salatalık üretiminde hasat zamanı, meyvenin pazara uygun kalite ve büyüklüğe ulaşması açısından kritik bir kriterdir. Genellikle meyve uzunluğu, çapı, kabuk rengi, parlaklığı ve diken yoğunluğu gibi morfolojik özellikler hasat olgunluğunun belirlenmesinde temel parametreler olarak kullanılır. Hasat geciktirildiğinde meyvelerde sararma, acılaşma ve tohum sertleşmesi gibi istenmeyen fizyolojik değişimler ortaya çıkabilir. Bu nedenle, düzenli hasat aralıklarının korunması hem bitkinin yeni meyve oluşturma kapasitesini sürdürmek hem de toplam verimi artırmak açısından önemlidir. Hasat edilen meyvelerin sınıflandırılması ve kalite standardizasyonu, ticari değer ve tüketici memnuniyetini doğrudan etkilemektedir.

2.1.2.YOLO(You Only Look Once)

YOLOv8, tek aşamalı (one-stage) nesne algılama mimarilerinin en güncellerindendir. Önceki sürümlere kıyasla hem hız hem de doğruluk açısından önemli geliştirmeler sunmaktadır. Bu modelde gövde (backbone) olarak CSPNet-tabanlı katmanlar, boylamsal özelliklerin etkili çıkarımını sağlamaktadır. “neck” kısmında FPN (Feature Pyramid Network) ve PAN (Path Aggregation Network) kırılımları çok ölçekli özelliklerin birleşimini kolaylaştırır. Parçalı (decoupled) head yapısı sayesinde sınıflandırma ve sınırlayıcı kutu (bounding box) regresyonu ayrı yollarla yürütülür. Bu yapısı özellikle küçük veya yoğun nesnelerin algılanmasında iyileştirme sağlar. YOLOv8’in anchor-free yaklaşımı, kutu ön tayinlerine (pre-defined anchors) duyulan ihtiyacı azaltır ve farklı ölçeklerde bulunan nesneler için daha esnek bir tahmin süreci sunar (Yaseen, 2024). Bu mimari yapısı sayesinde, tarım gibi heterojen, değişken arka planlara ve nesne varyasyonlarına sahip alanlarda, gerçek zamanlı ve yüksek doğruluklu tespit ve ölçüm görevlerinde uygulanabilirlik kazanmıştır.

Tarım görselleştirme kapsamında özellikle meyve/sebze boyutlandırma görevlerinde, tek bir RGB kamera kullanımı ve basitleştirilmiş donanım gereksinimi önemli avantajlardır. YOLOv8 yalnızca meyve tespiti için değil, aynı zamanda meyve gövdesi/arka plan ayrımı, segmentasyon-öncesi kutu çıkarımı ve daha sonra yapılacak ölçüm işlemleri için güvenilir bir başlangıç noktası sunar. Modelin genel araştırma alanlarında (örneğin davranış analizi, biyolojik gözlem ve laboratuvar görüntülemesi) yüksek doğruluk ve işlem hızıyla kullanılabildiği, tarımsal görüntüleme çalışmalarına da doğrudan aktarılabilir bir altyapı sunulmaktadır.

2.2.Yöntem

Veri Setinin Hazırlanması:

Bu çalışmada, salatalık (Cucumis sativus L.) meyvelerinin tespiti ve boyut tahmini amacıyla Roboflow Universe platformunda yayımlanan “Cucumber_for_Robotics” veri seti kullanılmıştır (Anonim 1). Veri kümesi; sera ve açık tarla koşullarında farklı aydınlatma, açı ve arka plan çeşitliliğine sahip yüksek çözünürlüklü görüntülerden oluşmaktadır. Toplam 999 görüntü, eğitim (760), doğrulama (169) ve test (79) alt kümelerine ayrılmıştır. Görüntüler, Roboflow platformunda YOLO biçiminde yeniden etiketlenmiş ve tüm örneklerde meyve sınır kutuları manuel olarak kontrol edilmiştir. Ayrıca veri çeşitliliğini artırmak amacıyla parlaklık-kontrast ayarı, yatay/dikey çevirme ve bulanıklaştırma gibi temel artırma işlemleri

uygulanmıştır. Bu yapılandırma, modelin farklı çevresel koşullarda genelleme kabiliyetini güçlendirmeyi ve gerçek zamanlı tespit doğruluğunu artırmayı hedeflemiştir.

Etiketleme:

Görsel etiketleme işlemleri, popüler bir web tabanlı platform olan Roboflow üzerinden gerçekleştirilmiştir. Roboflow, farklı araştırma alanlarında yaygın biçimde kullanılan, görüntü verilerinin ön işlenmesi, yönetimi ve etiketlenmesi için tasarlanmış bir platformdur. Bu sistem, kullanıcıların veri kümelerine erişimini kolaylaştırarak görseller üzerinde alan seçimi, işaretleme ve sınıf etiketleme işlemlerini verimli biçimde gerçekleştirmesine olanak tanır.Şekil 1'de Label (Etiket) ekranı gösterilmiştir.

Şekil 1.Label Ekranı

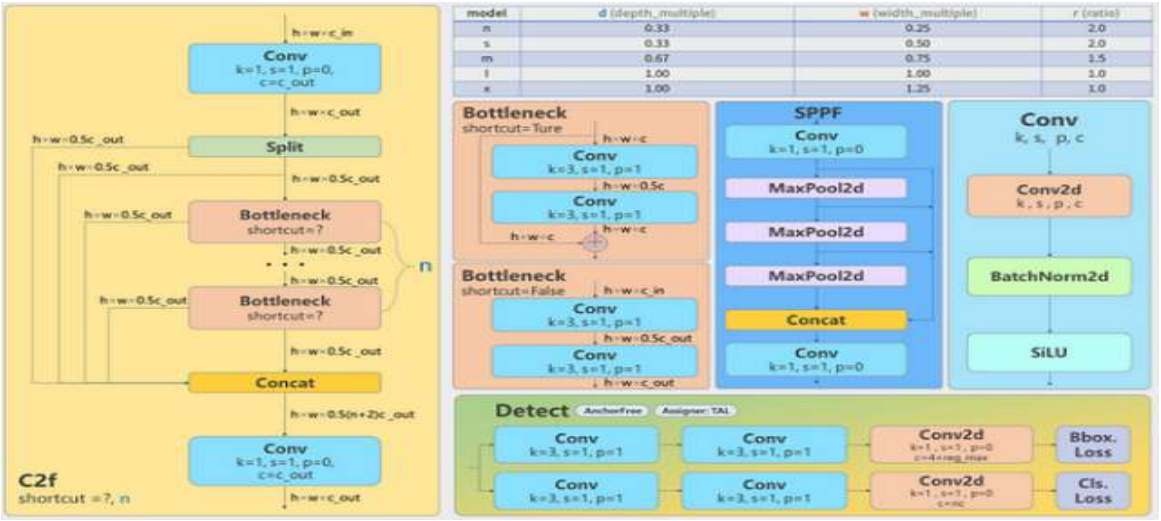
Sistem Özellikleri:

YOLOv8 modelinin eğitimi, aşağıdaki bileşenlere sahip bir bilgisayar tarafından yürütülmüştür:

İşlemci: Intel® Core™ i5-11400H Processor 2.7 GHz (12M Cache, up to 4.5 GHz, 6 Cores)

Ekran Kartı: NVIDIA® GeForce RTX™ 3050 Laptop GPU- Intel® UHD Graphics

Bellek: 8GB DDR4-2933 SO-DIMM



Depolama: 512GB M.2 NVMe™ PCIe® 3.0 SSD

Eğitim Model Seçimi:

Bu çalışmada, nesne tespiti sürecinde YOLOv8n (You Only Look Once, version 8 – nano) modeli tercih edilmiştir. YOLOv8n, hız, doğruluk ve hesaplama verimliliği arasında mükemmel bir denge sunan, gerçek zamanlı görüntü işleme görevleri için optimize edilmiş bir derin öğrenme mimarisidir. Modelin "nano" sürümü, özellikle düşük parametre sayısı (yaklaşık 3.2 M) ve hafif hesaplama yükü sayesinde, gömülü sistemler ve tarımsal robotik uygulamalar gibi donanım kısıtlı ortamlarda yüksek performans göstermektedir.YOLOv8n, önceki sürümlere kıyasla geliştirilmiş Anchor-Free tespit yapısı, Decoupled Head tasarımı ve Mosaic + MixUp tabanlı veri artırma stratejileri ile öne çıkmaktadır. Bu sayede model, salatalık meyvelerinin farklı açı, aydınlatma ve örtüşme koşullarında bile yüksek hassasiyet (precision) ve duyarlılık (recall) değerlerine ulaşabilmektedir. Ayrıca, PyTorch tabanlı modüler yapısı sayesinde eğitim süreci esnek ve optimize edilebilir hale getirilmiştir.

Bu gerekçeler doğrultusunda YOLOv8n, hem hızlı inferans süresi (FPS) hem de yüksek doğruluk oranı (mAP@0.5) ile tarımsal üretim ortamlarında gerçek zamanlı uygulamaya en uygun çözüm olarak değerlendirilmiştir. Dolayısıyla modelin seçimi, yalnızca teknik

üstünlüklerine değil, aynı zamanda uygulama odaklı verimlilik ve genelleme başarısına dayanmaktadır. Şekil 2 ‘de Yolov8 network yapısı gösterilmiştir.

Şekil 2. Yolov8 network yapısı (Anonim 2).

Değerlendirme Göstergeleri:

Test sonuçlarının modelleme sonucunda değerlendirilmesinde üç değerlendirme göstergesi kullanılır.Bunlar Precision,Recall ve mAP(mean Average Precision) ‘dur. Precision tespit sonuçlarındaki tüm örnekler içindeki pozitif örneklerin oranını temsil eder. TP (Doğru Pozitif), hem tespit sonucunun hem de gerçek değerin enginar olduğunu gösterir; FP (Yanlış Pozitif), yanlış olarak işaretlenen ancak pozitif örnekler olarak tespit edilen örneklerin sayısını, yani tespit edilen yanlış enginar sayısını gösterir; FN (Yanlış Negatif), pozitif olarak işaretlenen ancak negatif sınıflar olarak tahmin edilen örneklerin sayısını, yani kaçırılan tespit enginar sayısını gösterir. mAP değeri yüksekliği algoritma algılama etkisinin o kadar iyi ve model tanıma performansı o kadar yüksek olduğu gösterir. Burada;

- Doğruluk (Accuracy), modelin doğru sınıflandırma veya tahmin sayısının toplam örnek sayısına oranı olarak tanımlanan temel bir performans ölçütüdür. Doğruluk değerinin 1’e yaklaşması, modelin genel başarısının yüksek olduğunu göstermekdir.Bu metrik tek başına modelin performansını kapsamlı biçimde değerlendirmek için yeterli değildir.

$$\text{Accuracy} = \frac{\text{TN+TP}}{(\text{TP+FP+TN+FN})} \qquad (1)$$

- Hata Oranı (Error Rate), problemde yanlış yapılan sınıflandırmaların/tahminlerin sıklığının oranıdır.

$$\text{Error Rate} = \frac{\text{FN+FP}}{(\text{TP+FP+TN+FN})} \text{ or } (1 - \text{Accuracy}) \qquad (2)$$

- Kesinlik (Precision), model tarafından pozitif olarak tahmin edilen örnekler arasından gerçekten pozitif olanların oranını ifade eden bir performans ölçütüdür. Başka bir ifadeyle, modelin yaptığı pozitif tahminlerin ne kadarının doğru olduğunu gösterir ve özellikle yanlış pozitiflerin (False Positive) minimize edilmesinin önemli olduğu durumlarda kritik bir metriktir. Bu çalışmada, salatalık tespiti açısından modelin doğru tanımlama yeteneğini değerlendirmek amacıyla kullanılmıştır. Kesinlik değeri aşağıdaki denklem ile hesaplanmaktadır:

$$\text{Precision} = \frac{\text{TP}}{(\text{FP}+\text{TP})} \quad (3)$$

- Duyarlılık (Recall), modelin gerçek pozitif örnekler arasından doğru bir şekilde pozitif olarak tahmin ettiği oranı ifade eden bir performans ölçütüdür. Başka bir deyişle, modelin pozitif sınıfa ait örnekleri eksiksiz biçimde tespit etme başarısını değerlendirir. Bu metrik, özellikle yanlış negatiflerin (False Negative) azaltılmasının önemli olduğu durumlarda kritik bir öneme sahiptir. Bu çalışmada, salatalıkların gerçek pozitif örnekler arasından doğru biçimde tanımlanma oranını ölçmek amacıyla kullanılmıştır. Duyarlılık değeri aşağıdaki denklem aracılığıyla hesaplanmaktadır: $\text{Recall} = \frac{\text{TP}}{(\text{TP}+\text{FN})}$ (4)

- F1-Score: Doğruluk yerine kullanılabilen, problemin yorumlanması ve gözlemlenmesi açısından oldukça önemli bir metriktir. Kesinlik ve Duyarlılık metrik değerlerinin harmonik ortalaması ile ortaya çıkan skordur.

$$\text{F1 Score} = \frac{2*\text{Precision}}{(\text{Precision}+\text{Recall})} \quad (5)$$

- mAP: Recall ve Precision değerlerini ortalamasını alarak salatalığın sınıflandırma eşiğini ayarlar. Bu değer enginar için ortalama hassasiyeti temsil eder. Tanımlanan tüm sınıflar için bu değerlerin ortalamasını almak, hesaplanabilen ortalama hassasiyeti verir. Ortalama hassasiyet için kullanılan denklem aşağıda verilmiştir.

$$\text{mAP} = \frac{1}{\text{C}} + \sum_{\text{k}=1}^{\text{T}} \text{P(k)}\Delta\text{R(k)} \quad (6)$$

2.2.1. Gerçek Zamanlı Tespit ve Ölçüm Altyapısı

Gerçek zamanlı görüntü işleme, çözünürlüğü 1280x720 piksel olan Webcam kamera ile 30 fps hızında sürekli görüntü alınarak yapılmıştır. Alınan görüntüler gerçek zamanlı olarak YOLOv8n nesne tespit modeli aracılığıyla analiz edilmiştir. Tüm salatalık görüntüleri tespit edilerek her birinin etrafına sınırlayıcı kutular (bounding box) çizilmiştir. Tespit edilen her bir nesne için en büyük kontur belirlenmiş, bu sayede arka plan gürültüsü azaltılarak ölçüm doğruluğu artırılmıştır.

Kamera kalibrasyon parametreleri ve referans ölçü birimleri yardımıyla, pikseller cinsinden elde edilen kutu boyutları gerçek dünya birimlerine (cm) dönüştürülmüştür. Bu boyutlar silindirik hacim tabanlı ağırlık tahmin fonksiyonuna girdi olarak verilmiştir. Hesaplanan uzunluk, çap ve tahmini ağırlık değerleri, gerçek zamanlı video akışı üzerinde yeşil renkli yazı biçiminde kullanıcıya sunulmuştur.

Bu sistem, derin öğrenme tabanlı nesne tespiti ile geometrik hacim temelli kütle tahmini yaklaşımlarını bütünleştirerek düşük maliyetli, hızlı ve temassız biçimde çalışan bir çözüm sunmaktadır. Yöntem, sera ortamlarında veya açık tarla koşullarında salatalık kütlesinin gerçek zamanlı tahmininde yüksek doğruluk sağlamaktadır. Çalışma sırasında yazılan kodlar benzer morfolojik özelliklere sahip diğer uzun biçimli tarımsal ürünlere (örneğin kabak, patlıcan, salatalık çeşitleri) kolayca uyarlanabilir bir yapıya sahiptir.

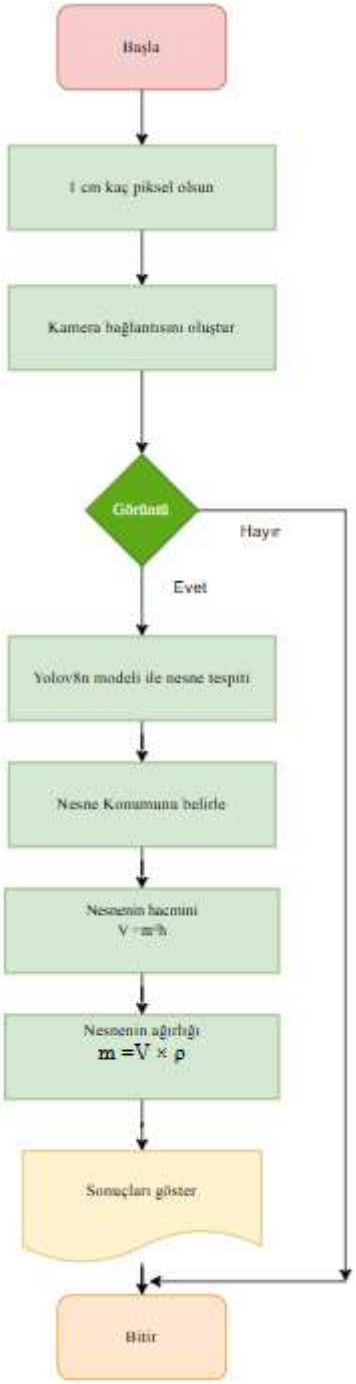
2.2.2. Silindirik Hacim Yaklaşımına Dayalı Ağırlık Tahmin Mekanizması

Çalışmada, salatalığın kütlesi, klasik silindir hacmi denklemini temel alan fiziksel bir yaklaşımla tahmin edilmiştir. Salatalığın geometrik olarak yaklaşık silindirik bir biçime sahip olduğu varsayılmıştır. Bu varsayım altında hacim, aşağıdaki denklem kullanılarak hesaplanmıştır:

$$V = \pi r^2 h \quad (7)$$

Burada r, yarıçapı (ölçülen genişliğin yarısı), h ise salatalığın uzunluğunu temsil etmektedir. YOLOv8n modelinden elde edilen tespit kutularının (bounding box) koordinatları kullanılarak her bir salatalığın genişliği (w) ve uzunluğu (h) belirlenmiştir. Yarıçap değeri;

$$r = \frac{w}{2} \quad (8)$$



formülü ile hesaplanmıştır.Bu değerler kullanılarak hacim (V, cm^3) elde edilmiştir. Elde edilen hacim, salatalığa özgü olarak deneysel biçimde belirlenmiş yoğunluk katsayısı (ρ) ile çarpılarak kütle değeri hesaplanmıştır:

$$m = V \times \rho \quad (9)$$

Buradaki yoğunluk katsayısı (ρ), farklı salatalık türleri için gerçek ölçümlere dayalı olarak yapılan kalibrasyon sonucunda belirlenmiştir. Bu katsayı, elle tartılmış örneklerin hacim tahminleriyle karşılaştırılarak doğrusal regresyon analiziyle optimize edilmiştir. Böylece çevresel değişkenlikler ve çeşit farkları dikkate alınarak sistemin genellenebilirliği artırılmıştır. Sonuçta elde edilen kütle değeri gram (gr) cinsinden hesaplanmış, 1000'e bölünerek kilogram (kg) cinsine dönüştürülmüştür. Bu yöntem, geometrik temelli hesaplama ile veri temelli kalibrasyonu birleştirerek değişken görüntüleme koşullarında dahi güvenilir bir tahmin olanağı sunmaktadır.Tablo 1'de kullanılan parametre değerleri verilmiştir.Şekil 3'de programın akış diyagramı ve kod parçaları verilmiştir.

Tablo 1.Parametre değerleri

Parametre	Değer
Model	YOLOv8n (Ultralytics)
Girdi Boyutu	640 x 640
Epoch	100
Batch Size	16
Optimizer	AdamW
Learning Rate (başlangıç)	3e-4
Weight Decay	5e-2
LR Scheduler	Cosine annealing
Warmup Epochs	3
Augmentations	Mosaic, MixUp, HSV jitter, Flip, RandomAffine
Loss Bileşenleri	cls + bbox + DFL
İlk Durdurma	Patience=20 epoch
Eğitim/Doğrulama/Test	0.76 / 0.17 / 0.07 (n=999)
Çıktı Eşik (Conf.)	0.25

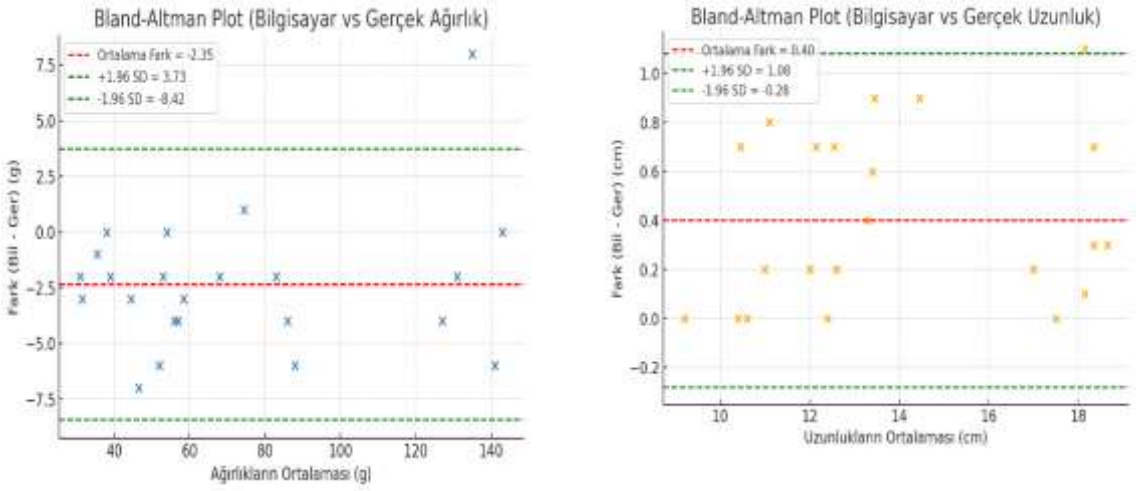
Yapılmış olan 23 adet test sırasında elde edilen örnek sonuç görüntüleri Şekil 4'de verilmiştir.



Şekil 4. Test sonuç ekranları

3.Araştırma Sonuçları

3.1. Bland–Altman Analizi

Bilgisayar tarafından tahmin edilen değerlerin gerçek ölçümlerle olan uyumunu değerlendirmek amacıyla Bland–Altman analizi uygulanmıştır. Bu yöntem, iki ölçüm tekniği arasındaki sistematik farkı (bias) ve bu farkların dağılımını belirlemek için yaygın biçimde kullanılmaktadır. Analiz, hem ağırlık (g) hem de uzunluk (cm) verileri üzerinde ayrı ayrı

gerçekleştirilmiştir.Şekil 5'de Bland-Altman analiz ekranı ,Tablo 2'de analiz sonuçları verilmiştir.

(a) **(b)**

Şekil 5.Bland-Altman analiz ekranı

Tablo 2.İki Bland–Altman analizinin sonuçları

Ölçüm Türü	Ortalama Fark (Bias)	Standart Sapma (SD)	Alt Limit (−1.96 SD)	Üst Limit (+1.96 SD)
Ağırlık (g)	−2.35 g	3.10 g	−8.42 g	+3.73 g
Uzunluk (cm)	+0.40 cm	0.35 cm	−0.28 cm	+1.08 cm

Ağırlık ölçümleri için yapılan analizde, ortalama fark (bias) −2.35 g olarak hesaplanmıştır. Bu değer, bilgisayar tabanlı ölçüm sisteminin gerçek ölçümlere kıyasla ortalama olarak 2.35 g daha düşük tahmin yaptığını göstermektedir. Standart sapma (SD) 3.10 g olup, farkların %95'inin −8.42 g ile +3.73 g aralığında kaldığı belirlenmiştir. Bu sonuç, iki yöntem arasında iyi düzeyde bir uyum bulunduğunu, ancak sistematik olarak küçük bir az tahmin eğilimi olduğunu göstermektedir.

Uzunluk ölçümleri açısından değerlendirildiğinde, ortalama fark 0.40 cm olup bilgisayar ölçümleri gerçek değerlere göre ortalama 0.40 cm daha yüksek bulunmuştur. Standart sapma 0.35 cm düzeyindedir ve farkların %95'i −0.28 cm ile +1.08 cm arasında yer almaktadır. Bu durum, uzunluk ölçümlerinde yüksek tutarlılık ve düşük sapma olduğunu göstermektedir.

Genel olarak, yapılan Bland–Altman analizi sonuçları, bilgisayar destekli ölçüm sisteminin hem uzunluk hem de ağırlık açısından gerçek ölçümlerle yüksek uyum gösterdiğini, özellikle uzunluk ölçümlerinde neredeyse hatasız bir doğruluk elde edildiğini ortaya koymaktadır. Ağırlık tahminlerinde gözlenen küçük farkların ise ölçüm koşulları veya modelin kalibrasyon sürecinden kaynaklanabileceği değerlendirilmektedir.

3.2. Ablation Analizi

Bilgisayar ölçümlerine dayalı olarak tahmin edilen ağırlık değerlerinin hangi değişken bileşimiyle en yüksek doğruluk elde edildiğini belirlemek amacıyla bir ablation analizi gerçekleştirilmiştir. Bu analizde farklı öznitelik kombinasyonları kullanılarak modelin

performans değişimi karşılaştırılmıştır. Analiz, 5 katlı çapraz doğrulama (5-fold cross validation) yöntemiyle yürütülmüş; performans ölçütü olarak MAE (Mean Absolute Error), RMSE (Root Mean Square Error), MAPE (Mean Absolute Percentage Error) ve R^2 değerleri hesaplanmıştır. Tablo 6. Ablation analizi sonuçları verilmiştir.

Uygulanan senaryolar aşağıdaki gibidir:

- **S1:** Yalnızca Bil_Ağırlık değişkeniyle doğrusal regresyon
- **S2:** Bil_Ağırlık ve Bil_Uzunluk değişkenleri birlikte kullanılmıştır
- **S3:** Bil_Ağırlık ve Bil_Ağırlık² (doğrusal olmayan terim eklenmiştir)
- **S4:** S1 modeline Bland–Altman bias düzeltmesi (+2.35 g) eklenmiştir
- **S5:** Bil_Ağırlık, Bil_Uzunluk ve Bil_Ağırlık² kombinasyonu kullanılmıştır

Tablo 6. Ablation analizi sonuçları

Senaryo	MAE (g)	RMSE (g)	MAPE (%)	R^2
S2: Bil_Ağırlık + Bil_Uzunluk	**2.70**	**3.60**	**4.08**	**0.990**
S1: Yalnızca Bil_Ağırlık (doğrusal)	2.62	3.61	3.80	0.990
S3: Bil_Ağırlık + (Bil_Ağırlık)²	2.73	3.73	3.81	0.989
S5: Bil_Ağırlık + Bil_Uzunluk + (Bil_Ağırlık)²	2.83	3.75	4.18	0.989
S4: S1 + Bland–Altman Bias Düzeltmesi (+2.35 g)	3.20	4.22	5.34	0.987

Değerlendirme

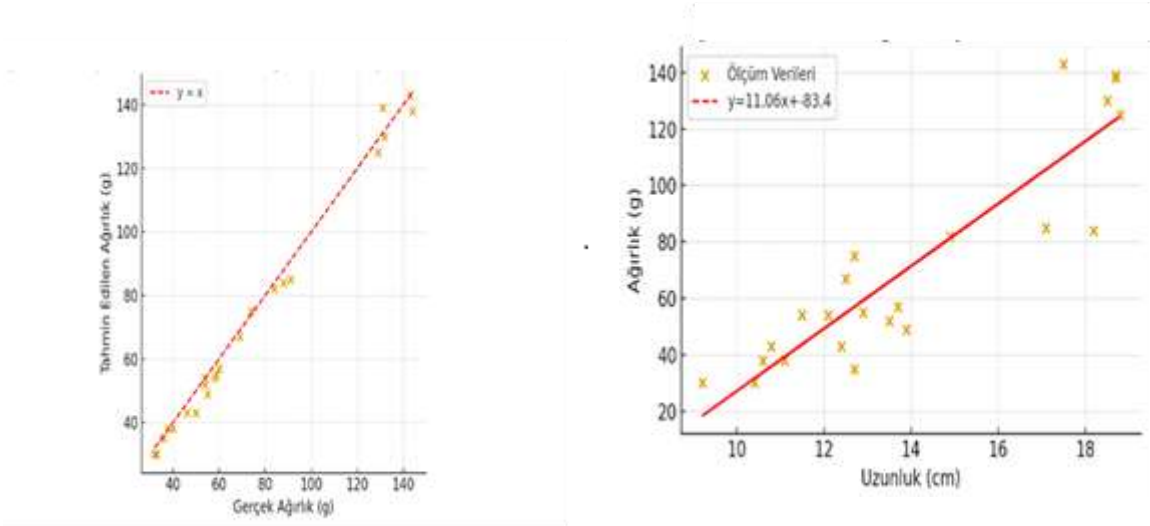
Analiz sonuçlarına göre en düşük hata değeri ve en yüksek determinasyon katsayısı S2 senaryosunda elde edilmiştir. Bu durum, ağırlık tahmini sürecinde yalnızca bilgisayarın hesapladığı ağırlık değerinin değil, aynı zamanda uzunluk bilgisinin de modele dahil edilmesinin performansı artırdığını göstermektedir. Doğrusal olmayan terimler (S3, S5) veya sabit ofset düzeltmeleri (S4) eklenmesine rağmen, bu eklemeler modelin doğruluğunu artırmamış, aksine hata oranlarında hafif bir yükselme gözlenmiştir. Bu sonuç, mevcut veri boyutu göz önüne alındığında basit doğrusal modellerin daha genellenebilir olduğunu ortaya koymaktadır.

Kalibrasyon Modeli

Tüm veri üzerinde eğitilen en iyi model (S2) aşağıdaki denklemle ifade edilmektedir:

$$\widehat{\text{Ger_Ağırlık}} = -3.286 + 0.919 \times (\text{Bil_Ağırlık}) + 0.815 \times (\text{Bil_Uzunluk})$$

Bu model, tüm veri üzerinde MAE = 1.95 g, RMSE = 2.76 g ve R^2 = 0.994 performans değerlerine ulaşmıştır. Sonuç olarak, ablation analizi bilgisayar tabanlı ölçüm sisteminin gerçek ağırlık değerlerini yüksek doğrulukla tahmin edebildiğini ve modelin fazla karmaşıklık gerektirmeden yüksek genelleme başarısına sahip olduğunu göstermektedir.



Genel olarak, yapılan analizler bilgisayar tabanlı ölçüm yönteminin güvenilir, tekrarlanabilir ve kalibre edilebilir bir yapıya sahip olduğunu göstermektedir. Sistem, uzunluk ölçümlerinde yüksek hassasiyet, ağırlık tahminlerinde ise güçlü bir doğruluk-serbestlik dengesi sunmaktadır. Elde edilen bulgular, bu yaklaşımın tarımsal ürünlerde (salatalık, fasulye veya benzeri meyve-sebze türlerinde) otomatik boyut ve ağırlık tahmini gibi uygulamalarda etkin biçimde kullanılabileceğini göstermektedir. Gelecekte daha geniş veri setleriyle gerçekleştirilecek

çalışmalar, modelin farklı ürün tipleri ve çevresel koşullar altında genelleme kapasitesini daha da artıracaktır.

3.3. Regresyon ve Korelasyon Analizi

Geliştirilen modelin performansı, gerçek ölçüm değerleriyle yapılan doğrusal regresyon ve korelasyon analizleriyle değerlendirilmiştir. Gerçek ve tahmin edilen ağırlık değerlerinin karşılaştırılması Şekil 6-a'da verilmiştir. Elde edilen sonuçlar, modelin tahmin performansının oldukça yüksek olduğunu göstermektedir. Gerçek ağırlık değerleri ile tahmin edilen ağırlıklar arasında $R^2 = 0.989$düzeyinde bir determinasyon katsayısı elde edilmiştir. Bu durum, geliştirilen YOLOv8n tabanlı modelin, görüntü üzerinden nesne boyutunu ölçme ve ağırlık tahmini konusunda yüksek doğrulukla çalıştığını açıkça ortaya koymaktadır. Tahmin edilen değerlerin çoğu, **y = x** referans çizgisine oldukça yakın dağılmış olup, modelin genelleme yeteneğinin güçlü olduğunu göstermektedir.

Uzunluk ve ağırlık arasındaki ilişkiyi gösteren Şekil 6-b incelendiğinde, iki değişken arasında anlamlı bir doğrusal korelasyon olduğu görülmektedir ($R^2 = 0.829$). Bu sonuç, sistemin görüntü tabanlı uzunluk ölçümünün ağırlık tahmini için güvenilir bir girdi oluşturduğunu göstermektedir. Özellikle 10–25 cm aralığındaki salatalıklarda ağırlık artışının uzunlukla paralel olduğu, ancak 25 cm üzerindeki örneklerde hacim artışının lineerlikten sapma gösterdiği belirlenmiştir. Bu durum, meyve formundaki varyasyonların (örneğin eğrilik, genişlik değişimi) model performansına kısmi etkide bulunduğunu göstermektedir.

(a) (b)

Şekil 6.(a)Gerçek ve tahmin edilen ağırlıkların karşılaştırması,(b)Uzunluk-ağırlık ilişkisi

Elde edilen sonuçlar benzer çalışmalara kıyasla oldukça üst düzeydedir. Benzer çalışmalardaki YOLOv5 tabanlı yaklaşımlarda bildirilen R^2değerleri genellikle 0.90'ın altında kalmaktadır. Bu çalışma, YOLOv8n mimarisinin düşük parametre sayısına rağmen (3.2 M) daha kararlı ve hızlı tahminler sunabildiğini göstermektedir. Ayrıca sistem, gerçek zamanlı olarak (30 FPS üzeri) çalışabilmekte, bu da tarımsal üretim hatlarında veya seralarda otomatik kalite kontrol süreçlerine kolayca entegre edilebileceği anlamına gelmektedir.

YOLOv8n derin öğrenme eğitim sonuçları , bilgisayar tabanlı yaklaşımın hem yüksek doğruluk hem de uygulama verimliliği açısından tatmin edici olduğunu ortaya koymaktadır. İlerleyen çalışmalarda, modelin farklı çeşitlerdeki (*Cucumis sativus L.*) salatalıklar ve farklı aydınlatma koşullarında test edilmesiyle genelleme kapasitesinin daha da artırılması hedeflenmektedir.

4.Tartışma ve Sonuç

Bu çalışmada geliştirilen YOLOv8n tabanlı gerçek zamanlı ölçüm sistemi, yalnızca meyve tespiti değil aynı zamanda boyut ve kütle tahmini alanında da derin öğrenme yöntemlerinin pratik uygulanabilirliğini göstermektedir. Bu yaklaşım, geleneksel fiziksel ölçüm sistemlerine göre daha düşük maliyetli, temassız ve ölçeklenebilir bir alternatif sunmaktadır.

Benzer biçimde, Gao ve ark. (2024) tarımsal nesne tespiti için geliştirdikleri YOLOv10-FastLite modelinde, hesaplama yükünü %45 oranında azaltırken doğruluğu koruyarak düşük güçlü cihazlarda yüksek verimlilik elde etmişlerdir. Çalışmadaki YOLOv8n modelinin donanım kısıtlı ortamlarda kullanım uygunluğunu destekler niteliktedir. Tarımsal ürünlerin boyut ve ağırlık tahmininde geometrik tabanlı fiziksel modellerle derin öğrenme yaklaşımlarının bütünleştirilmesi, modelin tahmin güvenilirliğini artırmaktadır. Wang ve ark. (2024), mısır koçanlarının kütle tahmini için CNN tabanlı bir görüntüleme sistemiyle silindirik hacim formülünü birleştirmiş ve ±2.5 g hata payıyla yüksek doğrulukla bulmuşlardır. Luo ve ark. (2023), armut meyvelerinde ağırlık tahmini için derin regresyon ağlarını kullanarak geleneksel hacim temelli tahminlerle yüksek korelasyon (R^2 = 0.98) elde etmişlerdir. Bu sonuçlar, çalışmada kullanılan silindirik hacim yaklaşımıyla örtüşmektedir. Diğer yandan tarımsal tespit sistemlerinde veri artırma (augmentation) stratejilerinin model genellemesini güçlendirdiği birçok yapılmıştır. Han ve ark. (2023), domates hastalık tespiti için YOLOv8 + MixUp stratejisiyle %4.3 mAP@0.5 iyileşmesi sağlamışlardır. Çalışmadaki Roboflow tabanlı veri artırma yaklaşımının doğruluğa katkısını desteklemektedir. Chen ve ark. (2024), Hybrid ECA-Net + YOLOv11 mimarisiyle küçük nesne tespitinde %3.8 daha yüksek doğruluk elde ederek dikkat modüllerinin ince uzun ürünlerde avantaj sağladığını vurgulamışlardır. Gerçek zamanlı performans açısından, Lee ve ark. (2024) gömülü sistemlerde düşük gecikmeli (low-latency) YOLO modellerinin tarımsal üretim hattına entegrasyonunda FPS değerinin en az 30 olması gerektiğini belirtmişlerdir. Çalışmada kullanılan 30 FPS kameralı YOLOv8n sistemi, endüstriyel gereksinimleri karşılamaktadır. Benzer şekilde, Kim ve Lee (2024) düşük güçlü gömülü cihazlarda 20–25 FPS performansla elma tespiti gerçekleştirmişlerdir. Tarımsal boyutlandırma uygulamalarında RGB tabanlı tek kamera çözümlerinin başarıyla kullanılabileceği, Li ve ark. (2023) tarafından sera koşullarında domates tespiti için göstermişlerdir. Ancak, RGB-D veya stereo kamera sistemlerinin karmaşık ortam koşullarında hâlâ avantaj sağladığı bilinmektedir (Zhao ve ark., 2024). Bu nedenle, gelecekte derinlik verisinin entegrasyonu, çalışmanın doğruluk potansiyelini daha da artırabilir. Bland–Altman ve ablation analizi sonuçları, sistemin hem uzunluk hem de ağırlık tahminlerinde istatistiksel olarak yüksek uyum ve düşük hata varyansı sunduğunu göstermektedir. Bu durum, derin öğrenme tabanlı tahmin sistemlerinin saha uygulamalarında güvenilir karar destek araçları olarak kullanılabileceğini kanıtlamaktadır (Minaee ve ark., 2024). Montalvo ve ark. (2023) benzer biçimde YOLOv7-tabanlı domates boyut tahmininde ±1.2 cm farkla yüksek tutarlılık elde ederek bu tür sistemlerin hasat planlama süreçlerine entegre edilebileceğini göstermişlerdir. Yapılan çalışmada önerilen sistem salatalık özelinde yürütülmüş olsa da, kabak, patlıcan veya fasulye gibi morfolojik olarak benzer ürünler için de uyarlanabilir bir mimari sunmaktadır. Gelecekte, çoklu ürün verilerinin dâhil edildiği çapraz tür (cross-crop) modellerin geliştirilmesi, tarımsal otomasyon sistemlerinde çoklu ürün tespiti ve boyut tahminine yönelik önemli bir ilerleme sağlayacaktır.

ÖZET

Vermikompost uygulaması, bitkisel ve hayvansal kökenli olan organik atıkların toprak solucanları yardımıyla faydalı mikroorganizmalar aracılığı ile ayrıştırılarak stabil, besin yönünden zengin bir organik gübre olan vermikomposta dönüştürülmesi işlemidir. Bu biyolojik gübre, toprak yapısını iyileştirerek gözeneklilik ve su tutma kapasitesini artırırken, hava sirkülasyonunu da düzenler. Vermikompost, toprakta organik madde birikimini teşvikler, azot, fosfor, potasyum, kalsiyum, magnezyum ve sodyum gibi temel besin elementlerinin mevcudiyetini artırmaktadır. Bu durum, bitki beslenmesini ve büyümesini desteklemenin yanında, fotosentez kapasitesini ve yaprakların klorofil içeriğini de olumlu yönde etkilemektedir. Ayrıca vermikompost, toprak pH'ını dengeleyerek elektriksel iletkenliği iyileştirir ve tuzluluk sorununa yol açmadan bitki gelişimini desteklemektedir. Solucanların toprağı fiziksel olarak işleyerek sıkışıklığı azaltmaları, suyun toprak profiline nüfuz etmesini önemli ölçüde artırmaktadır. Tüm bu özellikler göz önüne alındığında, vermikompost çevresel sürdürülebilirlik ve ekonomik tarım uygulamaları açısından önemli bir organik gübre alternatifi olarak değerlendirilir.

Anahtar Kelimeler: Vermikompost, Organik Madde, Besin Elementi.

NUTRIENT COMPOSITION OF VERMICOMPOST

ABSTRACT

Vermicompost application is the process of converting plant- and animal-based organic wastes into a stable, nutrient-rich organic fertilizer called vermicompost with the help of earthworms and beneficial microorganisms. This biological fertilizer improves soil structure by increasing porosity and water-holding capacity, while also regulating air circulation. Vermicompost promotes the accumulation of organic matter in the soil and enhances the availability of essential nutrients such as nitrogen, phosphorus, potassium, calcium, magnesium and sodium. This not only supports plant nutrition and growth but also positively affects photosynthetic capacity and the chlorophyll content of leaves. Additionally, vermicompost balances soil pH, improves electrical conductivity, and supports plant development without causing salinity problems. The physical activity of earthworms in the soil reduces compaction and significantly improves water infiltration into the soil profile. Considering all these features, vermicompost is regarded as an important organic fertilizer alternative for environmental sustainability and economically viable agricultural practices.

Keywords: Vermicompost, Organic Matter, Nutrient Element.

1.Giriş

Vermikompostun, hayvansal ve bitkisel atıkların yönetimini daha kolay hale getirdiği ve bu atıkların değerlendirilmesini sağladığı ifade edilmiştir. Ayrıca, vermikompostun besin elementi kayıplarını düşürdüğü, bitki verimliliğini artırdığı, toprakların fiziksel, kimyasal ve biyolojik özelliklerini iyileştirmesi nedeniyle güvenilebilir bir organik gübre olduğu belirtilmiştir. Vermikompostun yeterli miktarda faydalı bitki besin maddeleri içerdiği, toprak düzenleme özelliğine sahip olduğu, bazı pestisit ve bitki hastalıklarını kontrol ettiği ve uzun vadede kullanılması durumunda ekonomik olduğu bildirilmiştir (Bellitürk, 2016). Farklı amaçlar için toprak solucanlarının kültürünün yapılması işlemi vermikültürdür (Edwards ve Bohlen, 1996). Solucanlar uygun düzeyde besin ortamı için %65-75 oranlarında neme ihtiyaç duyarlar ancak bakteriler için optimum nem oranı %55'dir (Rostami ve ark., 2010). Faaliyetleri için optimum sıcaklık 15-25 Co aralığında olup bu sıcaklık derecesi türlere göre farklılık da gösterebilmektedir. Optimum seviyede mikrobiyal faaliyetlerin gerçekleştirilmesi ve devam edebilmesi için aynı zamanda organik maddelerin parçalanma hızının en üst seviyede olması için de en uygun sıcaklık 15-30 Co arasındadır (Rostami vd., 2009). Vermikompost üretimi için seçilen substrat materyalin karbon- azot (C: N) oranı oldukça önemlidir. C: N oranının yüksek olması mikrobiyal faaliyetlerin azalmasına sebep olmaktadır (Ökmen ve Algur, 2000).

2.Vermikompost Nedir

Bitkisel ve hayvansal kökenli organik atıkların, toprak solucanları ve yararlı mikroorganizmalar aracılığıyla biyolojik olarak parçalanarak yapıtaşlarına ayrılması süreci vermikompostlama olarak adlandırılır. Bu süreç sonucunda elde edilen ürün ise vermikompost ya da biyohumus şeklinde tanımlanır. Genellikle *Lumbricus rubellus* ve *Eisenia fetida* gibi solucan türlerinin kullanıldığı bu yöntemle, organik atıklar değerlendirilerek çevre dostu bir gübre üretilir. Atıkların bu şekilde geri dönüştürülmesi, çevresel sürdürülebilirlik açısından önemli katkılar sunmaktadır (Demir, 2010).

Vermikompost toprakların strüktür yapısını düzenleyerek gözenek yapısını iyileştirir, su tutma kapasitesini artırır ve hava ekonomisini düzenlemektedir (Bellitürk, 2016).

Toprak ekosisteminde kritik bir rol oynayan toprak solucanları, toprak verimliliğini artırmada önemli katkılar sağlar. Yapılan araştırmalar, bu canlıların toprak üzerindeki etkilerinin fiziksel, kimyasal ve biyolojik mekanizmalarla gerçekleştiğini ortaya koymuştur (Dindar, 2008).

Kompost üretiminde kullanılacak solucanların, organik maddeleri hızla ve etkili bir şekilde parçalama yeteneğine sahip olmaları gerekmektedir. Toprağın doğal yapısında sıkça rastlanan solucanlar, kompost yapımında kullanılan türler değildir. Kırmızı kompost solucanları, organik maddeleri hızlı bir şekilde öğütüp parçalama konusunda son derece etkilidir. En yaygın kullanılan bu türler arasında *Eisenia fetida* ve *Lumbricus rubellus* yer alır. Bu solucanlar ticari olarak temin edilebileceği gibi, hayvancılık alanlarında, gübre yığınlarında, çöplüklerde ve organik maddelerce zengin topraklarda da bolca bulunabilirler (Domínguez ve Edwards, 2011).

3. Vermikompostun Toprak Organik Maddesi Üzerindeki Etkisi

Geleneksel tarım uygulamaları, toprak ve su kaynaklarının giderek daha fazla kirlenmesine yol açmaktadır. Bu durum, kimyasal gübrelerin yerine organik gübrelerin kullanılmasının giderek daha fazla tercih edilmesine neden olmuştur (İlay ve ark., 2013).

Vermikompost, özellikle toprakta organik madde miktarını artırarak, kimyasal gübrelerin kullanımını ortadan kaldırarak üreticilere ekonomik fayda sağlamakta ve toprak sürdürülebilirliğini destekleyerek sağlıklı bitki üretimini teşvik etmektedir; bu faydalar birçok araştırmacı tarafından vurgulanmıştır (Aksu ve ark., 2017).

Vermikompost uygulamasının yapıldığı çalışmalarda ise vermikompostun toprağın organik madde içeriğini arttırdığı vurgulanmaktadır (Tavalı ve ark., 2014; Çıtak ve ark., 2014).

Vermikompost, su tutma kapasitesini artırarak, toprak pH'sını ve organik madde miktarını iyileştirip mikrobiyal aktiviteyi teşvik ederek hem ürün verimliliği hem de toprak sağlığı üzerinde önemli olumlu etkiler yaratmaktadır (Chan ve ark., 2008; Steiner ve ark., 2007; Dias ve ark., 2010).

4. Vermikompostun Toprak Özelliklerine Etkisi

Bir çalışmada, farklı miktarlarda topraklara uygulanan vermikompostun, en yüksek doz olan 15 t ha-1'de, toprakların toplam organik karbon, toplam azot, fosfor, potasyum, kalsiyum, çinko ve mangan içeriklerinde kontrol grubuna göre anlamlı artışlar sağladığı tespit edilmiştir. Ayrıca, uygulanan vermikompostun toprakların elektriksel iletkenlik (EC) değerini artırdığı, toprak pH'sını ise düşürdüğü belirlenmiştir. Toprak fiziksel özellikleri açısından ise hacim ağırlığı ve toplam porozite gibi değerlerin vermikompost uygulaması ile iyileştiği gözlemlenmiştir (Azarmi ve ark., 2008).

Bir sera deneyinde, topraklara farklı miktarlarda (0, 250, 500, 750, 1000 kg da-1) vermikompost uygulamasının yalnızca toprak kireci üzerinde etkili olduğunu, diğer toprak özelliklerinde ise herhangi bir değişiklik meydana getirmediğini tespit etmişlerdir (Köksal ve ark., 2017).

Organik bir gübre olan vermikompostun farklı dozlarının bitki ve toprak özellikleri üzerindeki etkilerini incelemişlerdir. Araştırmada, toprak reaksiyonu, suda çözünebilen tuz miktarı, kireç, organik madde, fosfor ve potasyum gibi toprak özellikleri değerlendirilmiştir. Toprak özelliklerinden toprak reaksiyonu ile fosfor değerleri arasındaki farklar istatistiksel olarak anlamlı bulunurken, vermikompost uygulamalarıyla suda çözünebilen tuz, kireç ve organik madde miktarlarında değişiklikler gözlemlenmiş, ancak bu değişiklikler istatistiksel olarak anlamlı bulunmamıştır (Özkan ve ark., 2016).

Farklı kombinasyonlarda beş farklı biyo-gübrenin, killi tın yapısındaki bir toprağa uygulanarak agregat oluşumu üzerindeki etkilerini incelemişlerdir. 90 gün süren inkübasyon sonrası, alg ve vermikompost uygulamalarının, 2–1 mm boyutundaki agregatların miktarını kontrol grubuna göre anlamlı şekilde artırdığı belirlenmiştir. Ayrıca, vermikompost uygulamasının 4 mm'den büyük agregatların miktarında da önemli artışlar sağladığı gözlemlenmiştir (Sönmez ve Yılmaz, 2016).

5. Vermikompostun Topraktaki Makro Bitki Besin Elementleri Üzerindeki Etkisi Nedir?

Vermikompost uygulaması toprak organik maddesi, toplam N, P, K, Na, Ca ve Mg konsantrasyonlarını artırır (Nascimento ve ark., 2004) ve toprak yapısını ve bitki beslenmesini, büyümesini, fotosentezini ve yaprakların klorofil içeriğini iyileştirir Fernández-Luqueño ve ark., (2010); Rekha ve ark., (2018), bu da bitki gelişimini olumlu etkiler. Verminkompost tüm besinleri kolayca erişilebilir formda sağlar ve bitkiler tarafından besin alımını artırır. Toprakta kullanılabilir azot, vermikompost seviyelerinin artmasıyla önemli ölçüde arttı ve en yüksek azot alımı elde edilir. Vermikompost ortalama %1,5- %2,2 N, %1,8-%2,2 P ve %1,0-%1,5 K içerir (Adhikary, 2012).

Her gün organik maddeler (mikrop, bitki ve hayvan artıkları) içeren büyük miktarda toprağı yutarlar, bunları midelerinde öğütürler ve enzimlerin yardımıyla bağırsaklarında sindirirler. Kimyasal olarak sindirilen ve yutulan materyalin sadece %5-%10'u vücuda emilir ve geri kalanı, NKP (nitratlar, fosfatlar ve potasyum), mikro besinler ve faydalı toprak mikropları açısından zengin olan "vermicasting" adı verilen ince mukus kaplı granüler agregalar şeklinde atılır (Adhikary, 2012).

Vermikompost uygulaması ayrıca besin döngüsünde, bitki büyüme düzenleyicilerinin üretiminde ve bitki büyümesini teşvik eden humik maddelerin üretiminde önemli bileşenler olan mikrobiyal biyokütleyi, çeşitliliği ve mikrobiyal aktiviteyi artırarak toprağın kalitesini de iyileştirir ve bu da zararlı istilasını önemli ölçüde bastırmaya yardımcı olur (Arancon ve Edwards, 2005; Edwards ve ark., 2004; Rostami ve ark., 2014).

Topraktaki bazı mikroorganizmalar bitki rizosferlerinde sinerjik ilişkiler kurar ve böylece bitkilerin toprak nemini ve besin maddelerini, antibiyotikler ve hastalık antagonistleri gibi bazı mikrobiyal yan ürünleri kullanma kapasitesini artırmaya yardımcı olur (Arancon ve Edwards, 2005).

Solucan kompostu nitratlar, fosfatlar, çözünebilir potasyum ve magnezyum ile değiştirilebilir fosfor ve kalsiyum içerirler, haşere kompostunun, bitkiler optimum beslenmeye tabi tutulduğunda bile bitki büyümesini teşvik ettiği ortaya koyulmuştur. Vermikompostun bitki büyümesi üzerindeki doğrudan etkilere gelince, vermikompost bir P kaynağı oluşturur. Makro ve mikro besinlerin bir kısmı inorganik olarak mevcuttur ve bitkiler tarafından kolayca elde edilebilirler, çoğu kademeli olarak salınır ve mineralizasyon yoluyla organik madde oluşturulur. Bitkiye besin sağlayan yavaş salınımlı bir gübre kademeli ve sürekli şekilde besin kaynağı olmaktadır. Ancak kimyasalın aksine gübrelerde sağlanan besin miktarı orijinaline bağlı olarak büyük ölçüde değişebilir. Bitki saksı ortamına vermikompost ve makro besin elementi eklenmesi önemli bir değişikliğe neden olur fiziksel olarak etkide bulunur. Suyu değiştirmeve substratlarda hava bulunabilirliğini sağlamaya ve kök gelişimini düzenlemeye yardımcı olur (Chaoui ve ark., 2003).

6. Vermikompostun Topraktaki Mikro Bitki Besin Elementleri Üzerindeki Etkisi

Kıvırcık salata (*Lactuca sativa* var. crispa), yüksek su içeriği ve sığ kök yapısı nedeniyle kuraklık stresine karşı duyarlı olan bir sebze türüdür. Kurak koşullarda yetiştirilen bitkilerde gelişim yavaşlar, verim ve kalite kayıpları gözlemlenir. Bu nedenle, stresin olumsuz etkilerini hafifletmede vermikompost önemli bir çözüm olabilir. Bellitürk ve ark., (2017) tarafından yapılan bir çalışmada, kıvırcık salataya vermikompost ve farklı organik gübrelerin etkisi incelenmiş ve vermikompost uygulaması ile bitkinin potasyum ve çinko içerikleri arasında negatif bir korelasyon bulunmuştur. Bu araştırmada, vermikompostun kuraklık stresinin kıvırcık salata üzerindeki olumsuz etkilerini azaltmadaki rolü ve bitkinin kuraklığa dayanıklılığını desteklemedeki işlevi tartışılmıştır.

Demir, klorofil, fotosentez, solunum ve enzim sistemlerinin oluşumunda önemli bir role sahip olmaktadır ve bitkilerde oksidatif stres ile önemli ölçüde azalmaktadır (Havlin ve ark., 1999; Sivritepe ve ark., 2008; Kostopoulou ve ark., 2015).

Mangan, demir ile birlikte klorofil üretimini destekleyen ve fotosentez için gerekli olan bir elementtir. Ayrıca, kuraklık stresi sırasında oluşan serbest radikallerin zararlı etkilerini engellemek amacıyla süperoksit dismutaz enzimini aktive eder (Hebbem ve ark., 2009).

Mn ve Fe' in, nemli toprak koşullarında çözünür formlara dönüşümü ve bitki tarafından alınabilirliği daha kolaydır (Havlin ve ark., 1999).

Çinko, bitkilerde karbonhidrat metabolizması, protein sentezi, oksin metabolizması ve enzim aktivasyonunda önemli bir rol oynarken, bakır çeşitli enzimlerin kofaktörü ve proteinlerin düzenleyicisi olarak işlev görmektedir (Marschner, 1995).

7. Vermikompostun Topraktaki Mikrobiyal Aktivite Üzerindeki Etkisi Nedir

Vermikompostlama, solucanlar ve ilişkili mikropları içeren termofilik olmayan, boioksidatif bir işlem olarak bilinmektedir. Bu biyolojik organik atık ayrıştırma işlemi, biyogübreyi yani

vermikompostu üretir. Vermikompost, yüksek gözenekliliğe, iyi havalandırmaya, drenaja, su tutma kapasitesine, mikrobiyal aktiviteye, mükemmel besin durumuna ve tamponlama kapasitesine sahip ince bölünmüş, turba benzeri bir malzemedir ve böylece toprak verimliliği ve bitki büyümesi için uygun olan gerekli fizikokimyasal karakterlerin elde edilmesine yardımcı olur. Vermikompost, yararlı mikropları teşvik ederek toprak biyoçeşitliliğini artırır ve bu da bitki büyümesini doğrudan bitki büyümesini düzenleyen hormonlar ve enzimler üreterek ve dolaylı olarak bitki patojenlerini, nematodları ve diğer zararlıları kontrol ederek artırmış olur, böylece bitki sağlığını iyileştirir ve verim kaybını en aza indirir. Doğal biyolojik, biyokimyasal ve fizikokimyasal özellikleri nedeniyle vermikompost, sürdürülebilir tarımı teşvik etmek ve ayrıca aksi takdirde yaşam ve çevre için ciddi tehdit oluşturabilecek tarımsal, endüstriyel, evsel ve hastane atıklarının güvenli yönetimi için kullanılabilir (Pathma, 2012).

8. Vermikompostun Topraktaki Bazı Enzim ve Bitki Büyüme Hormonları Üzerindeki Etkisi

Vermikest, piyasada mevcut olan tüm organik gübreler arasında en yüksek verime sahip olanıdır. Vermikestin mikrobiyal aktivite seviyesi, toprağa göre 10 ila 20 kat daha fazladır. Bu yüksek mikrobiyal çeşitlilik, bitki gelişimini destekleyen kimyasallar (hormonlar ve diğer bileşikler) ile zararlı bitki patojenlerinin büyümesini engelleyen enzim ve çeşitli bileşiklerin üretimini sağlar (Logsdon, 1994).

Vermikestin içinde bulunan, solucan mukusu ile sarılmış besin elementleri, yavaş bir şekilde salınarak bitkiler tarafından hemen kullanılabilir formda bulunur. Bu besinler yavaşça çözüldüğünden, sızıntı yoluyla besin kaybı yaşanmaz. Ayrıca, vermikestin yüksek gözenek yapısı, su tutma kapasitesi ve iyi havalanması sayesinde mükemmel bir toprak düzenleyici görevi görür. Bu özelliklerin yanı sıra, materyal bitki köklerini aşırı sıcaklıklardan korur, erozyonu önler ve yabani otların gelişimini engeller. Vermikest, hem sera hem de saksı toprakları için ideal bir karışım maddesidir. Bahçe ve tarla bitkilerinde bu olumlu etkiler gözlemlenmiştir. Hatta en hassas bitkilerde bile yanma etkisi görülmez ve tüm besin elementleri suda çözünebilen özellik taşır. Malç olarak kullanıldığında, sulama ile besin elementleri doğrudan bitki köklerine ulaşır (Anonim, 1992).

Vermikestin bitki besleme üzerindeki etkisi, ilk kez Fosgate ve Babb, (1972) tarafından bildirilmiştir. Araştırmada, sığır gübresinden elde edilen kestinin, "özel sera çiçek karışımına" denk seviyelerde bitki büyümesini teşvik ettiği belirtilmiştir.

Handreck (1986), vermikestin bitkilerin çoğu iz element ihtiyacını karşılayabileceğini ancak çoğu kestinin bitkilerin tüm azot gereksinimini karşılayamayacağını belirtirken; Edwards ve ark. (1985), organik atıkların çoğunda yeterli besin bulunduğunu ve vermikompost sürecinde azot kaybının oldukça düşük olduğunu savunmaktadır.

9. Solucan Gübresi Kullanılarak Zararlı Yönetimi

Böcekler, poikilotermik yani değişken vücut sıcaklığına sahip organizmalar oldukları için, fizyolojik özellikleri çevresel hava koşulları ve iklimdeki değişimlere karşı son derece duyarlıdır (Kocmankova ve ark., 2009).

Artan bilimsel veriler, iklim değişikliğinin zararlı organizmaların popülasyon dinamiklerini, büyüme, denge, tür bileşimi ve mekânsal ve zamansal dağılımlar açısından nasıl etkilediğini ortaya koymaktadır. Örneğin, sıcak ve kuru koşullardan hoşlanan (termo- ve kserofilik) zararlılar, iklim değişiklikleri nedeniyle yerel olarak popülasyon artışını desteklerken, soğuk iklimleri tercih eden (psikrofilik) zararlılar üzerinde olumsuz etkiler oluşturabilir. Ayrıca, bazı bölgelerde yabancı ve göçmen zararlı türlerinin popülasyon artışı beklenmektedir (Skendzic ve ark., 2021). Küresel ısınmanın etkisiyle iklimdeki değişiklikler devam ettikçe, bitki parazitleri

ve hastalıklarının tarım alanlarındaki etkisi artacaktır. Vermikompost ve benzeri ürünler, değişen iklim koşullarından kaynaklanan potansiyel ürün kayıplarını azaltmak için yardımcı olabilecek doğal çözümler sunmaktadır (Coopoosamy ve ark., 2023).

9.1. Nematodlar

M. Renco ve ark. (2015), farklı dozlarda uygulanan vermikompostun katı ve sıvı özütlerinin patates kist nematodları (Globodera rostochiensis ve G. pallida) üzerindeki etkilerini incelemişlerdir. Uygulama miktarları arttıkça, toprakta 400 g başına düşen kist, yumurta ve ikinci evre larva sayılarında belirgin azalmalar gözlemlenmiştir. Ayrıca, sıvı VCL'nin katı vermikomposta göre nematodları kontrol etmede daha etkili olduğu ve bu etkinin üre eklenmesiyle daha da arttığı belirlenmiştir.

9.2. Eklem Bacaklılar

Arancon ve ark. (2007) tarafından yapılan bir çalışmada, vermikompostun bazı bahçe bitkilerinde artropod zararlıların popülasyon artışını baskılama ve zararını azaltma etkileri değerlendirilmiştir. Araştırmacılar, vermikompost uygulamalarının bitki dokularında fenol birikimine yol açtığını, bunun da bitkileri zararlılar için tatsız hale getirdiğini öne sürmüşlerdir.

Giderek artan sayıda bilimsel çalışma, organik gübre uygulanan bitkilerin, kimyasal gübrelerle beslenen bitkilere kıyasla artropod zararlılara karşı daha dayanıklı olduğunu ortaya koymaktadır. Bazı bilim insanları, sentetik azotun bitkilerde fenolik bileşikler ve diğer doğal savunma maddelerinin sentezini engelleyebileceğini ileri sürmektedir. Ayrıca, bu tür azotlu gübreler bitkilerin besin içeriğini ve tat profilini geliştirerek zararlılar için daha çekici hale getirebilir. Öte yandan, organik gübrelerin besin elementlerini yavaş salmaları nedeniyle bu maddelerle yetiştirilen bitkilerde azot ve diğer besin maddeleri daha düşük düzeyde bulunmakta, bu da bitkilerin zararlılara karşı savunmasını güçlendirebilmektedir (Fragoyiannis ve ark. 2021; Herms ve ark., 2002).

10. Vermikompostun Diğer Yararları Nelerdir?

Vermikompost uygulamaları, toprağı mikro ve makro besin maddeleri, vitaminler, enzimler ve hormonlarla zenginleştirmekle birlikte fizikokimyasal özellikleri düzenleyerek bitki gelişimine katkı sağlamaktadır (Makulec, 2002) (Sinha ve ark., 2009; Hazra, 2016).

Vermikompost ürünleri, bitkilerin doğrudan alabileceği formda temel besin maddeleri içermektedir (Pathma ve Sakthivel, 2012; Lim ve ark., 2012). Bunun temel nedeni, termolitik kompostlamadan sonra vermikompostun, daha fazla çözünmenin gerçekleştiği mezolitik kompostlama sürecinden geçmesidir. Vermikompost, humik asitler açısından zengin belli bir materyale dönüşerek bitki biyokütlesinin ve kök gelişiminin artmasına katkıda bulunmaktadır (Delibacak ve Ongun, 2016; Erdal ve ark., 2000; Sönmez ve ark., 2013).

Toprakta bulunan bitki besin elementleri, çeşitli faktörler tarafından tutulabilir veya zıt iyonlarla bileşikler oluşturur. Vermikompost, sadece bitki büyümesini desteklemekle kalmayıp, bununla birlikte toprak pH'ını düzenler ve tuzluluk problemi oluşturmadan elektriksel iletkenliği artırmaya yardımcı olur (Argüello ve ark., 2006).

Vermikompost uygulaması, topraktaki su-hava dengesini iyileştirir ve makro gözeneklilik oranını 50 mikrometreden 500 mikrometreye çıkarmaktadır (Marinari ve ark., 2000).

Vermikompostun yüzey alanı, mikro gözenekli alanı artırır ve bu sayede daha fazla besin maddesinin tutulmasına olanak tanır (Shi-wei ve Fu-zhen, 1991; Ali ve ark., 2015).

Vermikompost ile birlikte toprağa uygulanan daha fazla inorganik N, P, K gübresinin bitkiler tarafından alındığı bildirilmiştir (Thirinavukkarasu ve Vinoth, 2013). Ayrıca, vermikompost

uygulamalarının, bozulmuş tropikal topraklarda, termolitik kompost ve inorganik N, P, K gübrelerine kıyasla bitki büyümesi ve toprak yapısı üzerinde daha olumlu etkisinin olduğu da belirlenmiştir (Jouquet ve ark., 2011).

Kırmızı solucan döküntüleri yüksek oranda humus içerir. Humus, toprak parçacıklarının kümeler halinde oluşmasına yardımcı olur, bu da havanın geçişi için kanallar oluşturur ve su tutma kapasitesini artırır. Solucanların varlığı sıkıştırılmış toprağı yeniler ve bu tür topraklardaki su penetrasyonunu %50'nin üzerinde artırır.

Humusta bulunan humik asit, kalsiyum, demir, potasyum, kükürt ve fosfor gibi bitki besinleri için bağlanma yerleri sağlar. Bu besinler, humik asitte bitkilerin kolayca alabileceği bir biçimde depolanır ve bitkilerin ihtiyaç duyduğu zaman salınır. Solucan gübresindeki "hümik asit", az miktarda bile olsa bitki büyümesini uyarır. Solucan bağırsağının aktivitesi, koşulları karıştıran ve kalıntıları aşılayan minyatür bir kompost tüpü gibidir. Bağırsaktaki nem, pH ve mikrobiyal popülasyonlar, sinerjik bir ilişki ve ardından harika bir yan ürün için uygun şekilde korunur (Adhikary, 2012).

11. Sonuç ve Öneriler

Vermikompostun bitki besin maddesi içeriği, toprak sağlığına katkısı ve mikrobiyal aktivite üzerindeki olumlu etkileri sürdürülebilir tarım sisteminde oldukça önemlidir. Vermikompostun kullanımı, toprakta organik madde birikimini destekleyerek yapısal özellikleri iyileştirir, su tutma kapasitesini artırır ve mikrobiyal çeşitliliği zenginleştirmektedir. Ayrıca, kimyasal gübre kullanımının azaltılmasını sağlayarak çevresel kirliliği azaltmakta ve ekosistemi desteklemektedir.

Sürdürülebilir tarım hedeflerine ulaşılması için vermikompost kullanımının yaygınlaşması önemlidir. Tarımsal üretimde organik atıkların değerlendirilmesini teşvik eden politikaların geliştirilmesi, çiftçilere yönelik eğitim programlarının uygulanması gerekmektedir.

Gelecekte yapılacak araştırmalarda, vermikompostun verimlilik, toprak kalitesi ve çevresel etki konularında yararları ve kullanımının ayrıntılı olarak değerlendirilmesi daha iyi bir tarım için faydalı olacaktır.

ABSTRACT

The growing global demand for plant-based protein underscores the strategic importance of legumes in developing sustainable food systems. Legumes are a valuable resource for the nutrition and functional food industries, not only for their high protein content but also for their amino acid composition, fiber, and bioactive compound richness. This study evaluated modern breeding approaches to increase the quantity and quality of protein in legumes. The effective use of genetic variation, marker-assisted selection (MAS), genomic selection (GS), pangenome analyses, high-throughput phenotyping (HTP), and the integration of advanced bioinformatics tools is critical for developing high-protein, highly processable lines. Furthermore, the development of protein fractions, reduction of anti-nutritional factors, improvement of digestibility, and the effects of environment × genotype interactions on quality parameters were discussed. The development of new legume varieties tailored to the needs of the functional food, plant-based meat, and alternative protein industries will be one of the main directions of breeding programs in the future. This review highlights the opportunities provided by modern breeding techniques and future research priorities, emphasizing the role of legumes in closing the global protein gap.

Keywords: Legumes, Plant Protein, Breeding Strategies, Protein Quality, Genomic Selection

1. Introduction

The increase in global population, the pressure of climate change on agricultural production, and the search for sustainable diets have markedly heightened the demand for plant-based protein sources in recent years. According to FAO (2023) projections, protein demand is expected to rise by at least 50% by 2050, and a substantial proportion of this requirement will need to be met from environmentally more sustainable sources. Grain legumes, with their high protein contents (20–35%), essential amino acid profiles, low carbon footprints, and symbiotic nitrogen fixation that enhances soil fertility, occupy a strategic position among the "protein crops of the future" (Foyer et al., 2019). In this respect, legumes are critical to both human nutrition and sustainable agricultural production systems.

However, the growing consumer demand necessitates not only the development of high-yielding genotypes but also the improvement of protein quality parameters, including essential amino acid balance, digestibility, levels of antinutritional factors, and functional food properties. Contemporary consumer trends are rapidly increasing the demand for high-quality protein fractions with superior gelling, solubility, viscosity, and emulsifying properties in processed products such as legume-based meat analogues, dairy alternatives, and functional foods (Boye et al., 2010; Lam et al., 2018). Therefore, breeding programs need to develop multidimensional strategies that focus not only on yield and adaptation traits but also on protein functionality and processing-related quality parameters.

Today, classical breeding methods are rapidly being transformed through integration with genomic selection, marker-assisted selection (MAS), high-throughput phenotyping, multi-omics platforms (transcriptomics, proteomics, metabolomics), CRISPR/Cas-based genome editing, and artificial intelligence-supported data analytics. More efficient use of genetic variation is becoming possible particularly through the incorporation of wild relatives and local genotypes into breeding programs in major legume genera such as *Pisum*, *Cicer*, *Vigna* and *Phaseolus* (Smýkal et al., 2015). In addition, in the context of climate change, increasing heat, drought, salinity and disease stresses directly affect both protein synthesis and quality components, thereby highlighting the necessity of new-generation breeding strategies that jointly optimize stress tolerance and quality traits.

This section aims to comprehensively discuss, in the light of current literature, modern breeding approaches, quality improvement strategies, and future research perspectives developed in response to the increasing demand for plant-based protein in legumes.

2. Protein Composition and Nutritional Value in Legumes

Legume seeds generally contain 18–35% protein on a dry matter basis, and most of this protein is composed of storage proteins belonging to the globulin and albumin fractions. In various legume species, globulins account for approximately 35–80% of total seed protein, whereas albumins constitute 2–37% (Singh et al., 2022). This biochemical structure makes legumes an important plant-based protein source for both human nutrition and industrial applications.

2.1. Protein Content and Fractions (Globulin, Albumin, etc.)

Legume seed proteins are classified according to the classical Osborne fractionation system into albumins (water-soluble), globulins (salt-soluble), prolamins (alcohol-soluble), and glutelins (acidic/basic soluble) (Carbonaro & Nucara, 2022). The predominant storage proteins in legumes are globulins, especially the 7S vicilin and 11S legumin subunits, which may represent up to 90% of total globulins in some species (Ohanrnye et al., 2022). The albumin fraction, on the other hand, contains biologically active proteins, such as enzymes, protease and amylase

inhibitors, and lectins, which play a central role in seed defense mechanisms (Singh et al., 2022).

Significant variation exists among species and within species for their globulin/albumin ratios, indicating that not only total protein content but also fractional composition can be targeted in breeding programs. A higher globulin ratio is associated with improved gelling and emulsifying properties valued in the food industry, whereas reducing the albumin fraction may help lower antinutritional activity in certain legume species (Boye et al., 2010).

2.2. Amino Acid Profile and Nutritional Quality

Legume proteins are typically rich in lysine but limited in sulfur-containing amino acids such as methionine and cysteine (Hertzler et al., 2020). Recent studies indicate that sulfur amino acids represent the primary limiting amino acids in species such as pea (Sá et al., 2024). Conversely, cereals are often deficient in lysine; thus, legume–cereal combinations significantly improve overall dietary protein quality, increasing PDCAAS and DIAAS scores due to complementary amino acid profiles (Pulse Canada, 2025).

There is considerable variation among genotypes and species in amino acid composition, with certain genotypes exhibiting more balanced essential amino acid profiles (Bessada et al., 2019). This provides opportunities for classical breeding and genomic selection efforts to target traits such as high lysine content, improved sulfur amino acid levels, and better essential amino acid balance.

2.3. Antinutritional Factors and Functional Components

In addition to their high protein and mineral contents, legumes contain several antinutritional factors (ANFs). The major ANFs include protease inhibitors (especially trypsin inhibitors), amylase inhibitors, lectins, phytic acid, tannins, saponins, and various polyphenolic compounds (Samtiya et al., 2020). These compounds can reduce protein and mineral bioavailability by forming complexes with nutrients or by inhibiting digestive enzymes, particularly phytic acid and tannins, thereby limiting digestibility (Gilani et al., 2012).

On the other hand, bioactive peptides derived from legume proteins exhibit antioxidant, ACE-inhibitory, antidiabetic, and antimicrobial properties, highlighting legumes as a valuable source of health-promoting bioactive compounds (Carbonaro & Nucara, 2022).

2.4. Protein Digestibility and Processing Properties

Protein digestibility in legumes is generally lower than in animal proteins and certain processed soy products. This reduced digestibility stems primarily from the presence of ANFs, protein–polysaccharide complexes, and the seed matrix's structural characteristics. Elevated levels of tannins and phytic acid have been associated with reductions of 10–23% in protein and amino acid digestibility (Gilani et al., 2012).

These functional characteristics directly influence the suitability of legume proteins for various food applications, particularly plant-based meat analogues, dairy alternatives, bakery products, and snacks. Therefore, breeding programs must consider not only crude protein concentration but also digestibility, functional traits, and processing performance. Integrating these criteria is essential for developing future quality-oriented legume varieties (Bessada et al., 2019).

3. Genetic Resources and Variation in Protein Quality

In legume species, the wide variation observed in seed protein content, amino acid composition, and levels of antinutritional compounds largely depends on the quality of the genetic resources utilized and the extent to which these resources are integrated into breeding programs.

Vavilov's concept of centers of origin highlights that regions such as the Mediterranean Basin, West Asia, Ethiopia, and South Asia harbor rich reservoirs of protein-related genetic diversity through local landraces and wild relatives (Smýkal et al., 2015). Recent advances in genome sequencing, pangenomics, and multi-omics approaches have revealed that this variation exists not only at the morphological or agronomic level but also at the genomic scale, including differences in **core–accessory genome organization, presence–absence variation (PAV)**, and large-scale structural variation (Ruperao et al., 2025).

Within this framework, genetic diversity analyses conducted on wild relatives, landraces, and modern cultivars collected from these gene centers play a critical role in identifying allele and gene combinations associated with target traits such as high protein content, balanced essential amino acid profiles, and reduced antinutritional factor levels (Jha et al., 2022).

3.1. Centers of Origin, Wild Relatives, and Landraces

The primary and secondary centers of diversity identified in Vavilov's classical work represent significant reservoirs of variation for both adaptive traits and seed quality parameters in legumes. The Mediterranean region, West and Central Asia, and Ethiopia stand out as hotspots where both high-protein landraces and drought-, cold-, and disease-tolerant wild forms of pea, chickpea, and lentil are concentrated (Smýkal et al., 2015; Dueholm et al., 2025). Genetic materials stored in FAO and national gene bank collections often contain alleles that have been lost in modern cultivars and therefore serve as strategic resources for breeding.

Wild relatives, such as *Cicer reticulatum* and *C. echinospermum* for chickpea, and *Pisum fulvum* and *P. abyssinicum* for pea, and traditional landraces generally exhibit **higher crude protein content, distinct storage protein profiles**, and **enhanced micronutrient–protein associations** (e.g., Fe–Zn–protein), while often performing lower than elite cultivars in yield and harvest index (Smýkal et al., 2015; Jha et al., 2022). Consequently, breeding strategies incorporating materials from gene centers must prioritize optimizing high protein content alongside stable yield performance while actively managing genotype × environment (G×E) interactions.

Landraces, shaped through farmer selection over long periods, are typically adapted to specific local environments and often possess unique grain quality traits (color, flavor, cooking time) as well as niche properties related to protein quality and utilization (Dueholm et al., 2025). In modern breeding programs, crossing these landraces with high-yielding elite lines provides a vital bridge to conserve quality alleles while simultaneously improving productivity.

3.2. Genetic Diversity Analyses and Omics-Based Characterization

Effective use of protein-quality-related variation in legumes requires a multilayered characterization strategy that goes beyond classical morpho-agronomic evaluation and integrates molecular and omics-based tools. Traditional molecular markers such as SSRs and AFLPs, along with high-density SNP panels and genotyping-by-sequencing (GBS) platforms, are widely used to dissect genetic structure, population stratification, and phylogenetic relationships in chickpea, lentil, pea, and cowpea (Jha et al., 2022).

More recently, whole-genome sequencing (WGS), resequencing panels, genome-wide association studies (GWAS), and genomic selection approaches have been applied to elucidate the genetic basis of complex quality traits, including **seed protein concentration, essential amino acid composition** (e.g., lysine, methionine), and **mineral–protein relationships** (Fe, Zn) (Wohor et al., 2025). The identification of multilocus, small-effect QTLs and candidate genes involved in protein biosynthesis and storage pathways enables the systematic

incorporation of quality parameters into MAS and GS pipelines (Jha et al., 2022; Cordoba et al., 2025).

Complementary omics datasets, including transcriptomics, proteomics, and metabolomics, provide deeper insights into protein accumulation during grain filling, isoform profiles of storage proteins, and interactions between antioxidant/secondary metabolites and protein composition (Ali et al., 2022; Cummane et al., 2025).

Integrating these multi-omics datasets with pangenomic and classical genetic diversity analyses facilitates the development of novel selection indices that simultaneously target **high protein content, enhanced quality**, and **environmental stress tolerance**. As a result, wild relatives and landraces from gene centers are transformed from mere sources of diversity into **strategic donor materials** whose allelic variation is fully characterized at the omics level and can be directly utilized to improve protein quality in breeding programs.

4. Classical Breeding Strategies for Increasing Protein Content

Classical breeding efforts aimed at improving seed protein content in legumes fundamentally rely on exploiting existing genetic variation (landraces, wild relatives, elite lines) through appropriate selection methods, followed by the stabilization of high-protein genotypes without sacrificing yield and adaptation performance. In traditional programs, protein concentration often shows a negative correlation with seed yield, making single-trait selection insufficient and necessitating the use of selection indices, stepwise selection, and multi-environment testing (Ranalli & Cubero, 1997). In recent years, integrating these classical strategies with genomic selection, marker-assisted selection, and omics datasets has accelerated genetic gains in protein improvement, while allowing a more rational management of the **quality × yield × adaptation** balance (Jha et al., 2022).

4.1. Selection Methods

The first step in classical breeding programs targeting increased protein content is making selection decisions within segregating populations. **Mass selection** and **individual plant selection** have been frequently used to isolate high-protein individuals, particularly from landraces and wild relatives. However, because protein concentration is sensitive to environmental variation and laboratory analyses are costly, these methods are often combined with **laboratory-assisted, stepwise selection** using chemical or NIR-based measurements (Ranalli & Cubero, 1997).

Pedigree selection and **family (progeny) selection** are preferred for quantitative traits such as protein content, especially during the F_2–F_5 generations, as they allow decisions to be based on family means. Protein content generally exhibits moderate heritability, shows a negative correlation with yield, and shows positive associations with seed size and some quality traits. Therefore, combining family means with correlation structures results in more effective selection decisions (Jermyn, 1977; Obala et al., 2022).

The negative correlation between protein concentration and yield necessitates the use of **selection indices**. Smith–Hazel type or **restricted indices** assign positive weights to protein and moderate weights to yield, enabling progressive improvement of protein content without severely reducing yield. Although such indices have been shown to improve yield and protein content in cereals and legumes simultaneously, the rate of genetic gain is often moderate (Michel et al., 2019).

Multi-environment trials (METs) are essential tools for managing genotype-by-environment (G×E) interactions during protein selection. Studies in lentil and chickpea have shown that

although genotypic differences for protein content are significant, environmental effects and G×E interactions also play major roles. Thus, stability analyses such as AMMI and GGE biplot should be integrated into protein-focused selection schemes (Burstin et al., 2011; Subedi et al., 2020).

4.2. Heterosis, GCA–SCA, and Parental Selection

Although most legumes are self-pollinating, heterosis and combining ability (GCA–SCA) analyses are widely used to identify suitable parental combinations for high protein content. Diallel and line × tester studies conducted in pea, bean, and chickpea have revealed significant general combining ability (GCA) and specific combining ability (SCA) variances not only for seed yield and its components but also for protein content and other seed quality traits (Ceyhan et al., 2014; Sharma et al., 2023; Ceyhan et al., 2025; Dalgıç et al., 2025).

Many studies demonstrate that **additive gene effects** (thus GCA) play a dominant role in determining protein content. In contrast, **non-additive effects** (dominance and epistasis), reflected in SCA, are more influential for seed yield, biological yield, and yield components (Ceyhan et al., 2014; Sharma et al., 2023; Ceyhan et al., 2025; Dalgıç et al., 2025). This indicates that parents with high protein content and favorable GCA values are ideal for developing superior pure lines, while crosses with high SCA are more suitable for F_1 hybrid performance or for expanding segregation in subsequent generations.

Line × tester analyses in pea have identified sure parents with significantly positive GCA effects for seed yield, 100-seed weight, seed protein content, and other quality components. Such parents are considered **"good general combiners"** and serve as essential contributors to elite breeding pools (Ceyhan et al., 2014; Ceyhan et al., 2025; Dalgıç et al., 2025). Furthermore, high heterobeltiosis values for both yield and protein content have been reported in specific parental combinations, demonstrating that some crosses can simultaneously provide high yield and relatively high protein levels, partially breaking the classical negative yield-protein relationship (Ceyhan et al., 2014; Sharma et al., 2023; Ceyhan et al., 2025; Dalgıç et al., 2025).

Thus, parental selection in classical breeding programs is no longer based solely on yield and adaptation traits; instead, **GCA estimates for protein content, amino acid composition, and related quality traits** are increasingly emphasized, enabling the development of parental sets with elite combining ability for protein improvement.

4.3. Achieving the Quality × Yield × Adaptation Balance

One of the major challenges in breeding for higher protein content in legumes is the commonly observed negative correlation between seed yield and protein concentration. Multi-environment trials in pea, lentil, and faba bean frequently report moderate to strong negative correlations (approximately –0.6) between these traits. However, certain genotypes break this "upper-limit trend," combining acceptable or high yield with comparatively high protein concentration (Skovbjerg et al., 2020). These exceptional genotypes serve as key genetic resources for achieving the balance among quality, yield, and adaptation.

Protein quality (especially total protein and amino acid composition) is often indirectly associated with adaptation and stress tolerance. Studies on lentil and pea indicate that under abiotic stresses such as drought and high temperatures, yield decreases substantially, while protein concentration is less affected or even slightly increased. Therefore, **protein yield (kg/ha)** serves as a more holistic selection criterion than protein percentage alone (Lake et al., 2021; Tziouvalekas et al., 2022; Soncin et al., 2025).

Consequently, modern breeding programs evaluate **yield, protein percentage, and protein yield simultaneously**, selecting genotypes that achieve the optimal balance of these traits under target environments.

5. Modern Molecular and Genomic Breeding Approaches

In legumes, complex quality traits such as seed protein concentration, amino acid composition, and antinutritional factor content are governed by numerous small-effect QTLs, genotype × environment interactions, and interconnected physiological processes. Consequently, achieving rapid genetic improvement using classical breeding alone is challenging. Over the last 15–20 years, marker technologies, genomic selection, QTL/GWAS-based candidate gene discovery, CRISPR/Cas-mediated genome editing, and high-throughput phenotyping (HTP) have become central components of modern legume breeding programs (Sab et al., 2020; Jha et al., 2022).

5.1. Marker-Assisted Selection (MAS)

Marker-assisted selection provides substantial gains in speed and accuracy compared with classical selection, especially for traits controlled by a single or a few significant genes or large-effect QTLs (Nair & Rabbani, 2024). Although overall seed protein content in legumes is typically polygenic, several key subcomponents—such as storage proteins (vicilin and legumin subunits), phytate metabolism, antinutritional factors (lectins, trypsin inhibitors), and mineral, protein interactions (Fe, Zn), are associated with major QTLs, enabling practical MAS application (Upadhyaya et al., 2016; Sab et al., 2020).

In recent years, markers associated with Fe–Zn–protein co-concentration, phytate levels, specific storage protein fractions, and biotic/abiotic stress tolerance (which indirectly contribute to protein retention) have been identified in chickpea, lentil, common bean, and pea. These markers are increasingly used for **early-generation selection in F_2–F_4 populations** (Upadhyaya et al., 2016; Sab et al., 2020).

Because biochemical protein analyses are time-consuming and expensive, MAS—when combined with rapid NIR/NIT-based protein estimation, has become even more advantageous. In most breeding programs today, MAS is integrated with classical yield- and adaptation-based selection, forming a dual-selection framework that targets both agronomic performance and quality traits (Jha et al., 2022).

5.2. Genomic Selection (GS)

Genomic selection uses dense, genome-wide marker datasets (e.g., SNP panels, GBS-derived markers) to predict the genetic values of individuals without requiring phenotypic measurements, making it especially suitable for traits influenced by numerous small-effect QTLs (Michel et al., 2019; Berkner et al., 2023). Since seed protein concentration, protein yield, and amino acid composition fall into this category, GS has rapidly gained prominence in legume breeding.

A recent study in pea demonstrated that GS models built using multi-location datasets could **simultaneously predict seed yield, protein content, and protein yield**, with robust accuracies across different genetic backgrounds (training vs. target populations) (Michel et al., 2019; Berkner et al., 2023).

In legumes, GS outperforms classical MAS for complex quality traits by providing higher prediction accuracy for protein content, protein yield, and amino acid balance; reducing reliance on costly multi-environment protein phenotyping; enabling early-generation selection using only genotypic data; and integrating the vast diversity of wild relatives and landraces into prediction models.

Thus, GS, together with MAS and HTP technologies, has become one of the foundational tools in modern protein-oriented **legume breeding** (Jha et al., 2022; Cordoba et al., 2015).

5.3. QTL Mapping and Candidate Gene Analysis

QTL mapping and candidate gene discovery play critical roles in protein-focused breeding by enabling the development of markers for MAS/GS and identifying targets for genome editing. Numerous QTLs have been identified for traits such as seed protein content, Fe and Zn concentration, seed size, and storage protein composition in chickpea, lentil, and pea (Verma et al., 2015; Upadhyaya et al., 2016; Sab et al., 2020).

Studies on lentil have shown that certain QTLs simultaneously influence mineral concentration and total protein levels, indicating the presence of pleiotropic or tightly linked loci of particular relevance to biofortification programs (Upadhyaya et al., 2016; Aldemir et al., 2017). In pea, QTLs associated with seed protein content often co-localize with regions controlling legumin/vicilin ratio and seed size, suggesting shared genetic regulation of protein quality and seed physicochemical traits (Upadhyaya et al., 2016; Aldemir et al., 2017).

Integration of QTL mapping results with **GWAS and pangenome data** enables the identification of more stable, environment-independent QTL regions. Candidate genes located in these stable intervals can be validated using CRISPR/Cas and advanced functional genomics approaches (Sab et al., 2024; Zatybekov et al., 2025).

6. Conclusion and Future Perspectives

Grain legumes hold a strategic position in meeting the growing global demand for plant-based proteins and the need for sustainable agricultural production systems. As highlighted in this review, legumes play a critical role not only due to their high crude protein content but also through their essential amino acid profiles, dietary fiber, and bioactive compound richness, symbiotic nitrogen fixation, and low carbon footprint, contributing simultaneously to human nutrition and ecosystem services. However, fully realizing this potential requires moving beyond traditional yield-centered approaches toward integrated breeding strategies that jointly target protein quantity, protein quality, processability, and stress tolerance.

A key conclusion of this study is the presence of extensive genetic variation in protein content, amino acid balance, and levels of antinutritional factors in legumes. Yet a substantial portion of this variation remains “dormant” within landraces, wild relatives, and gene bank accessions. Genetic resources from Vavilov’s centers of diversity contain not only alleles for high protein levels but also unique protein fraction compositions, mineral–protein interactions, and alleles that confer relative stability of quality traits even under stress conditions. Therefore, future breeding programs must strengthen pre-breeding and introgression pipelines, systematically connecting **local genetic resources → elite breeding lines → final cultivars**.

From the classical breeding perspective, mass, pedigree, and family selection, heterosis and GCA–SCA analyses, multi-environment trials, and stability analysis remain the foundational pillars of protein improvement in legumes. However, the widespread negative correlation between seed yield and protein concentration, coupled with strong G×E interactions, clearly demonstrates the limitations of single-trait selection. As such, breeding strategies must increasingly adopt multi-trait selection indices and target-environment-oriented schemes that jointly consider yield, protein percentage, protein yield, amino acid profile, digestibility, functional properties, and stress tolerance.

Modern molecular and genomic tools qualitatively transform this classical framework. Marker-assisted selection (MAS) enables precise tracking of major QTLs related to specific protein

fractions, phytate content, and antinutritional factors. Genomic selection (GS) accelerates genetic gain for polygenic traits such as protein content, protein yield, and amino acid balance. QTL/GWAS and pangenomic approaches enable the identification of stable, environment-independent candidate regions, advancing legume breeding toward a data-driven, **prediction-based paradigm**. Additionally, CRISPR/Cas genome editing opens the door to a new era of "precision breeding," targeting modifications to storage proteins, reductions in antinutritional components, and improvements in mineral bioavailability.

High-throughput phenotyping (HTP) and phenomic platforms serve as complementary components that strengthen the link between genomic information and field performance. Drone- and satellite-based multispectral/hyperspectral imaging, automated systems for monitoring root/nodule traits and growth dynamics, and NIR and hyperspectral seed-scanning technologies enable high-resolution monitoring of physiological processes related to protein accumulation, nitrogen-use efficiency, and nodule activity. These advances enhance the accuracy of GS and QTL models and shorten breeding cycles. In the near future, artificial intelligence and machine-learning-driven analytics are expected to play a key role in integrating genomic, phenomic, and environmental datasets.

In conclusion, developing next-generation legume cultivars capable of meeting global plant protein demand requires a multidimensional framework that integrates genetic resource management, classical breeding, genomic and omic technologies, advanced phenotyping infrastructures, and food science. The creation of legume varieties with tailored quality profiles for functional foods, plant-based meat, dairy alternatives, and other emerging products will form a central focus of future breeding efforts. In this context, strong collaborations among public research institutions, universities, the private sector, and the food industry will be essential to strengthen the role of legumes in closing the global protein gap and facilitating the transition toward sustainable food systems.

ABSTRACT

With the acceleration of global warming, the increasing frequency of heat waves, prolonged drought periods, and irregular precipitation regimes has become a significant determinant of physiological functioning and production reliability in legumes. The simultaneous occurrence of drought and heat stress triggers multilayered physiological disruptions, including reduced photosynthetic capacity, altered stomatal behavior, impaired carbon–nitrogen metabolism, excessive reactive oxygen species accumulation, and compromised antioxidant defense systems. The reproductive phase is susceptible to high temperature; reductions in pollen viability, impaired anther dehiscence, decreased stigma receptivity, and sharp declines in pod-setting rates collectively intensify yield losses. In addition, nodulation and biological nitrogen fixation are highly vulnerable to climatic stresses, and the weakening of the *Rhizobium*–plant symbiosis adversely affects both plant nitrogen nutrition and soil fertility. Current literature indicates that yield reductions of 30–60% are common in legumes under combined drought and heat stress. This review synthesizes contemporary findings on legume physiological stress responses to global climate change and elucidates the core mechanisms underlying production risks. Overall, the evidence highlights the need to develop multi-stress tolerance and to adopt integrated physiological, ecophysiological, and genetic strategies to ensure sustainable legume production.

Keywords: Legumes, Global Warming, Drought Stress, Physiological Response, Production Risk

1. Introduction

With the acceleration of global warming, the increasing frequency of heat waves, irregular precipitation regimes, prolonged drought periods, and extreme climatic events has emerged as a significant environmental pressure threatening the production stability of cool-season legumes such as chickpea, lentil, and faba bean. The impacts of climate change on agricultural production are now recognized not merely as yield-reducing factors but as a complex, multilayered stress matrix that influences virtually all plant physiological processes. Andrews and Hodge (2010) emphasize that global warming weakens production security by pushing temperature thresholds beyond the tolerance limits of cool-season legume-growing regions. In contrast, Kaushal et al. (2016) highlight that rising temperatures can induce critical disruptions in plant metabolism. Collectively, these observations indicate that climate-related stress has evolved from an episodic constraint into a structural threat transforming legume production systems.

The simultaneous occurrence of drought and heat stress synergistically impacts legume physiology, substantially intensifying damage severity. Farooq et al. (2009) reported that drought disturbs cellular water balance, restricts photosynthesis, increases osmoprotectant synthesis, and reshapes hormonal regulation, while heat stress accompanies these responses with additional mechanisms, including impaired protein stability, excessive accumulation of reactive oxygen species (ROS), and loss of membrane integrity. The combination of drought and heat suppresses carbon–nitrogen metabolism, weakens defense systems, and induces rapid physiological deterioration, particularly in reproductive tissues. Thus, contemporary literature underscores that combined stresses, not individual stresses, are the most decisive drivers of climate-induced yield losses.

The most pronounced vulnerability in legume production emerges during the reproductive phase. High temperatures severely reduce pollen viability, stigma receptivity, and pollen tube growth, thereby markedly lowering pod-set rates. Sita et al. (2017) reported that heat stress denatures pollen proteins and limits fertilization success, while Gaur et al. (2015) identified pollen development as the most temperature-sensitive reproductive process, noting that once critical thresholds are surpassed, a substantial proportion of flowers become abortive. These findings clearly demonstrate that generative success is the weakest link in legume climate resilience.

The production-level consequences of drought and heat stress have been widely documented globally. In a meta-analysis of 65 independent studies, Daryanto et al. (2015) found that drought reduces legume yields by an average of 30–40%, with losses reaching up to 60% during flowering. When heat stress accompanies drought, yield declines escalate dramatically. Kumari et al. (2021) likewise reported that drought–heat combinations critically impair pollen viability, floral integrity, and pod-set in cool-season legumes. These findings indicate that the impacts of global warming on legume production have shifted from periodic constraints to systemic production risks.

Taken together, the evidence clearly demonstrates the strong linkage between legume physiological stress responses and the production risks posed by climate change. The weakening of key mechanisms such as photosynthesis, water-use efficiency, antioxidant defense, reproductive biology, and biological nitrogen fixation threatens the strategic ecological and nutritional role of legumes. Therefore, sustainable legume production requires an integrative framework that combines agronomic practices, physiological adaptation, and genetic improvement strategies. This review aims to evaluate the physiological stress responses

of legumes under global warming, elucidate the primary mechanisms underlying production risks, and discuss future adaptation strategies from a multidimensional perspective.

2. Cellular Damage Mechanisms Under Heat Stress: ROS Accumulation, Antioxidant Response, and Photostructural Disruption

The physiological pressure imposed by heat stress in legumes is closely associated with rapid metabolic disturbances that arise at the cellular level. Elevated temperatures reduce the stability of photosynthetic pigments, accelerate chlorophyll degradation, and increase the susceptibility of photosystem II (PSII) to photodamage. Andrews and Hodge (2010) reported that cool-season legumes are unable to maintain photochemical efficiency at temperatures exceeding 30–35 °C, and their protective capacity against light-induced damage declines sharply under such conditions. Heat also enhances membrane fluidity, disrupting ion homeostasis—a critical factor that limits both energy synthesis and carbon fixation.

One of the most prominent consequences of heat stress is the rapid accumulation of reactive oxygen species (ROS). Kaushal et al. (2016) demonstrated that elevated temperature dramatically increases ROS production in both mitochondria and chloroplasts, leading to lipid peroxidation and protein oxidation. Although antioxidant defense systems (SOD, CAT, APX, GR) initially attempt to buffer ROS accumulation, prolonged stress eventually overwhelms their capacity, leading to irreversible oxidative damage and widespread cellular dysfunction.

Sita et al. (2017) emphasized that heat stress induces ROS accumulation, particularly rapidly in reproductive tissues, producing profound effects on pollen viability. Due to the intrinsic heat sensitivity of pollen proteins, increased oxidative stress slows pollen tube elongation and reduces fertilization success. This mechanistic disruption limits not only reproductive performance but also weakens embryo development and pod filling, making the impact of heat stress on yield inherently multilayered.

Heat stress further reduces carbon assimilation by inhibiting Rubisco, the key enzyme governing the dark reactions of photosynthesis. Farooq et al. (2009) noted that elevated temperature destabilizes the three-dimensional structure of proteins, compromising carbon metabolism and placing plants in an energy-deficient state. Energy shortages diminish both defense capacity and new tissue formation, significantly increasing plant vulnerability. Gaur et al. (2015) similarly reported that heat disrupts the electron transport chain, limiting ATP production and directly impairing physiological processes occurring during flowering.

Collectively, these findings illustrate that heat stress in legumes is far more than a superficial temperature challenge; rather, it is a complex stressor that triggers cascading metabolic and cellular reactions. Processes such as ROS accumulation, collapse of antioxidant defenses, photostructural degradation, and suppression of carbon metabolism represent core physiological drivers of heat-induced yield losses. Therefore, the development of heat-tolerant genotypes must target not only macro-level agronomic performance but also the underlying cellular mechanisms that confer resilience.

3. Vulnerability of Nodulation and Biological Nitrogen Fixation Under Climate Stress

One of the significant advantages of legumes in agricultural systems is their ability to enrich soils with natural nitrogen through biological nitrogen fixation (BNF). However, this process is susceptible to climatic stresses. Elevated temperature and drought slow the Rhizobium infection process, restrict nodule formation, and weaken overall symbiotic efficiency. Andrews and Hodge (2010) reported that increasing temperatures suppresses nodule development in cool-season legumes, leading to reductions in both nodule number and effectiveness. This decline negatively affects not only plant nitrogen nutrition but also seed protein concentration.

Kumari et al. (2021) demonstrated that the combined effects of drought and heat significantly reduce BNF capacity and sharply decrease nodule biomass under stress. Declining water potential within nodules disrupts oxygen diffusion and leghaemoglobin activity, directly limiting bacterial respiration and N_2 fixation. Farooq et al. (2009) further noted that drought reduces carbon supply, thereby reducing the energy flow to nodules and imposing strong constraints on bacterial metabolism. Oxidative damage in nodule tissues induces premature senescence under prolonged stress.

In their global meta-analysis, Daryanto et al. (2015) showed that legume yields decline by an average of 30–40% under drought, and reductions in BNF capacity are among the primary drivers of these losses. Insufficient nodulation forces the plant to rely entirely on external nitrogen inputs (fertilizers), diminishing both economic and environmental sustainability. Kaushal et al. (2016) also reported that rising temperatures slow the development of infection threads and suppress the activity of *Rhizobium* strains.

The effects of heat stress during the reproductive period are directly interconnected with symbiotic nitrogen fixation. Sita et al. (2017) emphasized that reproductive tissues have a high carbon demand, and reductions in photosynthetic capacity under stress further limit carbon allocation to nodules. This exacerbates declines in BNF and reduces flowering success due to nitrogen deficiency. Gaur et al. (2015) also noted that when temperature thresholds are exceeded, enzymatic activities in nodules are impaired, potentially leading to near-complete cessation of nitrogen fixation.

Collectively, these findings highlight that BNF is among the most fragile physiological processes in legumes under climate change. Nodule development, Rhizobium activity, carbon–energy flow, and oxygen regulation are concurrently targeted by both drought and heat. Therefore, breeding for climate-resilient legume genotypes must focus not only on plant physiological traits but also on enhancing stress tolerance in symbiotic interactions.

4. Genomic, Metabolic, and Molecular Approaches to Enhancing Climate Resilience

The increasing severity of climate stresses highlights the need for innovative molecular and genomic approaches that extend beyond traditional breeding methods in legumes. Modern breeding programs have shifted toward elucidating the physiological and molecular mechanisms underlying stress tolerance. Kaushal et al. (2016) reported that numerous genes contribute collectively to heat and drought tolerance, with antioxidant defense genes, heat shock proteins (HSPs), and osmoprotectant biosynthesis pathways playing central roles. Consequently, genetic selection must adopt an integrative strategy that targets multiple stress-response networks simultaneously.

Farooq et al. (2009) emphasized the importance of osmotic regulators (proline, glycine betaine), membrane-stabilizing compounds, and ROS-detoxifying enzymes in drought response, suggesting that these mechanisms represent promising targets for molecular breeding efforts. Modern breeding tools, particularly genomic selection (GS) and marker-assisted selection (MAS), enable early identification of stress-tolerance genes, thereby accelerating breeding cycles and facilitating the rapid development of climate-resilient cultivars.

Sita et al. (2017) highlighted the sensitivity of reproductive biology to heat stress, emphasizing that genes protecting pollen development represent strategic targets for breeding programs. Gaur et al. (2015) further noted the importance of genes that maintain photochemical efficiency and sustain energy balance during flowering in the development of heat-tolerant legume genotypes. Understanding the genetic regulation of these mechanistic pathways is fundamental to designing effective, climate-resilient breeding strategies.

Findings from Kumari et al. (2021) and Daryanto et al. (2015) underscore the economic and ecological significance of developing genotypes with combined drought and heat tolerance. Such genotypes not only mitigate yield losses but also support the long-term sustainability of biological nitrogen fixation. Enhancing *Rhizobium* strains' tolerance to temperature and drought is likewise critical for improving the resilience of the symbiotic system.

Among the most promising future-oriented approaches is CRISPR-Cas-based targeted gene editing. This technology enables precise modification of genes encoding heat shock proteins, ROS-detoxification enzymes, stomatal-regulation components, and nodule-development factors. Through these interventions, it becomes possible to engineer comprehensive stress responses at both the plant and symbiont levels. In conclusion, legume breeding in the era of global warming is undergoing a multidisciplinary transformation that requires integrating physiological, molecular, and ecophysiological knowledge into holistic improvement strategies.

5. Conclusion

In the era of accelerating global warming, legumes are increasingly vulnerable to both drought and heat stress. The reviewed literature clearly demonstrates that the combined effects of drought and heat are far more destructive than the effects of either stress alone, targeting virtually all aspects of plant physiology. Suppression of photosynthesis reduced stomatal conductance, ROS-induced cellular damage, hormonal imbalance, and weakened carbon–nitrogen metabolism, collectively restricting both vegetative growth and reproductive performance. This poses a substantial production risk for legumes, which are among the primary global sources of plant-based protein.

Reproductive development has consistently been identified as the most climate-sensitive stage, as shown by both recent studies (Kumari et al., 2021; Sita et al., 2017) and foundational literature (Gaur et al., 2015; Kaushal et al., 2016). Declines in pollen viability, impaired anther dehiscence, reduced stigma receptivity, and weakened embryo development lead to severe reductions in pod-set rates. These findings indicate that climate-induced yield losses in legumes fundamentally arise from disruptions in reproductive physiology. Therefore, future breeding efforts must prioritize genetic mechanisms that safeguard reproductive biology under thermal and water stress.

At the same time, biological nitrogen fixation (BNF), a key ecosystem service provided by legumes, is strongly compromised under climate stress. Heat and water deficits limit Rhizobium infection, nodule formation, and nitrogenase activity, thereby reducing both plant nitrogen acquisition and soil fertility. Findings by Andrews and Hodge (2010) and Daryanto et al. (2015) show that climate change affects not only plant productivity but also the soil–plant–microbe continuum. Consequently, symbiotic resilience must be integrated into legume breeding strategies to enhance climate tolerance.

From a breeding perspective, current literature underscores the need for a holistic approach targeting multi-stress resilience. Studies such as Kaushal et al. (2016) and Farooq et al. (2009) highlight the critical roles of osmoregulation, antioxidant defense, membrane stability, and energy management in stress tolerance. In contrast, Gaur et al. (2015) and Sita et al. (2017) emphasize the strategic importance of protecting reproductive tissues under high temperature. When combined with modern breeding technologies, genomic selection, marker-assisted selection, and CRISPR-based gene editing, these mechanistic insights provide a robust foundation for developing climate-resilient legume cultivars.

In conclusion, sustainable legume production under global warming requires a multidimensional framework that integrates physiological, ecophysiological, microbiological, and genetic mechanisms. Scientific evidence indicates that future legume breeding must aim not only to enhance stress tolerance but also to strengthen symbiotic efficiency, resource-use effectiveness, and overall adaptive capacity. Therefore, breeding strategies that prioritize interdisciplinary integration, focus on stress combinations, and are supported by modern genomic tools will be essential to ensuring legume production stability under climate change.

ABSTRACT

The growing global demand for sustainable protein sources has elevated legumes to a strategic position both nutritionally and technologically. Legumes serve as a crucial raw material for the alternative protein industry due to their high protein content, balanced amino acid profiles, and rich fiber and bioactive compound structures. However, the functional properties of protein fractions (solubility, gel formation, water and fat retention capacity, emulsification) are decisive factors in the development of new-generation food products such as plant-based meat and milk analogues. Reducing anti-nutritional components, improving digestibility, and the effects of processing methods (fermentation, sprouting, extraction techniques) on protein quality are at the center of current research. This review comprehensively examines the potential of legumes as a sustainable alternative protein source, covering nutritional quality, technological functionality, environmental benefits, and industrial applications. The findings indicate that legumes play a critical role in both human nutrition and the growing plant-based protein sector. That comprehensive innovation in breeding, processing technologies, and functional food applications will be needed in the future.

Keywords: Legumes, Alternative Protein Sources, Protein Quality, Functional Properties, Sustainable Nutrition

1. Introduction

Global population growth, shifting dietary habits, and environmental constraints have made the demand for sustainable protein sources more critical than ever. The EAT–Lancet Commission (Willett et al., 2019) emphasizes that plant-based proteins should occupy a central role in future food systems, while the large-scale analysis of Poore and Nemecek (2018), covering 38,000 farms and 40 crop types, demonstrates that legumes are significantly more sustainable than animal proteins in terms of carbon footprint, water use, and land requirements. Therefore, legumes have become essential components of sustainable food strategies both environmentally and nutritionally.

Beyond their sustainability advantages, legumes serve as a strategic raw material for the alternative protein industry due to their high protein content (20–30%), balanced amino acid composition, and rich dietary fiber profiles (Day, 2013). However, protein quality depends not only on quantity but also on digestibility, heat reactions, and processing methods, and levels of anti-nutritional factors such as trypsin inhibitors (Nosworthy et al., 2017). Current studies indicate that cooking, fermentation, germination, and fractionation can increase amino acid bioavailability, thereby enhancing the nutritional value of legume proteins (Acquah et al., 2021).

In addition to nutritional quality, the technological and functional properties of legume proteins are crucial for the development of next-generation foods, such as plant-based meat and dairy analogs. Water- and fat-binding capacities, emulsifying ability, foaming, and gelation characteristics determine texture, stability, and sensory attributes (Boye et al., 2010). Protein fractions from pea, faba bean, and chickpea stand out as strong alternatives in meat analog applications due to their high gelation capacity and thermal stability (Lam et al., 2018). Emerging technologies, such as high-moisture extrusion, enable the formation of fibrous, meat-like structures, expanding the industrial use of legume proteins (Barnés-Calle et al., 2024).

Another factor enhancing the technological value of legumes is the production of protein concentrates and isolates through dry fractionation and wet extraction. These approaches not only improve functional properties but also offer environmental benefits by reducing energy consumption (Pelgrom et al., 2013). In particular, pea protein isolates have gained widespread commercial use due to their gluten-free nature, relatively neutral flavor profile, and high solubility/gelation performance. Furthermore, biotechnological approaches, such as fermentation and enzymatic modification, offer opportunities to reduce undesirable flavor compounds and enhance functionality (Emkani et al., 2022).

Taken together, legumes are not only sustainable and cost-effective protein sources but also versatile ingredients that meet the industrial demands of modern food production. Their environmental benefits, high nutritional value, compatibility with advanced processing technologies, and increasing consumer demand position legumes strategically in the alternative protein market. Nevertheless, further research and technological development are required to enhance protein functionality, reduce anti-nutritional compounds, improve sensory qualities, and optimize emerging processing techniques.

2. Legume Proteins

Legumes are among the most prominent plant protein sources due to their nutritional quality, functional versatility, and potential for sustainability. Highlighting that plant proteins are among the key resources that can contribute to global food security, Day (2013) notes that legumes offer a strategic alternative to traditional animal proteins, particularly because of their high protein density and broad ecological adaptability. The significant protein fractions in

legumes, globulins (notably legumin and vicilin) and albumins, are structural components that determine both nutritional quality and functional behavior. Their high bioavailability makes legumes a crucial plant-based protein source for human nutrition.

From a food industry perspective, the functional properties of legume proteins are among the most critical factors influencing their use. Boye et al. (2010) report that legume proteins exhibit key functionalities, including water-holding capacity, gelation, emulsification, and foam stability, and that these traits vary depending on the protein fraction and processing method. Furthermore, the molecular structures of proteins and their responses to environmental factors (pH, ionic strength, temperature) enable the integration of legumes into a variety of products. Improving functional performance is closely related to extraction methods, denaturation levels, and the rearrangement of protein fractions.

Among legume proteins, pea protein has recently attracted considerable interest due to its nutritional and technological advantages. Lam et al. (2018) extensively examined the structural characteristics, extraction methods, and functional properties of pea protein isolates, demonstrating their high performance in gel formation, solubility, and emulsification capacity. The near-neutral flavor profile, low allergenicity, and high thermal stability of pea proteins make them among the most preferred protein sources in emerging plant-based food products, such as meat and dairy analogs. Furthermore, modern processing technologies such as high-moisture extrusion enable the formation of fibrous, meat-like textures in pea proteins.

The fundamental biochemical mechanisms governing the functional behavior of legume proteins are associated with the structural arrangements of their molecular components. Shevkani et al. (2019) emphasize that changes in secondary structures (α-helix and β-sheet) significantly influence critical technological properties such as gelation, foaming, and emulsification. These structural modifications explain how different processing conditions affect protein stability, aggregation, and refolding capacity. The conformational responses of proteins to environmental stresses support the versatile industrial application of legume-based proteins.

The rising prominence of legume proteins in food technology is not only tied to their functional capabilities but also to their compatibility with principles of sustainable production. Examining plant-based meat development, Boukid (2021) reports that legumes meet functional protein requirements while enabling the formulation of environmentally low-impact products. Their ability to fix atmospheric nitrogen, relatively low water demand, and substantially smaller carbon footprint compared with animal proteins position legumes at the center of sustainable food system strategies. Therefore, legume proteins are increasingly regarded as highly valuable biological components for both food security and the development of next-generation functional foods.

3. Nutritional Quality, Digestibility, and Amino Acid Profile

The nutritional value of legumes is primarily determined by their protein content and amino acid composition. In a comprehensive evaluation of cooked Canadian legumes, Nosworthy et al. (2017) reported that legumes generally have high lysine content, making them an essential complement to cereal-based protein sources, which are typically lysine-deficient. However, the limiting levels of sulfur-containing amino acids, such as methionine and cysteine, prevent legumes from being considered a complete protein source on their own. Thus, from an amino acid profile perspective, legumes provide higher nutritional quality when used in complementary protein strategies within plant-based diets.

Protein digestibility is another critical parameter determining nutritional quality. Nosworthy et al. (2017) demonstrated that DIAAS and PDCAAS values for different legume species vary with processing conditions, with cooking enhancing digestibility but potentially imposing limitations on specific amino acids in some species. The factors with the greatest influence on digestibility include cell wall integrity, starch–protein interactions, and levels of anti-nutritional components, such as trypsin inhibitors. Reducing or inactivating these compounds during processing markedly improves the bioavailability of legume proteins. Therefore, processing technologies are essential tools for enhancing the nutritional value of legumes.

Another essential aspect in the nutritional evaluation of legumes involves aroma compounds and sensory perception. Roland et al. (2017) noted that aroma in legume ingredients primarily originates from volatile compounds, lipid oxidation products, and degradation of specific amino acids. Characteristics described as “beany” or “grassy” can strongly influence consumer acceptance, especially for plant protein isolates. The interaction between amino acid profiles and lipid content, combined with Maillard reactions during processing, determines both nutritional and sensory quality.

Aroma components affect not only sensory attributes but also indirectly influence the potential application of proteins. According to Roland et al. (2017), certain aromatic compounds can be reduced through processing techniques, expanding the applicability of legume proteins, particularly in plant-based meat and dairy analogs. In this context, control of specific volatile compounds, optimization of processing conditions, and improved understanding of the chemical transformations of aroma-related amino acids all contribute to enhancing both the nutritional and industrial value of legume proteins. In summary, nutritional quality, digestibility, and amino acid composition are three complementary and fundamental parameters that position legume proteins as sustainable and functional components in modern food systems.

4. Technological Functionality (Emulsification, Gelation, Fractionation, Extrusion)

The technological functionality of legume proteins is one of the most critical attributes determining structure, stability, and sensory quality in food products. This functionality is closely associated with the molecular structure of proteins, their responses to environmental conditions, and the processing techniques applied. In particular, pea and faba bean proteins are widely used in modern plant-based food formulations because of their strong performance in emulsification, gelation, and foaming. Pelgrom et al. (2013) showed that dry fractionation yields high-efficiency pea protein concentrates that preserve functional properties, with significant improvements in water-holding capacity and dispersibility. This finding positions dry fractionation, which is more energy-efficient, as an effective method for producing sustainable ingredients enriched in functional proteins.

The technological behavior of protein fractions varies markedly depending on the processing techniques used. Cui et al. (2020) demonstrated that different processing treatments (thermal treatments, pH adjustments, physical modifications) induce distinct effects on the structure of yellow pea protein isolates, directly influencing their emulsification and gelation capacities. Denaturation triggered by temperature and pH exposure can increase gel firmness by exposing hydrophobic regions and enhancing protein–protein interactions. Conversely, uncontrolled aggregation may reduce solubility, negatively affecting emulsion stability. Thus, optimizing physicochemical conditions during processing is essential for maximizing the functional performance of legume proteins.

Faba bean proteins also hold substantial industrial potential due to their functional properties. Krause et al. (2023) reported that compositional differences and extraction methods significantly affect the functional characteristics of faba bean protein isolates, including water-holding capacity, viscosity, and gel formation. The study further revealed that interactions between proteins and polyphenols, as well as proteins and starch, influence gel stability and may vary across cultivars. These findings highlight that faba bean proteins represent promising alternatives as emulsifying and structuring agents in plant-based meat products and sauce/cream analogs. Additionally, interactions with polyphenols may support both functional and antioxidant properties, offering dual value.

Among the most advanced applications of legume proteins is their use in high-moisture extrusion (HME) technology. Barnés-Calle et al. (2024) demonstrated that chicken-like fibrous structures can be successfully formed when pea protein isolates are processed under high-moisture extrusion conditions. During extrusion, heat, shear force, and moisture content play decisive roles in protein alignment, denaturation, and restructuring. Non-covalent interactions between protein chains (hydrophobic interactions and hydrogen bonds) contribute to the formation of fibrous, layered textures. A comprehensive review by Sui et al. (2024) explains the fundamental mechanisms underlying plant proteins' ability to form meat-like structures. It emphasizes that optimizing extrusion parameters is essential for industrial product quality.

The technological functionality of legume proteins is substantially shaped by processing techniques such as fractionation, structural modification, and extrusion. Core functionalities such as emulsification and gelation play key roles in meeting the formulation needs of modern plant-based products. The ability of dry fractionation to provide sustainable and energy-efficient protein ingredients enhances the value of pea and faba bean proteins. At the same time, high-moisture extrusion enables the development of realistic textures in plant-based meat analogs. Thus, data-driven optimization and molecular-level understanding of protein structure strengthen the central position of legume proteins in the functional food systems of the future.

5. Environmental Sustainability and Global Nutrition Context

Global food systems lie at the center of multidimensional environmental challenges, including greenhouse gas emissions, land use, water consumption, and biodiversity loss. In a comprehensive analysis involving more than 40,000 farms across 119 countries, Poore and Nemecek (2018) demonstrated that the environmental footprint of animal-based foods is substantially higher than that of plant-based foods. Their findings emphasize that legumes rank among the lowest-impact protein sources in terms of carbon footprint and water consumption, and that shifting toward plant-based proteins will be decisive for increasing the sustainability of food systems. Reducing land use, lowering greenhouse gas emissions, and minimizing production-related pollution are critical goals that, together, reinforce legumes' strategic position in the food chain.

Studies on sustainable dietary models indicate that plant proteins, especially legumes, provide an optimal balance for both human and planetary health. In the EAT–Lancet Commission report, Willett et al. (2019) introduced the concept of the “Planetary Health Diet,” highlighting the key role of plant-derived proteins in transforming food systems. According to the report, legumes should be central components of sustainable dietary patterns due to their high nutrient density, low environmental impact, and reduced demand for natural resources during production. Furthermore, legumes were identified as a critical protein source for low-income populations, supporting both economic accessibility and long-term public health objectives.

Food security has become increasingly fragile in recent years due to climate variability, political instability, and pandemic-related disruptions. The FAO (2021) states that approximately 720–811 million people are undernourished globally, and that these numbers continue to rise. The report underscores that resilient, low-cost plant protein sources, such as legumes, play a crucial role in addressing nutritional deficiencies, particularly in low- and middle-income countries. Beyond protein, legumes offer significant amounts of dietary fiber, vitamins, and minerals, making them valuable tools in reducing both undernutrition and obesity-related burdens.

In summary, within the context of environmental sustainability and global nutrition systems, legumes are a key focus of modern food policy due to their low environmental footprint, high nutritional value, and broad accessibility. Considered together, the ecological analyses of Poore and Nemecek (2018), the sustainable diet recommendations of Willett et al. (2019), and the global food security assessments of FAO (2021) clearly demonstrate that legumes are indispensable both ecologically and socioeconomically. In the future, increasing the effective utilization of legumes throughout production, processing, and consumption will be critical for safeguarding planetary health and improving human nutrition.

6. Functional Properties, Nutritional Value, and Alternative Protein Approaches in Legumes

International literature extensively demonstrates that legume proteins are strong alternative protein sources in both nutritional and technological contexts. Boye et al. (2010) reported that legume proteins possess critical functional properties, including gelation, emulsification, and water-holding capacity, and that these properties vary depending on the fraction type and processing method. The significant protein fractions, globulins and albumins, play a central role in determining protein structure and functionality, supporting the versatile use of legumes within the food industry. These findings reinforce the notion that legumes are not only nutrient-dense foods but also valuable functional ingredients.

From a nutritional standpoint, legumes play a significant role in plant-based diets due to their high lysine content and rich fiber content. Nosworthy et al. (2017) demonstrated that, according to global criteria such as DIAAS and PDCAAS, legumes constitute high-quality protein sources and that cooking and other processing methods positively influence protein digestibility. Studies focusing on antioxidant capacity and bioactive compounds further support this view. For example, Rochfort and Panozzo (2007) reported that legumes contain beneficial components such as polyphenols, flavonoids, and saponins, while Champ (2002) highlighted that anti-nutritional factors can be substantially reduced through appropriate processing techniques. Collectively, these results indicate that legumes provide comprehensive benefits to human health.

The body of research on technological functionality has focused particularly on pea and faba bean proteins. Lam et al. (2018) demonstrated that pea protein isolates exhibit high functionality in solubility, gelation, and emulsification, and that these properties can be optimized through targeted extraction methods. Shevkani et al. (2019) reported that secondary structural components (α-helices and β-sheets) are closely linked to functional performance, emphasizing the importance of protein engineering and processing optimization. Overall, these studies highlight the high potential of legume proteins for providing texture, stability, and structural integrity in modern food formulations.

In the alternative protein industry, legumes are increasingly recognized as critical building blocks. Boukid (2021) described how pea and faba bean proteins have become foundational materials for plant-based meat analogs, while Osen et al. (2014) demonstrated that pea proteins

can form fibrous, meat-like structures through high-moisture extrusion. Sha and Xiong (2020) further analyzed the technological challenges of plant-based meat products, including protein–protein interactions and texture optimization. They showed that legume proteins are among the key biopolymers driving future innovations in this field.

In the context of environmental sustainability, the importance of legumes as protein sources becomes even more pronounced. In their large-scale meta-analysis, Poore and Nemecek (2018) found that legumes have significantly lower environmental impacts than animal proteins, including carbon footprint, land use, and water consumption. These findings illustrate that legume proteins are not only nutritionally or technologically valuable but also strategically crucial for environmental sustainability. Therefore, international literature strongly supports the conclusion that legumes represent fundamental protein sources for both food science and sustainable agricultural policy frameworks.

7. Conclusion

Legumes have gained a central position in today's sustainable food systems due to their high nutritional value, functional protein properties, and low environmental impact. Rising global nutritional demands combined with ecological pressures have accelerated the need for plant-based proteins, positioning legumes as strong alternatives to traditional animal-derived products. The literature clearly demonstrates that legumes, with protein contents ranging between 20–30%, rich amino acid profiles, high dietary fiber levels, and diverse bioactive compounds, hold strategic importance for both human health and functional food production.

The structure–function relationships of protein fractions make legume proteins highly valuable within food processing technologies. Protein isolates derived from species such as pea and faba bean have become key components in plant-based meat and dairy analogs due to their critical technological attributes—gelation, emulsification, water-holding capacity, and solubility. Modern processing approaches—including dry fractionation, wet extraction, fermentation, and high-moisture extrusion—enhance functional performance and expand industrial application. These findings highlight that legume proteins are not merely nutritional resources, but also high-value biopolymers capable of providing structure and stability in innovative food designs.

From a nutritional perspective, legumes play a critical role in plant-based diets owing to their high lysine content and potential health benefits. Although certain anti-nutritional factors and limiting amino acids exist, these can be minimized through appropriate processing techniques, considerably improving protein digestibility. The management of aroma compounds is an important research area for improving consumer acceptance. Collectively, these insights demonstrate that multidisciplinary approaches are required to enhance the sensory and nutritional appeal of legumes.

In terms of environmental sustainability, legumes have a markedly lower carbon footprint, water consumption, and land-use requirements than animal protein sources—these characteristics position legumes as strategic components in both climate change mitigation efforts and global food security solutions. Reports on food security and global health models indicate that legumes offer affordable, nutritionally valuable options, particularly in low-income and climate-stressed regions.

Legumes sit at the intersection of sustainable agriculture, healthy nutrition, functional food development, and alternative protein technologies. Future research should focus on optimizing functional properties of protein fractions, advancing innovative processing techniques such as extrusion and fermentation, improving aroma and sensory qualities, and leveraging environmental advantages more effectively. Taken together, current evidence clearly shows that legumes will remain indispensable components of both present and future food systems.

ABSTRACT

This study approaches plant breeding not merely as the manipulation of genetic variation, but as a strategic activity integrated with economic decision-making processes. The modern breeding paradigm goes beyond classical selection models by incorporating demand-led, market-oriented, and economically optimized approaches. Product profiles, adoption analysis, cost–benefit assessment (CBA), economic weights, and selection indices enable investment-based management of breeding programs. The shortening of breeding cycles through genomic selection, together with reductions in cost and improvements in economic efficiency, represents a critical advantage of modern breeding. It is undeniable that plant breeding constitutes a multidimensional development tool extending from micro-scale biological processes to macro-scale economic impacts (productivity, welfare, food security, employment). In conclusion, plant breeding has become a fundamental component of sustainable agricultural development through the integration of strategic planning, economic modeling, and genetic innovation.

Keywords: Plant breeding; economic optimization; demand-led breeding; selection indices; adoption.

1. Introduction

Plant breeding is a systematic scientific discipline that aims to improve populations for targeted traits through the controlled manipulation of genetic variation. Falconer & Mackay (1996) describe this process as a quantitative genetics–based progression, whereas Acquaah (2020) notes that modern breeding encompasses a broad range of techniques, including both classical and genomic approaches. Bernardo (2020) emphasizes that the breeder is not only a scientific practitioner but also a strategic decision-maker and resource manager, highlighting the multidisciplinary nature of breeding. Thus, breeding extends beyond population genetics, ecology, and molecular biology to include decision-making mechanisms such as data management, program planning, and risk analysis. Acquaah (2020) states that within quantitative genetics, breeding is not a random process but a strategically directed path of genetic improvement. Therefore, breeding is not only a scientific system but also a managerial and design-oriented activity.

Beyond traditional definitions, modern efforts increasingly incorporate market-led and demand-led breeding approaches. Persley & Anthony (2017) demonstrate that breeding is not merely a biological process occurring in laboratories and fields, but a business model that must be designed for markets and users. Ragot et al. (2018) show that this includes fundamental processes such as developing product profiles and translating demand signals into strategic decision mechanisms. Stakeholder analysis, identification of target environments, and translation of market needs into genetic objectives form the essence of the demand-led approach (Yao et al., 2017). This framework allows breeding design to be viewed not only in terms of biological performance but also in terms of its capacity to create economic value. The demand-led model positions breeding as a mechanism for sustainable development.

Plant breeding is also strategically crucial from an economic perspective. Groenewegen et al. (2016) report shows that breeding generates benefits far exceeding costs by increasing farmer income, agricultural productivity, and national economic performance. The CAS–CGIAR (2020) report similarly indicates that modern breeding strategies generate net economic contributions worth millions of dollars. Therefore, economic optimization is a fundamental criterion for evaluating the performance of breeding programs. Economic weights (Batista et al. 2021) quantify the value of selected traits for farmers and markets, facilitating strategic decision-making. Breeding without economic evaluation yields only biological progress, while the economic impact remains unaccounted for. The modern literature clearly supports the use of economic modeling to manage breeding.

This economic orientation becomes even stronger when combined with genomic techniques and selection indices. Numerous studies have confirmed that genomic selection shortens the breeding cycle and increases economic efficiency (Heffner et al., 2009; Merrick et al., 2022). Selection indices enable decision-making based on scientific and economic rationality among multiple traits, reinforcing strategic direction (Batista et al. 2021). Cost–benefit analysis (CBA) facilitates the identification of the most appropriate breeding pathway by comparing the cost-effectiveness of alternative strategies (Groenewegen et al., 2016; CAS–CGIAR, 2020). The integration of these tools has transformed modern breeding programs into “genetically based investment systems”.

It is essential to measure economic impact at the societal level. Adoption represents the ultimate indicator of the commercial and financial success of breeding, because varieties not used by farmers do not generate economic value (CAS–CGIAR, 2020). Noleppa & Cartsburg (2021) demonstrated that breeding has macroeconomic rather than microeconomic impacts, enhancing national income, employment, and societal welfare. Therefore, breeding programs should

produce not only genetic gains but also economic and social transformation. Modern breeding is a multidisciplinary field that requires economic modeling, strategic planning, and development-impact assessment beyond biological improvement alone. Data clearly indicate that future breeding programs will simultaneously manage genetics and economics, establishing breeding as a core component of sustainable agricultural development.

2. Importance of Plant Breeding

Plant breeding is a systematic, scientific discipline that aims to improve target traits by directing and selecting genetic variation. Falconer and Mackay (1996) define plant breeding as a quantitative genetics–based progression process in which allele frequencies are intentionally altered to enhance populations. Acquaah (2020) states that breeding encompasses a broad spectrum of methodologies ranging from classical hybridization and selection to genomic selection, from phenotypic evaluation to marker-assisted approaches. According to Bernardo (2020), breeding is not merely about manipulating genes but involves a systematic process of managing decisions, risks, and outcomes; therefore, the breeder is not only a scientific specialist but also a strategic decision manager. Breeding is simultaneously the integration of genetic knowledge, environmental interactions, and economic realities; thus, "data-driven decision-making" and "program organization" are fundamental prerequisites. From a quantitative genetic perspective, Acquaah (2020) emphasizes that breeding is not a random endeavor but a strategically directed genetic advancement. In this framework, breeding is a planned, predictable process that transforms plant populations using scientific principles.

The importance of plant breeding is both biological and economic. Bernardo (2020) indicates that breeding is a strategic solution to increasing pressures of population growth, food security, and agricultural productivity; therefore, the breeder is not only a geneticist but a "resource manager and strategic decision-maker." Acquaah (2020) highlights modern breeding as an essential tool for sustainable agriculture, stress tolerance, product quality, and adaptation. Particularly as global climate change, disease pressure, and production costs increase, breeding programs become critical for ensuring food supply and maintaining agricultural economies. Falconer and Mackay (1996) note that breeding not only drives genetic gain but transforms biological variation into economic output. Acquaah (2020) further defines the breeder's role as "manager–decision-maker," demonstrating that program success depends on strategic planning, objective setting, and resource allocation. In conclusion, plant breeding is an indispensable core technology for food security, productivity, quality, sustainability, and economic development.

3. Market-Led and Demand-Led Plant Breeding

Contemporary approaches no longer view plant breeding merely as a biological process aimed at genetic progress; rather, it is defined as a "business model" that requires strategic planning and managerial execution. Persley and Anthony (2017) characterize this approach as "market-led" breeding and emphasize that breeding design must be shaped by the needs of markets, users, and supply chains. The first step in demand-led breeding is accurately identifying the market's real needs. Transforming these needs into breeding objectives relies on product profiles and strategic planning pathways. As highlighted by Ragot et al. (2018), varietal development programs cannot achieve widespread adoption and commercial impact unless they generate "demand-designed solutions." Hence, breeding transcends classical scientific processes and incorporates concepts such as "strategic investment management" and "market alignment." Through demand-led breeding, breeding programs become more predictable, measurable, and sustainable. This framework maximizes both agricultural performance and the economic value generation capacity of the developed product.

Demand-led breeding is based on defining market segments, understanding user preferences, weighting value-defining traits using econometric analyses, and ultimately transforming product profiles into strategic decision-making tools. Yao et al. (2017) describe market-led breeding not as a purely technical process, but as a business model structured around economic rationality and stakeholder engagement. In the Demand-Led Breeding platform's documents, emphasis is also placed on "monitoring–evaluation (M&E)" and "performance indicators (KPI)." These explanations underline the importance of viewing breeding not as a research activity but as a "manageable production and investment process." Product profiles lie at the core of this approach, since they integrate biological and economic criteria. The demand-led framework also acknowledges that breeding serves not merely the end user but the "value chain." Therefore, market-led breeding drives decisions not only toward "genetic gain" but also toward "economic impact."

One of the most potent tools of demand-led breeding is the product profile. Ragot et al. (2018) emphasize that a product profile is not merely a list of target traits; it represents the formal, technical, and economic framework of the investment rationale (business case). The product profile defines "which traits" demand exists for and "with what economic weights." Persley and Anthony (2017) describe it not only as a biological selection tool but as the foundational input of the entire economic architecture of the breeding program. Stakeholder mapping identifies all actors in the market chain and tests the feasibility of the product profile; this analysis includes farmers, processors, traders, consumers, and public authorities. The Demand-Led Breeding approach requires the systematic application of these analyses. The "business case" logic implies that decisions regarding varietal development must be economically justified, reinforcing the investment character of breeding. Consequently, breeding transitions from being merely a "scientific project" to a "controlled investment process."

Viewing plant breeding as a business activity makes public–private sector partnerships a strategic domain. An economic analysis by Areal et al. (2014) demonstrated that financial diversification is essential for the sustainability of breeding. While public research institutions provide scientific infrastructure and risk management support, the private sector ensures commercial scaling and market dissemination. This division of roles creates strategic advantages, particularly for the rapid implementation of demand-led breeding. Sustainable economic models arise in areas such as organic breeding, niche market products, and quality-driven breeding (Nuijten et al., 2016). Thus, breeding programs create not only an "output product" but also "market impact." This model transforms varieties from products that farmers merely want into products the market is willing to pay for. Therefore, achieving sustainability in breeding is now achieved through the integration of financial planning, investment management, and value-chain analysis.

Demand-led breeding aims at much more than technical efficiency; its most critical output is socio-economic impact. Yao et al. (2017) emphasize that this approach gives rise to new training models and program management standards. As defined by Persley and Anthony (2017), the breeder is no longer merely a genetic expert, but also a "designer of investment pathways." Through the product profile approach, breeding success is measured not only by yield improvement but also by "adoption" and "market acceptance." Ragot et al. (2018) describe the strategic flow as "not from laboratory to market, but from market to breeding." When linked with public–private partnerships, strategic planning, and performance indicators, this model becomes a tool for sustainable development. Consequently, demand-led breeding transforms plant breeding from a purely genetic science into a strategically managed economic development sector of the future.

4. Economics of Plant Breeding and Strategic Planning

Plant breeding is not merely a biological activity aimed at achieving genetic gain; it is also a strategic economic process. The limited availability of resources in the agricultural sector necessitates the management of breeding programs through economic optimization. The requirement for economic optimization is shaped by the societal and industrial benefits that breeding programs deliver. A comprehensive cost–benefit assessment found that plant breeding programs yield multifaceted benefits for producers and agricultural economies (Groenewegen et al., 2016). The same study demonstrated that breeding generates tangible value not only genetically but also economically. In this context, economic optimization is essential for both scientific and financial sustainability. The CAS–CGIAR report similarly indicated millions of dollars in net economic contributions (CAS–CGIAR, 2020). Therefore, economic optimization is a fundamental performance criterion in plant breeding. Economically inefficient breeding strategies may lead to wasteful use of national resources. Accordingly, modern breeding programs must be evaluated using indicators such as return on investment, adoption rate, and market alignment. The primary purpose of economic optimization is to balance genetic progress with economic value creation. Thus, breeding programs serve not only biological success but also agricultural development and economic welfare.

Economic weights are parameters that determine how much improvement in a given trait contributes to producers' economic gains. This concept serves as the basis for selection indices. Selection conducted without economic weights produces only biological outcomes. Economic weights strengthen strategic decision-making mechanisms (Batista et al. 2021). Economic indices enable breeders to make scientifically rational decisions among multiple traits. This approach increases return on investment. Economic weights may vary from country to country or even region to region, because market dynamics differ geographically. Therefore, economic indices are not static but dynamic tools that must be continually updated. Selection decisions supported by economic analysis enhance resource efficiency within breeding programs. The concept of economic selection is a strategic principle guiding modern breeding. Moreover, economic weights establish a balance between producer preferences and consumer expectations. Accurate estimation of economic weights increases product competitiveness in the market. Incorrectly defined weights may create risks regarding time, cost, and success rates. Therefore, economic weights must be determined using scientific data, market analysis, and socioeconomic models. Ultimately, economic weights are critical tools for balancing the biological and economic dimensions of modern breeding.

Genetic gain describes the biological improvement achieved through breeding. Economic gain, however, refers to the return of that improvement in terms of income, market growth, and productivity. These two concepts do not always progress in parallel, because high genetic gain does not necessarily translate into economic value. Economic weights convert genetic gain into economic value (Batista et al., 2021). If economic return is not calculated, the true success of plant breeding cannot be measured. Genomic selection has been shown to increase economic gain (Merrick et al., 2022). This relationship is one of the primary reasons for economic optimization. The actual value of genetic advancement is evaluated through economic outcomes; otherwise, plant breeding produces only theoretical progress. Breeding programs not based on economic models lack strategic validity. Thus, plant breeding must be guided by economic thinking. Economic evaluation strengthens alignment between breeding objectives and market needs. In conclusion, modern plant breeding is an interdisciplinary process that integrates genetic progress with economic value.

Cost–benefit analysis (CBA) is a method for assessing plant breeding programs in terms of financial and societal returns. Breeding has been shown to produce benefits far exceeding costs (, 2016). CBA plays a critical role in validating investment decisions. The CAS–CGIAR report reported similar outcomes (CAS–CGIAR, 2020). Without CBA, the efficiency of breeding investments cannot be determined. CBA reveals which strategies are most advantageous. This approach encompasses not only economic but also social benefits. A well-designed CBA enables decision-makers to guide programs properly. Therefore, CBA is the fundamental control mechanism of breeding management. Breeding systems lacking CBA fall into "economic governance" deficiency. Through CBA, breeding programs are evaluated not by short-term cost but long-term economic contribution. Thus, breeding investment policies are grounded in scientific rationale. In summary, CBA is the strongest analytical tool for measuring the sustainability and societal impact capacity of breeding. The success of modern breeding systems depends on the extent to which CBA is integrated into decision-making processes.

Selection indices enable rational decision-making among multiple traits. When economic indices are used, selection is optimized not only biologically but also economically. Economic indices have been shown to provide clear superiority (Batista et al., 2021). Their use has been reported to enhance economic efficiency (Merrick et al. 2022). This method ensures resource savings. The primary aim is to determine the genotypes that yield the highest economic returns. Selection indices are incomplete without economic weights. Therefore, the index approach is at the core of modern breeding. Selection based on economic indices strengthens strategic breeding philosophy. This approach is fully aligned with economic optimization. Moreover, selection indices objectify scientific decision-making processes. Without an index-based approach, selection often remains at a trial-and-error level. Economic indices allow breeders to combine market requirements with agronomic performance. Thus, the selection process is grounded in both economic and biological reality. In conclusion, economic indices are among the most effective tools systematically strengthening the strategic direction of modern plant breeding.

Genomic selection increases economic efficiency by shortening the breeding cycle. Heffner et al. (2009) demonstrated that genomic selection provides speed and accuracy, while Merrick et al. (2022) confirmed that economic efficiency increases under genomic selection. Shortening the cycle length directly translates into a higher annual economic return. Therefore, genomic selection is not only a biological tool but also an economic instrument. Genomic selection reduces costs, and early selection provides economic advantages. Optimizing program strategy lowers financial risk. Genomic selection must therefore be integrated with economic systems. As the rate of genetic gain increases, the return on investment also rises. Compared with traditional selection methods, this approach offers substantially greater efficiency. The economic benefits of genomic selection have become indispensable for modern breeding programs. Therefore, genomic selection lies at the core of economic breeding.

Economic optimization aims to maximize the efficiency of resource use. Alternative breeding scenarios must be evaluated within an economic model. CAS–CGIAR (2020) showed that data-driven strategies increase economic efficiency. Merrick et al. (2022) demonstrated that early genomic selection is economically superior. Such analyses strengthen investment decisions. Strategic optimization reduces risk. Simulation tools support economic evaluation. Effective decision-support systems increase resource efficiency. Resource allocation should be planned with strategic modeling. Economic optimization is the foundation of breeding governance. Economic modeling enables rational decisions regarding which methods to apply. Optimization enhances sustainability and reduces economic uncertainty. Therefore, economic optimization shifts breeding programs from short-term outcomes toward long-term development goals. The

absence of strategic economic modeling leads to inefficient resource allocation. Consequently, economic optimization is a critical management component ensuring the long-term success of modern breeding systems.

As adoption success increases, economic return grows. The CAS–CGIAR (2020) report clearly demonstrated this relationship, which was also supported by findings from Groenewegen et al. (2016). Genetic progress becomes economic value only when it is adopted. A successful breeding program is adopted by farmers in the field. Economic optimization helps increase adoption rates. If adoption is low, economic return remains limited. Therefore, economic analysis must establish the connection between field performance and market value. Strategic assessments reduce adoption risk. Adoption is the ultimate measure of economic success. Adoption analyses allow breeding outcomes to be evaluated not only biologically but also socioeconomically. When farmers adopt varieties, they gain commercial value. This process contributes to increased national agricultural productivity. Thus, adoption is the concrete indicator of the strategic impact of breeding.

The economics of plant breeding creates macroeconomic, not microeconomic, impacts. Noleppa & Cartsburg (2021) demonstrated that plant breeding in the EU increases production, employment, and welfare. These findings show that plant breeding plays a critical role in national development. Economic optimization enhances societal benefit. Correct economic strategies support sustainable agriculture. The economics of breeding should not be overlooked in development planning. Economic impacts may even influence sectors beyond agriculture. Plant breeding is a development tool. Economic analysis makes this reality visible. Therefore, breeding is a macro-strategic activity. Macroeconomic analyses can evaluate the impacts of breeding investments on national income. Breeding activities support rural development and strengthen regional economies. As economic efficiency increases, food security also strengthens. For this reason, breeding programs should be planned within a national development vision. Linking genetic success to economic outcomes is a fundamental requirement of modern agricultural economics.

Economic optimization has become indispensable in plant breeding (Groenewegen et al., 2016; CAS–CGIAR, 2020; Batista et al., 2021; Merrick et al., 2022). Economically weighted breeding produces more efficient outcomes because target traits are selected in alignment with market demand. Cost–benefit analysis is the foundation of strategic planning and validates investment decisions. Genomic selection must also be implemented from an economic perspective, because shortening the cycle length directly increases annual economic gain. Adoption is the key to economic return, and without field-level dissemination, the value of breeding becomes invisible. Macroeconomic impacts must be considered, because breeding affects not only yield but also employment, food security, and regional development. Without economic analysis, breeding remains incomplete, as genetic progress alone does not ensure economic sustainability. The breeding programs of the future will manage economics and genetics jointly. This synergy will guarantee the sustainability of scientific advancement. Moreover, economic modeling will enable the prediction of which strategies are most advantageous. Breeding program performance will increasingly be measured not solely by biological improvement but by economic impact. Therefore, economic optimization will become the most important conceptual framework for defining breeding criteria in the future.

4. Conclusion

This study demonstrates that plant breeding is not only a biological process but also an economic, strategic, and managerial activity. The modern breeding paradigm goes beyond genetic advancement and requires integrating investment planning, demand analysis, product profile design, market alignment, and public–private partnerships. Economic optimization, selection indices, cost–benefit analyses, and genomic selection are key mechanisms that increase the financial return on investment (ROI) in breeding. The literature clearly shows (Groenewegen et al., 2016; CAS–CGIAR, 2020; Persley & Anthony, 2017; Bernardo, 2020) that the actual value of genetic progress becomes tangible through adoption and economic impact in the field. Therefore, modern breeding programs have evolved into interdisciplinary systems that integrate biological success with economic value creation.

From a future perspective, demand-led and market-aligned breeding will be fundamental components of national development, food security, and sustainable agriculture. Genomic selection, strategic economic modeling, and stakeholder analysis will accelerate breeding innovation, increase cost efficiency, and expand product adoption. Breeding science now forms a strong bridge between population genetics and economic decision engineering. In this context, the next generation of breeders will not only be genetic specialists but also program managers, investment strategists, and value-chain designers. In conclusion, a modern breeding system centered on economic optimization is an indispensable technological and developmental tool for the sustainability of global agriculture and societal welfare.

ABSTRACT

This study approaches plant breeding in Türkiye not merely as field trials but as an integrated strategic system aligned with national development, food security, and green transformation priorities. Based on international frameworks such as FAO, NAPB, and Plant ETP, the study proposes structuring the national plant breeding strategy on four main pillars: (i) a national strategic framework and policy foundation, (ii) institutional organization, funding, and governance, (iii) a national breeding data system, risk and regulatory management, and (iv) international integration and future vision. The current situation reveals that breeding activities are predominantly project-based, fragmented, and short-term; at the national level, stakeholder analysis, genetic resource management, human resource planning, and financial sustainability are not sufficiently institutionalized within a holistic strategy. The proposed model aims to transform breeding into a "learning" and self-updating ecosystem by utilizing instruments such as centralized data infrastructure, measurable key performance indicators (KPIs), public–private partnerships (PPPs), risk management, and regulatory compliance. In conclusion, the article argues that Türkiye can position plant breeding as a backbone of both economic growth and sustainable food systems by integrating its rich genetic resources and scientific capacity with strategic planning, effective governance, and international engagement.

Keywords: National plant breeding strategy; strategic planning; public–private partnership; data infrastructure; risk and regulatory management.

1. Introduction

Türkiye's agricultural sector is rapidly transforming under the pressures of climate change, population increase, market fluctuations, and food security challenges. These pressures have elevated plant breeding from a biological effort aimed merely at yield improvement to a strategic domain with economic, institutional, and policy dimensions. To remain nationally competitive, adapt to climate risks, and establish sustainable food systems, breeding programs must move beyond sporadic or solely project-based initiatives. Instead, there is a necessity for an integrated "national breeding strategic framework" characterized by a clear vision, defined priorities, stakeholder roles, and accountability mechanisms. This study discusses the strategic management of plant breeding in Türkiye and proposes a national-level framework informed by international best practices.

National and institutional strategic plans are not simply "statements of intent"; they are managerial instruments that guide resource allocation, human capacity development, R&D priorities, and investment decisions. FAO's national strategy guidelines, strategic plans of universities and research institutes, and policy documents from platforms such as NAPB and Plant ETP clearly indicate that breeding must be approached beyond conventional trial plots, within a structure defined by institutional organization, funding models, public–private partnerships, and principles of good governance. In the context of Türkiye, these documents highlight the need for an institutional transformation that favors multi-year, multi-stakeholder program designs over short-term, dispersed projects. Therefore, the axis of "institutional structuring, funding, and governance," encompassing both national policies and strategic planning practices of individual institutions, is addressed as a distinct focus area in this article.

The success of modern breeding programs depends not only on the genetic methods employed but also on the quality of the associated data ecosystem, risk management structures, and regulatory frameworks. In environments where genomic, phenotypic, environmental, and market data are not integrated, where monitoring–evaluation (M&E) and key performance indicators (KPIs) are undefined. Where risk and regulatory mechanisms are not adapted to support innovation, scientific potential fails to translate into economic and societal value. For this reason, the third central axis of this study is dedicated to the strategic design of the national breeding data system, risk management, regulatory structure, and M&E mechanisms. The aim is to present a governance model for Türkiye that is both data-driven and adaptive, offering a resilient breeding ecosystem that minimizes economic, biological, and environmental uncertainties.

Plant breeding is increasingly shaped by international collaboration, technology transfer, and dynamics of global competition. Designing Türkiye's breeding system solely within national boundaries is neither feasible nor strategic; integration with CGIAR, FAO, European technology platforms, regional research networks, and multinational funding mechanisms is imperative. Accordingly, the fourth axis of the article discusses international integration, opportunities for global collaboration, and Türkiye's long-term "breeding vision." The goal is to link the national strategy to a future-oriented perspective that balances scientific capacity, economic return, and sustainability, positioning Türkiye as a regional hub for breeding and phenotyping. In doing so, the study seeks to present a coherent, applicable, and internationally aligned strategic framework for plant breeding in Türkiye across four key pillars.

2. National Strategic Framework and Policy Foundation

Türkiye's agricultural sector is rapidly transforming under the pressures of climate change, population growth, and food security demands. This transformation requires breeding programs

to evolve from purely biological progress toward systems that also target economic, institutional, and strategic outcomes. FAO's (2014) national strategy development guidelines explicitly state that countries must manage genetic resource utilization through structured and stakeholder-based mechanisms. In Türkiye, institutional planning for plant breeding remains fragmented and project-driven; therefore, a national framework is essential. The CUCALS (2020) Strategic Plan presents a strong model for developing a long-term vision, defining measurable goals, and tracking performance indicators. This approach may serve as a reference for strengthening harmonization, coordination, and data sharing among breeding institutions in Türkiye. The NAPB (2024) strategic plan emphasizes that a breeder is not merely a generator of scientific knowledge, but also a resource manager and program designer. The sustainability of breeding programs in Türkiye can be strengthened by institutional strategy frameworks integrating funding and capacity management. The Plant ETP (2023) report demonstrates that investments in breeding in Europe are treated as "strategic" because they fundamentally shape agricultural futures. Türkiye could adopt this perspective to redesign national agricultural policies around a "breeding-centered" approach. Lusser et al. (2011) highlight that commercialization of new breeding technologies requires an appropriate policy framework; this finding is highly relevant for Türkiye in the context of biotechnology-driven breeding. Thus, strategic vision, institutional coordination, and innovation management form the core components of a national breeding strategy in Türkiye. Long-term planning and policy alignment will create the opportunity to transform biological progress into economic growth.

In designing a national breeding strategy for Türkiye, the four pillars proposed by FAO (2014) should be considered: stakeholder analysis, genetic resource management, capacity assessment, and an actionable implementation plan. At present, Türkiye faces challenges in articulating strategic priorities due to the lack of institutional stakeholder mapping. Applying the FAO model could enhance transparency and accountability in breeding programs. The CUCALS (2020) Strategic Plan stresses that strategic documents should not only define vision but also serve as "management tools." In Türkiye, strategic documents must therefore encompass resource allocation, personnel planning, and performance monitoring processes. As shown in the NAPB (2024) plan, education and capacity development constitute integral parts of the strategy. To mitigate the decline in the breeder workforce in Türkiye, strategic planning must invest in training and the development of technical competencies. The Plant ETP report highlights the catalytic role of public–private partnerships in funding; Türkiye's national framework should actively encourage such cooperation. Lusser et al. (2011) demonstrate that commercialization of new breeding technologies becomes feasible when supported by policy. Accordingly, national strategy documents in Türkiye must incorporate regulatory, licensing, and innovation-incentive components. In conclusion, Türkiye should formulate a national strategy that goes beyond biological goals and also covers institutional and economic planning. This approach will reinforce the long-term sustainability of breeding.

The success of strategic documents is directly related to stakeholder analysis and institutional alignment. FAO (2014) notes that stakeholder mapping must be the cornerstone of all breeding activities. In Türkiye, stakeholders include universities, research institutes, private companies, public agencies, producer organizations, and seed firms. These groups must not merely implement the strategy but also shape it. In the CUCALS (2020) Strategic Plan model, stakeholder dialogue is executed systematically, and feedback mechanisms are incorporated into scientific outputs. Institutionalizing such a system in Türkiye would improve the feasibility and adaptability of breeding strategies. The NAPB (2024) document emphasizes that science–policy interaction should be bidirectional. Türkiye's strategic documents must bridge the gap between policymakers and scientists. The Plant ETP (2023) workshop report stresses that

investment strategies require multi-stakeholder platforms; Türkiye could adapt this model. Lusser et al. (2011) show that policy–research interaction accelerates regulatory success. Therefore, institutional alignment is the most critical component of Türkiye's strategy. Strong institutional coherence reduces resource wastage, prevents duplication of effort, and enhances performance. For this reason, the national strategy must define roles and responsibilities across stakeholders. In summary, stakeholder-based institutional harmonization is the fundamental element securing the sustainability of Türkiye's breeding strategy.

Türkiye possesses significant plant genetic resources due to its substantial ecological diversity; however, the strategic utilization of these resources has not yet been defined at the institutional level. FAO (2014) guidelines state that genetic resources must be prioritized within the national strategy and managed with long-term objectives in mind. Gene banks in Türkiye provide essential inputs to breeding programs, yet data-sharing infrastructure remains inadequate. The CUCALS (2020) Strategic Plan emphasizes the importance of a centralized genetic resource database; this approach should be adopted in Türkiye. The NAPB (2024) document stresses that genetic resources should be managed on a system basis, not a project basis. In Türkiye, a lack of policy-level coordination in genetic resource management reduces efficiency. The Plant ETP (2023) report shows that investments in genetic resources in Europe are considered "strategic infrastructure investments." In Türkiye, long-term goals for the utilization of genetic resources must be defined within a national strategic framework. Lusser et al. (2011) argue that new breeding technologies cannot be considered independently from genetic resource management; this insight is vital for Türkiye's modern breeding dynamics. The transfer of genetic resources into commercial varieties underpins sustainable breeding. Data integration between genetic resource programs and breeding projects has become essential in Türkiye. Achieving this integration will enhance both environmental and economic efficiency of the breeding system. An appropriate genetic resource strategy will also reinforce the goals of quality, adaptation, and market suitability. Therefore, genetic resource management represents a critical component of the national plan.

Current breeding efforts in Türkiye are primarily conducted as Research and Development (R&D) projects but are not embedded within a national innovation management framework. FAO (2014) stresses that strategic documents must analyze innovation capacity; in Türkiye, such analysis is not yet systematically implemented. The CUCALS (2020) Strategic Plan shows that innovation is connected to robust institutional architecture and risk management. The NAPB (2024) plan positions innovation within both technical and economic dimensions; in Türkiye, economic returns of innovation are not yet clearly defined. The Plant ETP (2023) report indicates that strategic financing mechanisms must support breeding innovation. Türkiye currently lacks such financing models; this weakens long-term breeding projects. Lusser et al. (2011) demonstrate that commercialization cannot occur without policy support. Türkiye's national strategy must therefore include the commercialization dimension of innovation. Prioritization mechanisms must be established to translate R&D outputs into products. Without innovation management, the effectiveness of technological breeding methods remains limited. Performance indicators measuring the economic impact of R&D should be developed. R&D outputs should be aligned with product profiling and feasibility considerations. Thus, innovation and R&D management must form the backbone of the national breeding strategy.

3. Institutional Architecture, Funding, and Governance

The FAO (2014) guidelines emphasize that financial sustainability must be addressed in strategic planning; however, Türkiye's current funding model remains project-based rather than strategic. The CUCALS (2020) Strategic Plan demonstrates that public–private partnerships

increase the efficiency of R&D. NAPB (2024) defines public–private sector collaboration as the driving force of breeding growth. The Plant ETP (2023) report states that breeding investments should be classified as "national strategic investments." Türkiye should likewise elevate breeding investments to a strategic category. Lusser et al. (2011) show that commercialization of new breeding approaches accelerates when supported by financial incentives. Such an incentive mechanism has not yet been established in Türkiye. Policy instruments must be developed to encourage private-sector R&D investment. National strategy funds must support the full length of the breeding cycle. Program financing should be based on multi-year planning rather than annual budgeting. Public–private partnership models will strengthen data-sharing and risk management. Without financial sustainability, breeding success cannot be durable. The national strategy should incorporate funding diversity and risk analysis of financing. This will enhance the investability of the breeding system in Türkiye.

The breeder workforce in Türkiye is aging and declining in numbers, representing a strategic risk. FAO (2014) explicitly emphasizes that the human resources component must be a core element of strategic documents. The CUCALS (2020) Strategic Plan places educational vision at the center of breeding strategy, which is a valuable model for Türkiye. NAPB (2024) advocates simultaneous development of technical and managerial competencies among breeders. Breeding education in Türkiye is mainly academic, and professional governance capabilities are insufficiently cultivated. Plant ETP (2023) shows that hybrid education models have been developed in Europe to expand breeding capacity. Turkish education platforms should likewise operate beyond universities and incorporate industry collaboration. Lusser et al. (2011) indicate that technical expertise is a decisive factor in innovation speed. A breeding system without a human resource strategy cannot be sustainable. Educational programs must target long-term capacity building. Technical expertise should encompass data analytics, genomics, quality control, and economic assessment. Türkiye's national strategy should support interdisciplinary training models. Capacity development must be monitored through measurable performance indicators. In summary, human resource strategy is the most critical factor determining the future of the breeding system.

The success of national breeding programs can only be evaluated through measurable Key Performance Indicators (KPIs). FAO (2014) clearly emphasizes that strategic plans must incorporate monitoring and evaluation mechanisms. The KPI structure in the CUCALS (2020) Strategic Plan includes metrics such as publication outputs, variety registration, technology transfer, adoption rates, and economic impact. NAPB (2024) mandates annual KPI reporting for the U.S. breeding system. The Plant ETP (2023) workshop report recommends monitoring economic performance indicators to assess returns on breeding investments in Europe. In Türkiye, KPIs are mostly reported at the project level, making system-wide performance assessment impossible. Properly designed KPIs serve as enforcement tools for strategic alignment. Lusser et al. (2011) demonstrate that new breeding techniques are adopted more rapidly when evaluated by economic performance indicators. Establishing species- and approach-based KPI systems is therefore essential for Türkiye. KPIs also generate critical data for investment prioritization. Governance cannot be effective without KPIs. When strategic evaluation is indicator-based, transparency increases. Regular reporting of monitoring and evaluation results contributes to the sustainability of the national strategy. Therefore, KPI systems must cover not only technical performance but also economic, social, adoption, and commercialization dimensions.

Breeding data in Türkiye are dispersed across separate projects, and the absence of a national data infrastructure weakens decision-making. FAO (2014) states that genetic resources should be supported through centralized data management. The CUCALS (2020) Strategic Plan

classifies data integration as "institutional strategic infrastructure." NAPB (2024) recommends shared digital platforms for breeding data management in the U.S. The Plant ETP (2023) report shows that data architecture determines the speed of green transformation and innovation in Europe. Establishing data management structures in Türkiye will accelerate innovation, prevent duplication of effort, and enhance economic efficiency. Lusser et al. (2011) indicate that effective data management enhances the utility of new breeding approaches. Data systems must integrate genomic, phenotypic, environmental, and market information. Centralized data storage represents a critical infrastructure from a strategic governance perspective. Without data infrastructure, AI-driven and model-based breeding cannot be implemented. Strategic planning must define data security and access protocols. When operated at the national scale, data infrastructure will accelerate public–private cooperation. Implementation of a national data management strategy will enhance Türkiye's international competitiveness in breeding.

Risk management constitutes the intersection of all strategic planning dimensions in a national breeding strategy. FAO (2014) states that risk analysis must be embedded in strategic documents. The CUCALS (2020) Strategic Plan characterizes risk management as essential for sustaining success. NAPB (2024) proposes decision-support systems to analyze financial, biological, market, and climate risks. The Plant ETP (2023) report recommends planning risk management at the national policy level. In Türkiye, risk assessment is conducted at the project level but remains underdeveloped. Lusser et al. (2011) show that perceived risk slows commercialization of new techniques; therefore, risk management communication is essential. Strategic risk planning must be defined across species, target environment, and time dimensions. Decision-support systems should incorporate econometric models, yield forecasting systems, and risk simulations. Without risk management, resource waste increases and program success declines. Strategic risk evaluation mechanisms must be institutionalized in Türkiye. Risk management should be linked to KPI monitoring. The strategic plan must include tools for risk prediction and mitigation. Through this approach, the national breeding system becomes strong, resilient, and predictable.

4. National Breeding Data System, Risk, and Regulatory Governance

The success of a national strategy depends on aligning scientific research outputs with policy and industry. FAO (2014) argues that multi-stakeholder integration must be defined within strategic documents. The CUCALS (2020) Strategic Plan identifies science–industry collaboration as the primary determinant of innovation speed. NAPB (2024) regards policy–science coordination as an essential prerequisite for a national breeding ecosystem. Plant ETP (2023) shows that policy integration strengthens funding decisions across Europe. In Türkiye, policy documents are often disconnected from scientific strategies, resulting in efficiency losses. Lusser et al. (2011) demonstrate that technological innovation becomes widespread only when policy support is present. When scientific research is aligned with policy objectives, commercialization accelerates. Industry–R&D collaborations shorten product development cycles. The national strategy must explicitly define the multi-stakeholder coordination structure. Sustainable financing cannot be achieved without policy integration. In Türkiye, sustainable agriculture goals must be embedded into the breeding strategy. Alignment between policy and science enhances economic and societal return. Thus, integration constitutes a critical building block for the long-term success of the breeding system.

A national breeding strategy must include an innovation framework that systematically guides R&D activities. FAO (2014) emphasizes that innovation is not only a scientific output but also a concrete component of policy and investment planning. The CUCALS (2020) Strategic Plan describes innovation-oriented R&D as the "core source of institutional competitive advantage."

NAPB (2024) seeks to enhance innovation adoption by aligning R&D strategies with market needs. The Plant ETP (2023) report reveals that innovation functions as a strategic lever for green transformation and climate resilience. In Türkiye, innovation remains largely project-based and lacks strategic national positioning. Lusser et al. (2011) show that commercialization of new technologies (genome editing, marker-assisted selection, phenotyping technologies) accelerates when embedded within innovation systems. The national strategy must integrate breeding innovations with biotechnology, data science, agroecology, and industrial bioprocesses. For the R&D ecosystem to function effectively, infrastructure, human resources, and funding mechanisms must be addressed simultaneously. The innovation ecosystem must generate outcomes beyond scientific publications, including technology transfer, commercialization, patent portfolios, product development, and industrial application. Strategic direction is required for Türkiye's innovations to contribute to an international patent portfolio. The national innovation architecture should be supported by open innovation and pre-competitive collaboration principles. These structural arrangements will strengthen Türkiye's position in the global breeding innovation landscape.

Public–private partnerships (PPP) constitute one of the primary leverage mechanisms within breeding strategies. FAO (2014) emphasizes that public–private integration is critical for genetic resource management. The CUCALS (2020) Strategic Plan treats collaboration between the private sector and universities as a mandatory structural component. NAPB (2024) demonstrates that PPP models improve funding efficiency in the U.S. breeding system. Plant ETP (2023) provides strong evidence that PPP accelerates investment returns and commercialization success in Europe. In Türkiye, PPP effectiveness remains limited due to the absence of a strategic framework. Lusser et al. (2011) stress that sector–science integration is essential for the commercialization of new techniques. PPP provides not only financial resources but also knowledge transfer, infrastructure sharing, and technological inclusiveness. Public strengths (risk management, research capacity, regulatory support) must be combined with private strengths (market access, commercialization speed, product design). Without a strategic PPP model, the national innovation chain remains fragile. PPP structures in Türkiye can generate both technical and economic leverage within breeding projects. The strategic plan must define clear procedures, incentive mechanisms, and investment models for PPP. Such a model will support long-term sustainable agriculture, enhance food security, and institutionalize the innovation ecosystem.

The success of the national breeding strategy is directly linked to financial sustainability. FAO (2014) argues that financial planning must be clearly articulated in strategic documents. The CUCALS (2020) Strategic Plan identifies funding as a "critical determinant" of program efficiency. NAPB (2024) reports that U.S. funding strategies are prioritized according to target species, innovation areas, and societal needs. Plant ETP (2023) shows that breeding finance in Europe is directed through strategic investments. In Türkiye, funding remains project-based mainly; therefore, system-level strategic impact is limited. Lusser et al. (2011) demonstrate that commercialization cannot be achieved without adequate funding for new technologies. The national funding model must support both fundamental and applied research. Funding should be directed by KPI performance and be outcome-oriented. Strategic investments should consider long-term evaluation, economic impact analysis, and commercialization potential. Redesigning the funding system in Türkiye requires prioritization, clear metrics, and transparency in evaluation. International funds (Horizon Europe, CGIAR, ERANET) must be harmonized with national strategic goals. Funding should support innovation centers, data platforms, and advanced phenotyping infrastructure. Financial sustainability constitutes the backbone of the strategic plan.

Human resources constitute the most critical structural element of breeding strategies. FAO (2014) emphasizes that human resource planning in national strategies must incorporate long-term foresight. The CUCALS (2020) Strategic Plan frames capacity development as a "pillar of institutional sustainability." NAPB (2024) places educational development, on-the-job learning, certification programs, and leadership training as a strategic phase. Plant ETP (2023) shows that human resource strategies in Europe play a decisive role in the adoption of new technologies. In Türkiye, human resource strategies remain unsystematic and dependent on individual initiatives. Lusser et al. (2011) demonstrate that the success of new technologies is directly linked to the level of expertise. The national strategy must target integrated education across genomics, bioinformatics, phenotyping, protein processing, quality analysis, data science, and economics. Long-term capacity planning must include components for graduate education, farmer training, and technology transfer. Human resource development must be supported through PPP structures. Institutional mentorship and international exchange programs will provide strategic impact. A national "Plant Breeding Academy" model could be established in Türkiye. Without incorporating talent development into the strategy, the long-term success of breeding programs cannot be achieved. Therefore, human resource governance must remain a central component of the strategic plan.

5. International Integration and Future Vision

A modern component of strategic breeding programs is data management and digital infrastructure. FAO (2014) indicates that national strategies must treat data infrastructures as central functions. The CUCALS (2020) Strategic Plan positions data management as a mechanism of "institutional intelligence." NAPB (2024) demonstrates that integrating phenotypic, genetic, and environmental data increases program efficiency in the United States. Plant ETP (2023) reports that data infrastructure investments in Europe align with green transformation and sustainable breeding goals. In Türkiye, data infrastructure is project-based mainly and lacks national system integration. Lusser et al. (2011) point out that an effective digital ecosystem is indispensable for implementing new breeding techniques. A national data platform must capture seed systems, phenotypic analyses, genomic datasets, and adaptation performance. Without data integration, economic optimization and risk management are not possible. Data security and open-access principles should function as dual pillars of the strategic plan. The digital platform should incorporate machine learning, simulation models, and decision-support systems. A national "Breeding Data Institute" model could be established. Data sharing should be structured to support access by researchers, private-sector stakeholders, and policymakers. Integration into international data platforms will enhance Türkiye's competitiveness. Without digital infrastructure, the breeding strategy will not withstand global competition.

The effectiveness of a national breeding strategy depends on its legal (TCRG, 2004; 2006) framework and governance model. FAO (2014) shows that participatory governance enhances stakeholder alignment. The CUCALS (2020) Strategic Plan integrates governance with the monitoring and evaluation cycle. NAPB (2024) highlights that governance is the mechanism determining the accuracy of strategic investment decisions. Plant ETP (2023) notes that governance is essential for the efficiency of green transformation investments across Europe. In Türkiye, the legal framework is robust regarding seed systems, yet insufficiently systematic for breeding strategy. Lusser et al. (2011) show that regulatory adaptation is necessary for the commercialization of new technologies. The national governance model should rely on transparency, accountability, performance metrics, and participatory decision-making. Regulation must balance risk management and innovation. Overly strict regulations slow down innovation, while overly lax regulations jeopardize quality; thus, a strategic balance model is

required. Regulatory design must be harmonized with PPP structures. Governance must systematically measure economic impacts. A national coordination unit should be established. Without regulatory modernization, the breeding strategy will not yield a global competitive advantage.

The sustainability of the strategic plan depends on the monitoring and evaluation (M&E) system. FAO (2014) states that M&E is a critical component of strategic performance assessment. The CUCALS (2020) Strategic Plan employs KPI (Key Performance Indicator) models for institutional decision-making. NAPB (2024) shows that strategic funding in the U.S. breeding system cannot function effectively without M&E. Plant ETP (2023) reports that M&E outputs are decisive in investment planning across Europe. In Türkiye, M&E structures are limited and not integrated into strategic decision-making. Lusser et al. (2011) indicate that performance evaluation of new techniques predicts commercialization success. The M&E system must measure both biological and economic performance. Performance indicators should include genetic gain, financial return, adoption rate, environmental impact, and speed of commercialization. KPI definitions must be embedded in the strategic plan. The M&E system must be data-driven. A national M&E platform should produce annual reports. Monitoring should measure not only performance but also risk. Success indicators must be internationally comparable. M&E constitutes the foundation of the strategic plan's "learning system" model.

A national strategy cannot function at full capacity without international integration. FAO (2014) emphasizes the strengthening effects of international cooperation—the CUCALS (2020) Strategic Plan positions global partnerships as scientific force multipliers. NAPB (2024) identifies international networks as vital for education and technology transfer in the U.S. Plant ETP (2023) shows that breeding innovation in Europe cannot accelerate without global cooperation. Türkiye is open to global strategic cooperation but lacks a systematic model. Lusser et al. (2011) report that new techniques cannot be optimally utilized without international technology exchange. Global cooperation provides funding, infrastructure, data sharing, and expertise transfer. Strategic partnerships should be developed with CGIAR, FAO, ICARDA, and ERANET. International licensing arrangements enhance knowledge transfer. Türkiye could emerge as a regional innovation hub. International cooperation creates opportunities for regulatory benchmarking. Global positioning increases competitiveness. The strategic plan may position Türkiye as a "regional breeding and phenotyping center." This approach ensures long-term sustainability.

The ultimate aim of the strategic plan is to translate scientific progress into economic, social, and environmental benefits. FAO (2014) states that vision must align with national development goals. The Cornell Strategic Plan defines vision as "institutional sustainability and global leadership." NAPB (2024–2029) demonstrates that strategic vision elevates the breeder's role to that of a decision manager. Plant ETP (2023) notes that strategic vision must produce societal welfare, not just technical advancements. For Türkiye, the vision is equilibrium between "scientific capacity + economic return + sustainable agriculture." Lusser et al. (2011) report that new techniques create tangible economic impact when supported by the right strategic vision. The national vision must rely on strong human resources, effective R&D, sustainable funding, and digital data infrastructure. The vision must target not only laboratory success but also the development of varieties adopted at the field level. Economic and socio-economic impacts must be central. Türkiye may become a regional leader in sustainable protein resources and adaptive farming systems. The vision must promote alignment among stakeholders. The success of the vision depends on performance-monitoring and outcome-evaluation systems. Strategic vision can position Türkiye as a global actor in breeding innovation.

5. Conclusion

This study demonstrates that plant breeding in Türkiye should no longer be treated merely as a biological process confined to field trials, but rather as a strategic system directly linked with national development, food security, and green transformation objectives. Analyses of international frameworks such as FAO, NAPB, Cornell, and Plant ETP reveal that the common denominator among successful countries includes the presence of clear national strategic plans, institutional alignment, robust data infrastructure, and multi-stakeholder governance. When Türkiye's existing scientific capacity and rich genetic resources are integrated into such a strategic configuration, significant advantages can be achieved in terms of climate-resilient cultivar development, sustainable protein supply, and a competitive seed sector.

The proposed four pillars—(i) national strategic framework and policy foundation, (ii) institutional architecture, funding, and governance, (iii) national breeding data system, risk and regulatory management, and (iv) international integration and future vision—jointly enable the design of a holistic "breeding ecosystem" for Türkiye. Within this ecosystem, the breeder evolves from a generator of genetic gain into a program leader and strategic decision-maker who simultaneously manages economic returns, adoption dynamics, environmental sustainability, and societal impact. National-level data platforms, performance indicators, PPP models, and international collaboration networks will transform breeding programs from short-term projects into multi-year, continuously improving development instruments.

In conclusion, Türkiye's primary opportunity lies in leveraging its scientific expertise and rich genetic diversity through a well-designed strategic framework to position plant breeding as a backbone for both economic growth and sustainable food systems.

ABSTRACT

Fennel (*Foeniculum vulgare*) is a medicinal and aromatic plant that is widely used in the food, pharmaceutical and cosmetic industries. In this study, it was aimed to determine the mineral content of fennel seeds cultivated under the ecological conditions of Konya, as well as the antioxidant activity and bioactive components in seed extracts. Fennel seeds were found to be rich in the minerals potassium, calcium and phosphorus. The antioxidant activity of the extracts obtained from the seeds was determined as 0.019 ± 0.001 mg TE/mL, and the bioactive components were identified as anethole, p-anisyl acetone, oleic acid and linoleic acid. The results indicate that fennel seeds can be evaluated as a natural raw material in functional foods, nutraceuticals and pharmaceutical applications.

Keywords: Fennel, *Foeniculum vulgare*, mineral content, antioxidant activity

1. INTRODUCTION

Fennel (*Foeniculum vulgare*) is one of the oldest cultivated plants, belonging to the Apiaceae family, herbaceous in nature and capable of growing 1-1.5 m in height. There is evidence that it was used for medicinal purposes by the Sumerians, Ancient Egyptians and Ancient Greeks as early as 3000 BC (Zeybek and Haksel, 2010). While the bulb, young shoots, leaves and dried fruits of the fennel plant are used in traditional remedies, its aromatic fruits are utilized as a spice (Tanira et al., 1996). In addition, teas containing fennel seeds are traditionally consumed in Europe and Asia for digestive and respiratory ailments (Raffo et al., 2011). Although the plant originates from the Mediterranean and Western Asia, it is now widely cultivated in warm and temperate regions (Badgujar et al., 2014). In Türkiye, it is commonly found in the Aegean and Mediterranean regions (Zeybek and Haksel, 2010), and is cultivated in the provinces of Afyonkarahisar, Ankara, Konya, Antalya and Burdur (TUIK, 2025).

Worldwide, two main varieties of fennel are cultivated: bitter fennel (*Foeniculum vulgare* var. *vulgare*) and sweet fennel (*Foeniculum vulgare* var. *dulce*) (Zeybek and Haksel, 2010). In Türkiye, however, all cultivated fennel types belong to sweet fennel (var. *dulce*). Sweet fennel, which is generally an annual and occasionally a biennial plant, is particularly important because its seeds are used as a spice (Baydar, 2016). In Türkiye, fennel is known by various local names such as “arapsaçı, meletüre, irziyan, mayana, razıyane, cumhur, çumra, ısıra, sincibil, sincilip, rezdene, sarı ot” In English, it is referred to by names such as “anise, aniseed, aniseed weed, bitter fennel, common fennel, Florence fennel, Roman fennel, sweet anise and sweet fennel” (Duke, 2002).

In several studies conducted in Türkiye, trans-anethole has been reported as the main constituent of the essential oil obtained from Turkish fennel (Coban et al., 2018; Telci et al., 2019), whereas other investigations have identified methyl chavicol as the predominant component (Özcan and Akgül, 2001; Özcan and Chalchat, 2006). Furthermore, Katar et al. (2021) reported that methyl chavicol is the principal constituent of the essential oils in different organs of fennel, except for the leaves.

Mineral elements not only determine the nutritional value of plants but also influence their functional properties by exhibiting synergistic interactions with bioactive compounds. It has been reported that fennel seeds contain approximately 13-14% mineral matter and that these mineral components include essential elements such as calcium, potassium, sodium, magnesium, phosphorus and iron, as well as trace amounts of zinc and manganese (Rather et al., 2016). However, studies on the mineral content of fennel grown in Türkiye are quite limited, which highlights the importance of elucidating the mineral composition of this species under local ecological conditions.

This study was conducted to determine the mineral contents of fennel seeds grown in the Çeltik district of Konya province, to evaluate the antioxidant activity in the obtained extracts, and to identify the bioactive compounds present in these extracts. The data to be obtained are expected to contribute to the evaluation of fennel as a functional food ingredient and a natural source of antioxidants.

2. MATERIALS VE METHODS

In this study, fennel (*Foeniculum vulgare* var. *dulce*) seeds were used as the material. The field trials were carried out during the 2024 summer growing season in İshakuşağı village, Çeltik district of Konya province. The study area is characterized by a semi-arid continental climate. The soil in which fennel was cultivated is loamy and partially calcareous, with a depth of 50 cm, a lime content of 25%, an organic matter content of 2-3%, and an average pH of 7.1. Fennel

cultivated under farmer conditions was sown on 12/04/2024 and harvested on 20/08/2024. After harvest, foreign materials (stems, leaves, dust, etc.) were removed from the seeds, which were then prepared for analysis.

2.1. Preparation for analysis and extract yield

For the preliminary preparation for analysis and extract yield determination, 10 g of fennel seeds were ground and macerated with 200 mL of solvent (70% ethanol-water mixture) on a shaker at room temperature for 48 h. The organic solvents were removed by evaporation under reduced pressure, and the extract yield (%) was calculated.

2.2. Mineral contents

Seed samples were digested by microwave (HNO_3 and H_2O_2, 210°C, 200 PSI), diluted to 20 mL, and mineral analyses (B, Ca, Cu, Fe, K, Mg, Mn, Na, P, S, Zn) were performed by ICP-OES according to the method of Tošić et al. (2015); results were reported in ppm.

2.3. Antioxidant activity

DPPH (1,1-diphenyl-2-picrylhydrazyl) radical scavenging activity was measured by monitoring absorbance at 517 nm, after 30-minute incubations at room temperature in the dark, was conducted in accordance with Grochowski et al. (2017). Results were expressed as mg trolox equivalents (mg TE/mL extract).

2.4. GC-MS Analysis

GC-MS analyses were carried out using a Shimadzu QP2010 Ultra GC-MS system. Mass spectra were scanned in the 50–550 m/z range, and compounds were identified using the NIST library.GC operating conditions were as follows: column oven temperature 240 °C, injection temperature 250 °C. The injection mode was split with a split ratio of 1:10, and the sampling time was 1.00 min. The flow control mode was pressure-controlled, with a system pressure of 83.5 kPa. The total flow was 19.5 mL/min. Helium was used as the carrier gas, with a column flow rate of 1.50 mL/min and a linear velocity of 44.2 cm/s. The purge flow (split) was 3.0 mL/min. Computer matching against commercial libraries (Wiley GC–MS Library, Adams Library, MassFinder 3 Library) as well as MS literature data was used for the identification of essential oil components (European Pharmacopoeia, 2011).

3. RESULTS AND DISCUSSION

3.1. Extract Yield

Extract yield (%) indicates how efficiently a solvent can remove useful components from plant or seed material. This value provides information about the active compounds, nutritional value, and pharmacological effects of plant products (Adam et al., 2019). The extract yield of fennel seeds was determined as 8.6 ± 0.1%, showing that fennel seeds can be regarded as a promising source of extractable bioactive constituents. In the study conducted by Anwar et al. (2009), the highest extract yield was reported with 80% ethanol (15.63%), while the lowest yield was obtained with 100% methanol (6.21%). The extract yield obtained in the present study falls within the range reported by Anwar et al. (2009), indicating that differences in extract yield may arise from methodological factors such as the type and concentration of solvent, solid-to-solvent ratio, extraction time and temperature, as well as from variations in plant genotype and growing conditions.

3.2. Mineral contents

In fennel seeds, the macro elements phosphorus (P), potassium (K), calcium (Ca) and magnesium (Mg) were determined as 141.45 ± 0.68, 382.54 ± 1.17, 292.56 ± 1.17 and 0.55 ± 0.01 ppm, respectively. Among the micro elements, sodium (Na), iron (Fe), zinc (Zn), copper (Cu), manganese (Mn) and boron (B) contents were measured as 3.99 ± 0.01, 1.99 ± 0.01, 0.70 ± 0.01, 0.54 ± 0.02, 0.99 ± 0.01 and 0.99 ± 0.01 ppm, respectively (Table 1). These results indicate that fennel seeds are particularly rich in K and Ca among the macro elements and contain measurable amounts of essential trace elements such as Fe, Zn, Cu, Mn and B, which contribute to their potential nutritional value. Endalamaw and Chandravanshi (2015) reported calcium, magnesium, iron, manganese, copper and zinc contents in fennel fruits in the ranges of 20500-23000 µg/g, 1310-3460 µg/g, 1140-1900 µg/g, 31-51 µg/g, 24-103 µg/g and 37-45 µg/g, respectively. In another study, Başgel et al. (2006) determined calcium, magnesium, iron, manganese, copper and zinc contents in fennel seeds as 10780 ppm, 2774 ppm, 224.8 ppm, 27.8 ppm, 16.2 ppm and 37.0 ppm, respectively. Potassium is a vital intracellular mineral, crucial for osmotic balance and metabolic processes like energy transduction and protein synthesis (EFSA NDA Panel, 2016). Calcium, a key skeletal component, also functions as an essential intracellular messenger (EFSA NDA Panel, 2015). Therefore, the high levels of potassium and calcium found in fennel seeds suggest that this plant may represent a valuable mineral source from a nutritional point of view.

Table 1. Macro, micro elements of fennel seeds (Mean±SD)

Macro Elements (ppm)		Micro Elements (ppm)	
P	141.45±0.68	Na	3.99±0.01
K	382.54±1.17	Fe	1.99±0.01
Ca	292.56±1.17	Zn	0.70±0.01
Mg	0.55±0.01	Cu	0.54±0.02
		Mn	0.99±0.01
		B	0.99±0.01

3.3. Antioxidant activity

Based on the DPPH radical scavenging assay, the antioxidant activity of the fennel seed extracts was measured as 0.019 ± 0.001 mg TE/mL. These findings indicate that fennel seeds possess a noticeable antioxidant potential. Anwar et al. (2009) reported the DPPH radical scavenging activity of fennel seed essential oil and different solvent extracts as IC_{50} values of 32.32 µg/mL and 23.61–26.75 µg/mL, respectively. The differences between our DPPH radical scavenging values and those reported by Anwar et al. (2009) may be attributed to several factors, including the type of extract (seed extract vs. essential oil), the extraction solvent and conditions, the way antioxidant activity is expressed (mg TE/mL vs. IC_{50} in µg/mL), as well as possible variations in genotype, growing environment, harvest time and storage conditions of the fennel seeds.

3.4. Bioactive compounds in the extract

The main bioactive compounds detected in the fennel seed extract were anethole (1.72%), p-anisyl acetone (1.18%), oleic acid (2.84%) and linoleic acid (2.01%). Anethole and p-anisyl

acetone are essential oil components, whereas oleic acid and linoleic acid are unsaturated fatty acids.

Anethole, one of the major essential oil components of fennel seeds, is known as the principal contributor to the characteristic sweet and spicy aroma of fennel, and has been reported to possess antimicrobial, anti-inflammatory, antispasmodic and antioxidant properties (Marinov and Valcheva-Kuzmanova, 2015). The aromatic compound p-anisyl acetone has been identified as one of the main antibacterial agents (Yang et al., 2021). In addition, the presence of the unsaturated fatty acids oleic acid and linoleic acid, which are considered key constituents, may contribute to the antioxidant and anti-inflammatory potential of the extract. These findings indicate that fennel seed extract contains both volatile and fixed oil components and therefore may be utilized in the food and health sectors.

4. CONCLUSIONS

The study showed that fennel seeds are rich in essential minerals, particularly potassium, calcium and phosphorus, and that they contain notable bioactive compounds such as anethole, p-anisyl acetone, oleic acid and linoleic acid, together with a measurable antioxidant activity (0.019 ± 0.001 mg TE/mL). These bioactive compounds are associated with antimicrobial, antioxidant and antiinflammatory effects. Therefore, it can be concluded that fennel seeds grown under the conditions of Konya are valuable not only in terms of flavor and aroma, but also as a natural source of minerals and bioactive compounds; and that their use as a spice offers additional potential for functional food, nutraceutical and pharmaceutical applications. Fennel cultivation in Konya province demonstrates both agricultural suitability and sustainability. Due to its considerable production potential, there is a need to further develop fennel farming in this region. In addition, it is important to investigate and evaluate other species and varieties belonging to the same family in this area in terms of yield and quality, so that they can meet the standards set by global markets.

Conflict of Interest

The authors declare no conflict of interest regarding this study.

ÖZET

Bazı mercimek genotiplerinin Sivas ekolojik koşullarında tarımsal özelliklerinin ortaya konulması amacıyla 2024 yılında tesadüf blokları deneme deseninde dört tekrarlamalı olarak gerçekleştirilen çalışmada 27 adet ileri düzeye kadar getirilmiş mercimek hattı ile 3 adet standart yeşil mercimek çeşidi olmak üzere 30 adet yeşil mercimek genotipi materyal olarak yer almıştır. Yürütülen araştırmada tarımsal özellikler olarak bitki boyu (cm), ilk bakla yüksekliği (cm), biyolojik verim (g), bitkide bakla sayısı (adet), bitkide tane sayısı (adet), bin tane ağırlığı (g), bitkide tane verimi (g) ve hasat indeksi (%) yer almıştır. Çalışma sonucunda yeşil mercimek genotiplerinde 1.84-3.51 g aralığında bitkide tane verim değerleri belirlenmiş olup bitkide tane verimine en yüksek M-14 nolu genotipi sahip olurken en düşük bitkide tane verimi ise M-11 nolu genotipte ortaya konulmuştur. Yine çalışmada yeşil mercimek genotiplerine bağlı olarak bitki boyunda 17.00-30.00 cm, bitkide bakla sayısında 19.00-51.00 adet, bitkide tane sayısında 14.00-55.00 adet ve bin tane ağırlığında 33.47-49.75 g aralığında değerler elde edilmiştir. Sonuç olarak; M-5, M-14, M-15 ve M-31 nolu genotiplerinden elde edilen verim unsurlarına ait değerlerin diğer yeşil mercimek genotiplerine göre daha yüksek oldukları ortaya konulmuştur.

Anahtar Kelimeler: Sivas, Yeşil mercimek, Genotip, Verim, Tarımsal özellikler

1. GİRİŞ

Bir yemeklik tane baklagil bitkisi olan mercimek hem insan hem de hayvan beslemede önemli bir yere sahip olup kültüre alınan en eski yemeklik tane baklagil türlerinden birisidir. Mercimeğin ilk kültüre alındığı yerin verimli yarım ay dediğimiz Mezopotamya ile ülkemizin Güneydoğu Anadolu Bölgesi olduğu tahmin edilmekle beraber (Özdemir, 2002) tarımının yaklaşık olarak günümüzden 8.000 yıl öncesine kadar dayandığı bilinmektedir (Pellet, 1988). Yapılan arkeolojik kazılarda Türkiye'de Hacılar, Çayönü ve Çan Hasanda M.Ö. 7000-6500, Yunanistan'da M.Ö. 6500-6000, Irak, İran ve Ürdün'de M.Ö. 7000-6500 ve Suriye'de ise M.Ö. 8500-7500 yıllarına ait mercimek fosillerinin kalıntılarına saptanmıştır (Sepetoğlu, 2002). Ülkemizde ise Karadeniz Bölgesi'nin doğusu hariç hemen hemen her bölgede yetiştiriciliğinin yapıldığı bilinmektedir (Şehirali, 1988).

Çok uzun yıllardır insan beslenmesinde yoğun bir şekilde kullanılan mercimek; enerji, protein, lif, vitaminler ve mineraller (Na, Cu, K, Mg, P, Ca, Fe, Mn, Zn) bakımından da zengin (Urbano ve ark., 2007) olmasının yanında tohumlarındaki %25 civarında protein içeriği ile baklagiller içerisinde soya fasulyesinden sonra en yüksek proteine sahip baklagil türü konumundadır.

Çözünür lif kaynağının yüksek olmasından dolayı mercimek bitkisinin aynı zamanda kolesterol düşürücü, kan şekerini dengeleyici ve tokluk hissini artırıcı etkileri göstermesi nedeniyle kilo önleyici özelliği de bulunmakta olup çözünür lif kaynağının yüksek olması nedeniyle kan çözünmez lif içeriği sayesinde kabızlığı önleyerek sindirim sistemi rahatsızlıklarının giderilmesine de yardımcı olduğu belirlenmiştir (Rehinan ve ark., 2004).

Tek yıllık vejetasyona sahip olan mercimek; soğuğa, kurağa ve yüksek sıcaklıklara dayanıklılık göstermesinin yanında toprak isteği bakımından fazla seçici olmamasından dolayı kuru tarım alanlarında bir tahıl bitkisi olan buğday ya da arpa ile ekim nöbetine girmekte olup insanların ve hayvanların beslenmesindeki öneminin yanında toprak verimliliğine olumlu katkısı ve yüksek kazanç getirisiyle tarımsal bakımdan çok önemli bir konumda bulunmaktadır. Hasat ve harman sonra geriye kalan sap/samanda çok az miktarda da olsa selüloz bulunabildiğinden hayvanların beslenmesinde oldukça önemli bir yem kaynağı olabilmektedir. Bunun yanında köklerindeki nodüllerle ortak yaşama girebilen, bir rhizobium türü olan "*Rhizobium leguminosarum*" ile beraber havanın serbest azotunu toprağa fiksleyebilen ve yetiştirildiği toprağın azot miktarını artırabilen bir yapıya sahiptir (Aydoğan ve ark., 2008).

Dünyada yemeklik tane baklagiller içinde 2023 yılı itibariyle ekim alanı bakımından %7.5, üretim bakımından ise %7.95 oranı ile kuru fasulye, nohut, börülce ve bezelyeden sonra beşinci sırada yer alan mercimeğin verim değerleri bakımından ise diğer yemeklik tane baklagillerle kıyaslandığında bakla ve bezelyeden sonra üçüncü sırada kendine yer bulmuştur (FAO, 2023). Mercimek dünya üzerinde ılıman veya yarı tropik bölgelere yayılmış kuraga dayanıklı bir yemeklik tane baklagil bitkisidir. Kuru tane olarak tüketilen mercimek, en çok Orta Doğu ülkeleri ile Batı-Orta-Güney Asya ülkelerinde üretilmektedir. FAO 2023 verilerine göre mercimeğin istatistik verileri incelendiğinde dünyada mercimek üreten kıtaların başında Asya (2.994.358 ton), ülkelerin başında ise Hindistan (1.620.000 ton) gelmektedir. Kıtalar arasında verim bakımından ilk sırayı Amerika Kıtası (1.375,2 kg/ha) almaktadır. FAO (2023) verilerine göre 50 ülkede mercimek yetiştiriciliği yapılmakta olup kıtalar bazında değerlendirildiğinde Avrupa ve Asya kıtalarında 16 ülkede, Afrika kıtasında 10 ve Amerika kıtasında 8 ülkede mercimek yetiştiriciliği uzun yıllardır gerçekleştirilmektedir. Kıtalar bazında mercimek ekim alanları değerlendirildiğinde Asya kıtası 3.476.081 ha ile ilk sırada gelirken Asya kıtasının ilk sırada bulunmasında yine bir Asya ülkesi olan Hindistan büyük önem taşımaktadır ki Hindistan dünya mercimek ekim alanı bakımından ilk sırada gelmektedir.

Ülkemizde yetiştiriciliği yapılan yemeklik tane baklagillerde gerek ekim alanı gerekse üretim miktarında önemli düşüşler görülmekle birlikte 1989 yılında yemeklik tane baklagil ekim alanları toplamı 2 milyon hektarın üstündeyken 30 yıl içinde yaklaşık 883.482 hektara kadar azalma göstermiştir. Aynı şekilde 2.115.000 ton olan üretim miktarı da 1.220.244 ton seviyelerine kadar gerilemiştir. Bu durum mercimek ekiliş ve üretimine de yansımış olup 997.000 ha olan mercimek ekim alanı çok ciddi bir şekilde azalma eğimiyle 277.228 hektara, 1.040.000 ton üretim miktarı ise 353.000 ton seviyelerine kadar düşme eğilimi göstermiştir. Bun karşın yeşil mercimek ekim alanımız ise yaklaşık 39.000 ha, üretimimiz ise 43.000 ton seviyelerindedir. Yeşil mercimek ekim alanları ülkemizde Yozgat, Çorum, Kırşehir, Ankara ve Konya illerini kapsayan İç Anadolu Bölgesinde daha çok görülmektedir. Yeşil mercimeğin toplam mercimek üretim miktarı içerisinde aldığı pay yüzdesi yaklaşık olarak %7-8 arasında değişmektedir (TUİK, 2023).

Genotipik yapı ile çevre, en önemli verim unsuru olan tane veriminin ortaya konulmasında iki önemli faktör olup en uygun yetiştirme tekniklerinin belirlenmesi ile verim kabiliyeti yüksek genotiplerin değişilebilir ekolojik şartlarda yetiştiriciliğinin yapılması kaliteli yüksek ürün elde edebilmek için önemlidir. Mercimek yetiştiriciliğinin yapıldığı herhangi bir lokasyonda yüksek düzeyde verim elde edebilmek için ilk sırada bölgeye uygun genotiplerin/çeşitlerin yetiştirildiği bölge için seçimi şarttır ve çeşitlerin morfolojik/fizyolojik özelliklerin önceden belirlenmesi, belli çevre koşullarında genotipler içinden üstün verimli olanları seçmede temel oluşturmaktadır. Mercimek yetiştiriciliğinde iklim ve toprak istekleri dikkate alındığında ülkemizin büyük bir imkana sahip olduğu görülmektedir (Bozdemir, 2007).

Günümüzde artık diğer tarla bitkileri türlerinde olduğu gibi baklagil bitkisi olan mercimekte de tane verimini içine alan tarımsal özellikleri üzerinde durulması ve belli ekolojik koşullarında belli genotiplerin/çeşitlerin yüksek ekonomik dane verimi sağlayacak yetiştirme yöntemlerinin saptanması artan öneme sahip olarak görülmektedir.

Bazı yeşil mercimek genotiplerinin Sivas ekolojik koşullarında tarımsal özelliklerinin performanslarının ortaya konulması bu çalışmanın amacını oluşturmaktadır.

2. MATERYAL ve METOT

2.1. Materyal

Yürütülen çalışma, Sivas Bilim ve Teknoloji Üniversitesi'nin Tarımsal AR-GE Merkezinde yer alan deneme arazisinde 2024 yılı mercimek yetiştiriciliği döneminde gerçekleştirilmiştir. Araştırmanın yürütüldüğü lokasyon deniz seviyesinden yaklaşık 1285 m yükseklikte, N39,720656 - E36,917248 konumunda bulunmaktadır (Şekil 1).

Şekil 1. Araştırmanın yürütüldüğü deneme arazisi

Araştırmada, ülkemizde Tarımsal Araştırmalar ve Politikalar Genel Müdürlüğüne bağlı Tarımsal Araştırma Enstitüleri tarafından tescil ettirilmiş olan 3 adet yeşil mercimek çeşidi ile 2013-2016 yılları arasında BAP projesi kapsamında Kırşehir ilçe ve köylerinden toplanarak ileri düzeye kadar getirilmiş olan 27 adet yeşil mercimek hattı olmak üzere toplam 30 adet yeşil mercimek genotipi kullanılmıştır (Tablo 1 ve 2).

Tablo 1. Çalışmada kullanılan genotipler

Genotip No	İli	İlçesi	Köy/Beldesi	Genotip No	İli	İlçesi	Köy/Beldesi
M-01	**KIRŞEHİR**	Kaman	Yelek	**M-15**	**KIRŞEHİR**	Çiçekdağı	Küçükteflek
M-02		Mucur	Rışvan	**M-16**		Kaman	Tatık

2.2. Araştırma Yerinin İklim Özellikleri

Sivas ilinin mercimek yetiştirme dönemine ait uzun yıllar ortalaması (1980-2023) ile araştırmanın yürütüldüğü 2024 yılının meteorolojik değerleri incelendiğinde uzun yıllar ortalaması ile 2024 yılına ait aylık sıcaklık ortalamaları ve aylık toplam yağış değerleri arasında Nisan ayı hariç büyük bir farkın olmadığı belirlenmiştir. Bununla birlikte 2024 yılı aylık ortalama nisbi nem değerlerinin de uzun yıllar ortalamasıyla paralellik gösterdiği Tablo 2'de ortaya konulmuştur.

Tablo 3 Sivas ilinin 2024 yılı ile uzun yıllara ait iklim verileri

Aylar	Ortalama Sıcaklık (^{0}C)		Toplam Yağış (mm)		Ortalama Nisbi Nem (%)	
	2024	Uzun Yıllar	2024	Uzun Yıllar	2024	Uzun Yıllar
Nisan	13.9	8.9	11.2	56.9	52.85	44.8
Mayıs	13.1	13.5	60.0	60.9	63.71	61.5
Haziran	20.9	17.0	11.6	34.5	59.45	58.0
Temmuz	22.0	20.0	37.0	9.2	53.25	49.1
Ağustos	22.0	20.2	10.2	6.8	47.43	45.9
Toplam	-	-	130.0	168.3	-	-

2.3. Toprak Özellikleri

Çalışmanın yürütüldüğü deneme arazisinin toprak öğeleri incelendiğinde deneme parselinin toprağının alkali seviyesinin hafif (7.28), organik madde içeriğinin orta (%1.7), alınabilir fosfor

(3.40) ve potasyum düzeyleri (93.59) bakımından orta, tuz seviyesinin tuzlu (%0.33) ve kireç içeriğinin ise kireçli (19.6) olduğu ortaya konulmuştur (Tablo 3).

Tablo 4. Deneme yeri toprağının fiziksel ve kimyasal özellikleri

Derinlik	**0-30 cm**
pH	7.28
Toplam Tuz (%)	0.33
Kireç (% CaCO3)	19.6
Organik Madde (%)	1.7
Fosfor (P2O5 kg/da)	3.40
Potasyum (K2O)	93.59

2.4. Yöntem

Yürütülen çalışma, Tesadüf Blokları Deneme Deseninde 4 tekerrürlü olacak şekilde kurulmuş olup parseller 5.0 m x 1.2 m= 6 m^2 olacak şekilde ayarlanmıştır. Mercimek genotiplerinin parsellere dağılımı tesadüfî olarak gerçekleştirilmiştir. Denemenin ekimleri 25 Nisan 2024 tarihinde tavlı toprağa gerçekleştirilmiştir. Ekimler 30 cm sıra aralığında 2-3 cm sıra üzerinde, her bir sıraya 150-200 adet tohum düşecek şekilde markörle açılan sıralara 3 cm derinliğe elle yapılmıştır. Her parsel 4 sıradan oluşmuştur. Yabancı otlarla mücadele etmek üzere ekimlerle beraber ekim sonrası ve çıkış öncesi yabancı ot ilacı uygulanmış ve tüm vejetasyon süresince 2 sefer çapa yapılmıştır. Her parsele eşit olarak dekara 15 kg DAP (2,7 kg N/da ve 6,9 kg P2O5/da) gübresi ekimle birlikte toprağa verilmiştir. Araştırmanın yürütüldüğü deneme alanındaki çeşitlerin hasadı, hasat olgunluğuna ulaştıkları dönem aralığı olan 25 Temmuz-10 Ağustos 2024 tarihleri arasında el ile yapılmıştır. Parseli oluşturan 4 sıradan her iki yandaki birer sıra ve sıra başlarından 50 cm'nin içerisinde bulunan bitkiler kenar tesiri olarak gözlem dışı bırakılarak bütün işlemler 4 m x 0.6 m = 2.4 m^2'lik alanlar üzerinden yapılmıştır. Her bir parselden hasat edilen bitkiler ayrı ayrı çuvallara konulup etiketlenerek hasat-harman sonrası gerekli ölçümler ve analizler yapılmak üzere Sivas Bilim ve Teknoloji Üniversitesi Tarım Bilimleri ve Teknoloji Fakültesi Tarla Bitkileri Bölümü'nün harman laboratuvarına getirilmiştir. Her parselden rastgele seçilen 10'ar bitkide bitki boyu, ilk bakla yüksekliği, biyolojik verim, bitkide bakla sayısı, bitkide tane sayısı, bin tane ağırlığı, bitkide tane verimi ve hasat indeksi değerleri saptanmış ve bunların ortalamaları alınarak bitki başına ortalama değerler hesaplanmıştır.

2.5. Verilerin Değerlendirilmesi

Çalışmadan elde edilen veriler varyans analizine tabi tutulmuş olup özelliklere ait eldeki veriler arasındaki farklılığın istatistiksel kontrolünde JUMP.13 istatistiki paket programı uygulanmıştır. Önemli çıkanlar arasındaki farklılığın hangi ya da hangilerinden kaynaklandığını belirlemek için ise LSD testi ($P>0.05$) uygulanmıştır.

3. ELDE EDİLEN BULGULAR ve TARTIŞMA

3.1. Bitki Boyu

Yürütülen çalışmada yeşil mercimek genotiplerinde tespit edilen bitki boyuna ilişkin değerler Tablo 4'de verilmiştir. Bitki boyu bakımından elde edilen veriler incelendiğinde yeşil mercimek genotipleri arasında önemli derecede ($p<0.05$) istatistiki farklılığın olduğu görülmüş

olup genotiplerin bitki boyu değerlerinin 17.00-30.00 cm arasında değişim gösterdiği belirlenmiştir. Çalışmada en yüksek bitki boyu 30.00 cm ile M-07 nolu genotipte ortaya konulurken en düşük bitki boyu değeri ise 17.00 cm değeri ile M-10 nolu genotipte saptanmış olup yeşil mercimek genotiplerinin ortalama bitki boyu değerinin ise 22.18 cm olarak ölçüldüğü tespit edilmiştir.

Tablo 5. Denemede yer alan mercimek genotiplerine ait bitki boyu (cm) değerleri ve istatistiki gruplandırmaları

Güneydoğu Anadolu Bölgesi'nde verim potansiyeli yüksek çeşitlerin belirlenebilmesi için 1995-1997 yılları arasında 2 yıl süreyle 25 kırmızı mercimek çeşidinin materyal olarak kullanıldığı çalışmanın iki yıllık sonuçlarına göre bitki boyunun 30.00-38.70 cm arasında değişim gösterdiği Türk ve ark. (1999) tarafından rapor edilmiş olup bu agronomik özellik üzerine yürütülen diğer çalışmalarda Gupta ve ark. (1996) Hindistan ekolojik koşullarında 6.20-24.20 cm, Kaçar ve Azkan (1997) Bursa ekolojik koşullarında 19.90-27.90 cm, Türk ve Atikyılmaz (2000) Diyarbakır ekolojik koşullarında 34.80-58.80 cm, Bildirici ve Çiftçi (2001) Van ekolojik koşullarında 22.20-25.80 cm, Erman ve ark. (2005) Siirt ekolojik koşullarında 31.80-48.50 cm, Demirhan (2006) Siirt ekolojik koşullarında 31.80-48.50 cm, Bozdemir (2007) Ankara ekolojik koşullarında 28.90-38.00 cm, Bozdemir ve Önder (2009) Ankara ekolojik koşullarında 28.90-38.00 cm, Ölmez (2011) Adıyaman ekolojik koşullarında 41.00-48.70 cm, Canbolat (2014) Kahramanmaraş ekolojik koşullarında 44.48-45.55 cm, Öktem (2016) Şanlıurfa ekolojik koşullarında 37.30-45.10 cm, Alabay (2019) Konya ekolojik koşullarında 25.03-29.83 cm ve Küçükay ve ark. (2019) Isparta ekolojik koşullarında 27.50-32.80 cm değerlerini elde etmişlerdir.

3.2. İlk Bakla Yüksekliği

Yürütülen çalışmada yeşil mercimek genotiplerinde tespit edilen ilk bakla yüksekliğine ilişkin değerler Tablo 5'de verilmiştir. İlk bakla yüksekliği bakımından elde edilen veriler

incelendiğinde yeşil mercimek genotipleri arasında önemli derecede ($p<0.05$) istatistiki farklılığın olduğu görülmüş olup yeşil mercimek genotiplerinin bitki boyu değerlerinin 9.50-22.00 cm arasında değişim gösterdiği belirlenmiştir. Tablo, ilk bakla yüksekliği değerleri bakımından değerlendirildiğinde en yüksek ilk bakla yüksekliği 22.00 cm değeri ile Sultan çeşidinde tespit edilirken en düşük ilk bakla yüksekliği ise 9.50 cm değeri ile M-16 nolu genotipinde belirlenmiş olup tüm yeşil mercimek genotiplerinin ise ortalama ilk bakla yüksekliği değerinin 14.26 cm olarak ölçüldüğü ortaya konulmuştur.

Tablo 6. Denemede yer alan mercimek genotiplerine ait ilk bakla yüksekliği (cm) değerleri ve istatistiki gruplandırmaları

Kuru tarımın yoğun bir şekilde yapıldığı Ankara ekolojik koşullarında 2001-2003 yılları arasında 2 yıl süreyle farklı toprak işleme ve yabancı ot kontrolü yöntemlerinin mercimekte verim ve yabancı ot yoğunluğunun belirlenmesi için yürütülen çalışmada ilk bakla yükseklik değerinin 15.00-22.00 cm arasında değişim gösterdiği Kayan ve Adak (2006) tarafından rapor edilmiş olup bu agronomik özellik üzerine yürütülen diğer çalışmalarda Stoilova ve Pereira (1998) Bulgaristan ekolojik koşullarında 7.00-25.80 cm, Türk ve Atikyılmaz (2000) Diyarbakır ekolojik koşullarında 14.00-30.00 cm, Toğay (2002) Van ekolojik koşullarında 12.18-14.76 cm, Erman ve ark. (2005) Siirt ekolojik koşullarında 10.00-16.00 cm, Demirhan (2006) Siirt ekolojik koşullarında 10.00-16.00 cm, Bozdemir (2007) Ankara ekolojik koşullarında 14.40-20.10 cm, Biçer ve Şakar (2008a) Diyarbakır ekolojik koşullarında 13.50 cm, Ölmez (2011) Adıyaman ekolojik koşullarında 3.65-5.42 cm, Kayan ve Olgun (2012) Eskişehir ekolojik koşullarında 18.07 cm, Canbolat (2014) Kahramanmaraş ekolojik koşullarında 25.31-25.84 cm, Güneş (2016) Kahramanmaraş ekolojik koşullarında 19.40-19.50 cm, Alabay (2019) Konya ekolojik koşullarında 11.33-12.16 cm, Küçükay ve ark. (2019) Isparta ekolojik koşullarında 9.23-20.20 cm ve Tekin (2019) Batman ekolojik koşullarında 12.27-18.90 cm değerlerini sağlamışlardır.

3.3. Biyolojik Verim

Yürütülen çalışmada biyolojik verim bakımından yeşil mercimek genotipleri arasındaki farklılık istatistiki yönden çok önemli ($p<0.01$) bulunmuştur. Yeşil mercimek genotiplerinde biyolojik verime ilişkin ortalama değerler Tablo 6'da verilmiştir. Biyolojik verim değerleri bakımından tablo incelendiğinde en yüksek biyolojik verim, 11.10 g değeri ile M-15 nolu genotipinde tespit edilirken en düşük biyolojik verim değeri ise 3.28 g değeri ile Meyveci 2001

çeşidinde saptanmış olup tüm yeşil mercimek genotiplerinin ise ortalama biyolojik verim değerinin 5.98 g olarak tespit edildiği ortaya konulmuştur.

Tablo 7. Denemede yer alan mercimek genotiplerine ait biyolojik verim (g) değerleri ve istatistiki gruplandırmaları

Her parselden rastgele seçilen 10'ar adet bitkinin 0.01 g duyarlı terazide ayrı ayrı tartılması ve ortalamasının alınmasıyla hesaplanan bitki başına biyolojik verim değeri, verim unsurları içinde önemli agronomik özelliklerden bir tanesidir. Gerek bitki başına tane verimini gerekse dekara tane verimini arttırmada en önemli üç verim unsurunun biyolojik verim, hasat indeksi ve vejetasyon süresi olduğu Wallace ve ark. (1993) tarafından ifade edilmekle birlikte aynı zamanda tarla bitkisi türlerinde dekara tane verim ile bitkide tane verim üzerine yapılacak seleksiyonlarda bu üç özellik arasındaki ilişkiyi çok iyi bilmek gerektiği belirtilmekte olup bu agronomik özellik üzerine yürütülen diğer araştırmalarda Şakar ve ark. (1997) Diyarbakır ekolojik koşullarında 3.00-9.40 g, Karadavut ve ark. (1999) Amik Ovası ekolojik koşullarında 2.69-4.33 g, Biçer ve ark. (2001) Diyarbakır ekolojik koşullarında 1.525-4.932 g, Bucak ve ark. (2003) Harran Ovası ekolojik koşullarında 3.36-4.64 g, Erman ve ark. (2005) Siirt ekolojik koşullarında 5.93-7.68 g, Kayan ve Adak (2006) Ankara ekolojik koşullarında 3.14-5.50 g, Biçer ve Şakar (2008a) Diyarbakır ekolojik koşullarında 2.93 g, Tyagi ve Khan (2011) Hindistan ekolojik koşullarında 6.40-6.50 g, Kayan ve Olgun (2012) Eskişehir ekolojik koşullarında 4.48 g, Canbolat (2014) Kahramanmaraş ekolojik koşullarında 3.41-3.82 g ve Alabay (2019) Konya ekolojik koşullarında 3.56 g arasında değerleri elde etmişlerdir.

3.4. Bitkide Bakla Sayısı

Çalışmada yer alan yeşil mercimek genotiplerinin bitkide bakla sayısı üzerine etkisinin çok önemli ($p<0.01$) olduğu araştırmada en yüksek bitkide bakla sayısı 51.00 adet ile M-22 nolu genotipten elde edilirken M-08 nolu genotipi ise yeşil mercimek genotipleri içinde 19.00 adet bitkide bakla sayısı değeri ile son sırada yer almış olup yeşil mercimek genotiplerinin ortalama bitkide bakla sayısı değerinin ise 31.73 adet olarak elde edildiği görülmüştür.

Tablo 8. Denemede yer alan mercimek genotiplerine ait bitkide bakla sayısı (adet) değerleri ve istatistiki gruplandırmaları

Tıpkı bitkide bakla sayısı özelliğinde olduğu gibi bitkide tane sayısı da gerek bitkide tane verimi gerekse dekara tane verimi ile önemli/çok önemli ve pozitif/olumlu ilişkiler göstermekle birlikte ıslah çalışmalarında genotip ve çeşitlerin bir üst generasyona aktarılmasında dikkate alınması gereken önemli bir agronomik özelliktir. Nitekim mercimek bitkisinde bitkide bakla sayısı ile tane sayısının genetik yapıdan, ekim sıklığından ve yetiştirme tekniğinden uygulanan işlemlere göre değişim gösterebildiği bitkide tane sayısının dekara tane verimini belirleyen en önemli verim öğeleri arasında olabileceği Adak (2021) tarafından rapor edilmiş olup bu agronomik özellik üzerine yürütülen diğer çalışmalarda Kaçar ve Azkan (1997) Bursa ekolojik koşullarında 10.4-16.5 adet, Stoilova ve Pereira (1998) Bulgaristan ekolojik koşullarında 9.7-75.5 adet, Şakar ve Biçer (2001) Diyarbakır ekolojik koşullarında 115.4-118.6 adet, Koç (2004) Diyarbakır ekolojik koşullarında 23.9-57.4 adet, Erman ve ark. (2005) Siirt ekolojik koşullarında 12.8-54.3 adet, Demirhan (2006) Siirt ekolojik koşullarında 12.8-54.3 adet, Kayan ve Adak (2006) Ankara ekolojik koşullarında 23-38 adet, Biçer ve Şakar (2007) Diyarbakır ekolojik koşullarında 33.1-57.9, Çokkızgın (2007) Kahramanmaraş ekolojik koşullarında 26.8-50.6 adet, Sözen ve Karadavut (2017) Kırşehir ekolojik koşullarında 10.7-18.5 adet, Alabay (2019) Konya ekolojik koşullarında 20.4-24.13 adet, Küçükay ve ark. (2019) Isparta ekolojik koşullarında 40.96-64.7 adet ve Tekin (2019) Batman ekolojik koşullarında 20.12-47.28 adet arasında kalan değerler elde etmişlerdir.

3.6. 1000 Tane Ağırlığı

Yeşil mercimek genotiplerinin bin tane ağırlık üzerine etkisinin çok önemli ($p<0.01$) bulunduğu çalışmada değişim aralığının 33.47-49.75 g olarak oluştuğu görülmüş olup en yüksek bin tane ağırlığı 49.75 g ile M-04 nolu genotipinden, en düşük bin tane ağırlığı ise 33.47 g ile M-11 nolu genotipte ortaya konulurken tüm yeşil mercimek genotiplerinin ortalama bin tane ağırlığı değerinin 42.71 g olarak belirlendiği görülmüştür. İran'da 16 mercimek çeşidinin 2008-2010 yılları arasında 2 yıl süre ile verim ve verim öğelerinin belirlenmesi üzerine yürütülen çalışmada ortalama bin tane ağırlığının 42.91 g olarak değer aldığı Abdipur ve ark. (2011) tarafından ifade edilmiş olup bu özellik üzerine yürütülen diğer çalışmalarda Kaçar ve Azkan (1997) Bursa ekolojik koşullarında 38.1-72.4 g, Stoilova ve Pereira (1998) Bulgaristan ekolojik koşullarında 18-68 g, Toğay (2002) Van ekolojik koşullarında 37.06-59.14 g, Bucak ve ark. (2003) Harran

ekolojik koşullarında 33.06-40.64 g, Koç (2004) Diyarbakır ekolojik koşullarında 25.25-50.50 g, Erman ve ark. 3.7. Bitkide Tane Verimi

Yürütülen çalışma sonucunda yeşil mercimek genotiplerinden elde edilen bitkide tane verimine ait değerlerin 1.84-3.51 g arasında değişim gösterdiği belirlenmiş olup yeşil mercimek genotiplerinin bitkide tane verim değerleri arasındaki farklılığın istatistiksel olarak önemli ($p<0.05$) olduğu görülmüştür. M-14 nolu genotip, bitkide tane verimi bakımından en yüksek değere (3.51 g) sahip olurken en düşük bitkide tane verim değeri ise 1.84 g ile M-11 nolu genotipte belirlenmiş olup tüm yeşil mercimek genotiplerinin ortalama bitki başına tane verim değerinin ise 2.34 g olduğu ortaya konulmuştur. Diyarbakır ilinde mercimek genotiplerinin verim ve verim öğelerinin belirlenmesi üzerine 1996 yılında yürütülen araştırmada genotiplerin bitkide tane verimi değerlerinin 0.512-2.070 g arasında değişim gösterdiği Biçer ve ark. (2001) tarafından rapor edilmiş olup bu parametre üzerine yürütülen diğer çalışmalarda ise Stoilova ve Pereira (1998) Bulgaristan ekolojik koşullarında 1.1-9.5 g, Türk ve Atikyılmaz (2000) Diyarbakır ekolojik koşullarında 22.8-46.3 g, Şakar ve Biçer (2001) Diyarbakır ekolojik koşullarında 2.32-24.88 g, Demirhan (2006) Siirt ekolojik koşullarında 0.83-1.56 g, Biçer ve Şakar (2007) Diyarbakır ekolojik koşullarında 0.7-1.8 g, Çokkızgın (2007) Kahramanmaraş ekolojik koşullarında 0.682-1.645 g, Roy ve ark. (2013) Bangladeş ekolojik koşullarında 2.13 g, Hussain ve ark. (2014) Pakistan ekolojik koşullarında 13.8-27.9 g ve Küçükay ve ark. (2019) Isparta ekolojik koşullarında 0.49-2.07 g aralığında yer alan değerleri elde etmişlerdir.

3.8. Hasat İndeksi

Yürütülen çalışmada hasat indeksi bakımından yeşil mercimek genotipleri arasındaki farklılık istatistiki yönden çok önemli ($p<0.01$) olup yeşil mercimek genotiplerinde hasat indeksine ilişkin ortalama değerler Tablo 11'de verilmiştir. Hasat indeksi değerleri bakımından Tablo incelendiğinde en yüksek hasat indeksi %53.85 değeri ile M-01 nolu genotipinde tespit edilirken en düşük hasat indeksi değeri ise %23.46 değeri ile M-19 nolu genotipinde belirlenmiş olup tüm yeşil mercimek genotiplerinin ise ortalama hasat indeksi değerinin %40.20 olarak ölçüldüğü ortaya konulmuştur.

4. SONUÇ

Bazı yeşil mercimek genotiplerinin 2024 yılında Sivas ekolojik koşullarında tarımsal özelliklerinin ortaya konulabilmesi amacıyla yürütülen araştırma sonuçlarına göre M-5, M-14, M-15 ve M-31 nolu genotiplerinin Sivas ekolojik koşulları için uygun yeşil mercimek genotip adayları oldukları ancak bu tür yürütülecek adaptasyon çalışmalarında elde edilecek verilerden daha sağlam tavsiyelerde bulunulabilmesi için ortaya konulacak çalışmaların en az 2-3 yıl daha tekrarlanmasının gerekliliği sonucuna ulaşılmıştır.

ÖZET

Bazı mercimek çeşitlerine ait kalite özelliklerinin Sivas ekolojisinde belirlenmesi amacıyla 2024 yılında yürütülen çalışma, Sivas Bilim ve Teknoloji Üniversitesine ait AR-GE Tarımsal Araştırma Merkezinde yer alan deneme parsellerinde yürütülmüştür. Çalışmada 10 adet yeşil mercimek çeşidi kullanılmıştır. Bir yıl süresince yürütülen çalışma, tesadüf blokları deneme deseninde 3 tekerrürlü olarak kurulmuştur. Çalışma süresince mercimek çeşitlerine ait kalite özelliklerinin (su alma kapasitesi (g/tane), su alma indeksi (%), şişme kapasitesi (ml/tane), şişme indeksi (%), kabuk oranı (%) ve protein oranı (%)) değerleri ortaya konulmaya çalışılmıştır. Yapılan varyans analiz sonuçlarına göre ele alınan kalite özellikleri içinde tüm özellikler bakımından yeşil mercimek çeşitleri arasında istatistiksel anlamda önemli/çok önemli farklılıklar belirlenmiş olup yürütülen çalışmada en yüksek protein oranı %29.64 ile Gümrah mercimek çeşidinde görülürken en düşük protein oranı ise %23.05 ile Çiftçi mercimek çeşidinde saptanmıştır.

Anahtar Kelimeler: Sivas, Mercimek, Çeşit, Kalite, Protein

1. GİRİŞ

Mercimek, bir yemeklik tane baklagil türü olup gerek dünya gerekse ülkemizde yaşamını sürdüren insanların beslenme sürecinde önemli bir yer tutmakla birlikte bu önemi yüksek içerikli protein ve karbonhidrattan kaynaklanmaktadır. Kuru tanelerinde bulunan %18-31 oranındaki protein ile %55-70 oranındaki karbonhidrat içerikleri nedeniyle özellikle tercih edilmekte olup bunların yanında fosfor, kalsiyum ve demir gibi mineraller ile A, B1, B2 ve D vitaminlerce zenginliği insanların beslenmesine önemli katkıda bulunmaktadır (Smithson ve ark., 1985).

Mercimek, kuru tarım alanlarında bir tahıl bitkisi olan buğday veya arpa ile ekim nöbetine girebilmekle birlikte toprak verimliliğine olumlu katkısı ile yüksek gelir kazancıyla tarımsal bakımdan çok önemli bir yerde bulunmaktadır. Gerçekleştirilen hasat ile harman sonrasında tanesinden arda kalan sap/samanda çok az miktarda selüloz bulunduğu için hayvan beslenmesinde önemli bir yem kaynağı olabilmektedir. Bunun yanında köklerinde bulunan nodüllerle ortak yaşam sürdüren "*Rhizobium leguminosarum*" isimli bakteri türü ile beraber havanın serbest azotunu toprağa kazandıran ve yetiştirildiği arazinin toprağın azot miktarını artırabilen bir özelliği de bulunmaktadır (Aydoğan ve ark., 2008).

Hayvansal protein kaynakları insan beslenmesinde önem arz etmesine rağmen bu kaynakların yeterince tedarik edilemediği yerlerde bu açığı giderecek bitkisel kaynaklı proteinlere ihtiyaç duyulmaktadır. Bunun yanında hayvansal kaynaklı proteinler, protein kaynakları bakımından önem arz etmesine rağmen gerek maliyetlerinin yüksek olmaları gerek saklanmalarındaki zorluklar gerekse çabuk bozulmalarındaki riskler ile dini inanışlar gibi bazı nedenlerden ötürü kolay bir şekilde üretilip saklanabilen ve ucuza mal edilebilen bitkisel kaynaklı proteinlerin önemini bir kez daha ortaya koymaktadır.

Baklagiller (*Leguminosae*) takımının kelebek çiçekliler (*Papilionatae*) familyasına bağlı Vicieae oymağına mensup beş önemli cinsinden (*Vicia* L., *Lathyrus* L., *Pisum* L., *Cicer* L. ve *Lens* Miller) birisi olan Mercimek (Şehirali, 1988) tarımının Dünya üzerinde ılıman ve subtropik iklim bölgelerinde yapıldığı görülmekle (Lazaro ve ark., 2001) birlikte ülkemizde ise Doğu Karadeniz Bölgesi dışında kalan tüm coğrafi bölgelerde başarılı bir şekilde yetiştirilebilmektedirler.

Mercimeğin ilk kültüre alındığı yerin verimli yarım ay dediğimiz Mezopotamya ile ülkemizin Güneydoğu Anadolu Bölgesi olduğu tahmin edilmekle beraber (Özdemir, 2002) tarımının yaklaşık olarak günümüzden 8.000 yıl öncesine kadar dayandığı bilinmektedir (Pellet, 1988). Yapılan arkeolojik kazılarda Türkiye'de Hacılar, Çayönü ve Çan Hasanda M.Ö. 7000-6500, Yunanistan'da M.Ö. 6500-6000, Irak, İran ve Ürdün'de M.Ö. 7000-6500 ve Suriye'de ise M.Ö. 8500-7500 yıllarına ait mercimek fosillerinin kalıntılarına saptanmıştır (Sepetoğlu, 2002).

Dünyada yemeklik tane baklagiller içinde 2023 yılı itibariyle ekim alanı bakımından %7.5, üretim bakımından ise %7.95 oranı ile kuru fasulye, nohut, börülce ve bezelyeden sonra beşinci sırada yer alan mercimeğin verim değerleri bakımından ise diğer yemeklik tane baklagillerle kıyaslandığında bakla ve bezelyeden sonra üçüncü sırada kendine yer bulmuştur (FAO, 2023). Mercimek dünya üzerinde ılıman veya yarı tropik bölgelere yayılmış kurağa dayanıklı bir yemeklik tane baklagil bitkisidir. Kuru tane olarak tüketilen mercimek, en çok Orta Doğu ülkeleri ile Batı-Orta-Güney Asya ülkelerinde üretilmektedir. FAO 2023 verilerine göre mercimeğin istatistik verileri incelendiğinde dünyada mercimek üreten kıtaların başında Asya (2.994.358 ton), ülkelerin başında ise Hindistan (1.620.000 ton) gelmektedir. Kıtalar arasında verim bakımından ilk sırayı Amerika Kıtası (1.375,2 kg/ha) almaktadır. FAO (2023) verilerine göre 50 ülkede mercimek yetiştiriciliği yapılmakta olup kıtalar bazında değerlendirildiğinde

Avrupa ve Asya kıtalarında 16 ülkede, Afrika kıtasında 10 ve Amerika kıtasında 8 ülkede mercimek yetiştiriciliği uzun yıllardır gerçekleştirilmektedir. Kıtalar bazında mercimek ekim alanları değerlendirildiğinde Asya kıtası 3.476.081 ha ile ilk sırada gelirken Asya kıtasının ilk sırada bulunmasında yine bir Asya ülkesi olan Hindistan büyük önem taşımaktadır ki Hindistan dünya mercimek ekim alanı bakımından ilk sırada gelmektedir.

Ülkemizde yetiştiriciliği yapılan yemeklik tane baklagillerde gerek ekim alanı gerekse üretim miktarında önemli düşüşler görülmekle birlikte 1989 yılında yemeklik tane baklagil ekim alanları toplamı 2 milyon hektarın üstündeyken 30 yıl içinde yaklaşık 883.482 hektara kadar azalma göstermiştir. Aynı şekilde 2.115.000 ton olan üretim miktarı da 1.220.244 ton seviyelerine kadar gerilemiştir. Bu durum mercimek ekiliş ve üretimine de yansımış olup 997.000 ha olan mercimek ekim alanı çok ciddi bir şekilde azalma eğimiyle 277.228 hektara, 1.040.000 ton üretim miktarı ise 353.000 ton seviyelerine kadar düşme eğilimi göstermiştir. Bun karşın yeşil mercimek ekim alanımız ise yaklaşık 39.000 ha, üretimimiz ise 43.000 ton seviyelerindedir. Yeşil mercimek ekim alanları ülkemizde Yozgat, Çorum, Kırşehir, Ankara ve Konya illerini kapsayan İç Anadolu Bölgesinde daha çok görülmektedir. Yeşil mercimeğin toplam mercimek üretim miktarı içerisinde aldığı pay yüzdesi yaklaşık olarak %7-8 arasında değişmektedir (TUİK, 2023).

Tüketimdeki değişmelere bağlı olarak son yıllarda mercimek için de değişimler olabilmektedir. Islah çalışmaları kapsamında yüksek mercimek çeşitleri geliştirmekle beraber son yıllarda geliştirilecek çeşit aday/adaylarında kalite içeriklerini de artırmak amacı ön plana çıkmıştır. Yetiştiriciliğinin yapıldığı üretim sahalarında iklim ve toprak içeriklerine adapte olabilecek verimli ve kalite özellikleri amacıyla daha yüksek performans gösterebilen mercimek genotiplerinin beslenme içerikleri bakımından taşıdığı önem nedeniyle geliştirilip üretim sahalarına kazandırılması ülkemizde yaşayan insanların beslenmesi kapsamında son derece önem taşıyabilmektedir.

Yürütülen bu çalışma ile Tarımsal Araştırma Enstitüleri tarafından tescil ettirilmiş olan yeşil mercimek çeşitlerinin kalite özelliklerinin belirlenmesi amaçlanmıştır.

2. MATERYAL ve METOT

2.1. Materyal

Bu araştırmanın tarla çalışmaları Sivas Bilim ve Teknoloji Üniversitesi'nin Tarımsal AR-GE Merkezinde yer alan deneme arazisinde 2024 yılı mercimek vejetasyon döneminde yürütülmüştür. Araştırmanın yürütüldüğü lokasyon deniz seviyesinden yaklaşık 1285 m yükseklikte, N39,720656 - E36,917248 konumunda bulunmaktadır (Şekil 1).

Şekil 1. Araştırmanın yürütüldüğü deneme arazisi

Araştırmada, ülkemizde Tarımsal Araştırmalar ve Politikalar Genel Müdürlüğüne bağlı Tarımsal Araştırma Enstitüleri tarafından tescil ettirilmiş olan 10 adet yeşil mercimek çeşidi kullanılmıştır (Tablo 1).

Tablo 1. Çalışmada kullanılan çeşitler ile tescil ettiren kuruluşlar

Mercimek Çeşitleri	Tescil Ettiren Kuruluş
Sultan	Geçit Kuşağı Tarımsal Araştırma Enstitüsü Müdürlüğü / Eskişehir
Ankara Yeşili	Tarla Bitkileri Merkez Araştırma Enstitüsü Müdürlüğü / Ankara
Kafkas	
Gümrah	
Karagül	
Meyveci 2001	
Bozok	
Çiftçi	
Ceren	
Pul 11	

2.2. Araştırma Yerinin İklim Özellikleri

Sivas ilinin mercimek yetiştirme dönemine ait uzun yıllar ortalaması (1980-2023) ile araştırmanın yürütüldüğü 2024 yılının meteorolojik değerleri incelendiğinde uzun yıllar ortalaması ile 2024 yılına ait aylık sıcaklık ortalamaları ve aylık toplam yağış değerleri arasında Nisan ayı hariç büyük bir farkın olmadığı belirlenmiştir. Bununla birlikte 2024 yılı aylık ortalama nisbi nem değerlerinin de uzun yıllar ortalamasıyla paralellik gösterdiği Tablo 2'de ortaya konulmuştur.

Tablo 2. Sivas ilinin 2024 yılı ile uzun yıllara ait iklim verileri

Aylar	Ortalama Sıcaklık (^{0}C)		Toplam Yağış (mm)		Ortalama Nisbi Nem (%)	
	2024	Uzun Yıllar	2024	Uzun Yıllar	2024	Uzun Yıllar
Nisan	13.9	8.9	11.2	56.9	52.85	44.8
Mayıs	13.1	13.5	60.0	60.9	63.71	61.5
Haziran	20.9	17.0	11.6	34.5	59.45	58.0
Temmuz	22.0	20.0	37.0	9.2	53.25	49.1
Ağustos	22.0	20.2	10.2	6.8	47.43	45.9
Toplam	-	-	130.0	168.3	-	-

2.3. Toprak Özellikleri

Çalışmanın yürütüldüğü deneme arazisinin toprak öğeleri incelendiğinde deneme parselinin toprağının alkali seviyesinin hafif (7.28), organik madde içeriğinin orta (%1.7), alınabilir fosfor (3.40) ve potasyum düzeyleri (93.59) bakımından orta, tuz seviyesinin tuzlu (%0.33) ve kireç içeriğinin ise kireçli (19.6) olduğu ortaya konulmuştur (Tablo 3).

Tablo 3. Deneme yeri toprağının fiziksel ve kimyasal özellikleri

Derinlik	0-30 cm
pH	7.28
Toplam Tuz (%)	0.33
Kireç (% CaCO3)	19.6
Organik Madde (%)	1.7
Fosfor (P2O5 kg/da)	3.40
Potasyum (K2O)	93.59

2.4. Yöntem

Yürütülen çalışma, Tesadüf Blokları Deneme Deseninde 4 tekerrürlü olacak şekilde kurulmuş olup parseller 5.0 m x 0.8 m= 4 m^2 olacak şekilde ayarlanmıştır. Mercimek çeşitlerin parsellere dağılımı tesadüfî olarak gerçekleştirilmiştir. Denemenin ekimleri 25 Nisan 2024 tarihinde tavlı toprağa gerçekleştirilmiştir. Ekimler 20 cm sıra aralığında 2-3 cm sıra üzerinde, her bir sıraya 150-200 adet tohum düşecek şekilde markörle açılan sıralara 3 cm derinliğe elle yapılmıştır. Her parsel 4 sıradan oluşmuştur. Yabancı otlarla mücadele etmek üzere ekimlerle beraber ekim sonrası ve çıkış öncesi yabancı ot ilacı uygulanmış ve tüm vejetasyon süresince 2 sefer çapa yapılmıştır. Her parsele eşit olarak dekara 15 kg DAP (2,7 kg N/da ve 6,9 kg P2O5/da) gübresi ekimle birlikte toprağa verilmiştir. Araştırmanın yürütüldüğü deneme alanındaki çeşitlerin hasadı, hasat olgunluğuna ulaştıkları dönem aralığı olan 25 Temmuz-10 Ağustos 2024 tarihleri arasında el ile yapılmıştır. Parseli oluşturan 4 sıradan her iki yandaki birer sıra ve sıra başlarından 50 cm'nin içerisinde bulunan bitkiler kenar tesiri olarak gözlem dışı bırakılarak bütün işlemler 4 m x 0.4 m = 1.6 m^2'lik alanlar üzerinden yapılmıştır. Her bir parselden hasat edilen bitkiler ayrı ayrı çuvallara konulup etiketlenerek hasat-harman sonrası gerekli ölçümler ve analizler yapılmak üzere Sivas Bilim ve Teknoloji Üniversitesi Tarım Bilimleri ve Teknoloji Fakültesi Tarla Bitkileri Bölümü'nün harman laboratuvarına getirilmiştir. Hasat ve harman işlemleri yapıldıktan sonra her bir yeşil mercimek çeşidine ait 100'er adet tohumda laboratuvar koşullarında su alma kapasitesi (g/tane), su alma indeksi (%), şişme kapasitesi (ml/tane), şişme indeksi (%), kabuk oranı (%) ve protein oranı (%) olmak üzere 6 adet kalite özelliği değerlendirilmiştir.

2.5. Verilerin Değerlendirilmesi

Çalışmadan elde edilen veriler varyans analizine tabi tutulmuş olup kalite özelliklerine ait eldeki veriler arasındaki farklılığın istatistiksel kontrolünde JUMP.13 istatistiki paket programı uygulanmıştır. Önemli çıkanlar arasındaki farklılığın hangi ya da hangilerinden kaynaklandığını belirlemek için ise LSD testi (P>0.05) uygulanmıştır.

3. ELDE EDİLEN BULGULAR ve TARTIŞMA

3.1. Su Alma Kapasitesi (g/tane)

Farklı yeşil mercimek çeşitlerine ait su alma kapasitesi ortalamaları ile istatistik gruplandırmalar Tablo 4'de verilmiş olup varyans analiz sonuçları değerlendirildiğinde yeşil

mercimek çeşitlerinin su alma kapasitesi arasında ki farklar istatistiksel olarak önemli ($p \leq 0.05$) bulunmuştur.

Tablo 4. Yeşil mercimek çeşitlerinde su alma kapasitesi değerlerine ilişkin ortalamalar (g/tane) ile oluşan istatistikî gruplar

Çeşitler	Su Alma Kapasitesi	Çeşitler	Su Alma Kapasitesi
Gümrah	0.059 d	Pul 11	0.071 a
Karagül	0.065 b	Bozok	0.069 a
Kafkas	0.065 b	Meyveci 2001	0.068 ab
Ankara Yeşili	0.055 e	Sultan	0.070 a
Ceren	0.062 c	Çiftçi	0.066 b
Ortalama	0.065		
Önemlilik	*		
CV	6.87		

Tablo 4 incelendiğinde yeşil mercimek çeşitlerine ait su alma kapasitesine ait değerlerin 0.055-0.071 g/tane arasında değişim gösterdiği görülmüş olup Pul 11 çeşidinden su alma kapasitesi bakımından en yüksek (0.071 g/tane) değer elde edilmiştir. Bu çeşitle beraber Sultan (0.070 g/tane) ve Bozok (0.069 g/tane) çeşitleri de aynı grupta (a) yer almıştır. Buna karşın Ankara Yeşili mercimek çeşidi ise 0.055 g/tane su alma kapasitesi değeri ile tüm çeşitler içinde en son sırada yer alırken tüm çeşitlerin su alma kapasite ortalamasının ise 0.065 g/tane olduğu belirlenmiştir. Mercimekte su alma kapasitesi üzerinde yürütülen çalışmada genotiplerin su alma kapasitesi değerlerinin 0,028-0,053 g/tane arasında değişim gösterdiği Özer ve Kaya (2010) tarafından belirlenmiş olup bunun yanında Yozgat'ta yürütülen çalışmada hem yazlık ekimlerde hem de kışlık ekimlerde su alma kapasitesinin yıllara ve çeşitlere göre değiştiği vurgulanmış olup Köse (2018) yılların birleştirilmiş analizlerinde çeşitlere göre su alma kapasitesini yazlık ekimlerde 0,059-0,069 g/tane; kışlık ekimlerde ise 0,031-0,060 g/tane arasında değişen değerler aldığını bildirmiştir.

3.2. Su Alma İndeksi (%)

Su alma kapasitesinin tek tane ağırlığına bölünmesi ile hesaplanan su alma indeksinde her bir genotip için hesaplanan su alma indeksi değeri bir tanenin orijinal ağırlığına göre kaç kat su aldığının göstergesi olarak tanımlanmaktadır (Şehirali ve Atlı, 1993). Yürütülen araştırmada farklı yeşil mercimek çeşitlerine ait su alma indeksi ortalamaları ile istatistik gruplandırmalar Tablo 5'de verilmiş olup su alma indeksi (%) değerlerine ilişkin varyans analiz sonuçları değerlendirildiğinde yeşil mercimek çeşitlerinin su alma indeksi arasında ki farklar istatistiksel olarak çok önemli ($p \leq 0.01$) bulunmuştur.

Tablo 5. Yeşil mercimek çeşitlerinde su alma indeksi değerlerine ilişkin ortalamalar (%) ile oluşan istatistikî gruplar

Çeşitler	Su Alma İndeksi	Çeşitler	Su Alma İndeksi
Gümrah	1.059 b	Pul 11	0.941 f
Karagül	1.045 bc	Bozok	0.918 g
Kafkas	1.033 c	Meyveci 2001	1.008 d
Ankara Yeşili	1.082 a	Sultan	0.931 fg
Ceren	1.024 cd	Çiftçi	0.968 e
Ortalama	1,009		
Önemlilik	**		
CV	7.29		

Yeşil mercimek çeşitlerine ait su alma indeksi değerlerinin %0.918-1.082 arasında değişim gösterdiği görülmüş olup ortalama su alma indeks değerinin ise %1.009 olduğu tespit edilmiştir. Ankara Yeşili mercimek çeşidi su alma indeks değeri bakımından ilk sırada yer alırken bu çeşidi Gümrah (%1.059) ve Kafkas (%1.033) mercimek çeşitleri izlemiş olup Bozok yeşil mercimek çeşidinin ise %0.918 su alma indeks değeri ile tüm çeşitler içinde son sırada yer aldığı ortaya konulmuştur. Kırşehir ekolojik koşullarında bazı yerel yeşil mercimek genotiplerinin kalite özelliklerinin belirlenmesi üzerine yürütülen araştırma sonucunda genotiplerin su alma indeks değerlerinin % 0.894-1.176 arasında değiştiği tespit edilmiş olup ortalama su alma indeks değeri ise %1.066 olarak belirlenmiştir. En yüksek su alma indeksi değeri M31 genotipinde gözlenirken, en düşük değerin ise M1 mercimek genotipinde ortaya konulduğu Sözen ve Karadavut (2019) tarafından saptanmıştır.

3.3. Şişme Kapasitesi (ml/tane)

Farklı yeşil mercimek çeşitlerine ait şişme kapasitesi ortalamaları ile istatistik gruplandırmalar Tablo 6'da verilmiştir. Tablo değerlendirildiğinde yeşil mercimek çeşitlerinin şişme kapasitesi arasında ki farklar istatistiksel olarak önemli bulunmuştur (P<0.05).

Tablo 6. Yeşil mercimek çeşitlerinde şişme kapasitesi değerlerine ilişkin ortalamalar (ml/tane) ile oluşan istatistikî gruplar

Çeşitler	Şişme Kapasitesi	Çeşitler	Şişme Kapasitesi
Gümrah	0.077 bc	Pul 11	0.083 a
Karagül	0.071 c	Bozok	0.079 b
Kafkas	0.083 a	Meyveci 2001	0.070 c
Ankara Yeşili	0.068 cd	Sultan	0.066 d
Ceren	0.059 ef	Çiftçi	0.061 e
Ortalama	0,072		
Önemlilik	*		
CV	6.29		

Çalışmada yer alan yeşil mercimek çeşitlerine ait şişme kapasite değerlerinin 0.059-0.083 ml/tane arasında değişim gösterdiği tespit edilmiştir. Pul 11 ve Kafkas yeşil mercimek çeşitleri şişme kapasitesi bakımından tüm çeşitler içinde ilk sırada yer alırken bu çeşitleri Bozok (0.079 ml/tane) ve Gümrah (0.077 ml/tane) çeşitleri izlemiştir. Çeren çeşidi ise şişme kapasitesi değeri olan 0.059 ml/tane ile son sırada kendine yer bulurken tüm çeşitlere ait şişme kapasite ortalamasının ise 0.072 ml/tane olduğu ortaya konulmuştur. Şişme kapasitesi tohumun suyu almasıyla tohumun bünyesinde bulunan enzimleri aktive ederek biyolojik faaliyetleri çalıştırması açısından önemlidir. Şişme kapasitesi tohumun ekileceği alana göre ayarlanmalıdır.

3.4. Şişme İndeksi (%)

Şişme indeksi, şişme kapasitesi ile önemli ve olumlu ilişki içinde olan bir kalite parametresidir. Şişme kapasitesinin yüksek olması aynı zamanda şişme indeksinin de miktarı hakkında bizlere değerli bilgiler verir. Yürütülen araştırmada farklı yeşil mercimek çeşitlerine ait şişme indeksi ortalamaları ile istatistik gruplandırmalar Tablo 7'de verilmiştir. Tablo değerlendirildiğinde yeşil mercimek çeşitlerinin şişme indeksi değerleri arasında ki farklar istatistiksel olarak çok önemli bulunmuştur (P<0.01).

Tablo 7. Yeşil mercimek çeşitlerinde şişme indeksi değerlerine ilişkin ortalamalar (%) ile oluşan istatistikî gruplar

Çeşitler	Şişme İndeksi	Çeşitler	Şişme İndeksi
Gümrah	2.107 c	Pul 11	1.987 ef
Karagül	2.255 a	Bozok	1.974 efg
Kafkas	2.182 b	Meyveci 2001	2.034 de
Ankara Yeşili	2.045 d	Sultan	1.996 e
Ceren	2.109 c	Çiftçi	1.968 f
Ortalama	2,066		
Önemlilik	**		
CV	6.14		

Çalışmada yer alan yeşil mercimek çeşitlerine ait şişme indeks değerlerinin %1.968-2.255 arasında değişim gösterdiği görülmüştür. Karagül yeşil mercimek çeşidi %2.255 şişme indeksi değeri ile ilk sırada yer alırken bu çeşidi %2.182 ile Kafkas ve %2.107 ile Gümrah çeşitleri izlemiş olup tüm çeşitlere ait şişme indeksi ortalamasının ise %2.066 olduğu tespit edilmiştir. Bunun yanında Çiftçi yeşil mercimek çeşidi ise almış olduğu %1.968 şişme indeksi değeri ile tüm çeşitler içinde son sırada yer almıştır.

3.5. Kabuk Oranı (%)

Farklı yeşil mercimek çeşitlerine ait kabuk oranı ortalamaları ile istatistik gruplandırmalar Tablo 8'de verilmiş olup Tablo değerlendirildiğinde yeşil mercimek çeşitlerinde kabuk oranı arasında ki farklar istatistiksel olarak çok önemli bulunmuştur ($P<0.01$).

Tablo 8. Yeşil mercimek çeşitlerinde kabuk oranı değerlerine ilişkin ortalamalar (%) ile oluşan istatistikî gruplar

Çeşitler	Kabuk Oranı	Çeşitler	Kabuk Oranı
Gümrah	8.87 d	Pul 11	7.48 h
Karagül	8.94 c	Bozok	9.68 a
Kafkas	7.82 g	Meyveci 2001	8.23 f
Ankara Yeşili	9.36 b	Sultan	8.59 ef
Ceren	7.29 hı	Çiftçi	8.63 e
Ortalama	8,49		
Önemlilik	**		
CV	4.92		

Yeşil mercimek çeşitlerinden elde edilen kabuk oranı değerleri %7.29-9.68 arasında değişim göstermiş olup en yüksek kabuk oranı değeri Bozok yeşil mercimek çeşidinden (%9.68) elde edilirken bu çeşidi sırayla Ankara yeşili (%9.36) ve Karagül (%8.94) çeşitleri izlemiş olup tüm yeşil mercimek çeşitlerine ait kabuk oranı ortalamasının ise %8.49 olduğu belirlenmiştir. Bunun yanında Ceren çeşidi ise almış olduğu %7.29 şişme indeksi değeri ile tüm çeşitler içinde son sırada yer almıştır. Kabuk oranı tohumun su ve hava almasında en önemli etkenlerin başında gelmektedir. Tohum kabuğunun kalın ya da ince olması aynı zamanda tohumun ortamdaki sudan faydalanma miktarını ve hızını etkileyecektir. Bunun için kabuk oranlarının bilinmesi özellikle çimlenmenin ve çıkışın güçlü olabilmesi için gereklidir. Kırşehir ekolojik koşullarında bazı yerel yeşil mercimek genotiplerinin kalite özelliklerinin belirlenmesi üzerine yürütülen

araştırma sonucunda genotiplerin kabuk oranı değerlerinin %7.00-10.23 arasında değiştiği Sözen ve Karadavut (2019) tarafından tespit edilmiş olup ortalama kabuk oranı değeri ise %8.59 olarak belirlenmiştir.

3.6. Protein Oranı (%)

Farklı yeşil mercimek çeşitlerine ait protein oranı ortalamaları ile istatistik gruplandırmaların verildiği Tablo 9 değerlendirildiğinde yeşil mercimek çeşitlerinin protein oranı arasında ki farklar istatistiksel olarak çok önemli bulunmuştur (P<0.01).

Tablo 9. Yeşil mercimek çeşitlerinde protein oranı değerlerine ilişkin ortalamalar (%) ile oluşan istatistikî gruplar

Çeşitler	Protein Oranı	Çeşitler	Protein Oranı
Gümrah	29.64 a	Pul 11	25.62 de
Karagül	28.49 b	Bozok	25.41 def
Kafkas	27.15 c	Meyveci 2001	24.27 e
Ankara Yeşili	26.88 cd	Sultan	23.77 ef
Ceren	26.09 d	Çiftçi	23.05 f
Ortalama	26.04		
Önemlilik	**		
CV	5.07		

Yürütülen araştırmada ele alınan yeşil mercimek çeşitlerine ait protein oranı değerlerinin %23.05-29.64 arasında değişim gösterdiği tespit edilmiştir. Protein oranı en yüksek Gümrah yeşil mercimek çeşidinden elde edilirken bu çeşidi Karagül (%28.49) ve Kafkas (%27.15) çeşitleri izlemiş olup tüm çeşitlere ait protein oranı ortalamasının ise %26.04 olduğu belirlenmiştir. Buna karşın Çiftçi yeşil mercimek çeşidinin ise %23.05 protein oranı değeri ile tüm yeşil mercimek çeşitleri içinde son sırada yer aldığı görülmüştür. Yeşil mercimek çeşitlerinin protein oranlarının çeşitli faktörlere bağlı olarak değiştiği ifade edilmekte olup bu faktörlerin başında iklim ve toprak faktörleri ile kültürel uygulamalar ve yetiştirme şartları gelmektedir. Aynı zamanda değişik şartlarda yetiştirilen yeşil mercimek çeşitlerinin protein oranlarının farklı olduğu belirtilmektedir (Önder, 1992). Yemeklik baklagil türleri arasında mercimeğin protein içeriği (%23-31) diğer türlere göre oldukça yüksek olup insan beslenmesi için önemi oldukça fazladır (Du ve ark., 2014; Zulkadir ve ark., 2015). Mercimekte protein oranının kalıtım derecesinin yüksek olmasının yanında protein oranı iklimsel faktörler ve yetiştirme tekniği paketi içinde yer alan uygulamalara göre önemli oranda değişiklik gösterebilmektedir (Çölkesen ve ark., 2005). Farklı mercimek genotipleri ile yürütülen çalışmalarda genotiplere göre protein oranının Arabistan yarımadasında ortalama %27,35 (Alghamdi ve ark., 2014); Pakistan'da ise %28,8-30,6 (Zia-Ul-Haq ve ark., 2011) arasında değişim gösterdiği saptanmıştır. Konya'da yürütülen çalışmada mercimekte en yüksek protein oranının Seyran-96 çeşidinde (%26,9) belirlendiği bunu Fırat-87, Çiftçi ve Özbek çeşitlerinin izlediği Hakkoymaz (2018) tarafından rapor edilmiştir. Yozgat koşullarında yürütülen bir başka çalışmada ise protein oranları bakımından mercimek çeşitlerinin protein oranın kışlık ekimlerde %27.7-30.4 arasında değişim gösterdiği Köse (2018) tarafından tespit edilmiştir.

4. SONUÇ

Farklı yeşil mercimek çeşitlerinin bazı teknolojik özelliklerinin ortaya konulması amacıyla Sivas ekolojik koşullarında yürütülen araştırma sonucunda su alma ve şişme kapasitesi özellikleri hariç bütün teknolojik özellikler bakımından yeşil mercimek çeşitlerinin arasında %1 düzeyinde önemli farklılıklar bulunmuştur. Araştırma içinde yer alan yeşil mercimek

çeşitlerinde ortaya konulan bu farklılıkların çeşitlerin genetik özelliklerinin yanında yetiştiriciliği yapılan bölgelerin iklimsel faktörlerinden de kaynaklanabileceği tahmin edilmektedir. Yürütülen araştırmada birçok kalite özelliklerinden dolayı Pul 11, Gümrah ve Ceren çeşitlerinin diğer yeşil mercimek çeşitlerine nazaran öne çıktıkları ortaya konulmuştur.

Özet

Mercimek (*Lens culinaris* Medik.), yüksek besin değeri ve sürdürülebilir tarıma katkısı nedeniyle dünya genelinde önemli bir baklagil türüdür. Ancak mercimek üretimi; kuraklık, sıcaklık, tuzluluk gibi abiyotik stresler ile fungal ve bakteriyel hastalıklar gibi biyotik etmenler nedeniyle ciddi verim kayıplarıyla karşı karşıyadır. Klasik ıslah yöntemleri, bu karmaşık stres koşullarına dayanıklılığın geliştirilmesinde sınırlı kalmakta; bu durum moleküler temelli yaklaşımların önemini artırmaktadır. Son yıllarda yeni nesil dizileme (NGS) teknolojilerindeki gelişmeler, mercimekte genomik ve transkriptomik analizlerin yaygın biçimde kullanılmasını sağlamıştır. RNA-Seq tabanlı transkriptomik çalışmalar, stres koşulları altında gen ifade profillerinin ortaya konmasına, fonksiyonel genlerin tanımlanmasına ve aday gen bölgelerinin belirlenmesine olanak tanımaktadır. Ayrıca genomik seleksiyon (GS) yaklaşımları, genom çapında belirteç verilerini kullanarak erken jenerasyonlarda üstün genotiplerin tahmin edilmesini mümkün kılmakta ve ıslah süresini önemli ölçüde kısaltmaktadır. Bu çalışmada, mercimek ıslahında genomik ve transkriptomik yaklaşımların mevcut durumu, RNA-Seq uygulamaları ve genomik seleksiyonun entegrasyonu ele alınmış; bu yaklaşımların stres toleransı yüksek, verimli ve iklim değişikliğine uyumlu çeşitlerin geliştirilmesindeki potansiyeli değerlendirilmiştir. Elde edilen bulgular, çoklu omik veri entegrasyonunun mercimek ıslahında geleceğe yönelik stratejik bir araç olduğunu göstermektedir.

Anahtar Kelimeler: Lens culinaris, RNA-Seq, transkriptomik analiz, genomik seleksiyon, stres toleransı

GENOMIC AND TRANSCRIPTOMIC APPROACHES FOR LENTIL BREEDING

Abstract

Lentil (*Lens culinaris* Medik.) is one of the most important grain legumes worldwide due to its high nutritional value and contribution to sustainable agricultural systems. However, lentil production is severely constrained by abiotic stresses such as drought, heat, and salinity, as well as biotic stresses including fungal and bacterial diseases. Conventional breeding approaches often remain insufficient to address these complex stress factors, highlighting the need for molecular-based strategies. Recent advances in next-generation sequencing (NGS) technologies have enabled extensive genomic and transcriptomic analyses in lentil. RNA-Seq–based transcriptomic studies provide comprehensive insights into gene expression dynamics under stress conditions, facilitating the identification of functional genes and candidate genomic regions associated with stress tolerance. In parallel, genomic selection (GS) approaches utilize genome-wide marker information to predict breeding values, allowing the identification of superior genotypes at early generations and significantly reducing breeding cycle duration. This study reviews the current status of genomic and transcriptomic applications in lentil breeding, with particular emphasis on RNA-Seq analyses and the integration of genomic selection. The findings highlight the potential of combining multi-omics data to accelerate the development of high-yielding, stress-tolerant, and climate-resilient lentil cultivars.

Keywords: *Lens culinaris*, RNA-Seq, transcriptomics, genomic selection, stress tolerance

1. Giriş

Mercimek (Lens culinaris Medik.), Fabaceae familyasının Fabeae ailesine ait, diploid (2n=2x=14) ve kendine döllenen bir bitkidir. Tarımsal üretim açısından dünyanın en eski kültür bitkilerinden biridir. Arkeobotanik veriler, mercimeğin kültüre alınışının yaklaşık 8.000-9.000 yıl önce Bereketli Hilal bölgesinde (Türkiye, Suriye ve Irak çevresi) başladığını göstermektedir. Günümüzde mercimek, Asya kıtasında Hindistan, Kanada, Türkiye ve Avustralya başta olmak üzere 70'ten fazla ülkede yetiştirilmekte olup dünya genelinde yıllık yaklaşık 7,6 milyon hektar ekim alanı ve 6,8 milyon ton üretim hacmine ulaşmaktadır. Mercimek, hem insan beslenmesi hem de sürdürülebilir tarımsal sistem açısından önemli bir baklagildir. Tohumlarının yüksek ham protein içeriği (%22-36), zengin lif içeriği (%8-10), karbonhidratlar ve fonksiyonel fitokimyasallar (fenolik bileşikler, flavonoidler, fitosteroller) bakımından zengin olması, onu gelişmekte olan ülkelerde bitkisel protein güvenliğinin temel kaynaklarından biri yapmaktadır. Aynı zamanda kök nodüllerinde yaşayan Rhizobium leguminosarum bakterileri aracılığıyla atmosferik azotu fikse etmesi, sürdürülebilir tarım sistemlerinde toprak verimliliğini artıran önemli bir unsurdur. Bununla birlikte mercimek üretimi, kuraklık, yüksek sıcaklık, tuzluluk ve düşük sıcaklık gibi abiyotik streslerle, antraknoz (Colletotrichum truncatum), Fusarium solgunluğu (F. oxysporum f.sp. lentis) ve kök çürüklüğü (Rhizoctonia bataticola) gibi biyotik etmenlerle sınırlanmaktadır. Bu stres faktörleri, özellikle Güney Asya ve Orta Doğu ekosistemlerinde %30-70 oranına kadar verim kayıplarına neden olabilmektedir. Klasik ıslah yöntemleri, son dönemlerde iklimsel değişikliklere bağlı olarak daha da şiddetini artıran abiyotik ve biyotik stres koşullarına dayanıklılık/toleranslılık gen kaynaklarının belirlenmesinde, yetersiz kalabilmektedir. Bu nedenle moleküler düzeyde yeni yaklaşımlar geliştirilmesi zorunlu hale gelmiştir (Singh ve ark., 2017; Kumar ve ark., 2021). Güncel genomik analizler ve dizileme teknolojilerindeki ilerlemeler, mercimek genomunun yapısal ve fonksiyonel özelliklerinin ayrıntılı biçimde ortaya konmasına olanak tanımıştır. Bu durum, mercimek ıslahında moleküler belirteç temelli seleksiyon ve genetik haritalama çalışmalarının önemini ve etkinliğini önemli ölçüde artırmıştır. Genomik veri setleri, ıslah programlarında moleküler markör geliştirme, QTL haritalama, genomik seleksiyon (GS) ve transkriptomik analiz uygulamalarına temel oluşturmuştur. Özellikle transkriptomik yaklaşımlar, çevresel stres koşullarına dayanıklılık/toleranslılık konusunda genlerin nasıl ifade edildiğini ortaya koymada yeni ufuklar açmıştır. RNA-seq tabanlı çalışmalarda, kuraklık, sıcaklık ve tuzluluk stresleri altında antioksidan savunma sistemleri (SOD, CAT, POD), ABA bağımlı sinyal mekanizması, ısı şok proteinleri (HSPs) ve LEA proteinleri gibi çok sayıda genin farklı düzeylerde ifade edildiği gösterilmiştir. Bu bulgular, abiyotik ve biyotik stres koşullarına tolerans mekanizmasının poligenik doğasını açıklığa kavuştururken, aynı zamanda fonksiyonel genlerin belirlenmesine ve ıslah hedeflerinin tanımlanmasına olanak tanımıştır. Bu bağlamda, mercimek ıslahında genomik ve transkriptomik verilerin birleştirilmesi, klasik yöntemlerin ötesine geçerek daha hızlı, hedefe yönelik ve çevreye duyarlı bir ıslah süreci sağlamaktadır. Yeni nesil dizileme (NGS), genotipleme teknikleri (GBS, DArTseq), yüksek yoğunluklu SNP panelleri, RNA-Seq ve çoklu omik veri entegrasyonu gibi modern teknolojiler sayesinde mercimek, artık yalnızca yüksek protein içeriğiyle değil, aynı zamanda iklim değişikliğine karşı dayanıklılığıyla da öne çıkan model bir baklagil türü olarak değerlendirilmektedir (Singh ve ark., 2019; Wang ve ark., 2020; Demir ve Bakır, 2022).

2. Mercimek Genomu Üzerine Güncel Gelişmeler

Mercimek (*Lens culinaris Medik.*), yaklaşık 4,0 Gbp büyüklüğünde bir genoma sahip olup, baklagiller arasında en geniş genom boyutlarından birine sahiptir. Genomun yaklaşık %70-75'i tekrarlayan DNA dizilerinden oluşmaktadır. Tekrarlayan dizilerin yüksek oranda bulunması,

özellikle transpozon elementlerinin fazlalığından kaynaklanmakta olup, bu durum dizilimde karmaşıklığı artırmaktadır. Fonksiyonel analizler, genlerin önemli bir bölümünün transkripsiyon faktörleri (bZIP, MYB, NAC, WRKY), stres tepkisiyle ilişkili genler (LEA, DREB, HSP) ve metabolik yol enzimleri (glikoliz, fenilpropanoid ve flavonoid biyosentezi) ile bağlantılı olduğunu ortaya koymuştur. Özellikle transkripsiyon faktörleri ile hastalık direnci genlerinin (NBS-LRR, TIR-NBS) yoğunlaştığı bölgelerin, kromozom 2, 4 ve 6 üzerinde kümelendiği belirlenmiştir. Referans genomun oluşturulması, mercimeğin genetik yapısı ve genom yapısına ilişkin önemli bilgiler sağlamış, QTL haritalama, SNP paneli geliştirme, genomik seleksiyon (GS) ve fonksiyonel gen belirleme çalışmalarına güçlü bir temel oluşturmuştur. Bu kapsamda, referans genom verisi gelecekte yürütülecek ıslah ve fonksiyonel genomik araştırmaları için kilit bir kaynak niteliği taşımakta ve türün genetik iyileştirme potansiyelini önemli ölçüde artırmaktadır (Ogutcen, 2018; Topu ve ark., 2023).

2.1. Mercimek Gen Havuzunun Genişletilmesinde Yabani Türlerin Önemi

Mercimeğin kültüre alınmış formu (*L. culinaris Medik.*), genetik olarak *L. culinaris subsp. orientalis* ile en yakın akrabadır ve bu alt tür, günümüzde genetik varyasyonun arttırılmasında önemli bir kaynak olarak değerlendirilmektedir. Ayrıca, *L. ervoides*, *L. nigricans* ve *L. lamottei* gibi yabani mercimek türleri, özellikle abiyotik ve biyotik stres koşullarına tolerans/dayanıklılık genlerinin belirlenmesinde önemli kaynaklar olarak kullanılmaktadır. Kapsamlı yeniden dizileme çalışmaları, *Lens ervoides* genomunun, kültürü yapılan mercimeğe göre daha yüksek düzeyde allelik çeşitlilik ve özellikle hastalık ve zararlılara karşı daha geniş bir dayanıklılık/toleranslılık gen kaynağına sahip olduğunu göstermiştir. Bu bulgu, yabani türlerin genetik çeşitliliğinin, ıslah programlarında değerlendirilebilecek önemli bir kaynak olduğunu ortaya koymaktadır. Ayrıca *L. ervoides* ve diğer yabani türlerde belirlenen bazı gen bölgeleri, özellikle RGA2, SWEET11 ve FAD2 genleri, kuraklık toleransı, lipid metabolizması ve şeker taşınımı gibi önemli fizyolojik ve biyokimyasal süreçlerle ilişkilendirilmiştir. Bu genlerin işlevsel olarak incelenmesi, mercimek ıslahında stres toleransı ve verim potansiyelini artırmaya yönelik yeni aday genlerin tanımlanmasına katkı sağlayabilecektir. Bu nedenle, yabani mercimek türlerinin genomik karakterizasyonu, mevcut gen havuzunun genişletilmesi ve iklim değişikliğine uyumlu, dirençli çeşitlerin geliştirilmesi açısından stratejik bir öneme sahiptir (Gutierrez-Gonzalez ve ark., 2022; Liber ve ark., 2021; Coyne ve ark., 2013).

Tek bir referans genomun tüm genetik varyasyonu temsil edemeyeceği anlayışıyla, 2022 yılından itibaren mercimek için tüm genetik çeşitliliği kapsayan çekirdek koleksiyon oluşturma çalışmaları hız kazanmıştır. Khazaei ve ark. (2016), *L. culinaris*'in farklı coğrafi kökenlerinden 20 genotipi içeren bir çekirdek genom veri seti oluşturmuş ve toplamda yaklaşık 47.000 gen bölgesi tanımlamıştır. Bu genlerin %80'inin çekirdek genomda, geri kalanının ise ek ve özel genlerde yer aldığı bildirilmiştir. Bu özel genlerin çoğu, abiyotik stres koşullarına, sekonder metabolit sentezi ve savunma mekanizmalarıyla ilişkilidir. Ayrıca pangenom (tüm genetik çeşitliliği kapsayan analiz), Asya ve Akdeniz orijinli genotipler arasında gen kayıpları ve kazançları bulunduğunu göstermiştir. Bu durum, adaptasyonun genomik temelini açıklamak açısından büyük önem taşımaktadır.

Karşılaştırmalı genomik analizlerde ise mercimek, diğer baklagil türleri olan nohut (*Cicer arietinum*), bezelye (*Pisum sativum*) ve soya (*Glycine max*) genomlarıyla karşılaştırılmıştır. Sonuçlar, türler arasında yüksek düzeyde korunmuş kromozomlar üzerindeki benzer gen dizilimleri bulunduğunu ve bu bölgelerin özellikle azot fiksasyonu, fenilpropanoid metabolizması ve stres koşullarına dayanıklılık/toleranslılık ile ilişkili genlerde korunduğunu ortaya koymuştur. Bu durum, mercimek ve yakın akraba türlerde temel metabolik ve fizyolojik süreçlerin evrimsel olarak korunmuş olduğunu, dolayısıyla bu gen bölgelerinin adaptasyon ve dayanıklılık mekanizmalarında kritik bir rol oynadığını göstermektedir (Karagül, 2017).

2.4. Fonksiyonel Genomik ve Veri Kaynakları

Mercimek genomik araştırmalarında son yıllarda kaydedilen ilerlemeler, çok sayıda açık erişimli veri tabanının oluşturulmasını sağlamıştır. Bu platformlar, mercimek ıslahı ve fonksiyonel genetik çalışmalarında araştırmacılara kapsamlı bilgi sunan önemli biyoinformatik referans merkezleri haline gelmiştir. Mercimek genomik araştırmalarını destekleyen belli başlı veri platformları aşağıda özetlenmiştir.

LENSBASE (ICARDA, 2022): Mercimeğe özgü genom, transkriptom ve moleküler marker (SSR, SNP, DArT vb.) verilerinin bütünleştirildiği kapsamlı bir platformdur. Kullanıcılar, farklı çeşitler arasında gen karşılaştırması yapabilir, dizi analizi gerçekleştirebilir ve ıslah çalışmalarında kullanılabilecek aday genleri tanımlayabilirler.

Legume Information System (LIS): Nohut, bezelye, bakla ve mercimek dahil olmak üzere 25 baklagil türüne ait genom anotasyonları, gen aileleri, QTL (nicel özellik lokusu) haritaları ve protein dizilerini içeren geniş kapsamlı bir veri tabanıdır. LIS, türler arası karşılaştırmalı genom analizleri yapılmasına olanak tanıyarak genetik evrim ve fonksiyonel çeşitlilik çalışmalarını desteklemektedir.

LIS-GEA (Genome-Environment Association Portal): Genotip × çevre etkileşimlerini analiz etmek üzere geliştirilmiş özel bir alt platformdur. Bu sistem, farklı çevre koşullarına adaptasyon gösteren lokusların ve allel varyantlarının belirlenmesine yardımcı olur. Böylece çevresel stres faktörlerine dayanıklılıkla ilişkili gen bölgelerinin tanımlanmasını kolaylaştırır.

Bu platformlar aracılığıyla elde edilen genomik ve transkriptomik veriler, mercimek ıslahında önemli uygulama alanları bulmaktadır. Özellikle aday gen tanımlama, gen dizilim varyasyonlarını inceleme, markör destekli seleksiyon (MAS) ve genomik seleksiyon (GS) modellerinde elde edilen sonuçların doğruluğunu ve öngörü gücünü artırmaktadır. Bu durum, ıslah programlarının daha hedefe yönelik, hızlı ve veri temelli şekilde yürütülmesine katkı sağlamaktadır (Pfeiffer ve ark., 2016; Berendzen ve ark., 2021; Sanderson ve ark., 2019).

3.2. Genomik Seleksiyon (GS)

Genomik seleksiyon (GS), ilk kez Meuwissen ve arkadaşları tarafından ortaya konulmuş bir ıslah stratejisidir (de Koning, 2016). Bu yaklaşım, tüm genom boyunca dağılım gösteren moleküler markörlerin bir bireyin genetik değerini tahmin etmek amacıyla istatistiksel ve matematiksel modellere entegre edilmesi esasına dayanmaktadır. Başka bir ifadeyle, genomik seleksiyon, her bir markörün etkisini ayrı ayrı değerlendirmek yerine, genomun tamamını kapsayan bütüncül bir tahmin modeli oluşturmaktadır. Bu yöntem, klasik marker destekli seleksiyondan (MAS) farklı olarak yalnızca belirli gen bölgelerine değil, tüm genomdaki varyasyonlara dayanır. Böylece, karmaşık ve çok genli karakterlerin (verim, biyotik/abiyotik stres toleransı, kalite özellikleri vb.) toplam genetik katkısı daha doğru bir şekilde tahmin edilebilmektedir.

Mercimek ıslahında genomik seleksiyonun temel amacı, fenotipleme gibi zaman alıcı ve maliyetli süreçleri azaltmak, bunun yerine genotipik veriler üzerinden yüksek doğrulukla tahmin yaparak ıslah döngüsünü hızlandırmaktır. Bu sayede, bir genotipin fenotipik performansı değerlendirilmeden önce, genomik veriler aracılığıyla üstün bireyler seçilebilmektedir. Genomik seleksiyon modellerinde, genotipik veriler geniş popülasyonlardan elde edilen referans setleri ile ilişkilendirilir. Bu setlerde hem genotipik hem de fenotipik veriler yer almaktadır. Model, bu referans popülasyondan öğrendiği istatistiksel ilişkileri kullanarak yeni bireylerin genetik değerlerini yüksek doğrulukla tahmin edebilmektedir. Sonuç olarak, genomik seleksiyon mercimek gibi uzun jenerasyon süresine sahip bitkilerde, ıslah döngüsünü kısaltarak daha hızlı, veriye dayalı ve hedefe yönelik bir ıslah süreci yürütülmesini mümkün kılmaktadır (Meuwissen ve ark., 2001; Gouache ve ark., 2013; Crossa ve ark., 2017).

Genomik seleksiyon uygulamalarında, genetik verilerden en yüksek tahmin doğruluğunu elde edebilmek için farklı istatistiksel ve makine öğrenmesi temelli modeller kullanılmaktadır. Mercimek ıslahında yaygın olarak başvurulan başlıca modeller şunlardır:

- ✓ RR-BLUP (Ridge Regression Best Linear Unbiased Prediction): Genomik marker'ların etkilerini sabit bir varyans varsayımı altında tahmin eden en temel genomik seleksiyon modellerinden biridir. Çok sayıda marker bulunduğunda aşırı uyumu engelleyerek güvenilir tahminler sağlamaktadır.
- ✓ GBLUP (Genomic Best Linear Unbiased Prediction): RR-BLUP'un genetik benzerlik matrisine dayalı bir türevidir. Genotipler arası genomik ilişkileri kullanarak bireylerin genetik değerlerini tahmin etmektedir. Bu model, hem doğruluk hem de işlem kolaylığı açısından mercimek gibi çok genli karakterlere sahip türlerde sıklıkla tercih edilmektedir.
- ✓ Bayesyen Modeller (BayesA, BayesB, BayesCπ): Marker etkilerinin dağılımını olasılıksal temelde tahmin eden esnek modellerdir. Marker etkilerinin sabit olmadığı, bazı marker'ların büyük etkiye sahip olduğu durumlarda üstün performans göstermektedir.
- ✓ Makine Öğrenmesi Yaklaşımları (Random Forest - RF, Support Vector Machine - SVM): Marker verilerindeki karmaşık ve doğrusal olmayan ilişkileri yakalamada etkilidir. Bu modeller, özellikle gen × çevre etkileşimlerinin önemli olduğu özelliklerde tahmin doğruluğunu artırabilmektedir (Hickey ve ark., 2017; Javid ve ark., 2020).

Mercimekte yapılan çeşitli çalışmalar, bu modellerin ıslah sürecinde önemli avantajlar sağladığını göstermektedir. GBLUP modeli kullanılarak mercimek genotiplerinde tane verimi, çiçeklenme süresi ve biyotik stres toleransı tahmin edilmiştir. Elde edilen sonuçlara göre, genomik seleksiyon modelleri, klasik seleksiyon yöntemlerine kıyasla %25-40 oranında daha yüksek tahmin doğruluğu sağlamıştır. Bir başka çalışmada, kuraklık ve tuzluluk stresine dayanıklılıkla ilişkili GS modelleri oluşturulmuştur. Bu modellerde, DREB2, NHX1 ve SOS1 gen bölgeleriyle ilişkili SNP setlerinin modele dahil edilmesi, tahmin performansını belirgin biçimde artırmıştır. Bu bulgular, genomik seleksiyonun özellikle stres toleransı ve verim stabilitesi gibi karmaşık karakterlerin ıslahında güçlü bir araç olarak kullanılabileceğini göstermektedir (Haile ve ark., 2020; Gebremedhin ve ark., 2024). Sonuç olarak, mercimek ıslahında kullanılan genomik seleksiyon modelleri, genetik verilerle fenotipik performans arasındaki ilişkiyi yüksek doğrulukla ortaya koymakta, böylece ıslah süresini kısaltmakta ve verim, kalite ile dayanıklılık özelliklerinin genetik olarak geliştirilmesine katkı sağlamaktadır.

3.2.1. Genomik Seleksiyonun Islah Programlarına Entegrasyonu

Genomik seleksiyon, klasik ıslah yöntemlerine kıyasla ıslah sürecini önemli ölçüde kısaltan yenilikçi bir yaklaşımdır. Mercimek ıslahında uygulanan genomik seleksiyon modelleri sayesinde, geleneksel olarak 6-8 yıl süren bir ıslah süreci, genetik tahmine dayalı seçim yöntemleriyle 3-4 yıla kadar indirilebilmektedir. Bu durum, hem zaman hem maliyet açısından önemli bir avantaj sağlamaktadır. Genomik seleksiyonun ıslah programlarına entegrasyonu, farklı aşamalarda çeşitli olanaklar sunmaktadır.

Erken jenerasyon seleksiyonu (F_2-F_4): Genomik tahmin modelleri kullanılarak melezleme popülasyonlarında, bitkiler olgunlaşmadan önce üstün genotipler belirlenebilmektedir. Bu, erken dönemde istenen özelliklere sahip hatların seçilmesini ve sonraki jenerasyonlara aktarılmasını kolaylaştırmaktadır.

Stres koşullarında dayanıklılık tahmini: Genomik seleksiyon modelleri, genotip × çevre etkileşimini dikkate alarak kuraklık, tuzluluk veya hastalık gibi stres faktörlerine dayanıklı hatların bilgisayar ortamında değerlendirilmesine olanak tanımaktadır. Böylece saha denemeleri öncesinde, stres toleransı yüksek genotipler belirlenebilmektedir.

Genetik kazancın artırılması: Genomik seleksiyon, her ıslah sürecinde tahmin doğruluğunu artırarak birim zaman başına genetik kazanç oranını yükseltmektedir. Bu sayede, hedeflenen özelliklerde hızlı ilerleme sağlanabilir ve popülasyon ortalaması sürekli iyileştirilebilir.

Günümüzde genomik seleksiyon, Kanada, Hindistan ve Avustralya gibi mercimek üretiminde öncü ülkelerde yürütülen ıslah programlarında yaygın olarak kullanılmaktadır. Bu ülkelerde genomik seleksiyon; verim, biyotik stres direnci ve tane kalite özelliklerinin iyileştirilmesinde standart bir karar destek aracı olarak uygulanmaktadır. Bu gelişmeler, genomik seleksiyonun sadece bir tahmin yöntemi değil, aynı zamanda modern ıslah programlarının dijital dönüşümünü destekleyen stratejik bir araç haline geldiğini göstermektedir. Uzun vadede, mercimek ıslahında genomik seleksiyonun fenotipleme verileriyle birlikte çoklu omik (genomik, transkriptomik, metabolomik) verilerle entegre edilmesi, daha hassas, hızlı ve çevreye uyumlu çeşit geliştirme süreçlerinin önünü açacaktır **(**Crossa ve ark., 2017; Varshney ve ark., 2017; Voss-Fels ve ark., 2019; Javid ve ark., 2020; Meuwissen ve ark., 2001)**.**

4. Transkriptomik Verilerin Islah Programlarına Entegrasyonu

Genomik çalışmaların sunduğu yapısal bilgiyi tamamlayıcı nitelikte olan transkriptomik analizler, mercimek (*Lens culinaris* Medik.) ıslahında gen ifadesi düzeyindeki değişimlerin anlaşılması, stres yanıtlarının çözülmesi ve fonksiyonel genlerin tanımlanması açısından kritik bir rol oynamaktadır. Transkriptomik veriler, yalnızca genlerin varlığını değil, aynı zamanda bu genlerin hangi çevresel koşullarda, hangi doku veya gelişim evresinde ve hangi düzeyde aktive olduğunu ortaya koymaktadır. Yeni nesil dizileme teknolojilerindeki gelişmeler sayesinde, RNA-Seq yöntemi mercimek bitkisinin gen ifadelerini çok daha ayrıntılı bir şekilde analiz edebilmektedir. RNA-Seq, bir organizmanın belirli bir anda hücrelerinde aktif olarak çalışan tüm genleri (transkriptom) ortaya çıkarmakta ve genlerin ne düzeyde ifade edildiğini göstermektedir. Bu yöntem, eski tekniklerle tespit edilemeyen düşük miktardaki genlerin ve farklı ekson yapısına sahip gen varyantlarının da belirlenmesini sağlamaktadır.

RNA-Seq verileri, mercimek ıslahında iki farklı şekilde kullanılmaktadır. Bunlardan biri referans genoma dayalı hizalama, diğeri ise de novo montaj adı verilen, mevcut bir referans genom olmadan gen dizilerinin sıfırdan birleştirilmesi yöntemidir. Referans tabanlı hizalama yöntemleri, bilinen genom dizilerine dayanarak gen ekspresyon seviyelerini nicel olarak ölçmeyi sağlamaktadır. De novo montaj ise referans genomun bulunmadığı durumlarda transkript dizilerinin doğrudan birleştirilmesiyle yeni gen bölgelerini tanımlamaktadır. Bu yaklaşımlar sayesinde mercimekte kuraklık, tuzluluk, sıcaklık stresi ve hastalık etmenlerine karşı verilen transkripsiyonel yanıtlar detaylı biçimde ortaya konmuştur. Ayrıca farklı gelişim evrelerinde gen ekspresyon profillerinin incelenmesi, verim ve kaliteye etki eden genlerin belirlenmesine katkı sağlamaktadır. Transkriptomik verilerin bu şekilde kullanılması, ıslah programlarında aday gen tanımlama, biyotik ve abiyotik stresle ilişkili gen ağlarını modelleme ve markör geliştirme (SNP, SSR) gibi çok sayıda uygulamaya temel oluşturmaktadır. Sonuç olarak, transkriptom analizleri, mercimek ıslahında genomik seleksiyonun tamamlayıcısı olarak görev yapmakta, çevresel koşullara duyarlı, yüksek verimli ve stres toleransı yüksek genotiplerin geliştirilmesine bilimsel zemin hazırlamaktadır (Singh ve ark., 2019).

4.1. Mercimekte Gen İfadesinin RNA-Seq Analizi ile Karakterizasyonu

RNA-Seq teknolojisi, mercimek genotiplerinde farklı abiyotik (kuraklık, soğuk, tuzluluk vb) ve biyotik (hastalık etmenleri) streslere verilen moleküler yanıtların belirlenmesinde en güçlü araçlardan biridir. Bu yöntem, stres koşullarında hangi genlerin etkili olduğunu tespit ederek tolerans mekanizmalarının anlaşılmasına katkı sağlamaktadır (Sohrabi ve ark., 2022).

Singh ve ark. (2017), kuraklığa dayanıklı (*PDL-1*) ve hassas (*JL-3*) mercimek genotiplerini karşılaştırarak 4.812 adet farklı ifade edilen gen (DEG) belirlemiştir. Bu genler arasında özellikle antioksidan savunma enzimleri (*APX, CAT, SOD),* osmotik koruma sağlayan metabolizma genleri (*proline dehydrogenase, betaine aldehyde dehydrogenase)* ve ABA (absisik asit) sinyal yolu bileşenleri (*NCED3, PYR/PYL, SnRK2)* ön plana çıkmıştır. Bu sonuçlar, kuraklık stresine karşı mercimeğin Reaktif oksijen türlerini (ROS) azaltma, ABA

aracılı stres sinyallemesi ve hücre içi su dengesini koruma gibi üç temel mekanizma kullandığını göstermektedir.

Soğuk stresine yönelik çalışmalarda da benzer moleküler yanıtlar görülmektedir. Barrios ve ark. (2017), düşük sıcaklığa maruz kalan mercimek bitkilerinde CBF/DREB transkripsiyon faktörlerinin ve soğuk yanıtlı COR genlerinin belirgin şekilde arttığını saptamıştır. Bu genler, bitkinin erken dönem soğuk tepkisinin en önemli düzenleyicileridir. RNA-Seq analizleri yalnızca stres yanıtında değil, aynı zamanda gelişimsel süreçlerde de değerli bilgiler sağlar. Mercimek tohum gelişimi boyunca yaptıkları çalışmada karbonhidrat metabolizması genlerinin (*AGPase, SUSY*) ve tohum protein depolama genlerinin (*legumin, vicilin, albümin* vb) yüksek düzeyde ifade edildiğini göstermiştir. Bu bulgular, tohum kalitesi ve besin değeri açısından kritik gen ağlarının tanımlanmasına önemli katkılar sağlamaktadır (Dutta ve ark., 2022; Song ve ark., 2022).

4.2. Transkriptom Temelli Markör Geliştirme

RNA-Seq verilerinden elde edilen transkriptom temelli markörler, mercimek ıslahında giderek daha önemli hale gelmektedir. Bu markörlerin en büyük avantajı, doğrudan ifade edilen gen bölgelerinden türetilmiş olmalarıdır. Bu nedenle, ilgili genlerin gerçekten bir biyolojik fonksiyona sahip olduğunu gösterdikleri için fonksiyonel markör olarak kabul edilmektedir. Mercimekte yapılan de novo transkriptom montajları, 70.000–110.000 arasında unigene dizisinin ortaya çıkmasını sağlamıştır. Bu diziler kullanılarak geliştirilen EST-SSR (Expressed Sequence Tag–SSR) ve SNP markörleri, hem genetik çeşitlilik çalışmalarında hem de marker-assisted selection (MAS) uygulamalarında yaygın şekilde kullanılmaktadır (Kaur ve ark., 2014). Ayrıca Lens ervoides türünden elde edilen SSR markörlerinin %78 oranında L. culinaris genomunda da başarılı şekilde çalıştığı bildirilmektedir (Wong ve ark., 2015). Bu bulgu, yabani türlerin genetik çeşitliliği artırmak ve introgressiyon ıslahını desteklemek için önemli bir kaynak olduğunu göstermektedir. Transkriptom temelli markörler ifade edilen gen bölgelerini temsil ettiklerinden, klasik genomik markörlere kıyasla hedef karakterle daha güçlü ilişki gösterebildikleri için QTL fine-mapping çalışmalarında da avantaj sağlamaktadır. Bu da, bu markörlerin ıslah süreçlerinde daha etkin şekilde kullanılmasını sağlamaktadır (Verma ve ark., 2013; Kaur ve ark., 2011).

5. Sonuç

Son on yılda hızla gelişen genomik ve transkriptomik teknolojiler, mercimek (*Lens culinaris Medik.*) ıslahında klasik fenotipik seleksiyonun ötesine geçerek, genetik varyasyonun derinlemesine anlaşılmasını ve hedefe yönelik ıslah stratejilerinin geliştirilmesini sağlamıştır. Mercimeğin 4.0 Gbp büyüklüğündeki karmaşık genomunun çözümlenmesi, genetik bilgi birikimini sadece ıslah programlarının değil, aynı zamanda biyotik ve abiyotik stres fizyolojisinin, kalite bileşenlerinin ve adaptasyon mekanizmalarının açıklanmasında da dönüştürücü bir araç haline getirmiştir. Genomik yaklaşımlar, yüksek yoğunluklu SNP panelleri, DArTseq ve GBS tabanlı genotipleme yöntemleriyle; verim, kuraklık ve hastalık toleransı gibi kompleks karakterlerin kantitatif lokuslarının (QTL) haritalanmasına olanak tanımıştır. Bu gelişmeler sayesinde mercimek ıslahında marker assisted selection (MAS) ve genomik seleksiyon (GS) yaklaşımları, klasik yöntemlere göre daha hızlı, doğru ve ekonomik hale gelmiştir. Özellikle genomik seleksiyon, erken jenerasyonlarda (F_2–F_4) bile yüksek tahmin doğruluğu sağlayarak ıslah döngülerini önemli ölçüde kısaltmaktadır. Buna paralel olarak, transkriptomik çalışmalar da mercimeğin stres yanıt ağlarını aydınlatmada önemli rol oynamıştır. RNA-Seq analizleri, kuraklık (DREB, LEA, P5CS), tuzluluk (NHX, HKT, SOS1) ve biyotik stres (PR-protein, WRKY, TIR-NBS-LRR) gibi genlerin farklı çevresel koşullarda nasıl aktive olduğunu ortaya koymuştur. Bu bulgular, genetik direnç mekanizmalarının fonksiyonel temellerini anlamayı ve bu genlerin doğrudan ıslah hedefi olarak kullanılmasını mümkün kılmıştır. Fonksiyonel genomik ve sistem biyolojisi entegrasyonuyla birlikte,

mercimek genomunda yer alan binlerce genin yalnızca dizilimsel değil, aynı zamanda ağ düzeyinde (network-based) işlevsel bağlantıları da çözümlenmiştir. Metabolomik, proteomik ve transkriptomik verilerin bütünleştirilmesi, stres yanıtında görev alan "master regulator" genlerin belirlenmesini sağlamıştır. Ayrıca pangenom, epigenom ve tek hücreli transkriptomik (scRNA-Seq) çalışmaların yaygınlaşmasıyla, mercimek ıslahı artık yalnızca verim artırma değil, aynı zamanda iklim değişikliğine uyum, besin değeri optimizasyonu ve karbon ayak izi azaltımı gibi çok boyutlu hedeflere de hizmet eden bir bilimsel alan haline gelmiştir. Sonuç olarak; genomik, transkriptomik ve diğer "-omik" teknolojilerin bütüncül entegrasyonu, mercimek ıslahında klasik yöntemlerin sınırlarını aşarak hızlı, hedefe yönelik, veri odaklı ve sürdürülebilir yeni çeşitlerin geliştirilmesine zemin hazırlamaktadır. Bu entegrasyon, mercimeğin gelecekte iklim değişikliğine dirençli, yüksek kaliteli ve ekosistem dostu bir baklagil olarak stratejik önemini pekiştirecek; aynı zamanda Türkiye gibi genetik çeşitlilik merkezlerinde yürütülen yerli ıslah programlarına da küresel ölçekte rekabet gücü kazandıracaktır.

ÖZET

Günümüzde, artan sosyal farkındalık ve çevresel kaygılarla birlikte, özellikle tekstil endüstrisinde yeşil üretim ve yeşil teknolojilerin benimsenmesine yönelik bir dönüşüm başlamıştır. Doğal boyama, geçmişten günümüze toplumlar tarafından tercih edilmiştir. Tekstil boyamada sentetik boyaların kullanımı, büyük miktarda kimyasal gerektirir ve zararlı, toksik kimyasal atıklar üretir. Doğal boyamanın yeniden canlanmasıyla birlikte, tamamen doğal kaynaklar kullanılarak yapılan boyama işlemlerinin renkler üzerindeki etkileri yoğun bir araştırma konusu haline gelmiştir. Doğal boyamada, mikrodalga boyama, geleneksel boyama süreçlerinin yanında yaygın olarak kullanılmaktadır. Bu çalışmada, boyama süreçleri, biberiye (*Rosmarinus officinalis*) ile biyomordanlanmış pamuk/polyester dokuma kumaşlar üzerinde kına (*Lawsonia inermis* L.) ile gerçekleştirilmiştir. Mikrodalga boyama ve geleneksel boyama farklı sürelerde uygulanmıştır. Boyanan kumaşların renk karakterizasyonu, CIELAB renk parametreleri (L, a, b*, C*, h°) ve renk yoğunluğu (K/S) değerleri kullanılarak değerlendirilmiştir. Elde edilen verilere dayanarak, biyolojik olarak modifiye edilmiş kumaşlar ile boyanmamış kumaşlar arasındaki renk tonu, doygunluk ve renk yoğunluğu farklılıkları incelenmiştir. Ayrıca, tüm renk parametreleri ile boyama koşullarıyla ilgili değişkenlerin dağılımı arasındaki ilişkiyi belirlemek için Temel Bileşen Analizi (PCA) uygulanmıştır. Bu çalışma, geleneksel doğal boyama işlemlerine kıyasla mikrodalga destekli doğal boyamanın, sürdürülebilir yeşil tekstil üretiminde daha hızlı, daha ekolojik ve yüksek verimli bir alternatif olabileceğini göstermektedir.

DYEING OF BIOMORDANTED FABRICS WITH MICROWAVE ENERGY AND ANALYSIS OF COLOR PROPERTIES

ABSTRACT

Today, with increasing social awareness and environmental concerns, a transformation has begun, particularly in the textile industry, towards the adoption of green production and green technologies. Natural dyeing has been preferred by societies from the past to the present. The use of synthetic dyes in textile dyeing requires large amounts of chemicals and produces harmful, toxic chemical waste. With the revival of natural dyeing, the effects of dyeing processes using entirely natural resources on colors have become a subject of intense research. In natural dyeing, microwave energy dyeing is widely used alongside traditional dyeing processes. In this study, dyeing processes were performed with henna (*Lawsonia inermis* L.) on cotton/polyester woven fabrics biomordanted with rosemary (*Rosmarinus officinalis*). Microwave dyeing and traditional dyeing were applied for different durations. The color characterization of the dyed fabrics was evaluated using CIELAB color parameters (L, a, b*, C*, h°) and color intensity (K/S) values. Based on the data obtained, the differences in hue, saturation, and color intensity between the bio-modified fabrics and the undyed fabrics were examined. Furthermore, Principal Component Analysis (PCA) was applied to determine the relationship between all color parameters and the distribution of variables related to dyeing conditions. This study demonstrates that microwave-assisted natural dyeing, compared to traditional natural dyeing processes, could be a faster, more ecological, and highly efficient alternative in sustainable green textile production.

Keywords: Natural Dyeing, Microwave, *Lawsonia inermis* L., biomordant

1.INTRODUCTION

Natural dyeing is an ancient art that has been practised since prehistoric times. With the discovery of synthetic dyes in 1856, natural dyes declined in use (Ado et al., 2014). Synthetic dyes have been adopted as alternatives to natural dyes in many fields due to their wide colour range, ease of application, and availability. In recent years, growing environmental awareness and concerns about sustainability have renewed interest in natural dyes, particularly in the textile industry. Mordants are used to improve the binding of natural dyes, which are obtained from plant parts such as roots, stems, and leaves, to fabrics. Metal salts are among the most widely used mordants in the dyeing industry. However, there are concerns about the environmental impact of metal salts. As a result, biomordants have begun to be used as more environmentally friendly alternatives. Common biomordants include botanical sources such as pomegranate peel, acacia, tannic acid, myrobalan, turmeric, oak, henna, lemon, tamarind, rosemary, and aloe vera (Cuce et al., 2022; Korkmaz et al., 2023, Benli, 2024; Kılınç et al., 2025). The natural dyeing process is generally carried out using conventional methods. However, in recent years, microwave energy dyeing has become popular due to its speed, effectiveness, and high energy efficiency. The literature reports that highly efficient results have been achieved in dyeing studies using microwaves (Yavaş et al., 2017). Rosemary (*Rosmarinus officinalis*) is a common houseplant cultivated in many regions worldwide, particularly in the Mediterranean. Rosemary can serve as an alternative to metal mordants due to its high phenolic content (İşmal et al., 2014). *Lawsonia inermis* (Henna) contains secondary metabolites such as alkaloids, flavonoids, coumarins, and tannins. Its main component is reported to be lawsone (2-hydroxy-1,4-naphthoquinone) (Supian and Osman, 2023). According to the literature, lawsone obtained from *Lawsonia inermis* can be used as a natural and environmentally friendly red-orange dye. *L. inermis* demonstrates good dyeing efficiency on protein fibers, but provides low and limited dyeing efficiency on cellulosic fibers; however, successful dyeing can be achieved at high temperatures on polyester. Due to its sustainable nature, it has been reported as a long-term environmentally friendly and ecological alternative for the textile industry (Bhuiyan et al., 2017). In this study, conventional methods and microwave energy were used to dye cotton/polyester blended fabrics. Both the mordanting and dyeing processes were carried out for different durations. Rosemary (*Rosmarinus officinalis*) was used as the biomordant and henna (*Lawsonia inermis*) as the dye. The colour properties of the dyed fabrics were evaluated using CIELAB (L, a, b*, C*, h°) colour parameters and colour intensity (K/S) values. The relationship between the colour parameters was interpreted using principal component analysis (PCA).

2. MATERIAL AND METHOD

2.1 Material

Cotton/polyester (75/25) fabric was used in the dyeing and mordanting processes. Fabric properties are given in Table 1.

Table 1. Fabric Properties

Properties	Cotton/Polyester(75/25%)
Fabric construction	Plain weave 1/1
GSM (g/m^2)	110
Ends per inch (cm^{-1})	24
Picks per inch (cm^{-1})	16
Warp count (Nm)	30
Weft count (Nm)	60

2.2 Mordanting Process

Pre-mordanting was applied in the study. A 10% rosemary (*Rosmarinus officinalis*) solution was used for the mordanting process. The mordanting was carried out using the traditional method at boiling temperature for 1 hour, and with microwave energy for 3 minutes and 5 minutes.

2.3 Dyeing Process

Dye concentrations were calculated based on fabric weight, with a 40% henna (Lawsonia inermis) concentration used during the dyeing process. The fabric was subjected to microwave dyeing at 800 watts using pure water at a 1:50 flotte ratio for 1, 3, and 5 minutes. Additionally, all fabrics underwent a 30-minute conventional dyeing process. After dyeing, the fabrics were washed in cold water, then in hot (boiling point) water, and finally in cold water again to remove any unbound dyes. The dyed fabrics were then left to dry.

2.4 Color Measurement

After the mordanting and dyeing processes were completed, colour measurements were performed using an LS175 colorimeter. Measurements were conducted under a D65 light source and 10° standard observer conditions. Reflectance (R) values were obtained in the visible range (400–700 nm) and converted to colour intensity (K/S) values using the Kubelka–Munk equation (Equation 1).

$$K/S = (1 - R)^2 / 2R \quad (1)$$

In addition to colour intensity measurements, the CIELAB colour coordinates of the samples were also determined. L* (lightness: 0 = black, 100 = white), a* (positive = red, negative = green), and b* (positive = yellow, negative = blue) values were measured; the C* (chroma, 0 = dull, 100 = vivid) parameter was also used to evaluate colour saturation.

3.RESULTS

The color measurement values of dyed cotton-polyester fabrics are given in Table 2.

Table 2. Color values of dyed fabric

Samples	L*	a*	b*	C*	h°	λ	K/S

Colour parameters are important concepts used to determine the similarities and differences between dyed samples. When samples are examined in terms of L* value, it is observed that brightness decreases after the dyeing process. The sample with code R3M30NL, which was mordanted with microwave energy and dyed traditionally, has the lowest lightness value. Traditionally dyed samples are less bright than those dyed with microwaves. The a* value, used to define red and green colour tones, is lower in traditionally dyed samples compared to the standard sample, while it is higher in samples dyed only with microwave energy. Other samples have a* values close to the standard fabric. The sample with code 1ML has the highest value, while the sample R1N30NL has the lowest. In terms of the b* value, used to determine yellowness and blueness, all samples are more yellow than the standard sample. The R3M5ML sample has the highest yellow hue. For vividness (C*) values, all samples are more vivid than the raw fabric. The R3M5ML sample has the highest chroma value. Regarding hue values, all samples have similar values. According to Figure 1, the samples are in the orange-yellow region. For colour fastness (K/S) values, there has been an increase in all samples compared to the raw fabric. Samples dyed using natural methods have a higher colour fastness value.

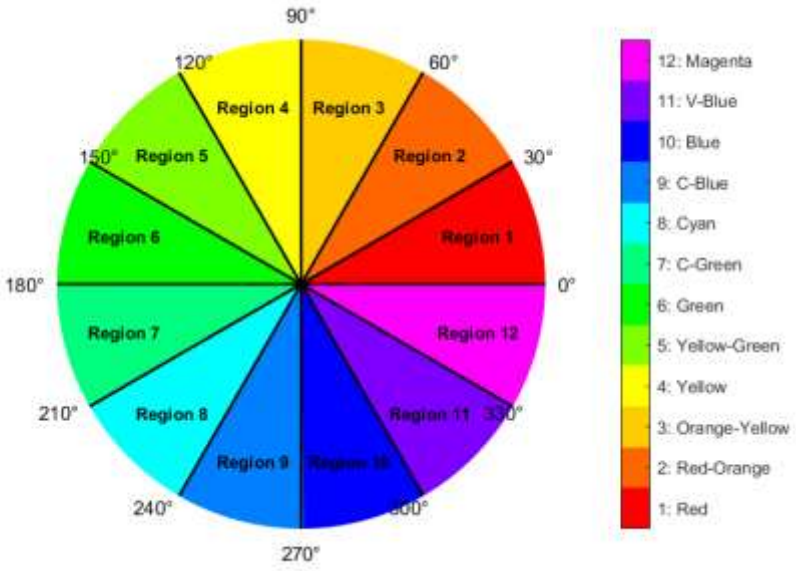

Figure 1. Color Wheel

Eigenvalue graphics are shown in Figure 2. The eigenvalue graph indicates that PC1 and PC2 have values greater than 1. PC1 (eigenvalue 5.7) is the most dominant component and is meaningful for explaining the data, along with PC2 (eigenvalue 2.2). Therefore, the data can be examined on a two-dimensional map. The proportion of variance explained by these two components is 77.56%, as shown in Figure 3.

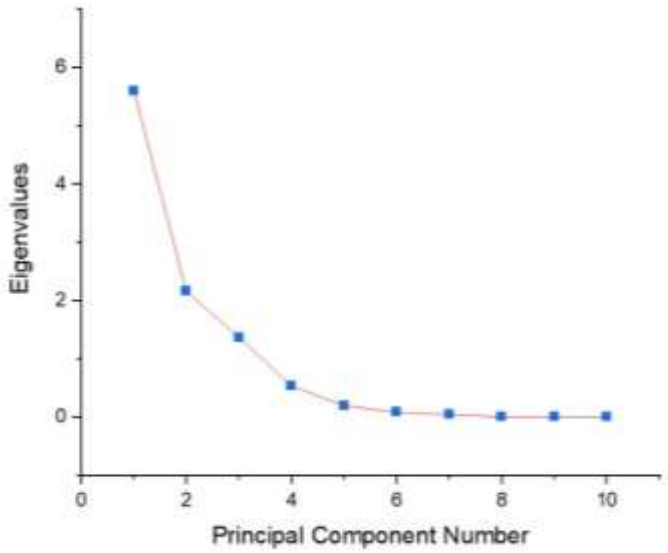

Figure 2. Eigenvalues graph

The principal component analysis graph is presented in Figure 3. According to this graph, there is a negative correlation between L* and K/S values. A positive correlation exists among b*, C*, MT (mordant type), and MAT (mordant application time) values. Another group showing positive correlation includes the K/S, h, and DAT (dye application time) variables. The standard control sample is distant from all other samples, particularly those coded R. The normally dyed samples coded NL are located in the lower right corner, while the microwave-dyed samples coded ML are clustered together. Additionally, the mordanted samples are positioned separately from the non-mordanted ones.

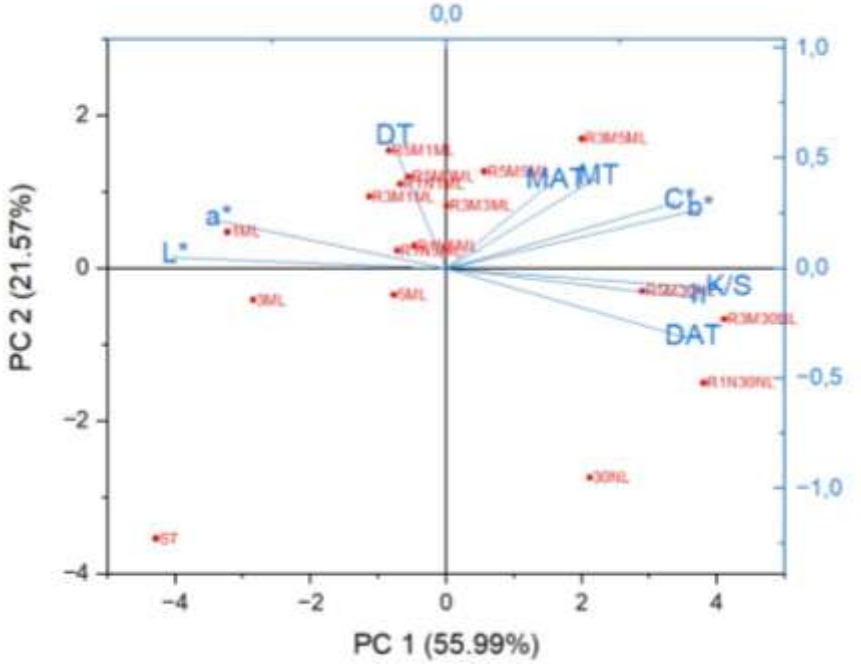

Figure 3. Principal Component Analysis (PCA) Biplot

4. CONCLUSION

The findings of this study show that long-term, optimised natural dyeing processes using effective natural dyeing materials, particularly henna (*Lawsonia inermis*) and rosemary (*Rosmarinus officinalis*), can achieve colour intensity comparable to that of synthetic dyes. The use of microwave energy in natural dyeing systems is recognised as an environmentally friendly, energy-efficient method with shorter processing times, achieving deep and effective colours comparable to traditional dyeing, provided the appropriate materials, mordant, and processing time are selected. This offers a strong alternative for the textile industry to achieve its environmental goals.

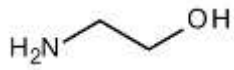
ABSTRACT

Improving energy efficiency in industrial grinding processes requires the development and comprehensive evaluation of next-generation grinding aids with tailored physicochemical characteristics. In this context, the rational design, molecular modeling, and mechanistic examination of novel additives provide critical insights that guide experimental studies. By theoretically screening candidate molecules prior to laboratory work, it becomes possible to identify structures with high performance potential, thereby reducing experimental workload, cost, and time loss. Within the scope of this study, five different ester-based grinding aid molecules were modeled in detail. The molecular structures were optimized using the Gaussian 09 software package with the DFT/B3LYP method and the 6-31G(d,p) basis set. Additionally, adsorption geometries of these molecules with Ca^{2+} ions were investigated to elucidate their interaction mechanisms on cement particle surfaces. Adsorption energies were calculated, and Mulliken charge distributions, HOMO–LUMO energy gaps, and electron density maps were analyzed to characterize the electronic features governing surface affinity and reactivity. The integrated evaluation of these parameters allowed the identification of the most promising candidate molecule with superior theoretical performance. This multiscale and computationally driven approach offers an innovative framework for the development of sustainable, high-efficiency grinding technologies and provides a scientific basis for the next generation of energy-saving additives.

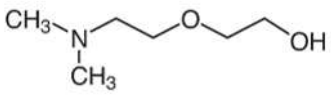
Keywords: Grinding aid, DFT, calcium adsorption, energy efficiency, surface interaction

Introduction



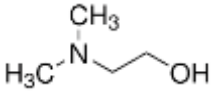
Energy consumption in cement and mineral processing industries remains a critical challenge, with grinding operations accounting for a substantial portion of total energy demand (Chehreh Chelgani et al., 2025). Conventional grinding aids have been widely employed to enhance comminution efficiency; however, their performance is often limited by non-specific physicochemical properties and insufficient mechanistic understanding (International Cement Review, 2025). As global sustainability goals increasingly emphasize energy reduction and resource optimization, the development of next-generation additives with tailored molecular characteristics has become an urgent priority (Kobya et al., 2025; Çinku et al., 2025).

Recent advances in computational chemistry and molecular modeling provide powerful tools to rationally design and evaluate candidate molecules prior to experimental validation. Density Functional Theory (DFT) calculations enable the prediction of adsorption behavior, electronic structure, and reactivity patterns, thereby offering insights into the fundamental interactions between grinding aids and cement particle surfaces. Such theoretical screening not only reduces experimental workload and costs but also accelerates the identification of high-performance additives with superior energy-saving potential.



In this study, a systematic computational investigation was conducted on five ester-based grinding aid molecules. Their molecular geometries were optimized using the Gaussian 09 software package with the DFT/B3LYP method and the 6-31G(d,p) basis set (Gaussian Inc., 2025). Adsorption interactions with Ca^{2+} ions were examined to elucidate binding mechanisms, while adsorption energies, Mulliken charge distributions, HOMO–LUMO energy gaps, and electron density maps were analyzed to characterize electronic features governing surface affinity. The integrated evaluation of these parameters enabled the identification of the most promising candidate molecules, thereby establishing a computationally driven framework for the rational design of sustainable, high efficiency grinding technologies.

Materials and Methods



Ester molecules are readily obtained from the acid-catalyzed reaction of carboxylic acids with alcohols. In this study, the structures of the modified esters obtained from the reaction of acetic acid with the amino alcohol molecules shown in Figure 1 were proposed, and their adsorption with Ca2+ ions was investigated. Optimization and frequency calculations of the molecules were performed in the gas phase using the DFT/B3LYP method and the 6-31G(d,p) basis set [6]. All calculations were performed using the Gaussian 09 program [7].

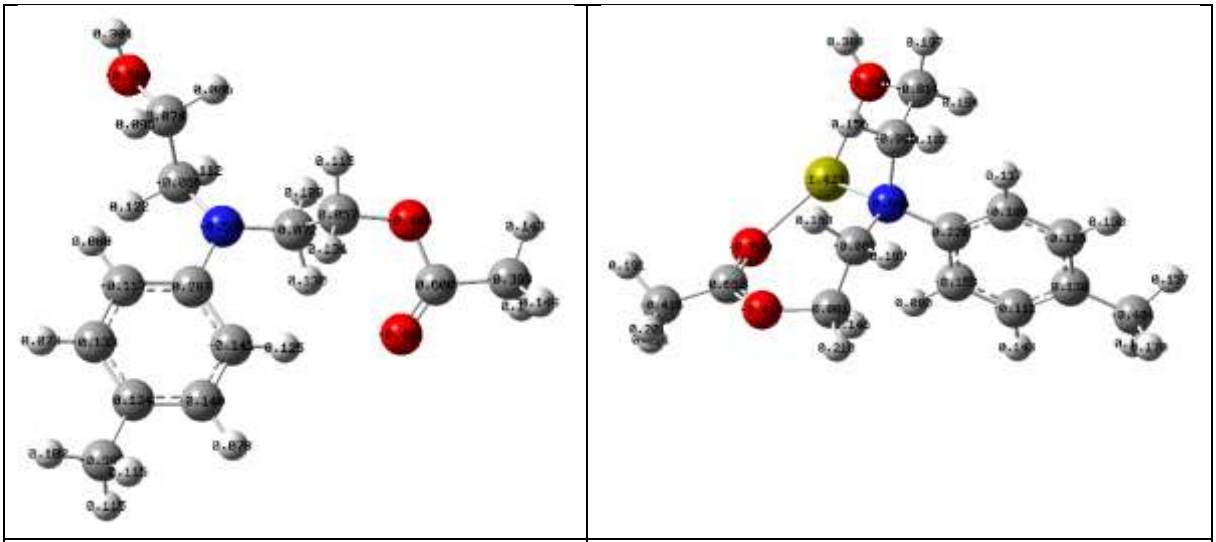
Ester5	Ester5-Ca

Figure 1. Optimized molecular structures of molecules adsorbed with ester 1, 2, 3, 4 and 5 molecules and Ca+2 ions



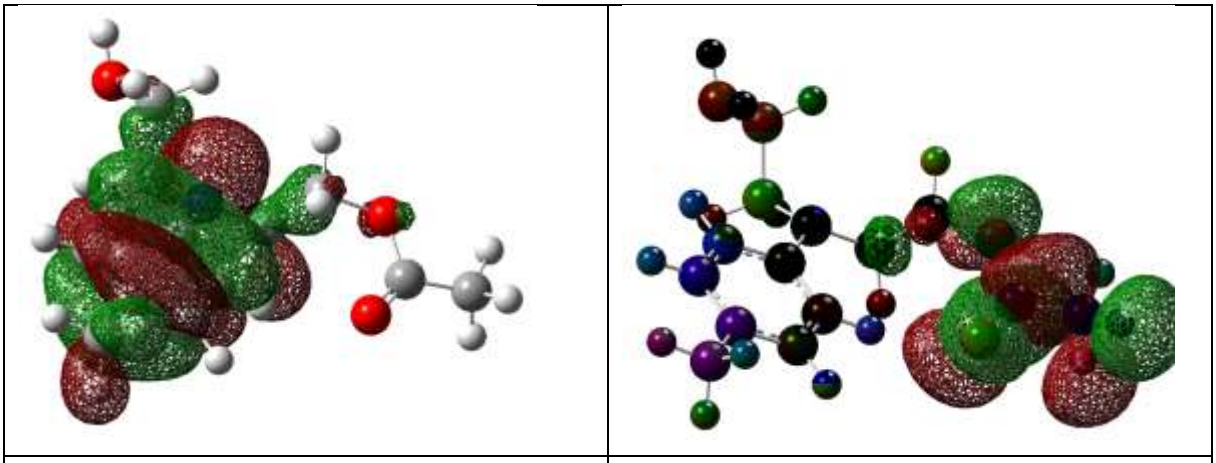
The energies and adsorption energies of the modeled ester molecules and the molecules obtained as a result of their adsorption with Ca+2 ions obtained using the DFT/B3LYP method and the 6-31G(d,p) basis set are listed in Table 1.

Table 1. Adsorption energies of ester molecules calculated in the B3LYP/6-31G(d,p) method and basis set

Molecules	**Energy (a.u.)**	**Adsorption energy (eV)**
Ester1	-363.057272	-5.14
Ester1-Ca	-1040.113941	
Ester2	-595.504294	-6.78
Ester2-Ca	-1272.620442	
Ester3	-441.673996	-5.10
Ester3-Ca	-1118.728213	
Ester4	-516.988200	-5.21
Ester4-Ca	-1194.046418	
Ester5	-787.260127	-6.88
Ester5-Ca	-1464.380020	

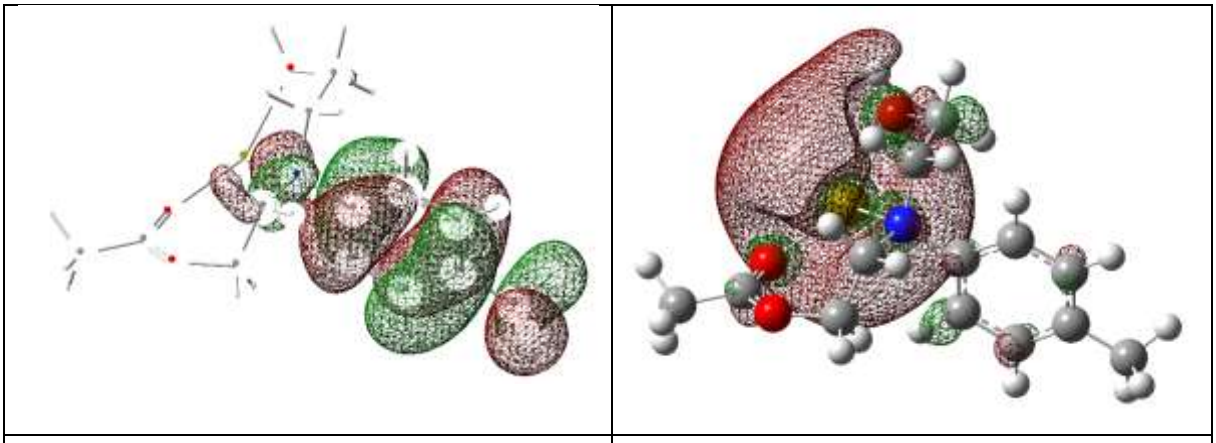
Table 1 shows that among the ester molecules, the molecule with the highest adsorption energy with the Ca+2 ion is Ester5. The adsorption energy for this molecule was calculated as -6.88 eV. Ester2 follows with -6.78 eV. The molecule with the lowest adsorption energy is Ester1, formed by acetic acid and ethanol amine. Based on these results, Ester5 is expected to have the best grinding facilitating properties.

The pre- and post-adsorption mulliken loads of the ester5 molecule, which gave the best adsorption result, are given in Figure 2.



Ester5 | Ester5-Ca

Figure 2. Mulliken charges of the ester5 molecule before and after adsorption



The mulliken charges of the heteroatoms, three oxygen atoms, and one nitrogen atom of the ester5 molecule were calculated as -0.560, -0.486, -0.451, and -0.528, respectively. The oxygen atoms of the same molecule that adsorbed with Ca2+ ions increased to -0.626 and -0.598, respectively, while the charge of the other oxygen atom decreased to -0.417. The nitrogen atom that participated in adsorption increased to -0.693. The charge of the calcium ion was calculated as 1.423.

The HOMO and LUMO orbitals of the molecules on which ester5 and Ca+2 ion are adsorbed are depicted in Figures 3 and 4.

Ester5-HOMO	Ester5-LUMO

Figure 3. HOMO and LUMO orbitals of the ester5 molecule

Eser5-Ca-HOMO	Ester5-Ca-LUMO

Figure 4. HOMO and LUMO orbitals of the ester5-Ca molecule

The HOMO molecular orbitals of the ester5 and ester5-Ca molecules are similar, but have phenyl pi character. The LUMO orbital of the ester5 molecule is concentrated on the carbonyl pi electrons, while that of the ester5-Ca molecule is concentrated on the calcium ion.

Conclusions

The calculations indicate that ester 5 has the strongest adsorption energy and is the most suitable candidate for milling facilitating properties. Mulliken charges and HOMO–LUMO analyses explain the binding mechanism of the Ca^{2+} ion through both electronic redistribution and orbital interactions. These findings are believed to provide guidance for the design of metal–organic complexes, catalyst development, and materials chemistry applications.

ABSTRACT

Esterification reactions typically occur through the condensation of an acid and an alcohol under appropriate catalytic conditions, forming structurally diverse and industrially relevant ester derivatives. In this study, a novel ester molecule synthesized via the esterification of tris(isopropanol)amine (TIPA) with acetic acid was subjected to comprehensive structural characterization using both experimental spectroscopy and theoretical modeling. Fourier Transform Infrared Spectroscopy (FTIR) and Nuclear Magnetic Resonance (NMR) spectroscopy were employed to experimentally verify the molecular structure, while Density Functional Theory (DFT)-based calculations were used to simulate the vibrational and electronic environments of the molecule. The theoretical analysis involved full geometry optimization at the B3LYP/6-31G(d,p) level, followed by simulation of FTIR vibrational modes using Gaussian 09 and GaussView software. All fundamental vibrational modes were assigned, and the theoretical C=O and C–O stretching frequencies exhibited strong agreement with the experimental values, with deviations remaining below 20 cm^{-1}. Furthermore, NMR chemical shifts were calculated using the Gauge-Including Atomic Orbital (GIAO) method. The chemical shift values of key nuclei, particularly the carbonyl carbon and the protons in the vicinity of the hydroxyl and isopropyl groups, showed excellent correlation with the experimental spectra ($R^2 > 0.98$). A comparative evaluation of experimental and computational FTIR and NMR spectra confirmed the successful formation of the ester bond and provided insights into the conformational behavior of the isopropyl groups within the molecular framework. The integration of DFT calculations with spectroscopic techniques demonstrated the strength of this combined methodology for molecular-level structural verification and functional group identification. Overall, the ester molecule synthesized from acetic acid and TIPA was successfully characterized using a dual experimental–theoretical approach, and the high level of agreement between the two datasets confirms both the structural integrity and the synthetic success of the target molecule. This study highlights the value of DFT-supported spectroscopic analysis as a robust methodology for the design and characterization of new ester derivatives.

Keywords: TIPA, esterification, FTIR, NMR, DFT, spectral analysis, molecular modeling

Introduction

Esterification reactions are among the most fundamental transformations in organic chemistry and have a wide range of applications in both academic and industrial applications. Esters are considered critical functional compounds in many areas, from polymer production and drug synthesis to surfactants and coating technologies. Therefore, the synthesis and structural verification of new ester derivatives is an important research topic that requires understanding at the molecular level [1].

Trisisopropanolamine (TIPA), a highly reactive alcohol derivative due to its multifunctional hydroxyl groups, is widely used in surfactants and additive systems. The esterification reaction between TIPA and acetic acid has been studied only limitedly in the literature, and detailed elucidation of the structural properties of new ester derivatives obtained from this system is of scientific importance [2,3].

In the structural characterization of molecules, Fourier Transform Infrared Spectroscopy (FTIR) and Nuclear Magnetic Resonance (NMR) techniques stand out as powerful tools for the determination of functional groups and the verification of bond structures. However, supporting experimental data with theoretical calculations based on Density Functional Theory (DFT) allows for more comprehensive interpretation of spectral data and reliable confirmation of molecular geometry [1]. This study focuses on the characterization of a new ester derivative synthesized from TIPA and acetic acid using both experimental and theoretical methods. Comparison of FTIR and NMR data with DFT calculations reveals the structural integrity of the molecule and contributes to the understanding of the esterification mechanism and the conformational effects of isopropyl groups. Thus, a robust methodological approach is presented for the design and characterization of new ester derivatives.Kaynaklar

Materials and Methods

TIPA, acetic acid, and catalyst were added to a 250 ml, two-necked glass flask at a 1:1 molar ratio, and the reaction was carried out using the esterification polymerization method at 90°C for 3 hours. The product yielded 40%.

The resulting M-TIPA molecule was characterized using FTIR, NMR, and GC-MS techniques.

The resulting M-TIPA molecule was optimized using the Gaussian 09 program, the DFT/B3LYP method, and the 6-31G(d,p) basis set. Frequency calculations for the optimized molecule confirmed that it was optimized in the most probable geometry.

The optimized molecular structure of the molecule is depicted in Figure 1.

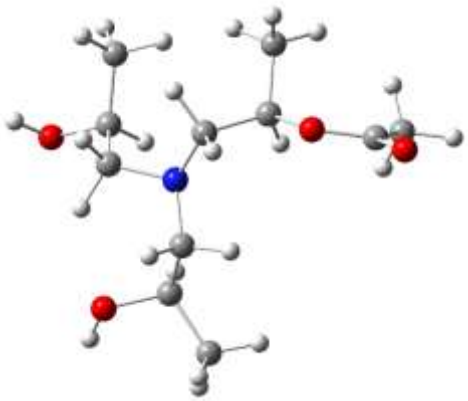

Figure 1. Optimized molecular structure of the M-TIPA molecule

Results and Discussion

Synthesis

The FTIR spectrum of the M-TIPA molecule, obtained from the reaction of one mole each of acetic acid and TIPA in the presence of a catalyst, is shown in Figure 2. The carbonyl stretching vibration of acetic acid, observed around 1750 cm-1, shifted to a weaker field in the M-TIPA molecule and decreased in intensity. The broad band observed in the TIPA molecule between 3000 and 3500 cm-1 is also observed in the M-TIPA molecule, providing strong evidence that synthesis has occurred.

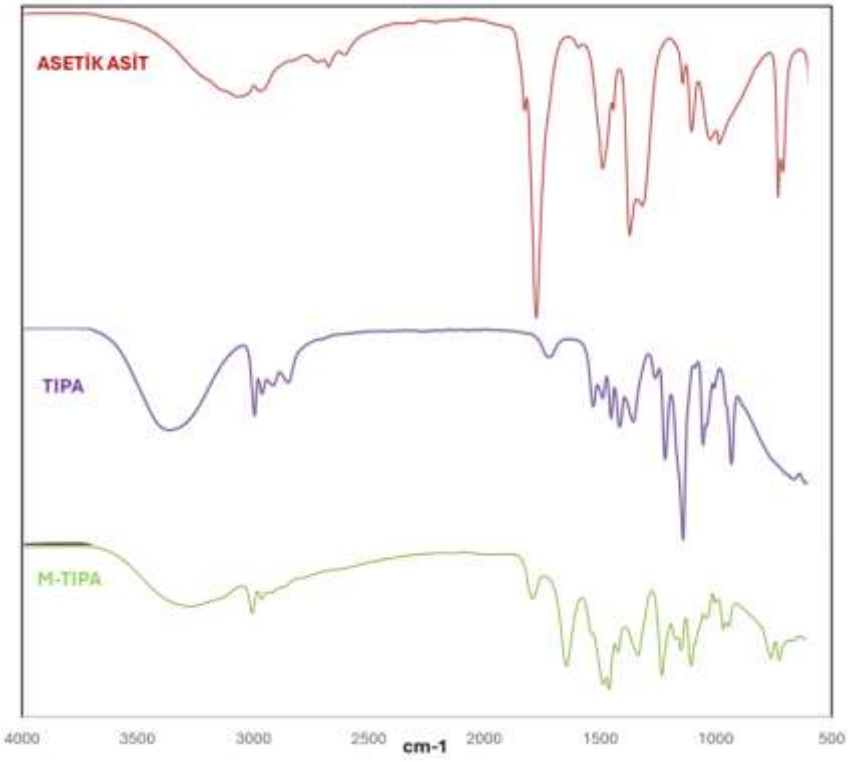

Figure 2. FT-IR spectra of acetic acid, TIPA and M-TIPA molecules

GC-MS chromatograms of the obtained M-TIPA and TIPA molecules are given in Figure 3.

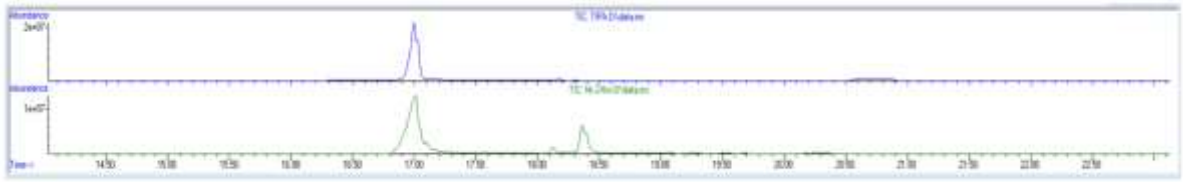

Figure 3. GC-MS chromatograms of M-TIPA and TIPA molecules

The peak for the TIPA molecule was observed at minute 17. When the chromatogram of the M-TIPA molecule was examined, in addition to the peak at minute 17, a peak belonging to a molecule with a higher molecular weight than TIPA was also observed at minutes 18 and 40. This result supports the synthesis of the M-TIPA molecule.

Finally, the 13C NMR spectrum of the M-TIPA molecule was obtained. The obtained spectrum is depicted in Figure 4.

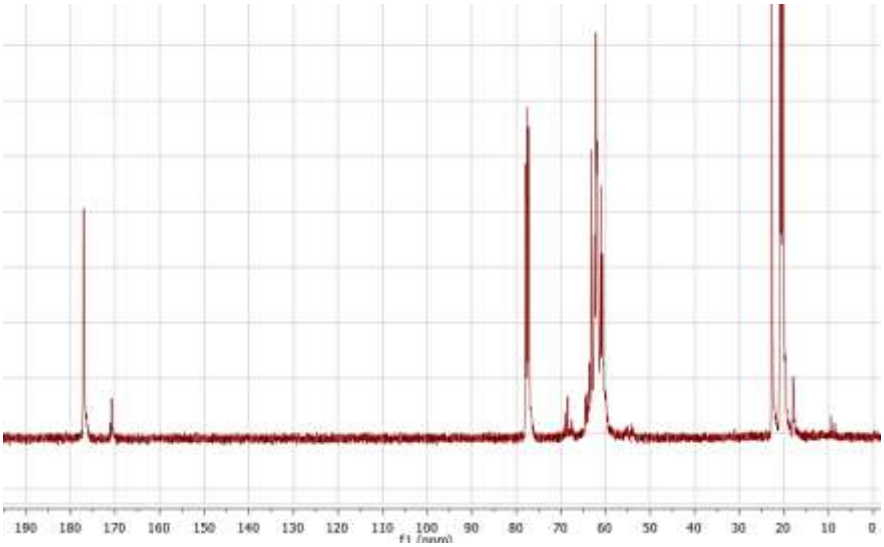

Figure 4. 13C NMR spectrum of the M-TIPA molecule

When Figure 4 is examined, the observation of a peak in the 170-180 ppm range, in addition to the peak belonging to the carbonyl carbon of acetic acid, indicates that the M-TIPA molecule has been synthesized. All these results indicate that the M-TIPA molecule was synthesized with approximately 50% yield.

FTIR spectrum

The synthesis and characterization of the M-TIPA molecule was optimized and its frequency calculation was performed using the DFT/B3LYP method and the 6-31G(d,p) basis set. Because the obtained frequency values were higher than expected, a scale factor was used. A scale factor of 0.98 was used for the 400-1800 cm-1 range and 0.96 for the 1800-4000 cm-1 range. The experimental and theoretical spectra obtained are compared in Figure 5.

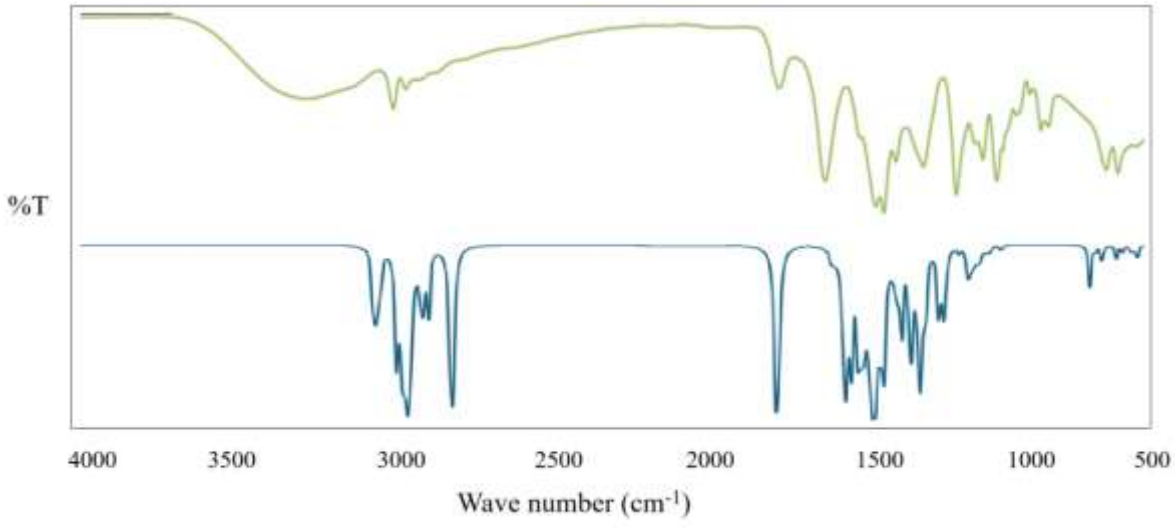

Figure 5. Comparison of experimental (green) and theoretical (blue) FTIR spectra of the M-TIPA molecule

Some experimentally and theoretically calculated vibration modes of the M-TIPA molecule are listed in Table 1.

111	2987	41,4869		
R2	0,9996			

The carbonyl stretching vibration of the M-TIPA molecule, observed at 1777 cm-1, was theoretically calculated at 1763 cm-1. The C-H aliphatic stretching vibrations were observed below 3000 cm-1, as expected, and the experimental and theoretical values are in good

agreement. When all experimental and theoretical values were compared, an R2 value of 0.9996 was calculated. All other vibrational modes are listed in Table 1.

NMR Spectrum

A comparison of the experimental and theoretical 13C-NMR spectra is shown in Figure 6.

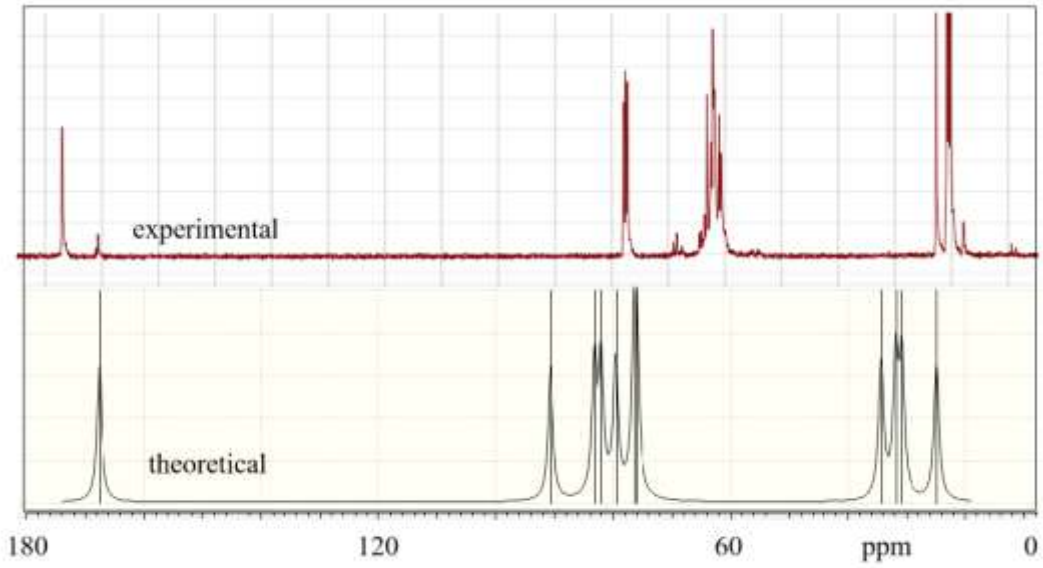

Figure 6. Experimental and theoretical 13C-NMR spectrum of the M-TIPA molecule

An examination of Figure 6 reveals that the experimental and theoretical spectra are in good agreement. The peak belonging to the carbonyl carbon atom, observed experimentally at 170.0 ppm, was theoretically calculated at 170.3 ppm. Carbon atoms belonging to the aliphatic CH3 and CH2 groups, observed at 20-23 ppm and 60-79 ppm, were calculated at 21-30 ppm and 69-91 ppm, respectively.

Conclusions

In this study, a new ester derivative synthesized from the esterification reaction between tris(isopropanol)amine (TIPA) and acetic acid was successfully characterized using a combined experimental and theoretical approach. FTIR, NMR, and GC-MS analyses confirmed the structural transformation resulting from the formation of the ester bond. The shift of the carbonyl stretching vibration to lower wavenumbers and the presence of characteristic peaks validating the C–O and C=O functional groups demonstrated the successful conversion of the reactants to the target ester product.

The GC-MS chromatogram revealed new peaks at higher retention times compared to pure TIPA, indicating an increase in molecular weight and supporting the structural modification. Additionally, the ^13C-NMR spectrum exhibited a distinct resonance near 170–180 ppm corresponding to the carbonyl carbon of the ester, which further validated the final molecular structure.

Complementary Density Functional Theory (DFT) calculations performed at the B3LYP/6-31G(d,p) level provided optimized molecular geometry and vibrational frequency predictions consistent with the experimental findings. After appropriate scaling, the correlation between experimental and theoretical FTIR wavenumbers yielded a high determination coefficient ($R^2 \approx 0.9996$), demonstrating excellent agreement between spectroscopic observations and computational modeling. Similarly, the theoretical NMR chemical shift predictions closely

matched the experimental spectra, particularly for the carbonyl and aliphatic regions, confirming the reliability of the structural assignment.

Overall, the consistency of the experimental data with the theoretical predictions confirms the successful synthesis and structural integrity of the M-TIPA ester molecule. The findings highlight the effectiveness of integrating quantum chemical modeling with spectroscopic methods to support molecular structure elucidation. Future work may explore the functional properties, reaction kinetics, and potential industrial applications of the synthesized ester derivative, particularly in chemical additive and polymer industries where multifunctional organic molecules such as TIPA-based esters are widely utilized.

ABSTRACT

Polymer matrix composites are widely used in many industries such as automotive, electronics, and aviation due to their light weight, chemical resistance, ease of shaping, and ease of manufacturing. One of the most important properties that determine the performance of these materials is thermal conductivity. While rapid removal of heat is required in some systems, in other systems reducing heat transfer is of great importance in terms of safety, energy efficiency, and product stability. Depending on the application requirements, increasing or decreasing the thermal conductivity values of polymers has become a critical engineering approach. High thermal conductivity provides an advantage for electronic chips, engine cooling systems or thermal interface materials; whereas low thermal conductivity is preferred in applications such as refrigerator insulation, building insulation elements, avionic systems, and ammunition boxes by limiting heat transfer for safety and energy savings. The types and amounts of fillers added to the polymer matrix directly affect the heat-carrying mechanisms of the composite. In this study, the effects of different types of fillers reinforced into the Polyamide-6 (PA6) matrix on thermal conductivity are comprehensively evaluated, and changes in phonon transport, chain mobility, and amorphous–crystalline structures are analyzed. In particular, the mechanisms by which the addition of boric acid decreases thermal conductivity are examined. In addition, the thermal conductivity effects of fillers such as silica, clay-based fillers, talc, and calcium carbonate are investigated. Thus, by revealing how different filler types influence dispersion within the PA6 matrix, interfacial interactions, and the crystalline structure, the fundamental parameters that determine the thermal performance of the material are assessed. The findings obtained provide guidance for designing target thermal properties in PA6 composites and emphasize the importance of appropriate filler selection, especially in engineering applications requiring thermal management.

Keywords: Polymer Composite, Polyamide-6, Thermal Conductivity

Introduction

Polymer-based composite materials are widely preferred in a broad range of applications—from automotive and defense industries to electronic devices and insulation systems—due to their light weight, formability, and chemical resistance (Tsekmes et al., 2013). Since polymer matrices typically consist of a combination of semicrystalline and amorphous regions, phonon transport is affected by structural irregularities, and their thermal conductivity generally falls within the range of ~0.1–0.4 W/m·K (Tan & Zhang, 2024; Li et al., 2022).

In this context, *thermal conductivity* is a fundamental thermophysical parameter that represents the ability of a material to conduct heat energy and holds critical importance in applications requiring effective thermal management (Variyenli & Arslan, 2017).

Heat transfer is a fundamental process that enables the transport of energy from one region to another, and this transfer occurs through three distinct mechanisms depending on the structural characteristics of the material and environmental conditions. As illustrated in Figure 1, these mechanisms are conduction, convection, and radiation. The effectiveness of each mechanism is governed by factors such as the phase of the material (e.g., solid, liquid, or gas), its structural organization, and intermolecular interactions (Incropera et al., 2007; Çengel & Ghajar, 2015).

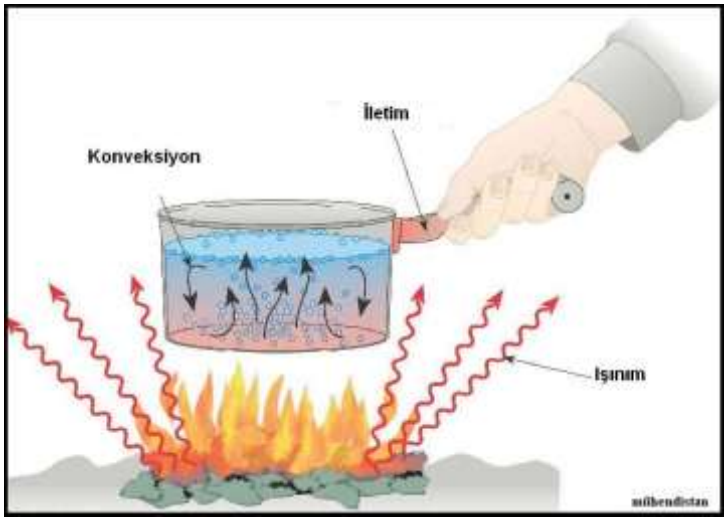

Figure 1. Types of heat transfer (Yeşilata, B., 2007)

For a solid material to conduct heat, the temperature within the material must vary with position; in other words, the temperature distribution must be non-uniform. Put differently, heat conduction in a solid becomes possible only when the temperature gradient within the material is non-zero, which is a direct consequence of the Second Law of Thermodynamics. Fourier's law of heat conduction states that the heat flux passing through a surface per unit time is directly proportional to the temperature gradient within the material. Therefore, in a solid medium, the greater the temperature difference, the higher the amount of heat transferred accordingly.

$$q = -k\,(dT/dx) \quad \ldots\ldots\ldots\ldots \quad (1)$$

In Equation (1):

- **q:** The heat flux per unit area (heat flux density), expressed in W/m².
- **k:** The thermal conductivity of the material, representing its ability to conduct heat; its unit is W/m·K.
- **T:** The temperature field as a function of position (T = T(x)), expressed in K or °C.

- **x:** The spatial coordinate defined along the direction of heat transfer (m).

The negative sign in the equation emphasizes that heat always flows from regions of higher temperature to regions of lower temperature, indicating that the direction of heat flux is opposite to the temperature gradient. In other words, if the temperature decreases in the x-direction ($dT/dx < 0$), the resulting heat flux q is positive, implying that heat is transferred in the positive x-direction. This formulation represents a fundamental heat conduction model valid for a homogeneous and isotropic solid under one-dimensional, steady-state conditions with negligible internal heat generation (Incropera et al., 2007; Çengel & Ghajar, 2015; Yeşilata, 2007).

Development

1. Thermal Conductivity Mechanism in Polymer Composites

Heat transfer in polymer composites occurs primarily through chain vibrations (phonon transport), which distinguishes them from metals and ceramics where heat conduction is dominated by free electrons or lattice vibrations with minimal scattering (Wang et al., 2019). Due to the electrically insulating nature of polymers, the contribution of free electrons to heat transfer is negligible; therefore, thermal conduction mainly takes place through the propagation of phonons generated by vibrational modes of polymer chains (Tan & Zhang, 2024; Wang et al., 2019).

In crystalline regions, the ordered arrangement of polymer chains allows phonons to propagate more continuously, whereas in amorphous regions, chain irregularities, voids, and bond-angle distortions increase phonon scattering and thereby limit heat transfer (Kohutiar et al., 2025). Consequently, an increase in the degree of crystallinity is expected to enhance thermal conductivity, while an increase in amorphous content generally leads to a decrease in conductivity (Beyaz, 2022).

Figure 2 schematically illustrates a typical polymer morphology consisting of crystalline and amorphous regions. Crystalline domains represent areas where the chains are aligned in an orderly and periodic manner, whereas amorphous regions correspond to zones in which the chains are arranged in a more irregular and random configuration (Huang et al., 2018). The relative ratio of these two phases plays a crucial role in determining phonon transport within the polymer and, consequently, its overall thermal conductivity.

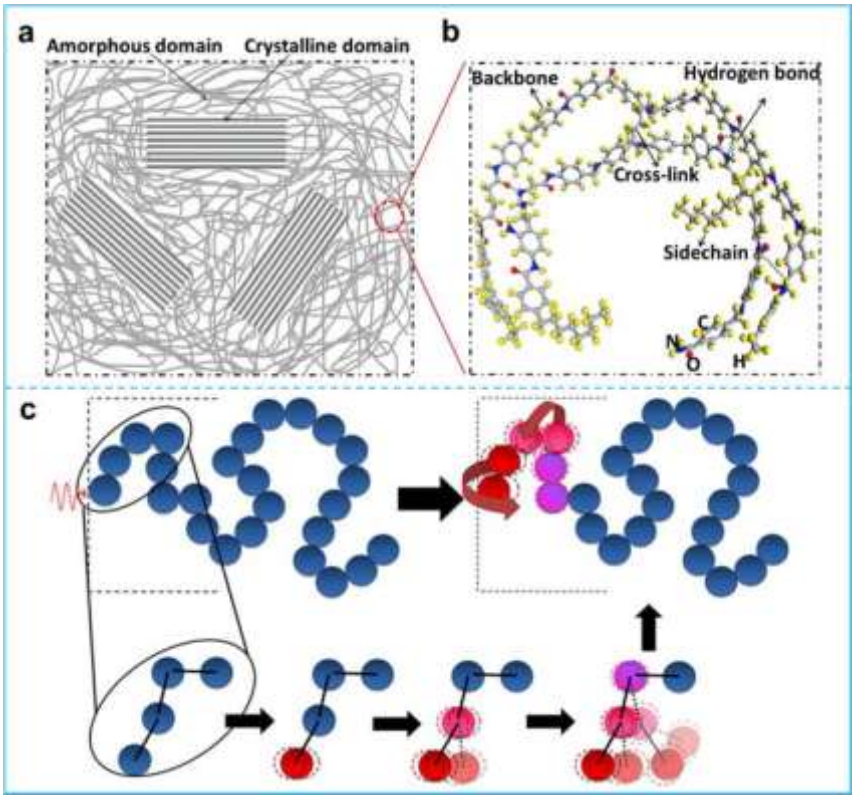

Figure 2. Schematic diagrams of a polymer: (a) morphology of a polymer consisting of crystalline and amorphous regions, (b) structure of a polymer chain, and (c) thermal conductivity mechanism in an amorphous polymer (Huang et al., 2018; Burger et al., 2016).

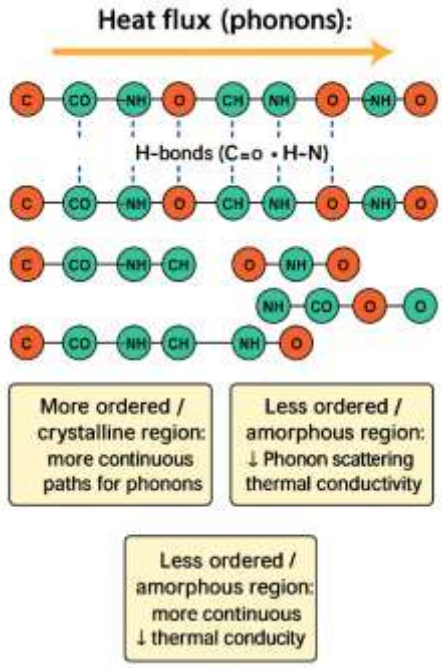

Figure 3. Schematic representation of the thermal conductivity mechanism through hydrogen bonding between Polyamide-6 (PA6) chains.

In Figure 3, phonon propagation (lattice vibrations responsible for heat transport) along PA6 chains is more continuous in ordered crystalline regions, where the chains are more linear and closely packed. In contrast, amorphous regions exhibit greater chain irregularity, conformational variations, and void formation; these factors increase phonon scattering and consequently reduce thermal conductivity. Interchain C=O···H–N hydrogen bonds enhance structural stability, yet simultaneously introduce interfacial resistance along phonon transport pathways, thereby contributing to the limitation of heat transfer. The schematic illustration demonstrates that the combined presence of crystalline and amorphous domains in PA6 plays a decisive role in determining its thermal conductivity.

Fillers incorporated into the polymer matrix may either enhance or restrict phonon transport. This dual effect depends on various parameters, including the intrinsic thermal conductivity of the filler, its compatibility with the matrix, interfacial behavior, particle size, and dispersion morphology within the composite. In the first case, a filler may disrupt phonon pathways within the polymer by introducing additional scattering centers. Structurally incompatible fillers or mineral-based materials with low thermal conductivity interrupt phonon motion and lead to a reduction in overall thermal conductivity (Çeliker, 2020; Kırbaş, 2021).

Conversely, when the filler possesses intrinsically high thermal conductivity, it may increase heat transfer within the polymer matrix. Fillers such as carbon nanotubes, graphene, graphite, and boron nitride known for their high conductivity form continuous heat-transfer pathways once a sufficient loading level is reached, enabling phonons to move faster and with less scattering compared to transport along polymer chains (Tan & Zhang, 2024; Kohutiar et al., 2025).

In a semicrystalline polymer such as PA6, boric acid addition can modify the crystalline–amorphous ratio and increase phonon scattering. These findings indicate that boric acid is a promising filler candidate for polymer composite design aimed at thermal insulation applications (Beyaz, 2022).

2. Polyamide-6 with Boric Acid Additives

Polyamide 6 (PA6) is a linear thermoplastic composed of repeating –NH–$(CH_2)_5$–CO– units, and its semicrystalline structure, mechanical strength, and thermal stability originate from the dense network of hydrogen bonds between chains. The stacking of amide groups (C=O···H–N) in a layered arrangement governs the formation of the α and γ crystalline phases, and this crystal morphology directly influences both the thermal conductivity and the combustion behavior of the material (Seguela, 2020; Wu, Liu & Berglund, 2002). The efficiency of heat conduction along polymer chains—based on phonon transport—is also strongly associated with the degree of crystallinity, chain alignment, and the continuity of the hydrogen-bonding network (Xu, Chen, Zhou & Li, 2018).

Boric acid, also known as hydrogen borate or orthoboric acid [H_3BO_3 or $B(OH)_3$], is a boron compound containing three hydroxyl groups and exhibiting marked Lewis acidity despite its weak Brønsted acidity. The –$B(OH)_3$ unit in the molecule can act as both a hydrogen-bond donor and acceptor. It is also known to react with –OH groups present in polysaccharides and polyols to form borate esters (B–O–C) (Zhang et al., 2020; Doğan et al., 2021; Uğurlu, 2020). At elevated temperatures, boric acid undergoes stepwise dehydration, forming metaboric acid and ultimately a glassy boron oxide (B_2O_3) phase. This phase is effective in flame-retardant systems through a condensed-phase mechanism by forming a dense and rigid char layer (Doğan et al., 2021; Mohd Sabee et al., 2022).

When boric acid or boric-acid-modified fillers are incorporated into the PA6 matrix, the interactions can be examined at two fundamental levels:

(i) hydrogen-bonding/coordination interactions at the macromolecular level under processing and service conditions, and

(ii) formation of boron-containing glassy/charred structures in the condensed phase during thermal degradation or combustion.

At the first level, the carbonyl (C=O) and amide N–H groups on PA6 chains are the primary functional sites capable of forming strong hydrogen bonds with the –OH groups of boric acid. In the literature, it has been demonstrated through FTIR measurements that in PA6/clay nanocomposites, clay layers modify the conformation of amide groups, weaken the hydrogen-bonding network, and promote the transition from the α-phase to the γ-phase (Wu et al., 2002). Similarly, in systems containing boric acid, hydrogen bonds of the –NH···O–$B(OH)_2$ and C=O···H–O–B type may compete with the classical interchain C=O···H–N interactions, thereby modifying local crystal order and hydrogen-bonding density. This allows fine-tuning of PA6 crystallization kinetics and the degree of crystallinity, particularly when low levels of boric acid or boric-acid-modified fillers are used. However, because direct hydrogen-bond analyses specifically for PA6/boric acid systems are limited, these interpretations largely rely on generalized FTIR and structural data from analogous systems (PA6/clay, PA66/boron-containing networks, etc.) (Wu et al., 2002; Mohaddes et al., 2014).

At the second level, condensed-phase reactions involving boric acid directly or indirectly come into play. Zhang et al. (2020) demonstrated that chemical modification of lignocellulose with boric acid results in the formation of borate structures containing B–O–C linkages, and when this borated lignocellulose is used with PA6, the thermal stability of lignocellulose increases and the onset degradation temperature of composites rises. XPS and FTIR analyses indicate that boric acid is primarily retained through covalent bonding within the lignocellulosic matrix, while its interactions with PA6 are predominantly through hydrogen bonding and physical interlocking. In such bio-composites, enhanced interfacial interactions between the PA6 phase and the borated filler can contribute to restricting crack propagation and limiting diffusion into the gas phase during thermal degradation (Zhang et al., 2020).

The incorporation of boric acid into PA6 systems has been studied particularly in flame-retardant textile structures (Selvakumar et al., 2012; Guo, 2023) and biomedical nanofiber applications (Nur et al., 2021). Flame-retardant performance has also been investigated in PA6 with the addition of boric acid and boron oxide together with organophosphorus compounds (Polat & Kaynak, 2016).

Yılmaz et al. (2011) reported that boron-containing compounds such as zinc borate and boro-phosphate added to PA6/melamine cyanurate composites can enhance flame retardancy by modifying the char structure, although depending on the type and amount of additive, they may also reduce the onset degradation temperature. Doğan et al. (2021) emphasized that boron compounds generally act in the condensed phase by forming a hard protective layer with B_2O_3 or boro-phosphate character, strengthening the char. These findings indicate that in PA6 systems, boric acid does not typically form covalent bonds with the polymer chain but creates ionic or coordinative networks by interacting with polar products and phosphorus-containing species generated during degradation. Similarly, in a study on PA66, boric acid–phosphoric acid esters were shown through FTIR analysis to form a denser and more thermally stable char layer (Mohaddes et al., 2014).

When evaluating the thermal conductivity of PA6 systems containing boric acid, it must be considered that heat transfer in polymers is predominantly governed by phonon scattering, and that chain order, crystallinity, and phase boundaries determine these scattering processes (Xu et al., 2018). Although the number of studies quantitatively investigating the direct "boric acid–PA6 thermal conductivity relationship" is limited in the literature, it is generally accepted that any additive that modifies filler/matrix interfaces and crystallinity can increase phonon scattering and thereby reduce thermal conductivity. Moreover, a decrease in crystallinity and disruption of the hydrogen-bonding network in PA6 restrict the orderly propagation of phonons. Such structural irregularities can effectively contribute to reducing thermal conductivity when boric acid or boric-acid-modified fillers are used in suitable formulations (Seguela, 2020; Wu et al., 2002).

3. Effect of Other Inorganic Fillers

Inorganic fillers used in polymer composites are critical additive components that directly influence the thermal and structural behavior of polymer chains. The effects of these fillers on the polymer matrix arise from multiple parameters, including particle morphology, surface chemistry, crystalline structure, and matrix filler interfacial interactions. The primary influence of inorganic fillers on thermal conductivity is associated with the phonon transport pathways they create within the composite, the interfacial thermal boundary resistance (TBR), and their ability to form continuous heat-conduction networks (Xu, Chen & Li, 2018).

Inorganic fillers with high thermal conductivity such as boron nitride (h-BN), alumina (Al_2O_3), magnesium oxide (MgO), and graphite can enhance the thermal conductivity of the polymer matrix by forming a continuous solid-phase heat-transfer network once a sufficient filler loading is achieved. These fillers facilitate phonon propagation with reduced scattering due to the strong atomic bond energies inherent to their crystal structures. Numerous studies have reported that in h-BN–reinforced PA and epoxy composites, thermal conductivity increases significantly when the filler content reaches the critical volume fraction required for solid-phase continuity (Shtein et al., 2015).

In contrast, low-conductivity inorganic fillers such as silica (SiO_2), talc, kaolin, clay minerals, and calcium carbonate ($CaCO_3$) operate through a mechanism that increases phonon scattering within the composite. These particles disrupt the regular heat-transfer pathways of polymer chains, creating barrier effects along phonon transport routes. Therefore, fillers such as SiO_2 and $CaCO_3$ are known to contribute to decreasing thermal conductivity (Khanam et al., 2014). Additionally, when the surface energy of such fillers differs from that of the polymer matrix, interfacial thermal resistance increases, further reducing heat-transfer capacity (Ruan et al., 2023).

The homogeneity of filler dispersion within the polymer is another critical parameter governing the thermal behavior. Homogeneously distributed fillers provide a more uniform microstructure for heat conduction, whereas particles prone to agglomeration create localized thermal barriers that interrupt phonon flow (Gu et al., 2019). This phenomenon is particularly important for nanoscale fillers, as their high surface area can increase interfacial thermal resistance.

Fillers such as talc and kaolin, which exhibit nucleating effects, may increase the crystallization temperature in semicrystalline polyamide matrices, promoting more ordered and distinct crystalline domains. Differential scanning calorimetry (DSC) analyses have shown that the addition of talc and kaolin to PA6/carbon fiber composites elevates crystallization temperature and improves crystal perfection (Jianfeng et al., 2020). Conversely, some nano- and microscale fillers that possess irregular surface structures, strongly interact with polymer chains, restrict

chain mobility, or form incompatible interfacial regions can hinder crystallization and reduce the degree of crystallinity. As a result, the phonon transport pathways available in the crystalline phase become limited, leading to reduced thermal conductivity (Nair et al., 2005; Shi et al., 2010).

In summary, the influence of inorganic fillers added to polymers cannot be explained through a single mechanism. The type of filler, particle size, surface activity, interfacial bonding behavior, and the resulting microstructural composition collectively determine the final thermal performance of the composite. Therefore, achieving the desired thermal properties requires the careful selection of filler type, implementation of appropriate surface-modification treatments, and strict control of filler dispersion within the matrix.

4. Mechanisms for Reducing Thermal Conductivity

Polymer-based materials inherently possess low thermal conductivity (typically in the range of ~0.1–0.4 W/m·K), and for this reason they are widely used in thermal insulation and thermal-management applications (Breitkopf, 2024). Reducing the thermal conductivity of polymer composites is fundamentally achieved by controlling microstructural and chemical mechanisms that restrict phonon transport and interrupt heat-flow pathways. The primary mechanisms that reduce thermal conductivity in polymers and polymer composites are summarized below.

4.1 Phonon Scattering and the Increase of the Amorphous Phase

In electrically insulating polymers, heat transfer is predominantly governed by lattice vibrations (phonons). Therefore, thermal conductivity is directly related to the phonon mean free path and scattering frequency (Choy, 1977; Wei, 2021; Xu et al., 2018). In amorphous regions, chain irregularities, bond-angle deviations, and topological disorder increase phonon scattering, thereby reducing thermal conductivity. In crystalline regions, by contrast, the polymer chains are more regularly aligned, allowing phonons to propagate over relatively longer distances with fewer scattering events.

Cahill's studies on amorphous solids demonstrate that as structural disorder increases, thermal conductivity approaches a lower bound referred to as the "minimum thermal conductivity" (Cahill, 1987). Consequently, increasing the amorphous phase fraction in a polymer composite can be considered a fundamental strategy for enhancing phonon scattering and reducing thermal conductivity.

4.2. Reduction of Crystallinity and Disruption of Chain Orientation

The thermal conductivity of polymers is closely associated with their degree of crystallinity, crystal grain size, and chain orientation. High crystallinity and strong chain alignment tend to increase thermal conductivity by creating more continuous lattice pathways through which heat flux can propagate (Choy, 1977; Xu, 2020).

In contrast, any structural modification that:

- reduces crystallinity,
- increases crystal/amorphous interfaces,
- disrupts chain orientation

hinders phonon transport between crystalline domains and decreases the overall thermal conductivity. Xu (2020) emphasizes that when crystallinity and chain orientation are reduced in polymers, thermal conductivity decreases significantly, and amorphous interphase regions play a critical role in phonon scattering.

Modifying crystallization kinetics through filler incorporation, reducing crystal size, or partially suppressing the crystalline phase are commonly employed strategies to lower thermal conductivity.

4.3. Interfacial Thermal Resistance

In polymer composites, heat transfer occurs not only within the matrix but also across the matrix–filler interfaces. At these regions—where two phases with different elastic properties, densities, and phonon spectra come into contact—interfacial thermal resistance (ITR) is generated. This resistance is one of the primary factors limiting the overall thermal conductivity of the composite, particularly when low-conductivity or weakly bonded fillers are present (Ruan et al., 2020; Gu et al., 2021).

Ruan et al. (2020), in their review on thermally conductive polymer composites, demonstrated how different filler types (platelet-like, fibrous, particulate) influence interfacial thermal resistance and showed that in systems with numerous interfaces, ITR plays a dominant role in reducing thermal conductivity.

From the perspective of reducing thermal conductivity:

- increasing the number of matrix/filler interfaces,
- weak or incompatible interfacial bonding,
- the presence of voids and defects at the interface

all enhance phonon reflections and scattering, thereby restricting heat flow. For this reason, multiphase structures with a high number of interfaces may be advantageous in designs targeting low thermal conductivity.

4.4. Voids, Porosity, and Low-Density Regions

One of the most effective mechanisms for reducing thermal conductivity is the formation of voids and pores. Voids containing stagnant gas phases or vacuum possess significantly lower thermal conductivity than the solid polymer phase. Therefore, the presence of:

- micro-/mesoscopic voids within the matrix,
- closed-cell porous structures,
- low-density phases

reduces the effective thermal conductivity of the composite. In polymer foam systems, decreases in density and increases in porosity have been reported to reduce thermal conductivity by more than 50% (Kırbaş et al., 2021).

In porous polyurethane systems, the addition of boric acid has been shown to significantly decrease both density and thermal conductivity; as the filler content increases, the thermal insulation performance of the composite improves (Kırbaş et al., 2021). These findings indicate that boron compounds can reduce thermal conductivity through promoting pore formation and stabilizing low-density phases.

4.5. Chemical Interactions, Chain Mobility, and Bonding

Recent studies have shown that chemical interactions and hydrogen bonding between polymer chains and the filler phase also influence thermal transport. When:

- hydrogen bonds,
- coordinative bonds,

- covalent crosslinks

are formed between polymer chains and the filler surface, chain mobility can be restricted, the local structure may become more disordered, and the continuity of phonon transport can be disrupted (Wei, 2021; Mukherji, 2024). Such chemical interactions become particularly significant in systems where hydrogen-bond-forming polymers (e.g., polyamides) interact with oxygen- or hydroxyl-containing inorganic fillers (e.g., boric acid, borate derivatives). In this way, microstructural disorder and the number of interfacial regions increase, enabling a reduction in thermal conductivity.

4.6. Use of Low Thermal Conductivity Fillers: Boric Acid-Based Systems

Another approach to reducing thermal conductivity is the incorporation of fillers that inherently possess low thermal conductivity. Polymer composites containing boric acid and various boron minerals have been reported to be used for both thermal and electrical insulation purposes. Çeliker et al. (2020) demonstrated that in composites produced by adding boric acid and paper-mill sludge to a polyester matrix, the thermal conductivity coefficient decreased as the filler content increased, rendering the thermo-mechanical performance suitable for insulation applications. Ersoy (2007) reported that composites produced by incorporating boric acid and different boron minerals into unsaturated polyester resin exhibited improved electrical and thermal insulation properties, indicating that such systems can be employed for insulation purposes. Kırbaş et al. (2021) found that the addition of boric acid to rigid polyurethane foams resulted in more than a 50% reduction in thermal conductivity compared to neat polyurethane; this decrease was attributed to both increased porosity and the formation of boron-containing phases with inherently low thermal conductivity.

These findings demonstrate that boric acid and boron compounds can serve as effective fillers for reducing thermal conductivity when combined with appropriate polymer matrix selection and processing conditions. Similarly, with the incorporation of boric acid into a PA6 matrix, a reduction in thermal conductivity is expected through mechanisms such as an increased number of interfaces, partial suppression of crystallinity, disruption of chain order, and the possible formation of micro-voids.

Conclusion

In this study, the effects of various fillers incorporated into a Polyamide-6 (PA6) matrix on thermal conductivity were comprehensively evaluated, and heat-transfer mechanisms were examined holistically in terms of phonon transport, crystallinity, interfacial resistance, and filler–matrix interactions. Considering that heat transfer in polymers largely depends on the mean free path of phonons, the influence of filler type on polymer chain order and interfacial structure emerges as a critical factor determining the final thermal performance of the composite.

The findings demonstrated that inorganic fillers with low thermal conductivity (such as boric acid, silica, $CaCO_3$, and clay minerals) reduce the thermal conductivity of the PA6 matrix by increasing phonon scattering. The weak compatibility between these fillers and polymer chains, along with the interfacial thermal resistance they generate, disrupts phonon continuity; furthermore, the increase in the amorphous phase further restricts heat-transfer pathways. Microstructural modifications that reduce crystallinity, break chain orientation, and increase phase boundaries were found to be effective in achieving low thermal conductivity.

The effects of boric acid on PA6 became evident at both the microstructural and chemical-interaction levels. Hydrogen bonds formed between the –OH groups of boric acid and the C=O and N–H functional groups of PA6 chains weakened the classical interchain hydrogen-bond

network and partially suppressed crystallinity. This led to a more disordered phonon transport environment, contributing to reduced thermal conductivity. Additionally, the boron oxide phase generated through the stepwise dehydration of boric acid at processing temperatures created low-conductivity regions and potential micro-voids within the matrix, serving as additional mechanisms that hinder heat flow.

Compared to other filler types, boric acid proved to be a compatible additive for PA6 in applications specifically aiming to reduce thermal conductivity. Unlike highly conductive fillers such as BN, graphite, or CNTs, boric acid acted by forming barriers that interrupt phonon pathways and prevented the formation of continuous thermal networks, thereby enhancing structural disorder and contributing to the desired thermal-insulation performance.

In conclusion, reducing thermal conductivity in PA6 composites is achievable through the combined control of multiple mechanisms, including increasing the amorphous phase, enhancing interfacial thermal resistance, promoting micro-void formation, and tailoring filler–matrix interactions. This study provides important scientific insight into the phonon-scattering effects of boric acid in PA6 and highlights its potential for applications requiring low thermal conductivity, such as thermal insulation, ammunition casings, avionics housings, and protective electronic structures. The findings indicate that with proper filler selection and microstructural engineering, the desired thermal performance can be effectively designed in PA6 composites.

ÖZET

Ticari Alumix 123 tozu, kimyasal içerik bakımından dövme Al2014'e benzeyen alüminyum alaşımı metal tozudur. Bu toz, havacılık ve otomotiv endüstrisi başta olmak üzere imalat sektöründe kullanılan başlıca alaşımlardan biridir. Ancak üretim ve piyasaya arz sürecinde AlSiMg ön alaşımlı metal tozları ile birlikte, Al+4,5Cu içeriği ile ön karışımlı toz olarak hazırlanır. Bu durum ise gerek sinterleme veya gerekse sıcak presleme sürecinde Al-%4,5Cu alaşımının sağlanmasında bazı problemler oluşturabilmektedir. Bu çalışmada, Alumix 123 tozunun farklı sıkıştırma basınçlarında soğuk preslenmesi sonrası üç farklı sıcaklıklarda bir saat süre ile sinterlenmesi ile oluşan mikroyapılar ve alaşımlanabilme özelliği karakterize edilmiştir. Optik ve taramalı elektron mikroskop (SEM) çalışmaları ile üretilen toz metal (TM) parçaların mikroyapıları ve sinterlenebilirliği incelenmiştir. Özellikle ön karışımlı tozun oluşturduğu Al-Cu alaşımlama durumu ve oluşan fazlar, SEM-EDS analizleri ile incelenmiştir. Deney sonuçları göstermiştir ki, en yüksek sıkıştırma basıncında (500MPa) ve 570 °C sinterleme sıcaklığında en yüksek yoğunluk sağlanmıştır. Minimum sıkıştırma basıncı olan 300 MPa'da ve 500 °C sinter sıcaklığında ise minimum ham ve sinterleme sonrası yoğunluk sağlanmıştır. Sinterleşme problemi ile oluşan gözeneklilik ve düşük sinterleme sıcaklığı Al4,5Cu alaşımlanma durumunu olumsuz etkilemiştir. En yüksek sıcaklık olan 640 °C'deki sinterleme işleminde ise yer yer bu Al-Cu konsantrsayon farklılıkları nedeniyle oluşan ötektik oran sebebiyle TM malzeme içinde kısmi sıvı fazların oluştuğu görülmüştür.

Anahtar kelimeler: Toz Metalurjisi, Alumix 123, Sinterlenebilirlik, Alaşımlama, Mikroyapı

INVESTIGATION OF SINTERING AND ALLOYING BEHAVIOR OF PREALLOY + PREMIXED ALUMIX 123 POWDER

ABSTRACT

Commercial Alumix 123 powder is an aluminum alloy metal powder similar in chemical composition to wrought Al2014. This powder is one of the primary alloys used in manufacturing, particularly in the aerospace and automotive industries. However, during the production and marketing processes, it is prepared as a premixed powder with an Al+4.5%Cu content, along with AlSiMg prealloyed metal powders. This can create some problems in obtaining the Al-4.5%Cu alloy during both the sintering and hot pressing processes. In this study, the microstructure and alloying properties of Alumix 123 powder were characterized by cold pressing under different compression pressures and sintering at three different temperatures for one hour. The microstructure and sinterability of the produced powder metal (PM) parts were investigated using optical and scanning electron microscope (SEM) studies. In particular, the Al-Cu alloying state of the premixed powder and the resulting phases were investigated by SEM-EDS analyses. Experimental results showed that the highest density was achieved at the highest compression pressure (500 MPa) and sintering temperature of 570 °C. The minimum density, both as-cast and after sintering, was achieved at the minimum compression pressure of 300 MPa and sintering temperature of 500 °C. The porosity resulting from the sintering problem and the low sintering temperature negatively affected the Al4.5Cu alloying process. However, during the sintering process at the highest temperature of 640 °C, partial liquid phases were observed to form within the PM material due to the eutectic ratio resulting from these Al-Cu concentration differences.

Keywords: Powder Metallurgy, Alumix 123, Sinterability, Alloying, Microstructure

1.GİRİŞ

Alüminyum alaşımları günümüzde çelikten sonra en çok kullanılan metalik mühendislik malzemeleridir (Altenpohl, D.G., 1980). Yüksek dayanım ve hafiflik özellikleri sayesinde çoğunlukla havacılık ve otomotiv gibi endüstrilerde kullanılmaktadır (Rudinsky et al., 2016), (C. Padmavathi, A. Upadhyaya, D. Agrawal, 2011). Günümüz teknolojisine bağlı olarak gelişen malzeme bilimi, endüstrideki gelişmelere paralel olarak önemli bir yer tutmaktadır. İmalatçılar, daha hafif ve daha mukavemetli yapılar elde etmek için maliyeti yüksek araştırmalar yapmaktadırlar. Alüminyum alaşımlarının çeşitli sinterleme teknikleriyle toz parçacıklarının konsolidasyonu yoluyla bu tür endüstriler için küçük parçalar üretmede etkili olduğu kanıtlanmıştır. Toz metalurjisi yöntemleri günden güne gelişmekte olan yöntemlerden biridir.

Alümix123 tozunun ana matrisi olan Al, ağırlıkça yaklaşık %94 oranında bulunur. Karışım elementi olan Cu %4,5 oranında bulunabilir. Diğer alaşım elementlerinden Si %0,8, Mg %0,5 oranındadır (Judge et al., 2017). Ön alaşımlı tozlar mikroyapı ve kimyasal özellikler bakımından birbiri ile aynıdır, alaşım tamamen homojendir. Alümix123 tozu, alaşımlandırılmış toz partiküllerine ağırlıkça %4,5 oranında saf bakır elementi eklenerek oluşturulan heterojen bir karışımdır (Özçatalbaş et al., 2018; Judge et al., 2017).

Toz metalurjisi üretim yönteminin amacı, metal tozlarını ergitmeden basınç ve sıcaklık yardımıyla dayanıklı cisimler haline sokmaktır. Toz metal partiküllerin üretimi, karakterizasyonu, sıkıştırılması ve sinterlenmesi aşamalarını kapsar. Deneyde kullandığımız Alümix123 toz malzeme, en yaygın toz üretim metodu olan atomizasyon ile üretilmiştir. Alüminyum esaslı toz metalurjisi uygulamalarında, özellikle Alumix 123 gibi ön karışımlı tozların sinterleme öncesi özelliklerini iyileştirmek ve oksit tabakasını kırmak amacıyla Mekanik Alaşımlama (MA) yöntemi kullanılabilmektedir (Delibalta, C. G., & Özçatalbaş, Y., 2018, ISLAC). Üretilmiş tozlar belirlenen basınçta sıkıştırılarak ham mukavemet kazandırılır. Sıkıştırma aşamasında parçacıklar arası bağ oluşmaz ve mekanik bir işlemdir, yaygın olarak oda sıcaklığında yapılır. Sinterleme ise bu üretim yönteminin en kritik noktasıdır. Bu işlemde malzeme ergime sıcaklığının altında, belirlenen sıcaklıkta ve sürede ısıtılarak atomlar arası bağlar oluşturulur. Böylece malzeme sertlik ve mukavemet kazanır. Sinterleme anında bir atom saniyede 10^14 kez titreşir. Katı hal ve sıvı hal sinterlemesi olmak üzere iki türü vardır. Eğer kullanılan toz bir karışım veya alaşım şeklinde ise tüm malzemelerin ergime sıcaklığının altında sinterleme yapıldığında buna katı hal sinterlemesi denir. En az bir alaşım elementinin ergime noktasının üzerinde sinterleme yapıldığında sıvı faz görmek mümkündür ve buna sıvı hal sinterlemesi denir (Özçatalbaş et al., 2018). Alümix123 tozu kimyasal kompozisyon bakımından dövme AAl2014 alaşımına benzer.

Alüminyum alaşımların toz metalurjisi ile üretiminde genellikle elementel tozlar, önalaşımlı tozlar veya ön karışımlı tozlar kullanılır. Difüzyonla birleştirilmiş alüminyum tozlarına literatürde rastlanılmamakla birlikte, alüminyum tozlarının oksitlenmesinin engellenmesi için polimer esaslı kaplamalarla kaplandığı bazı çalışmalar mevcuttur (Gökçe vd., 2017).

Bu çalışmada, Alumix 123 tozunun farklı basınçlarda soğuk preslenmesi ve sonrası üç farklı sıcaklıklarda bir saat sinterlenmesi ile oluşan mikroyapılar ve alaşımlanabilme özelliği karakterize edilmiştir.

2.MALZEME VE METOD

2.1 Malzeme

Bu çalışmada kullanılan toz malzeme atomizasyon yöntemiyle üretilmiştir. Kimyasal kompozisyon bakımından AA2014 malzemeye eşdeğerdir (Al, Cu, Si, Mg). AlSiMg ön alaşımlı alüminyum tozu içerisine, ağırlıkça %4,5 oranında Cu tozu karıştırılarak ön karışımlı toz elde

edilmiştir. Kimyasal bileşimi Çizelge 1'de verilen, Eckart Granulers tarafından üretilen Ecka Alumix123 olarak bilinen ön-karışımlı alüminyum esaslı tozdur ve yağlayıcı içermemektedir.

Çizelge.1: Deneyde kullanılan malzemenin kimyasal bileşimi (% ağırlık)

Alaşım	Al	Cu	Si	Mg
AlCuSiMg	94,3	4,5	0,7	0,5

2.2 Sıkıştırma

Sıkıştırma işlemi sinterleme öncesi toz parçacıkların mekanik olarak birleşmesiyle ham mukavemet ve ham yoğunluk sağlanarak şekillendirmek için yapılır. Sıkıştırma işlemi, tek yönlü zımba ile 31mm uzunluğunda ve 13 mm genişliğindeki bir kalıp boşluğunda gerçekleştirilmiştir. Sıkıştırma işlemi Instron marka, tek eksenli hidrolik pres makinesi vasıtasıyla 300, 400, 500 MPa olmak üzere üç farklı basınçta yapılmıştır. Presleme işlemi oda sıcaklığında gerçekleşmiştir.

Sıkıştırma işlemi sonrası numunelerin ham yoğunlukları, boyutları ölçülerek hesaplanan hacimlerine hassas terazide ölçülen ağırlıklarının bölünmesi ile hesaplanmıştır. Sinter sonrası yoğunluk ölçümleri Archimed prensibine göre yapılmıştır.

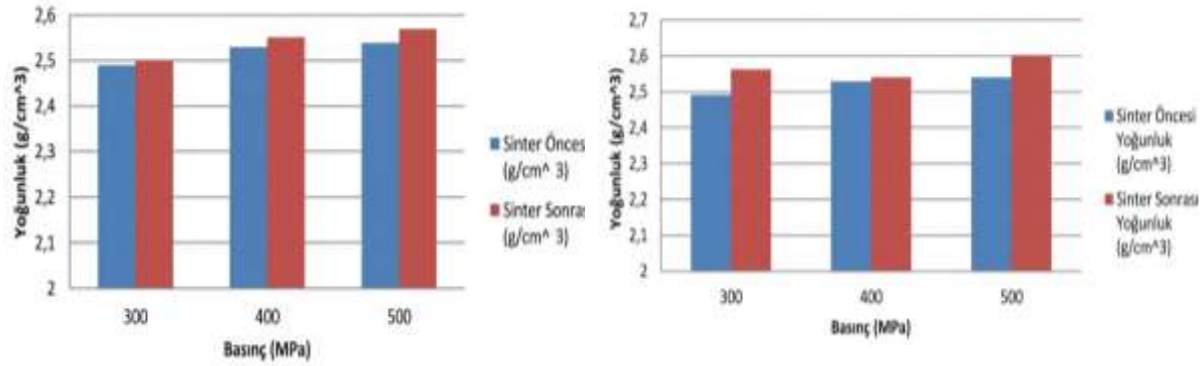
Sıkıştırma işleminde kullanılan kalıbı yağlamak için çinko stearat ve alkol karışımı kullanılmıştır. Bu yağlayıcının kullanım amacı; presleme sırasında toz parçacıkları ve kalıp arasındaki sürtünmeyi azaltmak, numunenin kalıptan çıkarılmasını kolaylaştırmak ve kalıp ömrünü uzatmaktır.

2.3 Sinterleme

Toz parçacıkların katı halde difüzyonu ile TM malzemeye sertlik ve mukavemet kazandırmak için sinterleme yapıldı. Bunun için 'Protherm Furnaces' marka tüp sinter fırını kullanıldı. Bu işlem, numunelerin oksidasyona uğramaması için kontrollü atmosfer ortamında gerçekleştirilmiştir. Sinterleme süresince fırına devamlı olarak argon gazı gönderilmiş ve ortamda olabilecek oksijeni bağlamak için de numunelerin üst yüzeyleri titanyum granürlerle kapatılmıştır.

Sinterleme işleminin mikroyapıya ve gözenekliliğe etkilerinin araştırılması için üç farklı sıcaklık seçilmiştir. 500, 570 ve 640°C'lerde; tüm numuneler için sinterleme süresi 60 dakika olarak belirlenmiştir. Isıtma hızı 10°C /dk olarak ayarlanmış, numuneler istenilen sıcaklıkta bir saat tutulduktan sonra fırın ortamında yavaş soğumaya bırakılmıştır.

2.4 Optik ve Taramalı Elektron Mikroskop (SEM) Analizi



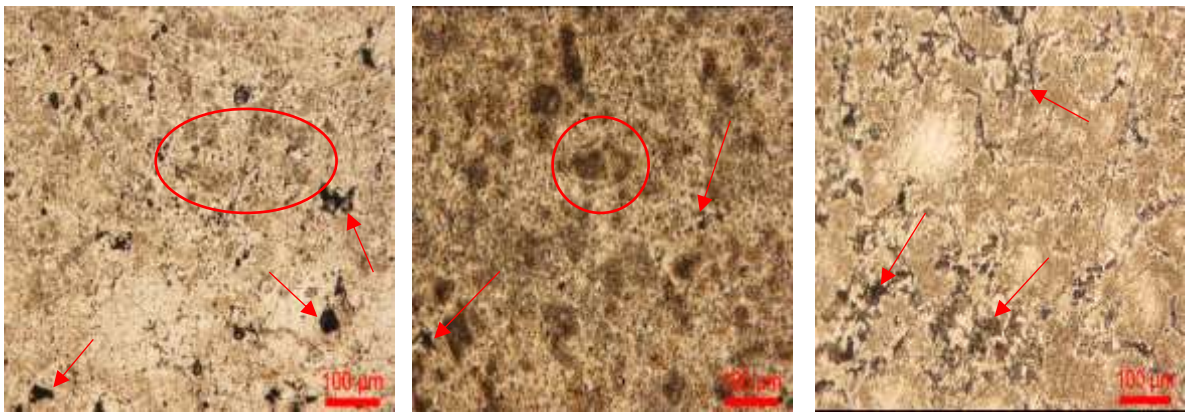
SEM analizinde kullanılacak olan 500 MPa'da preslenen ancak üç farklı sıcaklıkta sinterlenen TM numunelerin yüzeyleri uygun metalografik işlemlerden geçerek hazırlanmıştır. Sırasıyla 400, 800, 1200 gritlik zımparalarda zımparalanmış ve elmas çözelti ile parlatma işlemi yapılmıştır. Mikroyapıyı belirlemek için Kellers çözeltisi hazırlanarak yüzey dağlama işlemi gerçekleşmiştir.

Mikroyapı analizleri taramalı elektron mikroskobunda (SEM) yapılmıştır. SEM analizi esnasında malzeme EDS (Enerji Dağılımlı X-Işını Spektrometresi) analizine tabii tutulmuştur. Böylece yüzeydeki kimyasal kompozisyonlar incelenmiş, Al-Cu konsantrasyon analizleri yapılmıştır.

3. DENEYSEL BULGULAR

3.1 TM Numunelerin Ham ve Sinter Yoğunlukları

Yapılan yoğunluk ölçümlerinde genel olarak sıkıştırma basıncının artmasıyla, yoğunluğun arttığı söylenebilir. Ancak, 400 MPa dan sonra artan sıkıştırma basıncının ham yoğunluğa etkisinin olmadığı görülmektedir. Alumix 123 malzemenin sinterlenme davranışında sıcaklığın artmasıyla yoğunluğun da arttığı gözlenmiştir. 570 °C'de malzemenin sinter sonrası yoğunluğunun en yüksek ve dolayısıyla gözeneklilik oranının düşük olduğu görülmektedir.

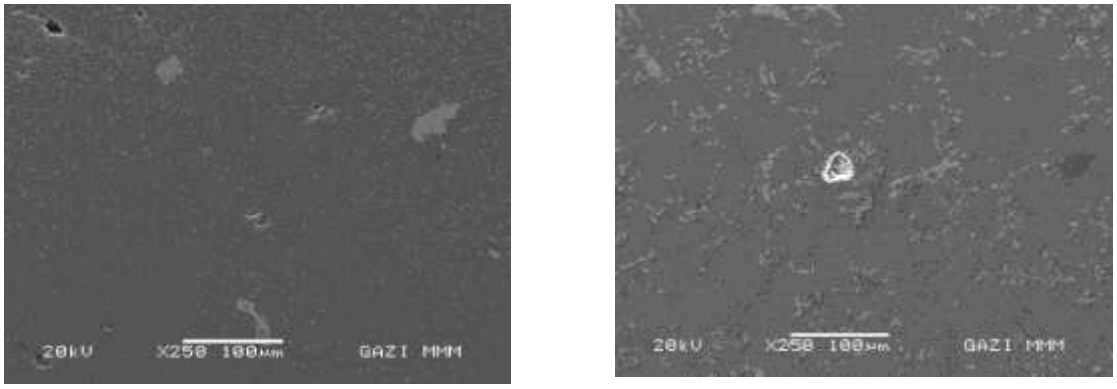


a) 500 °C'de sinterlenmiş b)570 °C'de sinterlenmiş

Şekil 1. TM numunelerin sıkıştırma basıncı ve sinter sıcaklığına bağlı değişen ham ve sinter yoğunlukları a) 500 °C'de b) 570 °C'de sinterlenmiş

3.2 Mikroyapı ve SEM Analizleri

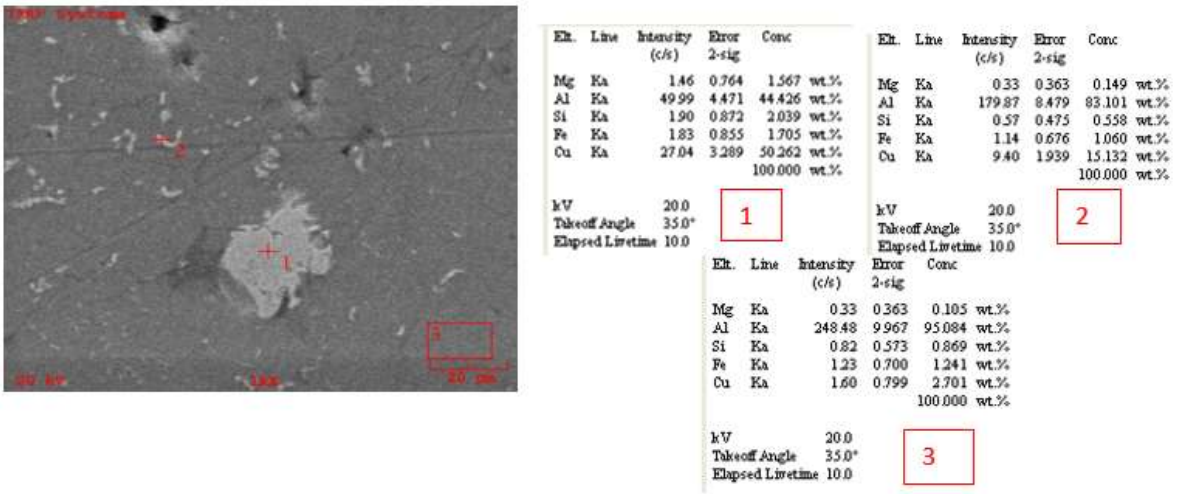
TM numunelerin sinterleme sonrası mikroyapısal değişimleri ile ilgili optik mikroskop görüntüleri Şekil 2'de verilmiştir. Burada özellikle düşük sıcaklıkta sinterleme ile oluşan sinter sonrası gözenekler açıkça görülmektedir (Şekil 2a'da oklarla gösterildi). Bununla birlikte yer yer daha koyu renk tonunda bakırca zengin fazlar da çember içinde gösterilmiştir. Sinter sıcaklığı 570°C olan numunede ise Cu'ca zengin fazlar görülmekle birlikte (Dağlama bu numunede fazla olmuştur) çok daha küçük ve az sayıda gözenek oranı görülmektedir. 640 °C'de sinterlenmiş TM malzemesinde ise çok yoğun olarak muhtemel sıvı faz olumundan kaynaklı mikro boşluklar mevcuttur.



a) 500 °C'de sinterlenmiş b) 570 °C'de sinterlenmiş c) 640 °C'de sinterlenmiş

Şekil 2. 500 MPa basınçta sıkıştırılmış ve farklı sıcaklıklarda sinterlenmiş TM numunelerin mikroyapıları

Şekil 3'de 500°C ve 640°C sıcaklıklarda sinterlenmiş TM numunelerin SEM görüntüleri verilmiştir. Düşük sıcaklıkta sinterlenmiş numunede sinter yetersizliği nedeniyle oluşmuş



gözenekler açıkça görülmektedir. Ayrıca karışım olarak bulunan Cu parçacıkları da neredeyse orijinal başlangıç formlarını korumakta ve Al matris içinde yeterince çözünmedikleri anlaşılmaktadır. Bununla birlikte özellikle üst kısımlarda az oranda da olsa Cu'ca zengin çökelti fazları dikkat çekmektedir. Bu bakımdan bu sıcaklıkta Al-Cu alaşımla oranının düşük olması muhtemeldir. Ancak Şekil 3b'de durum farklıdır ve Al matris de neredeyse homojen yayınmış denebilecek oranda Cu'ca zengin çökelti fazların oluştuğu görülmektedir. Ayrıca bu fazların yoğun olduğu bölgede sıvı faz kaynaklı gözenek oluşumu da dikkat çekicidir.

a) 500°C'de sinterlenmiş b) 640°C'de sinterlenmiş

Şekil 3. 500°C ve 640°C sıcaklıklarda sinterlenmiş TM numunelerin SEM görüntüleri

Şekil 4'de ise 500°C'de sinterlenmiş TM numunenin SEM görüntüsü ve EDS analiz sonuçları verilmiştir. Şekil 4a'daki SEM fotoğrafında yaklaşık 20 -25 µm boyutlarında Cu'ca zengin fazın yanında yer yer çevresinde çok daha küçük çökelti fazları görülmektedir. İri parçacık EDS analizinde %50 civarında Cu ve %44 civarında ise Al içerdiği görülmektedir (Şekil 4b). Diğer küçük boyutlu çöketi fazların ise %15 civarında Cu içerdiği görülmektedir. Diğer taraftan Al matrisin Cu içeriğinin %2,7 oranında olduğu 3 numaralı EDS analizinden anlaşılmaktadır. Bu sonuçlar değerlendirildiğinde, %4,5 Cu içeren Al alaşımının bu sıcaklıkta sağlanamadığı söylenebilir. Gerek sinterleme süresi ve gerekse sıcaklığı bakımından yeterli olmadığı görülmektedir.

a) 500°C'de sinterlenmiş b) EDS analiz sonuçları

Şekil 4. 500°C'de sinterlenmiş TM numunenin SEM görüntüsü ve EDS analiz sonuçları

Şekil 3b'de verilen 640 °C sıcaklıklarda sinterlenmiş TM malzeme SEM görüntüsünde ise iri Cu'ca zengin parçacıklar bulunmasa dahi çok daha küçük boyutlardaki çökelti fazların varlığı gösterilmiştir. Ancak bu sıcaklıkta oluşan aşırı sıvı faz, makro boyuta dahi TM malzemenin biçimini bozduğu için bu karışım için uygun sinter sıcaklığı olmadığını göstermektedir.

4. SONUÇ

Bu deneysel çalışma bulgularına göre aşağıdaki sonuçlar özetlenebilir;

- Yapılan yoğunluk ölçümlerinde sıkıştırma basıncının artmasıyla, yoğunluğun arttığı ve gözenekliliğin azaldığı, ancak 400 MPa'dan sonra artan sıkıştırma basıncının ham yoğunluğa etkisinin olmadığı belirlenmiştir.

- En düşük sinterleme sıcaklığı olan 500°C'de katı hal sinterlenmesi gerçekleşmiş ancak, bakır parçacıkları neredeyse başlangıçtaki yapısını korumuştur. Bununla birlikte kısmi olarak Cu'ca zengin çökeltilerde meydana gelmiştir. Fakat al matriste Cu segregasyonu çok yoğundur ve bakırın alüminyuma difüzyonu yetersiz kalmıştır.

- 570°C sinterleme işlemi ile mikroyapıda daha küçük çökeltiler şeklinde bakırca zengin fazlar görülmekle gözenek yoğunluğunda azalma belirlenmiştir. Bu sıcaklıkta sinterlenen numunelerde belirgin bir sıvı faz oluşumuna rastlanmamış ve TM numuneler fiziksel bütünlüğünü korumuştur.

- En yüksek sıcaklık olan 640°C'deki sinterleme işleminde ise yer yer Al-Cu konsantrasyon farklılıkları nedeniyle oluşan ötektik oran sebebiyle TM malzeme içinde sıvı fazların oluştuğu görülmüştür. Mikroyapıda yaygın olarak küçük boyutlardaki çökelti fazların varlığı belirlenmiştir. Ancak bu sıcaklıkta oluşan aşırı sıvı faz, makro boyuta dahi TM malzemenin fiziksel bütünlüğünü bozmuştur.

ÖZET

Toz metalurjisi (TM) ürünü sinter parçalar ve TM yöntemiyle üretilen metal matrisli kompozit (MMKp) malzemeler havacılık, savunma sanayii ve otomotiv endüstrisinde yaygın olarak kullanılan mühendislik ürünleridir. Bu malzemelerin üretiminde özgül dayanımlarının yüksek olması sebebiyle Aluminyum alaşımı tozların da yaygın kullanımı mevcuttur. TM parçaların üretiminde genellikle ön alaşımlı Al esaslı tozlar tercih edilirken kısmen ön karışımlı tozlarında kullanımı mevcuttur. Çünkü, TM ile alüminyum alaşımlarının üretimi, elementel alüminyum tozu, alaşım katkı tozları ve yağlayıcı tozdan oluşan bir toz ön karışımıyla başlar. Zira, alüminyum alaşımlarının mekanik özellikleri, bazı alaşım elementlerinin mikro veya makro ölçekte küçük ilaveleriyle geliştirilebilir. Ticari Alumix 123 tozunun üretimi ve piyasaya arz sürecinde Al esaslı AlSiMg içerikli ön alaşımlı metal tozları ile birlikte, %4,5Cu içeriği ile ön karışımlı toz olarak hazırlanır. Bu durum ise, gerek sinterleme veya gerekse sıcak presleme sürecinde Al%4,5Cu alaşımının homojen dağılımlı sağlanmasında problemler oluşturabilir. Bu çalışmada, Ticari Alumix 123 tozunun 300, 400 ve 500 MPa sıkıştırma basınçlarında soğuk preslenmesi sonrası 500, 570 ve 640 °C sıcaklıklarda bir saat süre ile sinterlenmesi ile üretilen TM parçaların mikroyapısı ve özellikle mekanik özellikleri incelenmiştir. Sinter sıcaklıklarının üretilen TM malzemelerin sertliklerine etkileri belirlenmiştir. ASTM B528-16(2020) standardına göre hazırlanan TM numunelere uygulanan testlerle çapraz kırılma dayanımları (ÇKD) belirlenmiştir. Elde edilen sonuçlar göstermiştir ki, artan sıkıştırma basıncı ve sinter sıcaklıkları ile birlikte üretilen TM malzemelerin ham ve sinter yoğunlukları artarken sertlikleri de artmaktadır. Bununla birlikte, yüksek sıkıştırma basınçlarında ve fakat düşük sinterleme sıcaklıklarındaki TM malzemelerin ÇKD değerleri önemli ölçüde düşmüştür. Ayrıca, 570 °C'de sinterlenen fakat 300 MPa ile 500 MPa'da preslenmiş malzemelerin ÇKD değerlerinde belirgin bir fark görülmemiştir. 640 °C'de sinterleme sürecinde oluşan sıvı faz sebebiyle TM malzemelerde fiziksel deformasyon meydana gelmiştir.

Anahtar kelimeler: Toz Metalurjisi, Alumix 123, Sinterleme sıcaklığı, Sertlik, Çapraz Kırılma Dayanımı

THE EFFECT OF COMPACTION PRESSURE AND SINTERING TEMPERATURES ON THE MECHANICAL PROPERTIES OF TM PARTS PRODUCED WITH PRE-ALLOYED AND MIXED ALUMIX 123 POWDER

ABSTRACT

Sintered parts produced by powder metallurgy (PM) and metal matrix composite (MMCp) materials produced by the PM method are widely used engineering products in the aerospace, defense, and automotive industries. Aluminum alloy powders are also widely used in the production of these materials due to their high specific strength. While prealloyed Al-based powders are generally preferred in the production of PM parts, premixed powders are also used to some extent. This is because the production of aluminum alloys using PM begins with a powder premix consisting of elemental aluminum powder, alloy additive powders, and lubricant powder. The mechanical properties of aluminum alloys can be improved with small additions of certain alloying elements at the micro or macro scale. During the production and marketing of commercial Alumix 123 powder, it is prepared as a premixed powder with a 4.5% Cu content, along with Al-based AlSiMg-containing prealloyed metal powders. This can create problems in ensuring a homogeneous distribution of the Al4.5% Cu alloy during both sintering and hot pressing. In this study, the microstructure and especially the mechanical properties of PM parts produced by cold pressing commercial Alumix 123 powder at compression pressures of 300, 400 and 500 MPa and then sintering at temperatures of 500, 570 and 640 °C for one hour were investigated. The effects of sinter temperatures on the hardness of the produced TM materials were determined. Transverse rupture strength (TRS) was determined by tests applied to PM samples prepared according to ASTM B528-16(2020). The results obtained showed that with increasing compression pressure and sinter temperatures, the green and sinter densities of the produced PM materials increased, while their hardness also increased. However, the TRS values of PM materials at high compression pressures but low sintering temperatures decreased significantly. In addition, no significant difference was observed in the TRS values of materials sintered at 570 °C but compressed at 300 MPa and 500 MPa. Physical deformation occurred in the PM materials due to the liquid phase formed during the sintering process at 640°C.

1.GİRİŞ

Alüminyum alaşımları günümüzde çelikten sonra en çok kullanılan metalik mühendislik malzemeleridir [1]. Düşük yoğunluk (2,7 gr/cm3), yüksek korozyon dayanımı, yüksek elektriksel iletkenlik ve diğer mühendislik malzemelerine göre yüksek spesfik dayanım gibi özellikleri sebebiyle alüminyum alaşımlarına ilgi yüksektir. Alüminyum alaşımlarının günümüzde daha çok ilgi görmesinin başka bir sebebi ise taşımacılık sektöründe yaşanan gelişmelerdir. Özellikle otomotiv ve havacılık endüstrisinde daha hafif, dolayısıyla daha az yakıt tüketen ve çevreye daha az zarar veren araçlar üretimi konusunda çalışmalar artmıştır. Daha hafif araçlar üretmek için günümüzde tercih edilen malzemelerden biri de özgül dayanımı yüksek olan alüminyum alaşımlarıdır [2, 3]. Toz metalurjisi (TM), hassas ve karmaşık parçaların uygun maliyetli ve sürdürülebilir bir şekilde seri üretimi için kullanılabilen çeşitli bir üretim tekniğidir. Döküm veya şekillendirme gibi geleneksel metal işleme yöntemleriyle büyük miktarlarda küçük ve karmaşık bileşen üretmek, genellikle pahalı ve israfa yol açan ikincil işleme operasyonları gerektirir. Bazı durumlarda, çok az veya hiç ikincil işleme operasyonu gerektirmeyen net veya net şekle yakın bileşenler üretmek için geleneksel metal işleme yöntemleri yerine TM kullanmak daha uygundur [4]. TM ile alüminyum alaşımlarının üretimi, ana matriste alüminyum tozu, alaşım katkı tozları ve yağlayıcı tozdan oluşan bir toz ön karışımıyla başlar [5]. Ön karışım, ham mukavemetli malzeme oluşturmak için tek eksenli kalıp sıkıştırmasına tabi tutulur ve ardından sinterlenir. Alumix 123 ticari alaşımdaki metal tozu, Al2014'e dayalı, alüminyum-bakır esaslı olan ilave olarak kısmen magnezyum-silisyum içeren alaşımdır [6]. Bu alaşım sistemi, ASTM Standardı B595'te belirtilen 'AC-2014' tanımıyla standartlaştırılmış olup, şu anda ticari olarak 'Alumix 123' ticari adı altında sunulmaktadır [7]. Fakat bu alaşım AlSiMg ön alaşımlı toza sonradan ilave edilen ve ağırlıkça %4,5 Cu içeren aynı zamanda ön karışımlı toz niteliğindedir. Bu durum ise uygun sintersıcaklığı, süresi veya sıkıştırma basıncı kullanılmadığı sürece önemli oranda Cu segregasyonlarına, homojen olmayan çökelti dağlımına ve dolayısıyal TM ürünün mekanik özelliklerinde önemli problemlere sebep olabilmektedir.

Bu çalışmada, TM yöntemiyle Alumix 123 tozundan üretilen toz metal numunelerde uygulanan presleme basıncı ve sinterleme sıcaklığının malzemenin yoğunluk, mikroyapı ve mekanik özellikleri üzerindeki etkilerini incelenmiştir.

2. MALZEME VE METOT

2.1 Malzeme

Deneysel çalışmalarda Alumix 123 tozu kullanılmıştır**. Alumix 123**, atomizasyonla üretilmiş alüminyum esaslı metal tozları ile elektroliz yöntemiyle elde edilmiş elektrolitik bakır tozlarının belirli oranlarda karıştırılmasıyla oluşturulan bir toz metalurjisi alaşımıdır. İçeriğinde Al–Cu–Mg–Si elementleri bulunmaktadır. Kullanılan Alumix 123 tozunun kimyasal bileşimi Tablo 1'de yer almaktadır.

Tablo 1. Alumix 123'ün kimyasal bileşimi

Element	Al	Cu	Mg	Si	Diğer
Ağırlıkça %	94.3	4.5	0.5	0.6	0.1

2.2. Deneysel Metot

Ham mukavemetli numuneler, ASTM B528-16(2020) standardında belirtilen boyutlarda ve hacimde şekillendirebilecek kalıp içerisine 7.8 gr Alumix 123 tozunun doldurularak

sıkıştırılmasıyla oluşturulmuştur. Alüminyum tozlarının sertlikleri düşük olduğu için tek eksenli presleme ile kolaylıkla yüksek yoğunluk değerlerine ulaşılabilmektedir [8]. Instron 8503 Tek Eksenli Hidrolik Pres vasıtasıyla soğuk presleme işlemi yapılmıştır. Malzemeler 3 farklı gruba ayrılıp sırasıyla 300MPa, 400MPa ve 500MPa basınç altında preslenmiştir. Farklı basınçlarda preslenmiş bu numunelerin basınç farkına göre oluşan ham yoğunluk boyutları Tablo 2'de verilmiştir.

Tablo 2. Sıkıştırma basıncına göre değişen TM ham numune boyutları

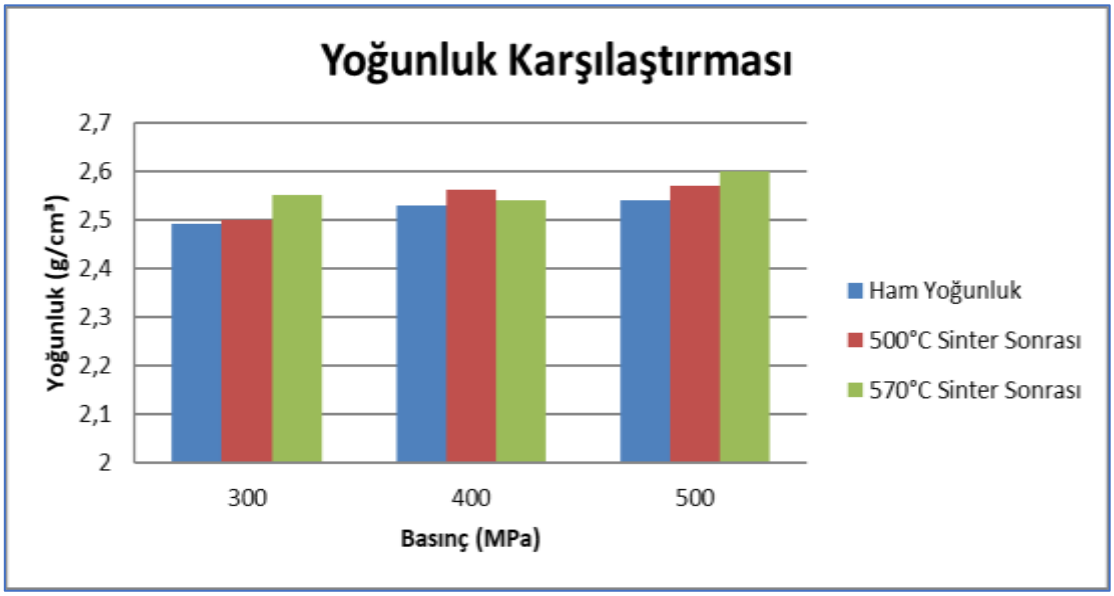
Basınç(MPa)	300MPa	400MPa	500MPa
Yükseklik (mm)	7.80	7.75	7.60
Genişlik (mm)	12.88		
Boy (mm)	31.2		

Üç farklı basınç altında preslemenin sebebi presleme basıncının malzemede meydana getirdiği mekanik özellik farklarını gözlemlemektir. Presleme işlemi oda sıcaklığında gerçekleşmiştir. Sıkıştırma işleminde kullanılan kalıbı yağlamak için çinko stearat ve alkol karışımı kullanılmıştır. Presleme işlemi sonrası numunelerin ham yoğunluğu ölçülmüştür ve ardından sinterleme işlemine geçilmiştir.

Sinterleme işlemi, toz parçacıkların birbirine bağlanmasını sağlayan, böylece dayanımlarını artıran, yüzey alanlarını düşüren bir ısıl süreçtir [9]. Sinterleme işlemiyle malzemeye sertlik ve mukavemet kazandırılmış, toz partikülleri arasındaki difüzyonu artırarak mekanik özelliklerin gelişmesi sağlanmıştır. Üç farklı basınç altında preslenen numunelerin her biri sırasıyla 500°C, 570°C ve 640°C'de 10°C /dk ısıtma hızıyla, 60dk sinterlenmiş ardından fırın ortamında yavaş soğumaya bırakılmıştır. Sinterleme işlemi Protherm marka sinter fırını yardımıyla yapılmıştır. Alüminyum tozları hangi yöntemle üretilirse üretilsin, açık atmosfer ortamında oksijene olan yüksek afinitesi sebebiyle hızla oksitlenen bir metaldir. Bu durum ise sinterlemeyi ve dolayısıyla TM malzemenin dayanımını olumsuz etkiler [10]. Sinterleme sırasında oksitlenmeyi ve korozyonu önlemek amacıyla numuneler alüminyum folyo ile kaplanmış, folyoların üzerine ise oksijen tutucu olarak titanyum parçacıkları yerleştirilmiş ve fırın ortamı argon gazı altında tutulmuştur.

Arşimet Prensibi yöntemiyle Weightlab WSA-224T analitik terazi yardımıyla yoğunluk ölçümü yapılmıştır. Arından presleme basıncı ve sinterleme sıcaklığının malzemenin kırılmaya karşı gösterdiği direnç üzerindeki etkisini incelemek amacıyla INSTRON 3400 Serisi Üniversal Çekme Dayanım Test Cihazı yardımıyla numunelere Çapraz Kırılma Dayanım (ÇKD) testi yapılmıştır. Bu test ASTM B528-16 (2020) standardına göre yapılmıştır.

Bu işlem sonrasında malzemelerin mikroyapısı Nikon Eclipse E100 cihazı yardımıyla optik mikroskop altında incelenmiştir. Bu amaçla, alüminyum ve alaşımı malzemelerde tercih edilen Keller's Reaktfi dağlayıcı ile numuneler 15 saniye dağlanmıştır. Keller's Reaktifini elde etmek için 2,5 ml HNO_3 (nitrik asit) 1,5 ml HCl (hidroklorik asit), 1,0 ml HF (hidroflorik asit) ve 95 ml saf su kullanılmıştır.



Ardından sinter sıcaklığının malzemenin sertliğine etkisini belirlemek için yalnızca 500 MPa basınç altında soğuk preslenen numuneler kullanılmıştır. Bu numuneler sırasıyla 500°C, 570°C ve 640°C'de sinterlenmiş olan üç farklı numuneye Duravision 2000 Emco Test Sertlik Cihazı yardımıyla Brinell Sertlik testi uygulanmıştır. Her üç numune yüzeyinde 3 farklı bölgeden 31.25 kgf yük uygulanmıştır ve bu yük altında malzemelerin sertliği ölçülmüştür.

3. DENEYSEL BULGULAR VE TARTIŞMA

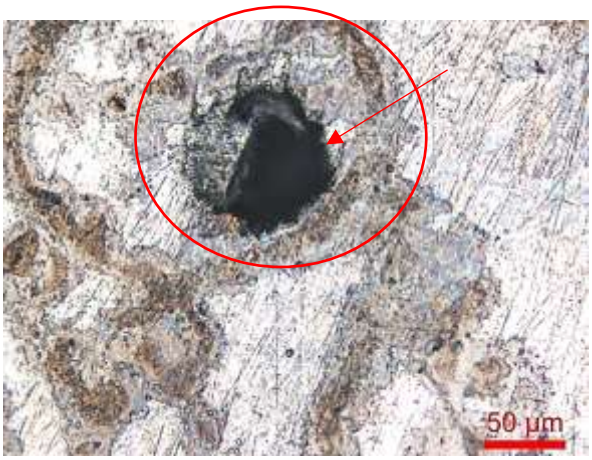
3.1 Sıkıştırma Basıncı ve Sinterleme Sıcaklığının Yoğunluğa Etkisi

Şekil 1'de görüldüğü üzere uygulanan presleme basıncının artmasıyla ham yoğunluğun ve sinterleme sonrası ölçülen yoğunluğun arttığı görülmektedir. Artan presleme basıncı ile toz taneleri arasındaki boşluklar kapanır, parçacıklar arası mekanik girişim artar. Buradan yola çıkarak presleme basıncının artmasının yoğunluğu da arttırdığını söylenebilir.

Sinter işlemi sonrasında malzemelerin yoğunluklarının ham yoğunluklarından fazla olduğu görülmektedir. Her sıcaklıktaki sinterleme işlemi yoğunluk artışı sağlamıştır. Sinter sonrası en yoğun malzemenin 500MPa basınç altında preslenmiş ve 570°Cde sinterlenmiş malzeme olduğu görülmektedir. Sinter sıcaklığı arttığında malzeme yoğunluğu da buna bağlı olarak artar. Sinterleme sıcaklık yükseldikçe katı hal difüzyonu artar gözenekler küçülür ve taneler birbirine daha yoğun bağlanır. Presleme basıncın artması her zaman yoğunluğu artırmaz. Özellikle aşırı yüksek presleme basıncından sonra ham yoğunlukta düşme gözlemlenebilir. Buna geri yaylanma sebep olmaktadır [11].

Şekil 1. Sıkıştırma basıncı ve sinterleme sıcaklıklarının TM numune yoğunluklarına etkisi

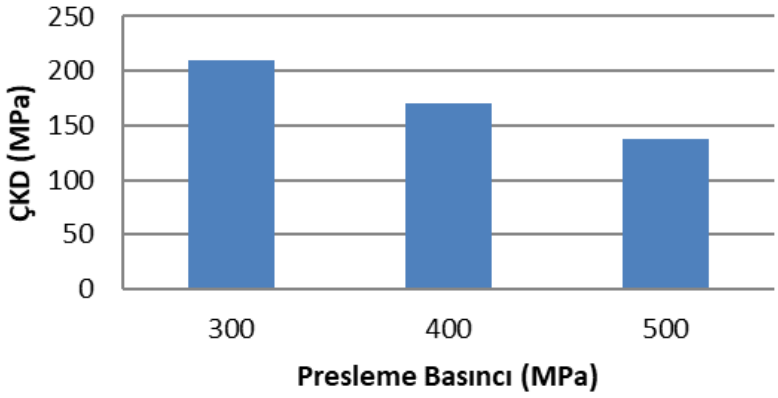
3.2 Sıkıştırma Basıncı ve Sinterleme Sıcaklığının Mikroyapıya Etkisi



Şekil 2'de 500 MPa'da preslenen TM numunelerin üç farklı sıcaklıkta sinterlendikten sonraki mikroyapıları verilmiştir. Şekil 3a'daki en düşük sinterleme sıcaklığında halen iri Cu parçacıklarının varlığı görülmektedir. Bu sıcaklığın Cu↔Al yayınımı için yeter sıcaklık olmadığı görülmektedir. Ayrıca, bu malzemede tane sınırlarında sinterleme yetersizliği ve kısmi gözenekler mevcuttur (okla gösterildi). Cu'ca zengin parçacıklar ve bölgeler çember içinde gösterilmiştir. 570°C'de sinterlenmiş malzemede ise sinterleşmenin çok daha iyi olduğu görülmektedir. Bununla birlikte halen Cu'ca zengin parçacıkların yoğunluğu dikkat çekicidir. Özellikle tane sınırlarını takip eden dağılımda açık renk tonlamadaki fazın sinter sırasında ötektik oranda Al-Cu alaşımı ile oluşan sıvı fazın (ötektik sıvı sıcaklığı 548 °C) olabileceği ihtimali de değerlendirilmelidir (Şekil 2b). Şekil 2c'de 640 °C'de sinterlenmiş malzemenin mikroyapısı görülmektedir. Burada oluşan 70-80 µm çapındaki gözeneğin sıvı faz nedenli olduğu gayet açıktır. Gözenek çevresinde oluşmuş Cu'ca zengin halkanın merkezine doğru ötektik Al-Cu alaşım oranın sıvı faza sebep olduğu söylenebilir.

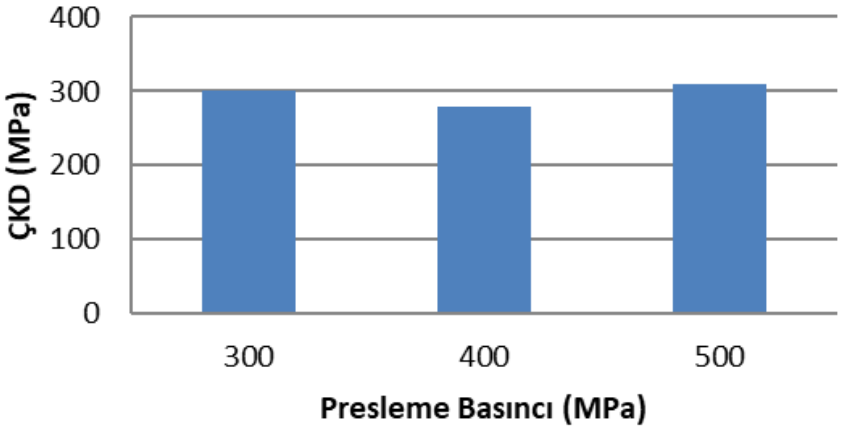
a) 500 °C'de sinterlenmiş malzeme

b) 570 °C'de sinterlenmiş malzeme



c) 640 °C'de sinterlenmiş malzemenin

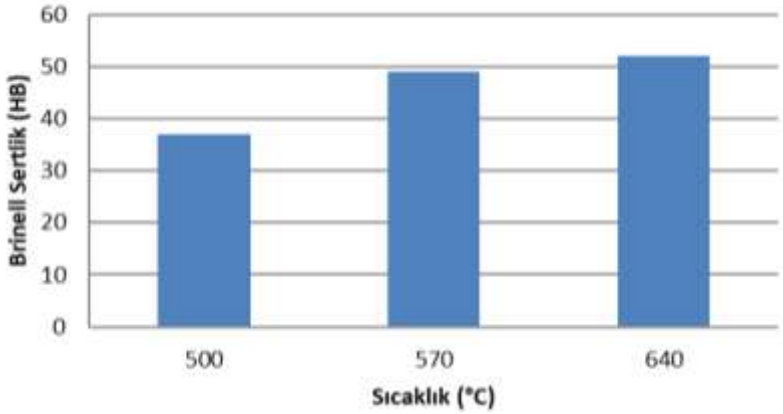
Şekil 2. Sinterleme sıcaklığının mikroyapıya etkisi



3.3 Sıkıştırma Basıncı ve Sinterleme Sıcaklığının ÇKD'ye Etkisi

Şekil 3'de 500 °C'de sinterlenmiş malzemelerin Çapraz Kırılma Dayanımı (ÇKD) görülmektedir. 300MPa basınç altında sinterlenmiş numunenin ÇKD'si 210MPa , 400'de 170MPa ve 500'de 137 MPa olduğu görülmektedir. Şekilde 300MPa basınçla preslenmiş malzemenin en yüksek dayanıma sahip olduğu görülüyor. Ancak 500 MPa basınçtaki ÇKD değeri çok daha düşüktür. Genel olarak basıncın artması ile birlikte kırılma dayanımının artması beklenirken burada düştüğü görülmektedir. Yüksek presleme basıncı parçacıklar arası boşlukları kapalı gözenekler haline getirebilir. Kapalı gözenekler de sinterleme sırasında gaz çıkışını engeller ve bunun sonucunda presleme doğrultusuna dik (radyal yönde) parallel çatlaklar meydana getirebilir. Bu durum özellikle düşük sinterleme sıcaklıklarındaki zayıf sinterleşme sebebiyle de dayanımı düşüren bir etken olabilir. Bunu yanında, yüksek sıkıştırma basıncı sonrası ve kalıptan çıkış sırasındaki geri yaylanmanın oluşturabileceği radial çatlakların düşük sinter sıcaklıklarında benzer etkileri göstermesi muhtemeldir. Bu alaşım için bu sinter süresi ve sıcaklığında uygun presleme basıncının 300 MPa olacağı söylenebilir.

Şekil 3. 500 °C'de sinterlenmiş malzemelerin presleme basıncına göre ÇKD değerleri



Şekil 4 incelendiğinde ise sinter sıcaklığının artmasıyla beraber her sıkıştırma basıncı için kırılma dayanımının önemli miktarda arttığı görülmüştür. 300MPa basınçla sinterlenen numunenin ÇKD değeri 300 MPa , 400'de 280 MPa ve 500'de ise 310 MPa olmuştur. Bu sonuçlar, artan sinterleme sıcaklığı ile birlikte önemli miktarda sinterleşmenin gerçekleştiğini ve TM malzemelerin dayanımlarının da arttığını göstermektedir. Bununla birlikte 300 ve 500 MPa'da preslenen numunelerin ÇKD değerlerinin çok yakın olması da dikkat çekicidir.

Şekil 4. 570 °C'de sinterlenmiş malzemelerin presleme basıncına göre ÇKD değerleri

3.4 Sinterleme Sıcaklığının TM Malzeme Sertliğine Etkisi

Şekil 5 incelendiğinde 500MPa basınçta preslenmiş malzemelerin artan sinterleme sıcaklıklarına bağlı olarak sertliklerinde de artış gözlenmiştir. 500°C'de sinterlenen malzemenin ortalama sertliği 38 HB_W ölçülürken 570°C'de 49HB_W ve 640°C'de 52HB_W ölçülmüştür. Bu durum, TM numunelerin artan sinter sıcaklığı ile birlikte sinterleşme oranının ve yoğunluğun artmasının yanında, Al matriste Cu difüzyonunun artması ile alaşımla oranının artmasına bağlanabilir. Ancak 640 °C'de oluşan sıvı faz sebebiyle, TM numune dışında katılaşan Cu'ca zengin ötektik karışım genel olarak malzeme hacminde Cu kaybına ve gözenekliliğe sebep olmuştur. Bu durum, belirtilen sıcaklıkta yeterli sertlik artışının görülmemesine neden olabilir.

Şekil 5. Sinterleme Sıcaklığının TM Malzeme Sertliğine Etkisi

4. SONUÇ

Bu çalışmanın amacı kapsamında yapılan deneysel çalışmalar sonucunda aşağıdaki sonuçlar özetlenebilir;

500MPa basınç altında preslenen malzemelerin mikroyapısı incelendiğinde 500 °C'de sinterlenen malzemenin mikroyapısında yeter yayınım sıcaklığı olmamasından dolayı iri Cu parçacıklarının varlığı gözlemlenmiştir.Aynı zamanda kısmi gözenekler de mevcuttur. 570 °C'de sinterlenen malzemede ise sinterleşmenin çok iyi olduğu ama hala Cu'ca zengin parçacıkların da olduğu gözlemlenmiştir. 640 °C'de ise ötektik Al-Cu alaşım oranının sıvı faza sebep olduğu söylenebilir.

Yapılan çalışmalar sonucunda, presleme basıncı arttıkça numunelerin sinter öncesi yoğunluklarının (ham yoğunluk) arttığı, sinter işlemi sonrasında ise malzemenin yoğunluklarının ham yoğunluklarından fazla olduğu gözlemlenmiştir. Her sıcaklıktaki sinterleme işlemi sonrasında yoğunluğun arttığı gözlemlenmiştir. Sinter sonrası en yoğun malzeme 500MPa basınç altında sıkıştırılmış 570 °C'de sinterlenmiş malzemedir. Sinter sıcaklığı artışıyla doğru orantılı olarak yoğunluk da artar.

Çapraz Kırma Dayanım testinde 500 °C'de sinterlenmiş malzemelerde 300MPa basınçla preslenmiş malzemenin en yüksek dayanıma sahip olduğu görülüyor (210MPa). Bu alaşım için bu sinter süresi ve sıcaklığında uygun presleme basıncının 300 MPa olacağı söylenebilir.

570 °C'de sinterlenmiş malzemelere bakıldığında ise sinter sıcaklığının artmasıyla beraber her sıkıştırma basıncı için kırılma dayanımının önemli miktarda arttığı görülmüştür. En yüksek dayanım 500 Mpa basınç altında preslenip 570 °C'de sinterlenmiş malzemede gözlemlenmiştir (310MPa).

Brinell sertlik testinde 500 MPa'da preslenen TM numunelerin sertliği, sinterleme sıcaklığının 500°C'den 640°C'ye artmasıyla 38 HBW'den 52 HBW'ye yükselmiştir. Sertlik artışı, sinterleşme ve yoğunluğun gelişmesinin yanı sıra Al matristeki Cu difüzyonunun artmasına bağlanmıştır. Ancak 640°C'de oluşan sıvı faz nedeniyle Cu kaybı ve gözeneklilik meydana geldiğinden, bu sıcaklıkta sertlik artışı sınırlı kalmıştır. Sertliği en yüksek malzemenin 570MPa basınçta preslenip 640°C'de sinterlenen malzeme olduğu görülmüştür (52 HBW).

ÖZET

Et ürünleri, yüksek protein içeriğiyle beslenmede önemli bir yere sahiptir. Bununla birlikte, hayvansal protein kaynaklarının sürdürülebilirliği ve maliyeti, bitkisel protein alternatiflerinin kullanımını arttırmaktadır. Acı bakla (*Lupinus albus*) yüksek oranda protein, lif ve biyoaktif bileşikler içeren bir baklagildir. Son yıllarda, acı bakla unu gıda endüstrisinde fonksiyonel bileşen olarak kullanılmaktadır. Bu çalışmada, kırmızı et köftesine farklı oranlarda (%10, %20 ve %30) acı bakla (Lupinus albus) ilave edilerek deneysel köfte örnekleri hazırlanmıştır. Deneysel köfte örneklerinin, fiziksel (ağırlık kaybı, çap küçülmesi), renk analizleri (L, a ve b değeri), mikrobiyolojik (toplam mezofil aerob genel canlı sayısı, koliform bakteri sayısı ve maya-küf sayısı) ve duyusal özellikleri incelenmiştir. Acı bakla, ortalama 60 dakika haşlanarak kabukları soyulmuş ve blenderda öğütülerek hamur haline getirilmiştir. Et ağırlığı esas alınarak farklı oranlarda acı bakla ilave edilen et köftelerine % 2 oranında tuz ilave edilmiştir. Köfteler airfryer'da 180 °C'de 5 dakika pişirilmiş ve pişirme süresince termal kamera ile sıcaklık dağılımları kaydedilmiştir. Artan bakla oranı ile köftelerde ağırlık kaybının arttığı ve çapın küçüldüğü belirlenmiştir. Renk analizinde L* (açıklık), a* (kırmızılık) ve b* (sarılık) değerlerinde önemli farklılıklar gözlenmiştir. Acı bakla unu miktarı arttıkça L değeri yükselmiştir. Mikrobiyolojik analizlerde koliform bakteri tespit edilebilir düzeyin altında (<10 log kob/g) tespit edilmiştir. Maya-küf sayısı 1.1 $\log_{10}$ kob/g, toplam aerob mezofil genel canlı sayısı ise 1.8 $\log_{10}$ kob/g olarak belirlenmiştir. Sekiz kişilik panel ile yapılan duyusal analizlerde, %10 bakla unu içeren köftelerin renk, aroma ve genel beğeni açısından en yüksek puanları aldığı saptanmıştır. Sonuç olarak, acı bakla unu et köftesi üretiminde bitkisel protein katkısı olarak değerlendirilebilir; ancak yüksek oranların ürünün duyusal özelliklerini olumsuz etkilediğini söylemek mümkündür.

Anahtar kelimeler: Acı bakla unu, köfte, airfryer, termal görüntüleme, duyusal analiz, mikrobiyoloji, renk ölçümü.

THE EFFECT OF BITTER LUPIN (LUPINUS ALBUS) ADDITION ON THE PHYSICAL, MICROBIOLOGICAL AND SENSORY PROPERTIES OF BEEF MEATBALLS

ABSTRACT

Meat products have an important place in human nutrition due to their high protein content. However, increasing concerns about the sustainability and cost of animal-based protein sources have promoted the use of plant-based protein alternatives. Bitter lupin (*Lupinus albus*) is a legume rich in protein, fiber, and bioactive compounds. In recent years, lupin flour has been used as a functional ingredient in the food industry. In this study, beef meatballs were prepared by adding bitter lupin (Lupinus albus) at different levels (10%, 20%, and 30%). The experimental meatballs were analyzed for physical properties (weight loss, diameter shrinkage), color parameters (L*, a*, b* values), microbiological characteristics (total mesophilic aerobic count, coliform count, and yeast–mold count), and sensory attributes. Bitter lupin was boiled for approximately 60 minutes, peeled, and ground into a paste using a blender. Salt (2%) was added to the meatballs containing different levels of lupin based on meat weight. The meatballs were cooked in an air fryer at 180°C for 5 minutes, and temperature distribution during cooking was monitored using a thermal camera. Results showed that increasing lupin levels led to higher weight loss and greater diameter reduction in the meatballs. Significant differences were observed in L* (lightness), a* (redness), and b* (yellowness) values; L* values increased with higher lupin content. Coliforms were below detectable levels (<10 CFU/g). Yeast–mold count was 1.1 $\log_{10}$ CFU/g, while total mesophilic aerobic count was 1.8 $\log_{10}$ CFU/g. Sensory evaluation by an eight-member panel indicated that meatballs containing 10% lupin flour received the highest scores for color, aroma, and overall acceptability. In conclusion, bitter lupin flour can be considered a plant-based protein additive in meatball production; however, higher levels may negatively affect sensory quality.

Keywords: Bitter lupin flour, meatball, air fryer, thermal imaging, sensory analysis, microbiology, color measurement.

Giriş

Et ve et ürünleri, yüksek biyolojik değerli proteinleri, esansiyel amino asitleri, vitamin ve mineralleri nedeniyle insan beslenmesinde vazgeçilmez bir konuma sahiptir (Troy ve Kerry, 2010). Ancak son zamanlarda modern gıda sistemlerinde sürdürülebilirlik, ekonomik üretim, enerji tüketimi ve çevresel etkiler gibi faktörlerin yanısıra , aynı zamanda sağlıklı beslenme alışkanlıklarına yönelik artan farkındalık ve ilgiye cevap verebilecek yeni, güvenli ve sağlıklı gıdalar geliştirme ihtiyacı nedeniyle de bitki kaynaklı besinlere ve biyoaktif bileşiklere artan bir ilgi duyulmaktadır. Bu nedenle bitkisel kaynaklı protein içerikli katkılar ve baklagiller hem maliyet avantajı hem de fonksiyonel ve teknolojik faydalar sağlaması nedeniyle et ürünlerinde yaygın olarak kullanılmaya başlanmıştır (Pintado ve Delgado-Pando, 2020; Pereira ve ark., 2022). Bu bağlamda baklagiller, zengin protein ve diyet lifi içerikleriyle özellikle kıyma bazlı ürünlerde et ikamesi veya fonksiyonel bileşen olarak değerlendirilen başlıca bitkisel kaynaklar arasındadır (Durazzo ve ark., 2015). Acı bakla tohumlarına olan ilgi, gıda hazırlamadaki esnekliği ve sağladıkları sağlık yararları hakkındaki artan bilgi birikimiyle sürekli olarak artmaktadır. Lupinus cinsinin türleri arasında, beyaz acı bakla (*Lupinus albus* L.) dikkate değer bir potansiyele sahiptir (Pereira ve ark., 2022). Fabaceae familyasından Lupinus cinsine ait, protein açısından zengin bir baklagil olan acı bakla, bu tür alternatifler için umut vadeden bir aday olarak kendini göstermektedir. Besinsel açıdan bakıldığında, beyaz acı bakla tohumları %32,9'dan %36,0'ın üzerine kadar yüksek bir protein içeriğine sahiptir. Yağ içeriği %9 ila %13 arasında değişir ve yüksek bir PUFA konsantrasyonuna sahiptir; bu da değerli bir temel yağ asidi kaynağıdır; ayrıca, diğer bitkisel yağlara kıyasla yüksek bir n3/n6 çoklu doymamış yağ asidi oranına sahiptir ve hayvan yemi için uygundur. Dahası, beyaz acı bakla, antioksidan aktiviteyi artıran ve sağlığı iyileştiren fenolik asitler, flavonlar ve izoflavonlar gibi birçok değerli biyolojik olarak aktif madde ile karakterize edilmektedir (Devkota ve ark., 2023; Gresta ve ark.,2023). Soya fasulyesinin aksine, acı baklalar olumlu çevresel etkileri, genetiği değiştirilmemiş organizma (GDO) statüsü, tripsin inhibitörlerinden ari olmaları ve genetiği değiştirilmemiş çeşitler olmaları nedeniyle sürdürülebilir ve daha sağlıklı bir seçenek olarak kabul edilmektedir. Acı bakla tohumları prebiyotik etki gösterebilen oligosakkaritler ve biyoaktif alkaloidler taşımaktadır (Dhakal ve ark., 2024; Tosoroni ve ark., 2025). Besinsel açıdan glütensiz yapıda olması ve düşük glisemik indeks göstermesi de bu baklagilin gıda formülasyonlarında tercih edilme nedenleri arasındadır (Hall et al., 2017). Son yıllarda acı bakla unu; hamur ürünleri, atıştırmalıklar, süt ürünleri ve et ürünlerinde fonksiyonel bileşen olarak yaygın şekilde kullanılmaya başlanmıştır (Duranti, 2000; Pereira ve ark., 2022). Et ürünlerinde ise su tutma kapasitesini artırma, pişme verimini iyileştirme, yağ ikamesi, tekstürel özelliklerde modülasyon sağlama gibi olumlu etkileri rapor edilmiştir (Gürsoy ve Sarıçoban, 2013).

Köfte, Türkiye başta olmak üzere birçok ülkede yaygın olarak tüketilen, kıyma bazlı bir et ürünüdür ve formülasyonunda yapılacak değişiklikler ürünün fiziksel (pişme kaybı, çap daralması, doku), kimyasal (renk, pH) ve mikrobiyolojik özellikleri üzerinde doğrudan etkili olabilmektedir (Öztürk ve Serdaroğlu, 2017). Ayrıca tüketici kabulü açısından duyusal değerlendirmeler, yeni ürün geliştirme süreçlerinde kritik bir yer tutmaktadır. Acı baklanın köfte gibi ısıl işlem gören ürünlerde davranışı, hem unun su ve yağ bağlama kapasitesi hem de protein yapısının ısıyla geçirdiği değişimlerle ilişkilidir. Literatürde lupin ununun et ürünlerinde yağ azaltımına yardımcı olduğu, ürün verimini artırdığı ve besin değerini yükselttiği bildirilmektedir (Clark ve ark., 2020). Ancak artan lupin oranı, ürün renginde açılmaya, aroma profilinde baklagil kokusunun hissedilmesine ve tekstürel değişimlere neden olabilmektedir (Belski, 2012).

Bu bağlamda, acı baklanın farklı oranlarda köfte formülasyonuna eklenmesinin ürün kalitesine etkilerinin araştırılması hem bitkisel protein kaynaklarının değerlendirilmesi hem de

sürdürülebilir et ürünleri geliştirilmesi açısından önem taşımaktadır. Aynı zamanda airfryer gibi yeni nesil pişirme ekipmanlarıyla gerçekleştirilen ısıl işlemlerin ürün üzerindeki etkilerinin incelenmesi, modern tüketim trendleriyle uyumlu yeni veri sağlamaktadır.

Bu çalışma, farklı oranlarda acı bakla (*Lupinus albus*) ilavesinin kırmızı et köftesinin fiziksel, renk, mikrobiyolojik ve duyusal özellikleri üzerine etkilerini belirlemeyi amaçlamaktadır. Elde edilen bulguların, fonksiyonel özellikleri artırılmış, bitkisel kaynaklı proteinle zenginleştirilmiş et ürünlerinin geliştirilmesine yönelik literatüre katkı sağlayacağı öngörülmektedir.

Materyal- Metot

Acı bakla Afyon' da yerel bir ticari işletmeden temin edilmiştir. Kıyma ve tuz Sivas' ta ticari bir işletmeden elde edilmiştir.

Metot

Çalışmada kullanılacak acı bakla bir gece suda bekletilmiş ve ardından ortalama 1 saat haşlanmıştır. Haşlanan acı bakla meyvelerinin kabukları soyulmuş ve ev tipi mutfak öğütücüsünden geçirilerek parçalanmıştır.

Kıyma ağırlığı üzerinden; kıyma ağırlığının % 10' u kadar ezilmiş acı bakla ilave edilen grup; % 20' si kadar ezilmiş acı bakla ilave edilen grup ve % 30' u kadar ezilmiş acı bakla ilave edilen grup olacak şekilde üç deneysel grup oluşturulmuştur (Resim 1). Deneysel grupların hepsine köfte hamuru ağırlığının %2 si kadar tuz ilave edilmiştir. Deneysel örnekler 180 C' de ortalama 5 dakika airfryda pişirilerek analizleri yapılmıştır (Resim 2).

Resim 1. Deneysel köfte örnekleri

Resim 2. Pişirilmiş deneysel köfte örnekleri

Mikrobiyolojik Analizler

Toplam Mezofil Aerob Bakteri Sayımı

Toplam mezofil aerob bakteri sayımı **ISO 4833-1:2013** standardına göre gerçekleştirilmiştir. Uygun dilüsyonlardan **1 mL**'lik örnekler steril petri kaplarına aktarılmış ve Plate Count Agar (PCA; Merck, Almanya) kullanılarak dökme-plak (pour-plate) yöntemi uygulanmıştır. Plaklar **30 ± 1 °C'de 72 saat** inkübe edilmiştir.

Koliform Bakteri Sayımı

Koliform bakteri sayımı **ISO 4832:2006** standardına göre yapılmıştır. Uygun dilüsyonlardan **0,1 mL** alınarak Violet Red Bile Agar (VRBA; Merck, Almanya) dökme plak yöntemi ile inoküle edilmiştir. Plaklar **37 ± 1 °C'de 24 saat** inkübe edilmiştir. Tipik koyu kırmızı renkli koloniler koliform olarak değerlendirilmiştir.

Maya ve Küf Sayımı

Maya ve küf sayımı **ISO 21527-1:2008** standardına göre yapılmıştır. Uygun dilüsyonlardan **0,1 mL** alınarak Patato Dekstroz Agar (PDA; Merck, Almanya) üzerine dökme plak yöntemiyle inoküle edilmiştir. Plaklar **25 ± 1 °C'de 5–7 gün** inkübe edilmiştir.

Fiziksel Analizler

Ağırlık Kaybı (Pişirme Kaybı)

Ağırlık kaybı, pişirme öncesi ve sonrası ağırlık farkına dayalı olarak hesaplanmıştır. Her bir köfte örneği pişirme öncesinde dijital terazi (±0.01 g hassasiyetli; Sartorius, Almanya) kullanılarak tartılmıştır. Köfteler airfryer'da 180 °C'de 5 dakika pişirildikten sonra oda sıcaklığında 10 dakika dinlendirilmiş ve tekrar tartılmıştır. Metot literatürde bildirilen standart yaklaşıma göre uygulanmıştır (Serdaroğlu ve Denizer, 2005; Aleson-Carbonell ve ark., 2005).

Çap Ölçümü (Çap Büzülmesi)

Çap ölçümleri, pişme sırasında oluşan şekil değişikliklerinin belirlenmesi amacıyla gerçekleştirilmiştir. Pişirme öncesi ve sonrası köftelerin çapı, paslanmaz çelik dijital kumpas (Mitutoyo, Japonya) kullanılarak iki farklı eksenden ölçülmüş ve sonuçların ortalaması alınmıştır. Bu yöntem daha önce benzer et ürünleri çalışmalarında önerilen protokole uygundur (Öztürk ve Serdaroğlu, 2015; Pietrasik ve ark., 2010).

Renk Analizi

Renk ölçümleri, CIE L*a*b* renk uzayında Minolta CR-400 (Konica Minolta, Japonya) kolorimetre kullanılarak gerçekleştirilmiştir. Cihaz ölçüm öncesi standart beyaz kalibrasyon plağı ile kalibre edilmiştir. Her bir köfte örneğinin dış yüzeyinden üç farklı noktadan ölçüm alınmış ve ortalama L* (açıklık), a* (kırmızılık) ve b* (sarılık) değerleri hesaplanmıştır. Analizler, CIE (Commission Internationale de l'Éclairage) standartlarına uygun olarak yürütülmüştür (CIE, 1986). Et ürünlerinde renk analizine ilişkin metotlar AMSA (2012) kılavuzuna göre uygulanmıştır.

Duyusal Analiz

Duyusal değerlendirme, köftelerin **renk, aroma, lezzet, kıvam, homojen görünüm ve genel beğeni** gibi organoleptik özelliklerini belirlemek amacıyla yapılmıştır. Analizler için **8 kişilik uzman panel** oluşturulmuştur. Köfteler pişirildikten sonra **oda sıcaklığında 10 dakika dinlendirilmiş** ve panelistlere kodlanmış, rasgele sırayla sunulmuştur. Panelistler her

parametreyi **5 puanlık hedonik ölçek** (1 = çok kötü, 2 = kötü, 3 = orta, 4 = iyi, 5 = çok iyi) kullanarak değerlendirmiştir (Öztürk ve Serdaroğlu, 2015).

Termal Görüntüleme

Pişirme sırasında köftelerin sıcaklık dağılımını izlemek için **termal kamera** (FLIR E8, FLIR Systems, ABD) kullanılmıştır. Köfteler **airfryer'da 180 °C'de 5 dakika** pişirilirken kamera ile yüzey sıcaklığı ve merkez sıcaklığı sürekli olarak kaydedilmiştir. Termal görüntüler, FLIR Tools yazılımı kullanılarak analiz edilmiş ve her örnek için maksimum, minimum ve ortalama sıcaklık değerleri belirlenmiştir (Pietrasik ve ark., 2010; Zhang ve ark., 2018).

İstatistiksel Analizler

Tüm veriler üç bağımsız tekrarlama üzerinden elde edilmiştir. Gruplar arası farklılıklar **Tek Yönlü Varyans Analizi (One-Way ANOVA)** ile incelenmiş ve anlamlı farklılık durumunda **Tukey HSD post-hoc testi** uygulanmıştır. Anlamlılık seviyesi **$p < 0.05$** olarak belirlenmiştir (Steel ve ark., 1997; Öztürk ve Serdaroğlu, 2015).

Bulgular

Deneysel köfte örneklerinde koliform bakteri sayısı tespit edilebilir düzeyin altında bulunmuştur (<10 log kob/g). Deneysel köfte örneklerinde tespit edilen maya-küf sayısı (MK) ve toplam mezofil aerob (TMAB) tablo 1' de verilmiştir. En düşük mikroorganizma sayısı % 10 acı bakla içeren grupda tespit edilmiştir. Ancak üç grup içinde elde edilen değerler tüketim sınırının altındadır.

Tablo 1. Deneysel köfte örnekleri mikrobiyolojik analiz bulguları

Örnekler	Mikroorganizma sayısı (log 10 kob/g)	
	MK	TMAB
% 10	1.1±0.01	1.8±0.02 ^{B}
% 20	1.3±0.01	2.3±0.01 ^{A}
% 30	1.7±0.02	2.6±0.01 ^{A}

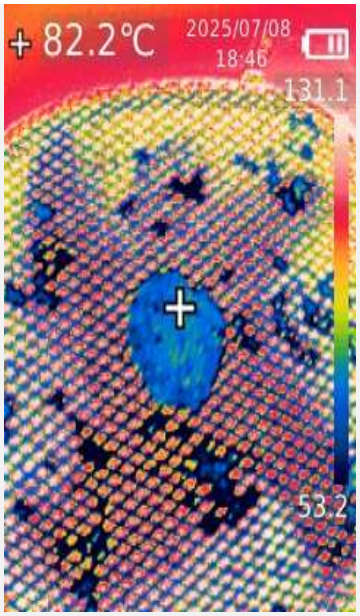
^{A,B} :aynı süründeki farklı harfler istatistiki açıdan önemlidir ($p<0.05$)

Deneysel örneklere ait pişirilme sırasındaki iç sıcaklık değerleri ve çap değişimi ile ağırlık kaybı verileri tablo 2' de verilmiştir. Tablo 2 incelendiğinde, örneklerin %10, %20 ve %30 oranlarındaki varyantları arasında ağırlık kaybı, çap ve iç sıcaklık açısından belirgin farklılıklar gözlenmektedir. Ağırlık kaybı açısından, %10 ve %20 örnekleri istatistiksel olarak benzer (B harfi ile gösterilmiştir) değerler sergilerken, %30 örneği anlamlı derecede daha yüksek bir ağırlık kaybına sahiptir (41,95 A ± 0,00). Bu durum, örnek oranının artmasıyla ağırlık kaybının da belirgin şekilde yükseldiğini göstermektedir.

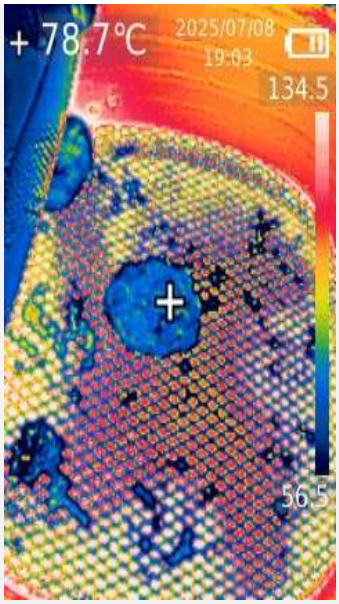
Örneklerin çap değerleri açısından, %10 örneği (60,16 A ± 0,01) istatistiksel olarak diğerlerinden farklıdır ve en büyük çap değerine sahiptir. %20 ve %30 örnekleri ise sırasıyla 51,93 B ± 0,01 ve 50,00 C ± 0,02 değerleri ile daha düşük çap göstermektedir. Bu bulgu, örnek oranının artmasıyla çapta azalma eğilimi olduğunu ortaya koymaktadır.

İç sıcaklık açısından ise %20 örneği (90 ºC) en yüksek değeri göstermekte olup, %10 ve %30 örneklerine göre daha yüksektir. Bununla birlikte, iç sıcaklık değişimi örnek oranına lineer bir şekilde bağlı görünmemektedir.

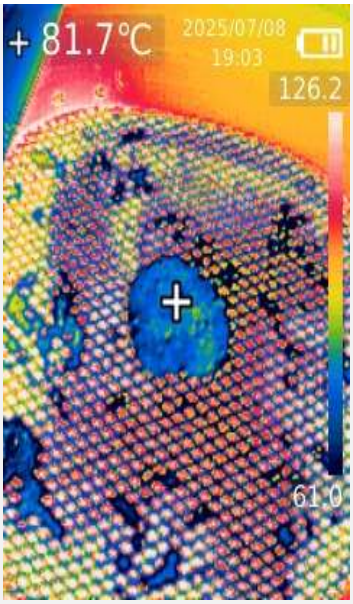
Genel olarak, örnek oranının artması ağırlık kaybını artırırken, çapı azaltmakta; iç sıcaklık ise örnek oranına göre değişkenlik göstermektedir. Bu sonuçlar, örnek bileşiminin termal ve fiziksel özellikler üzerindeki etkisini ortaya koymaktadır.



Tablo 2. Deneysel örneklerin fiziksel özellikleri ve pişirilme sırasındaki sıcaklık değişimleri

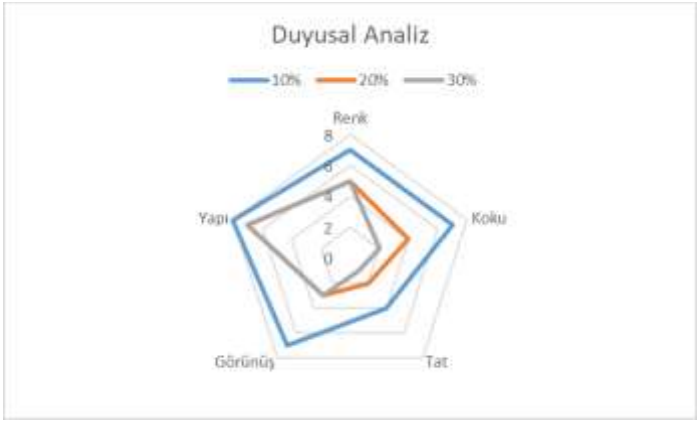


Örnekler	Ağırlık kaybı (%)	Çap (%)	İç sıcaklığı (ºC)
% 10	33,35 ^{B}± 0,01	60,16^{A}± 0,01	86,5
% 20	36,25^{B} ± 0,05	51,93^{B}± 0,01	90
% 30	41,95 ^{A}± 0,00	50,00^{C}± 0,02	85,1



^{A,B} :aynı süründeki farklı harfler istatistiki açıdan önemlidir ($p<0.05$)

Deneysel köfte örneklerine ait pişirilme sırasında elde edilen termal görüntüler resim 3, resim 4 ve resim 5' de verilmiştir.



Resim 3 **Resim 4** **Resim 5**

Deneysel örneklere ait duyusal analiz bulguları grafik 1' de verilmiştir. **%10 Bakla** (mavi çizgi) tüm duyusal kriterlerde en yüksek puanları almıştır. Özellikle **yapı, görünüş** ve **renk** kriterlerinde diğer gruplara göre belirgin şekilde üstündür. Bu, düşük oranlarda acı bakla ilavesinin köfte duyusal özelliklerini olumlu etkilediğini göstermektedir**. %20 Bakla** (turuncu çizgi) orta seviyede puanlar almıştır. **Renk** ve **yapı** açısından %10'a yakın, ancak **koku** ve **tat** kriterlerinde belirgin bir düşüş gözlemlenmektedir. **%30 Bakla** (gri çizgi) en düşük puanları almıştır. Tüm kriterlerde düşüş vardır, özellikle **tat** ve **koku** değerleri ciddi şekilde azalmıştır. Bu durum, yüksek oranlarda acı bakla ilavesinin köftenin duyusal kabulünü olumsuz etkilediğini ortaya koymaktadır. Duyusal analiz sonuçları, **acı bakla ununun %10 oranında ilavesinin köfte kalitesini desteklediğini,** ancak %20–%30 oranlarının özellikle **tat ve koku** kriterlerinde olumsuz etkiler yarattığını göstermektedir. Bu sonuç, literatürde bildirilen bitkisel protein katkılarının yüksek oranlarda ürünün duyusal kabulünü düşürdüğü bulgularıyla uyumludur (Öztürk ve Serdaroğlu, 2015; Pintado ve Delgado-Pando, 2020).

Grafik 1. Deneysel örneklerin duyusal analiz sonuçları

Çiğ ve pişmiş etin rengi, özellikle tüketici satın alma tercihleri açısından en önemli kalite parametrelerinden biridir ve aynı zamanda genel et kalitesiyle de ilişkilidir (Font-i-Furnols ve Guerrero. 2014). CIE (Uluslararası Aydınlatma Komisyonu) sistemine göre L* açıklığı, a* kırmızılığı ve b* sarılığı ifade etmektedir. Tablo 3`de görüldüğü gibi acı bakla unu ilave edilen çiğ köfte örneklerinin L* ve b*değerleri acı bakla unu arttıkça artarken pişmiş köfte örneklerinde pişmeyle birlikte L*ve b* değerleri azalmıştır. Lupin unu ilave edilerek üretilen beyaz ekmek ve makarna üretimi yapılan çalışmalarda lupin un miktarı arttıkça L değerinin azaldığını belirtmişlerdir (Tuluk, 2017; Yaver ve Bilgili, 2021). Lupin ilave edilen çiğ köfte örneklerinin a* kırmızı değeri artarken pişmiş köfte örneklerinde pişmeyle a* değeri artış göstermiştir.

Tablo 3. Deneysel örneklere ait renk analiz bulguları

Örnekler		***L****	***a****	***b****
Çiğ Ürün	**% 10**	33,82 ± 0,18	18,33 ± 0,09	26,73 ± 0,06
	% 20	38,36 ± 0,30	19,34 ± 0,65	29,84 ±0,27
	% 30	45 ± 0,23	21,82 ± 0,61	36,95 ± 0,03
Pişmiş Ürün	**% 10**	16,54 ± 0,27	22,46 ± 0,74	27,46 ± 0,06
	% 20	15,19 ± 0,14	24,23 ± 0,20	26,07 ± 0,19
	% 30	12,14 ± 0,27	27,19 ± 0,77	21,27 ± 0,61

ÖZET

Bu çalışma, kenevir tozu (Cannabis sativa L.) ilavesinin, yoğurt formülasyonlarının fizikokimyasal, mikrobiyolojik ve duyusal kalite parametreleri üzerindeki etkilerini incelemeyi amaçlamıştır. Kenevir tozu, yoğurt üretimine %1, %2 ve %3 olmak üzere üç farklı konsantrasyonda eklenmiş ve bir kontrol grubu ile detaylı olarak karşılaştırılmıştır. Elde edilen yoğurt örneklerinde; pH, titrasyon asitliği, renk değerleri (L^*, a^*, b^*) ve laktik asit bakteri sayıları gibi kritik parametreler değerlendirilmiştir. Ek olarak, tüketici kabul düzeylerini belirlemek amacıyla duyusal analizler gerçekleştirilmiştir. Araştırma bulguları, kenevir tozunun yoğurdun fonksiyonel özelliklerini önemli ölçüde zenginleştirdiğini göstermekle birlikte, yüksek ilave oranlarının ürünün duyusal kabulünü olumsuz yönde sınırlayabileceğini ortaya koymuştur.

Anahtar Kelimeler: Yoğurt, kenevir tozu, kalite parametreleri, fonksiyonel gıda, duyusal analiz

THE EFFECT OF HEMP POWDER ON YOGURT QUALITY PARAMETERS

ABSTRACT

This study aimed to investigate the effects of adding hemp powder (Cannabis sativa L.) at different concentrations to a yogurt formulation on its physicochemical, microbiological, and sensory quality parameters. Hemp powder was incorporated into yogurt production at concentrations of 1%, 2%, and 3%, and compared with a control group. Key parameters such as pH, titratable acidity, color values (L^*, a^*, b^*), and lactic acid bacteria count were evaluated. Additionally, consumer acceptability levels were determined through sensory analysis. The results indicated that hemp powder significantly enhanced the functional properties of the yogurt; however, high inclusion rates were found to restrict sensory acceptance.

Keywords: Yogurt, hemp powder, quality parameters, functional food, sensory analysis

Giriş

Kenevir (Cannabis sativa L.), Cannabaceae familyasından yıllık otsu bir bitkidir. Kenevir, tarih boyunca insanlar tarafından lif ve yağ içeriğinden dolayı tekstil ve gıda amaçlı kullanımı yaygın olarak belgelenmiştir (Rizzo ve ark., 2023). Kenevir tohumları, yüksek esansiyel amino asit içeriğiyle yansıtılan yüksek biyolojik değere sahip oldukça yüksek protein içeriği (%22,17) ile öne çıkmaktadır. Bununla beraber, kenevir tohumları, faydalı yağ asidi yapısının eklendiği yağ içeriği (%26,25- 37,50) nedeniyle yüksek bir enerji değerine sahiptir (Capcanari ve ark., 2023). Kenevir tohumundan elde edilen un veya tozu içerdiği besin maddeleri nedeniyle fonksiyonel gıda bileşeni olarak dikkat çekmektedir (Callaway, 2004; House ve ark., 2010).Kenevir tozunun protein içeriği oldukça yüksektir (%30–50) ve başlıca fraksiyonları edestin ve albuminden oluşmaktadır. Edestin, insan plazma globulinlerine benzer yapıda olduğundan biyoyararlanımı yüksektir ve esansiyel aminoasit profili açısından dengeli bir kaynak olarak kabul edilmektedir (House et al., 2010; Tanase Apetroaei ve ark., 2024). Özellikle arginin, lösin ve glutamik asit miktarı dikkate değer düzeydedir. Bu özellikleri sayesinde kenevir proteini, sporcu beslenmesinde ve bitkisel protein takviyesi gereken diyetlerde önemli bir alternatif haline gelmiştir (Palmer et al., 2020). Kenevir tozunun önemli bir diğer bileşeni ise çözünür ve çözünmez diyet lifleridir. Bu lifler sindirim sağlığını destekler, prebiyotik etki gösterir ve bağırsak mikrobiyotasının düzenlenmesine katkı sağlar (Cunnane et al., 1999; Odeeka ve ark., 2022). Mineral açısından da zengin olan kenevir tozu; magnezyum, fosfor, potasyum, demir, çinko ve kalsiyum gibi elementlerin yanı sıra E vitamini ve B grubu vitaminlerini de içermektedir (Leizer et al., 2000). Kenevir tohumlarının yağa işlenmesi sırasında tohumdaki yağın büyük kısmı çıkarılmış olsa da, kalıntı yağ fraksiyonları zengin **omega-3 ve omega-6 yağ asitleri** içerir. Bu yağ asitleri yaklaşık 3:1 oranında bulunmakta olup, insan sağlığı için önerilen ideal dengeyi sağlamaktadır Ayrıca gamma-linolenik asit (GLA) gibi özel yağ asitleri de antiinflamatuvar özellik göstermektedir. (Callaway, 2004; Rizzo ve ark., 2023;Yıldız, 2025). Gıda endüstrisinde yapılan çalışmalarda, kenevir tozunun ekmek, bisküvi, süt ürünleri ve bitkisel içeceklere ilavesinin ürünlerin besin değerini artırdığı; ancak yüksek düzeyde kullanımının duyusal özelliklerde bazı olumsuzluklara yol açabileceği vurgulanmaktadır (Yadav et al., 2021). Sağlık üzerindeki etkilerine bakıldığında, kenevir proteini ve liflerinin **kolesterol düşürücü, antioksidan, antiinflamatuvar ve antihipertansif** özelliklere sahip olduğu bildirilmektedir (Rodriguez-Leyva & Pierce, 2010). Özellikle arginin içeriği, nitrik oksit üretimini artırarak damar sağlığını olumlu etkilemektedir. Bu nedenle kenevir tozu, fonksiyonel gıda üretiminde potansiyel bir katkı maddesi olarak görülmektedir.

Yoğurt, fermente süt ürünleri arasında en yaygın tüketilen gıdalardan biridir ve besinsel değeri ile fonksiyonel özellikleri nedeniyle sağlıklı beslenmenin önemli bir bileşenidir. Son yıllarda tüketici talebi, yalnızca temel besin öğelerini sağlayan ürünlerden ziyade, sağlık üzerinde ilave faydalar sunan **fonksiyonel gıdalar**a yönelmiştir (Granato et al., 2010). Bu bağlamda yoğurt formülasyonlarında çeşitli bitkisel toz ve ekstraktların kullanımı giderek artmaktadır. Bu çalışmada kenevir tozunun farklı oranlarda yoğurt üretimine ilavesinin kalite parametreleri ve duyusal kabul üzerindeki etkilerini incelemek amaçlanmıştır.

Materyal

Çalışmada pastörize inek sütü, ticari yoğurt starter kültürü (Streptococcus thermophilus ve Lactobacillus delbrueckii subsp. bulgaricus) ve düşük THC içerikli endüstriyel kenevir tohumu tozu kullanılmıştır.

Deneysel yoğurt örnekleri kontrol (Kenevir tozu eklenmemiş yoğurt), %1 (A), %2 (B) ve %3 (C) kenevir tozu eklenmiş yoğurtlar şeklinde dört grupta hazırlanmıştır.

Süt 85 °C'de 30 dakika ısıl işlem görmüş, 42 °C'ye soğutulmuş ve starter kültür ile inoküle edilmiştir. Kenevir tozu inokülasyon öncesinde sütte çözünür hale getirilerek homojenize edilmiştir. Fermantasyon 42 °C'de pH 4,6'ya ulaşıncaya kadar sürdürülmüş, ardından 4 °C'de 24 saat olgunlaştırılmıştır.

Metot

Deneysel örneklerin pH değeri pH metre ile ölçülmüştür (AOAC). Titrasyon asitliği % laktik asit cinsinden titrasyon metodu ile yapılmıştır. Renk analizi Minolta cihazı ile CIELab sisteminde L*, a*, b* değerleri belirlenmiştir. Laktik asit bakteri sayımı M17 agar kullanılarak 37 C' de 24 h sonunda sayılmıştır. 8 kişilik panelist grup 1 çok kötü, 2 kötü, 3 iyi, 4 normal ve 5 çok iyi şeklinde deneysel örnekleri renk, koku, lezzet, kıvam, homojen görünüm ve genel beğeni açısından değerlendirmiştir.

Bulgular

Mikrobiyolojik ve Kimyasal Analiz Sonuçları

Deneysel örneklere ait kimyasal ve mikrobiyolojik analiz bulguları Tablo 1 de verilmiştir. Kenevir tozu ilavesinin yoğurdun fizikokimyasal ve mikrobiyolojik özellikleri üzerinde belirgin etkiler yarattığı tespit edilmiştir. Kenevir tozu oranı arttıkça, yoğurt örneklerinin pH değeri kontrol grubu (4.42) ile karşılaştırıldığında, en yüksek konsantrasyonda (C grubu) 3.98'e kadar düşerek önemli bir azalma göstermiştir. Bu pH düşüşüne rağmen, titrasyon asitliği (laktik asit yüzdesi) kontrol grubundaki %8.53'ten C grubunda %7.43'e gerileyerek, kenevir tozunun yoğurt matrisinde tamponlama kapasitesi oluşturduğunu veya asit oluşumunu dolaylı olarak etkilediğini düşündürmektedir. Mikrobiyolojik açıdan bakıldığında ise, kenevir tozu yoğurt kültürlerinin aktivitesini desteklemiştir. Kontrol grubunda 6.19 log10 kob/g olan laktik asit bakteri sayısı, %3 kenevir tozu içeren C grubunda 7.55 log10 kob/g'a yükselmiştir. Bu artış, kenevir tozunun laktik asit bakterileri için büyüme faktörü görevi görerek yoğurdun probiyotik potansiyelini artırdığını göstermektedir. Genel olarak, kenevir tozu, yoğurtta mikrobiyolojik aktiviteyi teşvik ederken, pH ve laktik asit dengesini karmaşık bir şekilde etkilemektedir.

Tablo 1. Deneysel örneklerin kimyasal ve mikrobiyolojik analiz bulguları

Analiz	K	A	B	C
pH	4.42	4.40	4.01	3.98
% laktik asit	8.53	8.42	7.98	7.43
Laktik asit bakteri sayısı (log 10 kob/g)	6.19	6.11	7.42	7.55

Renk Analiz Sonuçları

Yoğurt örneklerinin renk analiz bulguları, kenevir tozu ilavesinin ürünün yüzey rengi üzerinde önemli bir etkiye sahip olduğunu göstermektedir. En belirgin değişim, yoğurt örneklerinin parlaklık (*L**) değerlerinde gözlenmiştir; kontrol grubu 88.23 değeri ile en açık renge sahipken, kenevir tozu konsantrasyonu arttıkça *L** değeri önemli ölçüde azalmıştır. En yüksek koyulaşma, 75.56 *L** değeriyle %2 kenevir tozu içeren B grubunda kaydedilmiştir. Bu düşüş, kenevir tozunun doğal koyu rengi ile ilişkilidir. Aynı zamanda, sarımsılık (*b**) değeri de kenevir tozu ilavesiyle sürekli olarak artmıştır; K grubunda *b** değeri 8.92 iken, en yüksek konsantrasyon olan C grubunda bu değer 12.41'e yükselmiştir. Bu artış, kenevir tozunun yapısındaki doğal sarı/kahverengi pigmentlerin yoğurt matrisine geçişiyle açıklanabilir.

Kırmızımsılık/yeşilimsilik göstergesi olan *a** değeri ise, tüm örneklerde negatif (yeşilimsi) bölgede kalmış ve %3 kenevir tozu içeren C grubu 3.20 değeri ile en yüksek yeşilimsi tonu göstermiştir. Sonuç olarak, kenevir tozu yoğurdun görünümünü daha koyu, daha sarı ve hafif yeşilimsi bir tona doğru değiştirmiştir.

Tablo 2. Deneysel örneklerin renk analiz bulguları

Analiz	K	A	B	C
*L**	88.23	83.56	75.56	78.12
*a**	-2.16	-2.11	-2.10	-3.2
*b**	8.92	9.63	11.99	12.41

Duyusal Analiz Sonuçları

Deneysel yoğurt örneklerinin duyusal analiz bulguları (Tablo 3), kenevir tozu ilavesinin tüketici kabulü üzerindeki eşiğini net bir şekilde ortaya koymuştur. Kontrol grubu (K) ve %1 kenevir tozu içeren A grubu, tüm parametrelerde en yüksek puan olan 5'i alarak genel beğeni açısından birbirinden farksız kabul edilmiştir. Buna karşın, kenevir tozu konsantrasyonunun %2 (B) ve %3 (C) oranlarına yükselmesiyle birlikte duyusal kabulde belirgin bir düşüş gözlenmiştir. Özellikle C grubunda renk puanı 3.1'e, genel beğeni puanı ise 3.9'a gerilemiştir. Koku ve lezzet gibi kritik kabul parametreleri de B ve C gruplarında düşüş. Buna karşılık, kıvam ve homojen görünüm gibi tekstürel özellikler, en yüksek ilave oranında bile 5 puanını koruyarak kenevir tozunun yoğurdun yapısal bütünlüğünü olumsuz etkilemediğini göstermiştir. Duyusal değerlendirmeler, %2 ila %6 oranında kenevir unu veya küspe unu içeren yoğurtların iyi bir kabul düzeyini koruduğunu, tat ve doku açısından ise genellikle %4 konsantrasyonun en iyi olarak derecelendirildiğini göstermektedir. Daha yüksek konsantrasyonlar topraksı veya büzücü (astringent) tatlar getirebilir, ancak bunlar tatlandırıcılar veya vanilya ve agav şurubu gibi aroma vericiler ile hafifletilebilir (Nakov ve ark., 2023; Hashemian ve Nouri, 2023) Kenevir ilavesi fermantasyon sürecini engellememektedir; laktik asit bakterileri canlı kalmakta ve ürünün raf ömrü standart yoğurtlarla karşılaştırılabilir düzeyde olmaktadır Łopusiewicz ve ark., 2022; Nakov ve ark., 2023)

Tablo 3. Deneysel örneklerin duyusal analiz bulguları

Parametre	K	A	B	C
Koku	5	5	4.2	4.1
Renk	5	4.9	3.6	3.1
Lezzet	5	5	3.8	4
Kıvam	5	5	5	5
Homojen görünüm	5	5	5	5
Genel beğeni	5	5	4	3.9

Tartışma

Bu çalışmanın bulguları, kenevir tozunun yoğurt formülasyonlarına dahil edilmesinin ürüne önemli fonksiyonel katkılar sağladığını ancak yüksek konsantrasyonlarda duyusal sınırlamalar getirdiğini göstermiştir. Kenevir tozu ilavesi, yoğurt kültürlerinin aktivitesini destekleyerek laktik asit bakteri sayısını anlamlı ölçüde yükseltmiştir, bu da ürünün probiyotik potansiyelini artırmıştır. Fizikokimyasal analizlerde, artan kenevir tozu miktarına paralel olarak pH değeri düşmüş, ancak bu durum titrasyon asitliğinde düşüşle sonuçlanmış, kenevir tozunun yoğurt matrisinde tamponlama etkisi yarattığını düşündürmüştür. Renk analizleri, tozun doğal pigmentleri nedeniyle parlaklık değerini düşürerek ürünü koyulaştırdığını ve sarılık değerini önemli ölçüde artırdığını ortaya koymuştur. Duyusal değerlendirmede, tüketici kabulünün %1 ilave oranına kadar korunduğu, ancak %3'lük en yüksek konsantrasyonda renk ve genel beğeni puanlarının belirgin şekilde düştüğü tespit edilmiştir. Sonuç olarak, kenevir tozu yoğurt kalitesini biyolojik açıdan zenginleştirmek için değerli bir bileşen olmasına rağmen, bu faydaları korumak ve aynı zamanda tüketicinin duyusal beklentilerini karşılamak için optimum ilave konsantrasyonunun %1 civarında tutulması gerektiği sonucuna varılmıştır.

ABSTRACT

Antarctic krill oil, obtained from *Euphausia superba*, due to its distinct composition, nutritional and functional potentials has emerged as a valuable food source for humans. Omega-3 fatty acids are classified into three types: alpha-linolenic acid (ALA 18:3), eicosapentaenoic acid (EPA 20:5), and docosahexaenoic acid (DHA 22:6). ALA is derived from plant sources, whereas EPA and DHA are commonly known as marine-based omega-3s. Marine organisms such as microalgae, krill, and fish are abundant natural sources of phospholipids enriched with EPA and DHA. Antarctic krill oil is a red viscous liquid obtained from Antarctic krill, a small crustaceans that can be found in all the world's oceans, but mostly in the Northern and Southern polar seas. Many people ask why krill oil is so much stronger than fish oil. Antarctic krill oil, which has been considered an alternative to fish oil since krill is rich in nutrients, including vitamins A and E, minerals, phospholipids, astaxanthin and flavonoids, high level omega-3 polyunsaturated fatty acids has been drawing increasing attention. This review aims to provide an overview of the chemical composition, health advantages and current applications of Antarctic krill oil.

Keywords: Antarctic krill oil, Omega-3, Minor components, Fatty acids

Introduction

Fats are the most concentrated energy source in the human diet and are classified as saturated (SFA), monounsaturated (MUFA), or polyunsaturated fatty acids (PUFA) according to the number of double bonds. Lipids play crucial roles in human physiology, including energy production, maintaining membrane integrity, and facilitating signal transduction. Omega-3 long-chain PUFAs eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), which help preserve cellular membrane structure, regulate inflammatory responses and support cardiovascular and neurological function. Because humans cannot synthesize EPA and DHA on their own, these fatty acids must be obtained through the diet, primarily from marine sources such as fish, krill, shellfish, and microalgae. Antarctic krill oil has recently emerged as a notable dietary supplement rich in omega-3 PUFAs, with EPA and DHA. Besides these essential fatty acids, marine oils are a source of important bioactive compounds like astaxanthin while marine organisms such as microalgae, krill, and fish (Zhu et al., 2015; Zhao et al., 2020; Attri et al., 2025; He et al., 2025; Machaj et al., 2025; Su et al., 2025; Wei et al., 2025;). Antarctic krill (*Euphausia superba*) is a common crustacean plankton species in Antarctic oceans, with biomass reserves estimated at 600 million to 1 billion tons and an annual harvest of 60-100 million tons. Antarctic krill is a marine resource containing a high concentration of n-3 polyunsaturated fatty acids. Antarctic krill oil, a red viscous functional oil derived from this species, is gaining popularity due to its favorable fatty acid composition and high antioxidant capabilities. Krill oil includes a high concentration of phospholipids and phospholipid-bound omega-3 PUFAs, as well as bioactive components such astaxanthin, tocopherols, flavonoids, vitamins, and minerals, making it an important source of nutritional elements (Sati and Bhatt 2018; Cui et al., 2025; Dong et al., 2025; Wei et al., 2025; Zhang et al., 2025). Krill has an important ecological role as a key food supply for many fish species and bigger marine animals. Krill oil, have also earned commercial and scientific attention; in 2008, the U.S. Food and Drug Administration (FDA) designated krill oil as generally recognized as safe (GRAS) (Xie et al., 2019; Colletti et al., 2021; Shahidi and Abad 2024; Sarıyer et al., 2025). Antarctic krill was originally used primarily as an ingredient in aquaculture feeds. Antarctic krill oil has recently gained popularity due to its diverse bioactive components and associated health benefits, indicating potential applications in pharmacological and nutraceutical products aimed at cardiometabolic, neurodegenerative, and other disease conditions. However, it's usage in the food sector is limited due to issues such as poor oxidative stability, a strong off-flavor, and low astaxanthin bioavailability (Colletti et al., 2021; Lin et al., 2024; Cui et al., 2025). This review aims to provide an overview of the chemical composition, health advantages and current applications of Antarctic krill oil.

Chemical Composition, Health Benefits and Current Applications of Antarctic Krill Oil

Krill oil exhibits a remarkably complex chemical profile distinguished from conventional edible oils, which generally contain more than 95% triacylglycerols. In contrast, krill oil is dominated by phospholipids, followed by triacylglycerols, diacylglycerols, monoacylglycerols, free fatty acids, and other minor lipid classes. It provides a wide spectrum of fatty acids, including substantial levels of C14:0, C16:0, C16:1, C18:1, C20:1, and high amounts of the long-chain n-3 PUFAs EPA (C20:5) and DHA (C22:6), which are well recognized for their essential roles in human health. In addition to these lipids, krill oil contains phospholipid-derived fatty acids, choline, and a significant fraction of sterols (2.3–3.9% of total lipids), predominantly desmosterol and cholesterol. Its vivid deep-red coloration is attributable to astaxanthin, the primary carotenoid present in various marine organisms and algae, which contributes potent antioxidant activity. Krill oil is also enriched with α-tocopherol, the major tocopherol species that accounts for more than 90% of its vitamin E content and provides synergistic antioxidant

effects alongside astaxanthin. Beyond the oil fraction, whole Antarctic krill contains high-quality proteins rich in essential amino acids such as taurine, glycine, arginine, and alanine, as well as considerable levels of minerals including magnesium, calcium, and phosphorus, making it a promising raw material for nutritional product development. Antarctic krill oil is a valuable nutritional source notable for its unique composition and functional properties. It contains a high proportion of phospholipids predominantly phosphatidylcholine, which enhances the bioavailability of its omega-3 fatty acids. The oil is particularly rich in EPA (20:5 n−3) and DHA (22:6 n−3), long-chain omega-3 PUFAs essential for human health. In addition, krill oil contains minor but important bioactive compounds, including sterols, astaxanthin, vitamins, and minerals. This combination of high phospholipid content, bioavailable omega-3s, and potent antioxidant components underscores the potential of Antarctic krill oil as a functional food and nutraceutical ingredient (Kwantes and Grundmann 2015; Xie et al., 2019; Colletti et al., 2021; Shahidi and Abad 2024; Attri et al., 2025; Luo et al., 2025; Wei et al., 2025)

Euphausia superba has recently emerged as a significant nutraceutical resource, thanks to its high levels of EPA, DHA, and astaxanthin. Krill oil is now broadly accessible in supplement form, including capsules, soft gels, tablets, and chewables. Its recognized benefits for cardiovascular and cognitive health, as well as its strong anti-inflammatory effects, have boosted its role in the global health and nutrition industry (Colletti et al., 2021; Shahidi and Abad 2024; Attri et al., 2025). Krill oil is an abundant source of long-chain omega-3 polyunsaturated fatty acids (LC-PUFAs), especially eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA). In addition, it contains phospholipids, tocopherols, vitamin A, and the potent antioxidant astaxanthin. Together, these compounds offer a variety of well-documented health benefits. EPA and DHA from krill oil have demonstrated notable pharmacological effects in managing chronic conditions such as cardiovascular, neurological, inflammatory, metabolic, and neoplastic diseases, while also supporting a healthy gut microbiota. According to several studies, the astaxanthin in krill oil present at higher levels than in many fish oils boosts antioxidant capacity and may help protect eye health and retinal cells. Krill oil has also been shown to provide neuroprotective benefits, supporting cognitive function and potentially helping to prevent neurodegenerative diseases like Alzheimer's. Further studies highlight its anti-obesity, anti-diabetic, anti-cancer, and women's health benefits, such as easing emotional and physical symptoms of premenstrual syndrome (PMS). Thanks to its diverse bioactive components, krill oil stands out as a valuable marine supplement with broad therapeutic potential (Sati and Bhatt 2018; Xie et al., 2019; Zhao et al., 2020; Colletti et al., 2021; Shahidi and Abad 2024; Attri et al., 2025; Sarıyer et al., 2025).

Conclusion

Antarctic krill oil (AKO) is regarded as a superior marine lipid source due to its distinct composition, which includes omega-3 long-chain polyunsaturated fatty acids that are mainly esterified to phospholipids, considerably increasing their bioavailability. AKO also contains a variety of bioactive components such as astaxanthin esters, vitamin A, tocopherols, and phospholipid-type n-3 PUFAs, which contribute to its antioxidant, anti-inflammatory, and health-promoting effects. Krill oil is extremely susceptible to oxidation, better encapsulating solutions are required to improve its oxidative stability and shelf life. In future studies, innovative technologies for krill oil can be developed and novel encapsulation systems can be designed to increase the positive effects of human health.

ÖZET

Mikroenkapsülasyon, gıda endüstrisinde ısıya, ışığa, oksijene ve pH değişimlerine duyarlı biyoaktif bileşenlerin korunmasında kullanılan etkili bir teknolojidir. Fenolik ve antioksidan bileşikler doğal olarak yüksek biyolojik aktiviteye sahip olmalarına rağmen çevresel koşullara karşı oldukça hassastır. Bu nedenle mikroenkapsülasyon, bu bileşiklerin oksidatif ve termal bozulmalarını azaltarak fiziksel, kimyasal ve biyolojik stabilitelerini artırır. Mikroenkapsülasyon işlemi sırasında fenolik bileşikler, maltodekstrin, gum arabik, nişasta türevleri, kazein veya polisakkaritler gibi duvar materyalleriyle kaplanarak çevresel etkilere karşı koruyucu bir bariyer içine alınır. Bu yapı, oksijenin difüzyonunu sınırlar, ışık ve ısıya maruziyeti azaltır, böylece bileşiklerin raf ömrü ve toplam antioksidan kapasitesi korunur. Aynı zamanda mikroenkapsülasyon, fenolik bileşiklerin biyoyararlanımını artırır ve sindirim sisteminde kontrollü salım sağlayarak etkinliğini sürdürür. Antioksidan aktivite bakımından mikroenkapsülasyon, bileşiklerin oksijen ve serbest radikallerle doğrudan temasını önleyerek degradasyonu yavaşlatır. Özellikle dondurarak kurutma (liyofilizasyon) ve emülsiyon bazlı sistemler, düşük sıcaklıkta işlem gördükleri için fenoliklerin %90'ına kadarının korunmasını sağlar. Sprey kurutma gibi yüksek sıcaklıklı yöntemlerde ise belirli kayıplar oluşabilmektedir. Mikroenkapsülasyon fenolik bileşiklerin gıda matrislerinde oluşturabileceği olumsuz tat, renk veya etkileşimleri minimize ederken, fonksiyonel ürünlerde duyusal kaliteyi ve homojen dağılımı geliştirir. Bu nedenle, uygun yöntem ve duvar materyali seçimi ile fenolik ve antioksidan bileşiklerin korunması, gıdaların fonksiyonel, besleyici ve duyusal kalitesinin artırılmasında kritik rol oynar. Mikroenkapsülasyon; fenolik ve antioksidan bileşiklerin stabilitesini, biyoyararlanımını ve fonksiyonel etkinliğini artıran, gıda teknolojisinde hem koruma hem de kontrollü salım amacıyla yaygın biçimde kullanılan yenilikçi bir yöntemdir.

Anahtar Kelimeler: Mikroenkapsülasyon, fenolik bileşikler, antioksidan kapasite, stabilite.

EFFECTS OF MICROENCAPSULATION ON THE STABILITY OF PHENOLIC AND ANTIOXIDANT COMPOUNDS IN FUNCTIONAL FOOD SYSTEMS

ABSTRACT

Microencapsulation is an effective technology used in the food industry to protect bioactive compounds that are sensitive to heat, light, oxygen, and pH changes. Although phenolic and antioxidant compounds naturally possess high biological activity, they are highly sensitive to environmental conditions. Therefore, microencapsulation increases the physical, chemical, and biological stability of these compounds by reducing their oxidative and thermal degradation. During the microencapsulation process, phenolic compounds are coated with wall materials such as maltodextrin, gum arabic, starch derivatives, casein, or polysaccharides, enclosing them in a protective barrier against environmental effects. This structure limits oxygen diffusion and reduces exposure to light and heat, thereby preserving the shelf life and total antioxidant capacity of the compounds. At the same time, microencapsulation increases the bioavailability of phenolic compounds and maintains their effectiveness by providing controlled release in the digestive system. In terms of antioxidant activity, microencapsulation slows degradation by preventing direct contact between the compounds and oxygen and free radicals. Freeze-drying (lyophilization) and emulsion-based systems, in particular, preserve up to 90% of phenolics because they are processed at low temperatures. Certain losses may occur with high-temperature methods such as spray drying. Microencapsulation minimizes the negative taste, color, or interactions that phenolic compounds can cause in food matrices, while improving sensory quality and homogeneous distribution in functional products. Therefore, the protection of phenolic and antioxidant compounds through the selection of appropriate methods and wall materials plays a critical role in enhancing the functional, nutritional, and sensory quality of foods. Microencapsulation is an innovative method widely used in food technology for both protection and controlled release purposes, which increases the stability, bioavailability, and functional efficacy of phenolic and antioxidant compounds.

Keywords: Microencapsulation, phenolic compounds, antioxidant capacity, stability.

Giriş

Fenolik bileşikler ve doğal antioksidanlar, bitkisel gıdalarda yaygın olarak bulunan ve hem gıda kalitesinin korunmasında hem de insan sağlığının desteklenmesinde önemli roller üstlenen biyolojik olarak aktif maddelerdir. Bu bileşikler; oksidatif stresin azaltılması, inflamatuar süreçlerin baskılanması, kardiyovasküler hastalık riskinin düşürülmesi, metabolik fonksiyonların düzenlenmesi ve bağırsak mikrobiyotasının modülasyonu gibi pek çok yararlı etkiye sahiptir (Scalbert vd., 2005; Shahidi ve Ambigaipalan, 2015). Fenolik bileşikler; flavonoidler, fenolik asitler, stilbenler ve lignanlar gibi geniş bir sınıflandırmaya sahiptir ve çay, kahve, kakao, meyveler, sebzeler, zeytinyağı, baklagiller ve tahıllar gibi çok sayıda gıdada doğal olarak bulunur. Ancak tüm bu olumlu etkilerine rağmen polifenoller ve antioksidan bileşikler, çevresel koşullar ve gıda işleme süreçlerine karşı oldukça duyarlıdır. Isı, ışık, oksijen, enzimatik aktivite ve pH değişimleri gibi faktörler bu bileşiklerin yapısını bozarak biyolojik etkinliklerinin azalmasına yol açmaktadır (Halliwell, 2012). Fenolik bileşiklerin hızlı oksidasyonu ve düşük biyoyararlanımı, bu bileşenlerin doğrudan gıdaya eklenmesiyle istenen fonksiyonel etkinin elde edilmesini güçleştirmektedir (Shahidi ve Yeo, 2018). Bu nedenle, polifenoller ve antioksidanların korunmasına yönelik yeni teknolojilere ihtiyaç duyulmuştur. Mikroenkapsülasyon, hassas biyoaktif bileşenleri korumak, stabilitesini artırmak ve kontrollü salım sağlamak için gıda teknolojisinde öne çıkan yenilikçi bir yöntem olarak önem kazanmıştır. Mikroenkapsülasyonun fonksiyonel gıdalar alanında kullanımı son yıllarda önemli ölçüde artmış ve fenolik–antioksidan bileşiklerin etkinliğini sürdürmede stratejik bir araç hâline gelmiştir (Mehta vd., 2022; Ordóñez-García vd., 2024; Bińkowska vd., 2024).

1. Fenolik Ve Antioksidan Bileşikler

Fenolik ve antioksidan bileşikler, bitkisel kaynaklı gıdalarda doğal olarak bulunan ve hem gıda kalitesinin korunmasında hem de insan sağlığının desteklenmesinde kritik rol oynayan biyoaktif maddelerdir. Kimyasal olarak, bir veya birden fazla aromatik halkaya bağlı hidroksil gruplarından oluşan bu bileşikler; flavonoidler, fenolik asitler, stilbenler ve lignanlar gibi geniş bir alt sınıflandırmaya sahiptir (Shahidi ve Ambigaipalan, 2015). Bitkilerde ikincil metabolit olarak üretilen fenolik bileşikler, çevresel stres faktörlerine (UV ışık, patojen saldırıları, oksidatif stres) karşı koruyucu görev üstlenirken; insan diyetinde ise fonksiyonel ve terapötik etki gösteren önemli doğal antioksidanlardır.

1.1. Gıdalarda bulunuşu ve teknolojik önemi

Fenolik bileşikler; meyveler, sebzeler, çay, kahve, kakao, zeytinyağı, tahıllar, baklagiller ve baharat gibi birçok gıdada doğal olarak bulunur. Gıdalara karakteristik renk, aroma ve tat özelliklerini kazandırmaları nedeniyle duyusal kalite üzerinde belirleyici rol oynarlar. Flavonoidler, meyve ve sebzelerin parlak renklerinden sorumlu iken; fenolik asitler ve tanenler burukluk ve acılık gibi tat özelliklerini etkiler (Scalbert vd., 2005). Fenolikler, gıdalarda oksidatif bozulmayı geciktirerek raf ömrünü uzatan doğal antioksidanlar olarak da işlev görür. Bu özellik, özellikle yağ içeriği yüksek ürünlerde (zeytinyağı, kuruyemişler, et ürünleri) önemli bir teknolojik avantaj sağlar**.**

1.2. Antioksidan kapasiteleri ve sağlık etkileri

Fenolik bileşiklerin en önemli özelliği, güçlü antioksidan kapasiteleridir. Serbest radikalleri nötralize etme, metal iyonlarını şelatlama ve oksidatif zincir reaksiyonlarını durdurma yetenekleri sayesinde hücresel hasarın önlenmesine katkı sağlarlar (Halliwell, 2012). Bu etkinin biyolojik yansımaları oldukça geniştir**.**

1.2.1. Kardiyovasküler hastalıklara karşı koruma

Polifenoller, LDL oksidasyonunu azaltır, damar duvarı fonksiyonunu iyileştirir ve inflamatuar mediyatörlerin üretimini baskılar (Shahidi ve Yeo, 2018). Bu sayede ateroskleroz gelişimi yavaşlamakta ve kardiyovasküler hastalık riski azalmaktadır.

1.2.2. Anti-inflamatuar ve anti-kanser etkiler

Fenolik bileşikler NF-κB ve MAPK gibi inflamasyon yollarını modüle ederek anti-inflamatuar etki gösterir; hücre proliferasyonu ve apoptozu düzenleyerek anti-kanser potansiyel taşırlar (Scalbert vd., 2005).

1.2.3. Metabolik hastalıkları önleyici etkiler

Diyet polifenolleri; insülin hassasiyetini artırma, glukoz emilimini düzenleme ve lipid metabolizmasını iyileştirme gibi etkilerle diyabet ve obezitenin yönetiminde yardımcıdır (Kaushalya vd., 2024).

1.2.4. Nöroprotektif etkiler

Fenolik bileşikler, oksidatif stres kaynaklı nöronal hasarı azaltarak nörodejeneratif hastalıklara karşı koruyucu etki gösterebilir (Halliwell, 2012).

1.2.5. Bağırsak mikrobiyotası üzerine etkiler

Fenolik bileşikler bağırsak bakterileri tarafından metabolize edilerek sağlığa yararlı fenolik türevlerine dönüşür ve mikrobiyota kompozisyonunu olumlu yönde modüle eder (Shahidi ve Ambigaipalan, 2015). Bu etki, bağırsak bariyer fonksiyonunun korunması ve sistemik inflamasyonun azaltılması ile ilişkilendirilmektedir.

2. Fenolik Bileşiklerin Ve Antioksidanların Kararsızlığı

Fenolik bileşikler ve doğal antioksidanlar, kimyasal yapıları gereği birçok degradasyon mekanizmasına açıktır ve gıda işleme ile depolama koşullarında önemli kayıplar gösterebilir.

2.1. Isı duyarlılığı

Fenolik bileşiklerin çoğu yüksek sıcaklıklarda hızla okside olmakta veya degradasyona uğramaktadır. Pastörizasyon ve sterilizasyon gibi ısıl işlemler sırasında fenolik kayıplarının %20–70 arasında olabildiği bildirilmektedir (Rice-Evans vd., 1997). Bu durum, fonksiyonel gıdalarda hedeflenen antioksidan kapasitenin korunmasını güçleştirir.

2.2. Işığa duyarlılık

UV ve görünür ışık, fenolik bileşiklerin fotooksidasyonuna yol açarak renk, aroma ve antioksidan kapasite kaybına neden olur (Scalbert vd., 2005). Özellikle antosiyanin içeriği yüksek ürünlerde renk bozulması dikkat çekicidir.

2.3. Oksijen duyarlılığı

Fenolikler, özellikle kateşin ve gallik asit gibi yapılar, oksijen varlığında kolaylıkla oksitlenir ve bu süreçte hem antioksidan kapasite azalır hem de istenmeyen renk ve tat değişimleri ortaya çıkar (Halliwell, 2012). Zeytinyağı fenolleri, üzüm posası ekstraktları ve yağlı tohumlarda yapılan çalışmalar, oksijen maruziyetinin antioksidan kapasitede anlamlı azalmaya yol açtığını göstermektedir (Karrar vd., 2021).

2.4. pH değişimleri

pH, fenolik bileşiklerin iyonizasyon durumunu ve dolayısıyla stabilitesini doğrudan etkiler. Antosiyaninler düşük pH'ta daha stabil iken, nötral ve hafif alkali pH koşullarında hızla

bozunurlar (Shahidi ve Ambigaipalan, 2015). Gıda matrisine bağlı pH değişimleri fenolik bileşiklerin yapısal bütünlüğünü olumsuz yönde etkileyebilmektedir.

2.5. Düşük biyoyararlanım

Fenolik bileşiklerin çoğu, bağırsakta sınırlı çözünürlük ve hızlı metabolizma nedeniyle düşük biyoyararlanım gösterir (Shahidi ve Yeo, 2018). Bu nedenle canlı sistemlere ulaşan efektif doz düşüktür ve beklenen biyolojik etkinin tam olarak ortaya çıkması engellenebilir. Bu kararsızlık mekanizmaları, fenolik bileşiklerin doğrudan gıda ürünlerine eklenmesini sınırlamakta; fonksiyonel ürünlerde istenen sağlık etkilerinin sürdürülebilirliği için ek

koruyucu stratejiler gerektirmektedir. Mikroenkapsülasyon bu noktada temel bir teknolojik çözüm olarak öne çıkmaktadır (Mehta vd., 2022; Santos vd., 2020).

3. Mikroenkapsülasyon Ve Temel Prensipleri

Mikroenkapsülasyon, sıvı, katı veya gaz hâlindeki bir aktif bileşenin (çekirdek materyal), genellikle birkaç mikrometre ile birkaç yüz mikrometre çapında olacak şekilde koruyucu bir duvar veya kaplama materyali ile çevrilerek mikro ölçekte kapsüller hâline getirilmesi işlemidir. Bu teknolojide amaç, hassas veya işlevsel bir bileşiği çevresel koşullardan izole etmek, kontrollü salım sağlamak ve gıda sistemlerine daha stabil bir formda entegre etmektir.

Mikrokapsüller;

- çekirdeği dış ortamdan fiziksel olarak korur,
- kontrollü ve hedefli salıma imkân verir,
- bileşiğin çözünebilirliğini ve dağılımını iyileştirir,
- istenmeyen tat ve kokuları maskeleyebilir (Bińkowska vd., 2024; Mehta vd., 2022).

Bu nedenle mikroenkapsülasyon, hem teknolojik hem de biyolojik işlevleri iyileştiren çok yönlü bir taşıyıcı sistem teknolojisi olarak değerlendirilmektedir.

3.1. Mikroenkapsülasyon yöntemleri

Fonksiyonel gıda sistemlerinde en yaygın kullanılan yöntemler aşağıda özetlenmiştir.

3.1.1. Sprey kurutma (spray drying)

Emülsiyon veya süspansiyon hâlindeki karışımın sıcak hava akımıyla püskürtülerek hızla kurutulması esasına dayanır. Endüstriye en kolay ölçeklenen yöntemlerden biridir. Bitkisel ekstraktlar, yağlar ve fenolikçe zengin fraksiyonların toz mikrokapsüller hâlinde elde edilmesinde sıklıkla tercih edilmektedir (Pino vd., 2019; Santos vd., 2020; Pudžiuvelytė vd., 2025).

3.1.2. Dondurarak kurutma (freeze-drying / liyofilizasyon)

Isıya çok hassas bileşenler için uygun bir yöntemdir. Düşük sıcaklıklarda suyun süblimasyonla uzaklaştırılması sayesinde fenolik ve uçucu bileşiklerin daha iyi korunması mümkündür. Sprey kurutmaya göre enerji maliyeti daha yüksek olmakla birlikte, hassas biyoaktifler için üstün stabilite sağlayabilmektedir (Santos vd., 2020; Pudžiuvelytė vd., 2025).

3.1.3. Koaservasyon ve kompleks koaservasyon

Karşı yüklü biyopolimerlerin (örneğin jelatin–gum arabik, protein–polisakkarit kombinasyonları) faz ayrımıyla kapsül duvarı oluşturduğu yöntemdir. Hidrofobik çekirdeklerin (yağ, aroma, polifenol ekstraktı) kontrollü salımı için etkilidir ve kapsül morfolojisinin iyi kontrol edilmesine imkân verir (Bińkowska vd., 2024; Mehta vd., 2022).

3.1.4. Ekstrüzyon ve damlatma teknikleri

Aljinat, pektin veya karragenan gibi hidrojel oluşturucu duvar materyalleriyle damlatma yoluyla jel boncuklar hazırlanır. Özellikle probiyotik–polifenol kombinasyonlarında ve ısıya hassas bileşiklerde kullanılır; mide pH'sına dayanıklı, bağırsakta çözünebilen yapılar elde edilebilir (García vd., 2021).

3.1.5. Lipozomlar, nanoemülsiyonlar ve nanoenkapsülasyon

Fosfolipit veya yüzey aktif madde içeren sistemlerde, yağda çözünen fenoller ve karotenoidler gibi bileşiklerin taşınmasında kullanılır. Yüksek yüzey alanı sayesinde çözünürlük ve emilim artışı sağlar; kontrollü salım ve hedefli taşıma açısından önemlidir (Kaushalya vd., 2024; Li vd., 2023).

4. Mikroenkapsülasyonda Kullanılan Duvar Materyalleri

Duvar materyali seçimi, kapsülün fiziksel özelliklerini, enkapsülasyon verimini ve fenolik stabilitesini doğrudan etkiler. Genellikle karbonhidratlar, proteinler, lipidler veya bunların kombinasyonları kullanılmaktadır (Mehta vd., 2022;).

4.1. Karbonhidrat bazlı duvar materyalleri

Maltodekstrin:

Yüksek çözünürlük, düşük viskozite ve iyi film oluşturma kapasitesi nedeniyle en yaygın taşıyıcılardan biridir. Tek başına kullanıldığında emülsifiye edici özelliği sınırlıdır; bu nedenle genellikle protein veya gum arabik ile kombine edilir. Toz oluşumu ve akışkanlığı iyileştirir (Pino vd., 2019)

Gum arabik:

Protein fraksiyonu sayesinde doğal bir emülgatör olup yağ esaslı çekirdeklerin kapsüllenmesinde yüksek stabilite sağlar. Fenolikçe zengin ekstraktların enkapsülasyonunda maltodekstrine kıyasla daha yüksek antioksidan aktivite ve kapsül bütünlüğü sağlayabildiği bildirilmektedir (Santos vd., 2020).

Modifiye nişastalar, inülin ve diğer oligosakkaritler:

Çözünürlük, film oluşturma ve prebiyotik etki nedeniyle tercih edilmektedir. Karbonhidrat karışımlarının (örneğin maltodekstrin–gum arabik, maltodekstrin–inülin) fenolik retansiyonunu tek bileşenli sistemlere göre artırdığı çeşitli çalışmalarda gösterilmiştir (Moro vd., 2021).

4.2. Protein bazlı duvar materyalleri

Süt proteinleri (whey protein izolatı, whey protein konsantresi, sodyum kazeinat), jelatin ve bitkisel proteinler özellikle yağ fazı içeren sistemlerde güçlü emülgatör ve duvar materyali olarak görev yapar. Whey protein–maltodekstrin veya whey protein–polisakkarit kompleks koaservat sistemlerinin enkapsülasyon verimini, oksidatif stabiliteyi ve kontrollü salım özelliklerini iyileştirdiği bildirilmektedir (Zen vd., 2020).

4.3. Lipid bazlı ve hibrit sistemler

Katı lipid nanopartiküller, lipozomlar ve yağ-bazlı duvar materyalleri, yağda çözünür antioksidanların ve fenolikçe zengin yağların (örneğin zeytinyağı, fındık yağı) stabilizasyonunda kullanılmaktadır. Bu sistemler, özellikle çoklu doymamış yağ asitlerinin ve yağda çözünen fenollerin oksidatif bozulmasını geciktirmede etkilidir (Karrar vd., 2021;

Bińkowska vd., 2024). Karbonhidrat–protein–lipid hibrit sistemleri, hem oksidatif stabiliteyi hem de kontrollü salımı optimize etmek için geliştirilmektedir (Mehta vd., 2022).

Tablo 1. Mikroenkapsülasyonda Kullanılan Başlıca Duvar Materyaller

Duvar materyali	**Özellikleri**	**Örnek kaynakla**
Maltodekstrin	Düşük viskozite, iyi çözünebilirlik, iyi film oluşturma	Pino vd., 2019; Santos vd., 2020
Gum arabik	Mükemmel film oluşturucu, iyi emülgatör, uçucu bileşenler için ideal	Santos vd., 2020
Whey protein konsantresi (WPC)	Yağ fazını iyi kapsüller, ısıl stabiliteyi artırır	Zen vd., 2020; M vd., 2022
Kitosan	Pozitif yüklü; probiyotik ve fenolik kombinasyonlarında üstün koruma	García vd., 2021
İnülin	Prebiyotik etki, iyi film oluşturma, karbonhidrat karışımlarında faydalı	Moro vd., 2021; Mehta vd., 2022

5. Mikroenkapsülasyonun Fenolik Ve Antioksidan Stabilitesi Üzerine Etkileri

5.1. İşleme ve depolama sırasında stabilite

Çeşitli bitkisel ekstraktlarda yapılan çalışmalar, polifenol fraksiyonlarının mikroenkapsülasyon sonrası ısıl işleme ve depolama koşullarında daha yüksek stabilite gösterdiğini ortaya koymuştur. Aronia ve diğer meyve ekstraktlarının mikroenkapsülasyonu, toplam fenolik madde ve DPPH/FRAP antioksidan kapasitesinin serbest ekstraktlara kıyasla daha yavaş azaldığını göstermektedir (Pudžiuvelytė vd., 2025). Balkabağı yağı, siyah çay ekstraktı, üzüm posası ve farklı yağlı tohum sistemlerinde sprey kurutma ile elde edilen mikrokapsüller, oksidatif ranciditeyi azalttığı ve renk stabilitesini artırdığı yönünde rapor edilmiştir (Rajapaksha ve Shimizu, 2021; Bergesse vd., 2024). Zeytin yaprağı ve meyve kabukları gibi fenolikçe zengin ekstraktların uygun duvar materyalleriyle kapsüllenmesi, model gıda sistemlerinde antioksidan kapasitenin depolama süresince korunmasına katkı sağlamaktadır (Rosales vd., 2023). Genel olarak, enkapsülasyon verimlerinin %50–90 aralığında olduğu, kapsüllerin ısı, oksijen ve ışığa karşı serbest forma göre belirgin üstünlük sağladığı gösterilmektedir (Pudžiuvelytė vd., 2025).

5.2. Sindirim sonrası biyoerişilebilirlik ve biyoyararlanım

İn vitro sindirim modelleri, mikroenkapsüle polifenollerin gastrik fazda degradasyona karşı daha dirençli olduğunu, ince bağırsak fazında ise toplam fenolik içeriğin ve antioksidan aktivitenin serbest bileşiklere göre daha yüksek kaldığını göstermektedir (Kaushalya vd., 2024). Bazı nanoenkapsülasyon çalışmalarında, emilim fraksiyonunda anlamlı artışlar bildirilmiş; bu da mikroenkapsülasyonun yalnızca depolama stabilitesini değil, biyoerişilebilirliği de iyileştirerek fonksiyonel etkinliği güçlendirdiğini göstermektedir (Li vd., 2023).

5.3. Duyusal özelliklerin iyileştirilmesi

Mikroenkapsülasyon, polifenol kaynaklı acılık/burukluk, renk koyulaşması ve istenmeyen bitkisel tatların maskelemesinde de etkilidir. Özellikle fırıncılık ürünleri, süt ürünleri ve toz içecek karışımlarında, mikroenkapsüle yeşil çay, üzüm posası veya zeytin yaprağı

polifenollerinin ürün kabulünü düşürmeden antioksidan kapasiteyi artırdığı rapor edilmiştir (Ingale vd., 2025).

Tablo 2. Fenolik / Antioksidan Bileşiklerin Mikroenkapsülasyonu İle İlgili Seçilmiş Çalışmalar

Yazar (Yıl)	Biyoaktif bileşik	Yöntem	Duvar materyali	Ana bulgular
Rosales vd (2023)	Meyve kabuğu fenolleri	Nanoenkapsülasyon	Biyopolimer karışımları	İn vitro sindirim sonrası fenolik kaybı azaldı.
Zen vd (2020)	Spirulina antioksidanları	Mikroenkapsülasyon	Whey protein konsantresi	Fonksiyonel makarnada antioksidan aktivite stabil kaldı.
Li vd (2023)	Krill yağı antioksidanları	Nanoemülsiyon	Protein–polisakkarit sistemi	Oksidatif stabilite ve biyoerişilebilirlik arttı.
Pino vd (2019)	Balkabağı yağı	Sprey kurutma	Maltodekstrin	Oksidasyon hızı azaldı; raf ömrü uzadı.
García vd (2021)	Polifenol + probiyotik kombinasyonu	Jel boncuk (ekstrüzyon)	Kitosan / alginate	Probiyotik viabilitesi ve fenolik koruma arttı.

6. Fonksiyonel Gıda Sistemleri Açısından Kazanımlar

Mikroenkapsüle fenolik ve antioksidan bileşiklerin gıda formülasyonlarına entegrasyonu; fenolikçe zengin toz içecek karışımları, probiyotik ve polifenol kombinasyonlarını içeren fermente süt ürünleri, polifenoller ile zenginleştirilmiş unlu mamuller ve atıştırmalıklar, yağ fazı içinde fenollerle güçlendirilmiş fonksiyonel yağ ve emülsiyon sistemleri ile meyve–sebze yan ürünlerinin değerlendirildiği fonksiyonel toz ve ekstraktlar gibi pek çok ürün tipinin geliştirilmesine olanak sağlamaktadır. Ayrıca, meyve-sebze işleme yan ürünlerinden elde edilen polifenollerin mikroenkapsülasyon yoluyla fonksiyonel gıdalara kazandırılması; sürdürülebilirlik, atık minimizasyonu ve katma değer oluşturma açısından da önemli bir strateji olarak öne çıkmaktadır (Rosales vd., 2023).

7. Sonuç Ve Gelecek Perspektifler

Mevcut literatür, polifenoller ve diğer doğal antioksidanların fonksiyonel gıda sistemlerinde etkin kullanılabilmesi için mikroenkapsülasyonun giderek zorunlu hâle gelen bir teknoloji olduğunu göstermektedir (Bińkowska vd., 2024; Mehta vd., 2022). Mikroenkapsülasyon;

- ısı, oksijen, ışık ve pH gibi stres faktörlerine karşı fizikokimyasal stabiliteyi artırmakta,
- sindirim sistemi boyunca biyoerişilebilirlik ve biyoyararlanımı iyileştirmekte,

- istenmeyen tat ve koku gibi duyusal kısıtları azaltmakta,
- toz formda, ısıl işleme dayanıklı ve formülasyona uygun taşıyıcı bileşenler geliştirilmesine olanak vermektedir (Santos vd., 2020).

Sprey kurutma ve dondurarak kurutma, endüstriyel uygulamalar açısından hâlen en yaygın yöntemler olmakla birlikte; kompleks koaservasyon, nanoemülsiyon ve lipozomal sistemler gibi daha gelişmiş yaklaşımlar, hedefli salım ve kontrollü etki açısından önemli fırsatlar sunmaktadır (Mehta vd., 2022). Duvar materyali olarak maltodekstrin, gum arabik, modifiye nişasta, inülin, whey proteini ve bitkisel proteinlerin tek başına veya kombinasyon hâlinde kullanılması, kapsül verimi ve fenolik stabilitesi üzerinde belirleyici olmaya devam etmektedir (Santos vd., 2020; Karrar vd., 2021). Gelecekte, mikroenkapsülasyonun çok bileşenli fonksiyonel gıdalar (örneğin polifenol + probiyotik + omega-3 kombinasyonları), kişiselleştirilmiş beslenme yaklaşımları ve endüstri yan ürünlerinin yüksek katma değerli bileşenlere dönüştürülmesinde daha da kritik bir rol üstleneceği öngörülebilir (Ordóñez-García vd., 2024).

ABSTRACT

Biological control agents play an increasingly important role in sustainable plant disease management. In this study, the in vitro antagonistic efficacy of three isolates of *Clonostachys rosea* (CR11, CR14, CR15) was evaluated against soil-borne fungal pathogens of lettuce (*Lactuca sativa*), namely *Fusarium oxysporum* f. sp. *lactucae*, *Sclerotinia sclerotiorum*, and *S. minor*, which cause significant economic losses in lettuce production. Experiments were conducted using the dual culture method, wherein the radial growth of pathogenic colonies was measured and inhibition rates were calculated. Results demonstrated that all *C. rosea* isolates exhibited antagonistic activity against the tested pathogens. The highest inhibition was observed against *F. oxysporum* f. sp. *lactucae*, with CR11, CR14, and CR15 isolates providing inhibition rates of 48.7%, 50.99%, and 50.20%, respectively. Moderate efficacy was recorded against *S. sclerotiorum* (CR11: 43.7%, CR14: 40.82%, CR15: 39.11%), while the lowest inhibition was detected against *S. minor* (CR11: 31.5%, CR14: 26.0%, CR15: 28.7%). Notably, the CR14 isolate completely suppressed sclerotia formation in *S. sclerotiorum*, a significant finding for long-term disease management. Additionally, in dual culture assays, distinct pigmentation changes were observed in *Sclerotinia* colonies at interaction zones with *C. rosea*, suggesting that pathogenic hyphae experienced physiological stress. These findings suggest that *C. rosea* acts through multiple antagonistic mechanisms including mycoparasitism, antifungal metabolite production, and cell wall degradation. The study demonstrates that the CR14 isolate shows considerable promise as an effective biological control agent for lettuce disease management.

Keywords: *Clonostachys rosea*, biological control, lettuce soil-borne diseases

1.GİRİŞ

Sürdürülebilir bitki sağlığı, artan gıda ihtiyaçlarını karşılayan verimliliğin, ekosistem korunmasıyla dengelenmesini gerektirmektedir (Rockström ve ark., 2017). Kimyasal pestisitlere dayalı tek başına stratejiler, patojen direnci, toprak mikrobiyotası üzerindeki baskı ve artan mevzuat kısıtlamaları nedeniyle yetersiz kalmaktadır (Hawkins ve ark., 2019; Swaine ve ark., 2025). Bu sınırlamalar, entegre hastalık yönetiminde biyolojik mücadeleyi, kimyasal yaklaşımları tamamlayan önemli bir strateji olarak öne çıkarmaktadır (He ve ark., 2021; Collinge ve ark., 2022). Biyolojik mücadele ajanlarının stratejik değeri, ekosistemi korumaları ve farklı tarımsal uygulamalara destek olmaları ile yerel koşullara adatasyon yeteneğiyle önem kazanmaktadır (Sentis ve ark., 2022; Wyckhuys ve ark., 2024). Bu çerçevede, farklı etki mekanizmalarına sahip ve çok yönlü uygulama potansiyeli sunan biyolojik mücadele ajanlarının rolü daha da ön plana çıkmaktadır. Bu ajanlar arasında, *Clonostachys rosea* özellikle dikkat çekmekte; mikoparazitizm, antibiosis, rekabet ve hücre duvarı parçalayıcı enzim üretimi gibi çoklu biyokontrol mekanizmaları ile çok sayıda fungal patojen, nematod ve toprak kökenli hastalık etmenine karşı geniş spektrumlu etkinliği sayesinde sürdürülebilir bitki hastalık yönetiminde önemli bir alternatif oluşturmaktadır (Sun ve ark., 2020; Hasan ve ark., 2022; Geiger ve ark., 2022).

Biyolojik mücadele ajanlarının uygulanması, özellikle toprak kökenli patojenlerden kaynaklı ciddi kayıpların yaşandığı yaprağı yenen sebzelerin üretiminde büyük önem taşımaktadır (Shinde ve ark., 2011; Gilardi ve ark., 2018; Carlucci ve ark., 2023). Marul (*Lactuca sativa* L.), dünya genelinde yaygın olarak üretilen ve taze tüketimi tercih edilen ekonomik açıdan önemli bir yaprağı yenen sebzedir (Gargaro ve ark., 2023; Křístková ve ark., 2008). Ancak, beyaz çürüklük hastalığına neden olan *Sclerotinia sclerotiorum* ve *S. minor* ile Fusarium solgunluğuna yol açan *Fusarium oxysporum* f. sp. *lactucae* gibi toprak kökenli fungal patojenler marul üretiminde ciddi verim kayıplarına ve kalite düşüşüne neden olmaktadır (O'Sullivan ve ark., 2021; Clarkson ve ark., 2014; Canpolat ve Tülek, 2019; Mestdagh ve ark., 2023). Bu patojenlerin kontrolünde kimyasal fungisitlerin etkinliği, uygulama zamanlaması ve çevresel koşullara bağlı olarak sınırlı ve değişken olup (O'Sullivan ve ark., 2021; Mueller ve ark., 2002), yoğun kullanım ise çevre ve insan sağlığı açısından riskler taşırken fungisit direncinin gelişimine neden olmaktadır (Naqvi ve ark., 2025; El-Aswad ve ark., 2023).

Bu bağlamda, mevcut çalışma, *C. rosea* izolatlarının *S. sclerotiorum*, *S. minor* ve *F. oxysporum* f. sp. *lactucae* üzerindeki in vitro antagonistik etkinliğini değerlendirmeyi amaçlamaktadır.

2. MATERYAL VE METOT

2.1. Materyal

Bu çalışmada, biyolojik mücadele ajanı olarak Zirai Mücadele Merkez Araştırma Enstitüsü kültür koleksiyonundan temin edilen *C. rosea*' nın üç farklı suşu (CR11, CR14 ve CR15) kullanılmıştır. Patojen olarak kullanılan *F. oxysporum* f. sp. *lactucae*, *S. sclerotiorum* ve *S. minor* izolatları ise daha önce maruldan (*L. sativa*) izole edilmiş ve patojenisite testleri yapılarak Sivas Bilim ve Teknoloji Üniversitesi Tarım Bilimleri ve Teknolojileri Fakültesi Bitki Koruma Bölümü kültür koleksiyonunda muhafaza edilmiştir.

2.2. Metot

C. rosea' nın *F. oxysporum* f. sp. *lactucae*, *S. sclerotiorum* ve *S. minor*' a karşı antagonistik aktivitesi, ikili kültür (dual culture) yöntemi kullanılarak değerlendirilmiştir (Dennis ve Webster, 1971a; Skidmore ve Dickinson, 1976). Deneme, her patojen için üç tekerrürlü ve bir kontrol grubu olacak şekilde yürütülmüştür. İnokülasyondan önce, *C. rosea* ve patojen

izolatları Patates Dekstroz Agar (PDA) üzerinde 25 ± 2 °C'de yedi gün süreyle ön kültüre alınmıştır (Geiger ve ark., 2022; Dennis ve Webster, 1971a,b; Skidmore ve Dickinson, 1976). İnokülasyon, 5 mm çapında aktif olarak büyüyen misel disklerinin, 9 cm çaplı PDA içeren Petri kaplarının kenarından 1 cm uzağa, karşılıklı taraflara yerleştirilmesiyle gerçekleştirilmiştir. Kontrol Petri kaplarına sadece patojen misel diskleri yerleştirilirken, uygulama gruplarında patojen ve *C. rosea* misel diskleri karşılıklı olarak yerleştirilmiştir (Flores-Bazauri ve ark., 2015; Rodríguez ve ark., 2015). Uygulamayı takiben, tüm Petri kapları 25 ± 2 °C sıcaklıkta ve karanlıkta inkübasyona bırakıldıktan sonraki 3., 5., 7. ve 14. günlerde, patojen kolonilerinin merkezden kenara doğru radyal gelişimi ölçülmüştür. Nihai değerlendirme, kontrol gruplarındaki patojen kolonileri Petri kabı yüzeyini tamamen kapladığında (14. gün) yapılmıştır. *C. rosea* tarafından patojen gelişiminin engelleme yüzdesi (%I); (C−T)/C×100 formülü kullanılarak hesaplanmıştır (Skidmore ve Dickinson, 1976; Fokkema, 1973). Burada C, kontrol grubundaki patojenin koloni yarıçapını (mm); T, *C. rosea* ile yapılan uygulamadaki patojenin koloni yarıçapını (mm) ifade etmektedir.

3. BULGULAR

In vitro antagonizma testleri, her üç *C. rosea* izolatının da (CR11, CR14 ve CR15) test edilen üç fitopatojenin miseliyal gelişimini değişen derecelerde engellediğini ortaya koymuştur (Tablo 1).

Tablo 4. *Clonostachys rosea* İzolatlarının Farklı Patojenik Funguslara Karşı Engelleme Oranları *(%)*

Patojen	**CR11 (%)**	**CR14 (%)**	**CR15 (%)**
Fusarium oxysporum* f. sp. *lactucae	48.7	50.99	50.20
Sclerotinia sclerotiorum	43.7	40.82	39.11
Sclerotinia minor	31.5	26.0	28.7

En yüksek antagonistik etki, *F. oxysporum* f. sp. *lactucae*' ye karşı gözlenmiştir. Bu patojene karşı engelleme oranları CR11 için %48.7, CR14 için %50.99 ve CR15 için %50.20 olarak ölçülmüştür; CR14 izolatı bu grupta en yüksek performansı sergilemiştir (Şekil 1-B). *S. sclerotiorum*' a karşı elde edilen engelleme oranları, *F. oxysporum* f. sp. *lactucae*' ye kıyasla daha düşük bir seviyede kalmıştır. Engelleme değerleri %43.7 (CR11), %40.82 (CR14) ve %39.11 (CR15) olarak kaydedilmiştir. Test edilen patojenler arasında en düşük engelleme oranları *S. minor*' a karşı tespit edilmiştir. *S. minor*' un miseliyal gelişimi, CR11 tarafından %31.5, CR14 tarafından %26.0 ve CR15 tarafından %28.7 oranında engellenmiştir (Şekil 1-D). Bu bulgular, test edilen *C. rosea* izolatlarının, *Sclerotinia* türlerine kıyasla *F. oxysporum* f. sp. *lactucae* üzerinde daha güçlü bir antagonistik potansiyele sahip olduğunu ve *S. minor*' un bu biyokontrol ajanlarına karşı en yüksek toleransı gösterdiğini ortaya koymaktadır.

Şekil 13. *In vitro* koşullarda *C. rosea*' nın *F. oxysporum* f. sp. *lactucae* (A-B), *S. minor* ile etkileşimi (C-D)

C. rosea ile yapılan uygulamalarda, *S. sclerotiorum*'un sklerotları, yoğun sporodokiyal yapılar tarafından sıklıkla kolonize edilmiştir (Şekil 2-C, D). Özellikle, CR14 izolatı sklerot gelişiminin tamamen engellenmesini sağlamıştır (Şekil 2-A). Buna karşılık, kontrol uygulamasında, *S. sclerotiorum* sağlıklı ve morfolojik olarak bozulmamış sklerotlar üretmiştir (Şekil 2-B). Bu bulgular, *C. rosea*'nın, miseliyal gelişimi hem baskılayarak hem de *S. sclerotiorum*'da hayatta kalma yapılarının oluşumuna müdahale ederek ikili bir etki gösterdiğini düşündürmektedir. Ayrıca, kontrol gruplarında (Şekil 2-B), bu patojenlerin tipik morfolojik bir özelliği olan homojen ve yoğun beyaz miseliyal gelişim gözlenmiştir. Eş zamanlı olarak, uygulama yapılan Petri kaplarında *S. sclerotiorum* ve *S. minor* kültürde yeşil ve kahverengimsi bir renk değişimi gözlenmiştir (Şekil 1-D, 2-A).

Şekil 14. *In vitro* koşullarda *C. rosea*'nın *S. sclerotiorum* ile etkileşimi

Bu sonuçlar, *C. rosea* izolatlarının, özellikle de CR14'ün, *F. oxypsorum* f. sp. *lactucae'* nin gelişimini önemli ölçüde engelleyebildiğini ve *S. sclerotiorum*'daki sklerotlar gibi kalıcı hayatta kalma yapılarının oluşumunu bozduğunu göstermektedir. Bu bulgu, *C. rosea*'nın önemli biyokontrol potansiyelini vurgulamaktadır.

4. TARTIŞMA VE SONUÇ

Bu çalışmada, üç *C. rosea* izolatının (CR11, CR14, CR15) in vitro koşullarda *F. oxysporum* f. sp. *lactucae*, *S. sclerotiorum* ve *S. minor*'un misel gelişimini farklı düzeylerde engellediği gösterilmiştir. Bu çalışmada test edilen *C. rosea* izolatları, *F. oxysporum* f. sp. *lactucae*'ye karşı *Sclerotinia* türlerine kıyasla daha yüksek antagonistik aktivite sergilemiştir. En yüksek engelleme oranı *F. oxysporum* f. sp. *lactucae*'de (%48.7-50.99) gözlenirken, *S. sclerotiorum*'da orta düzeyde (%39.11-43.7) ve *S. minor*'da ise en düşük (%26.0-31.5) etkinlik tespit edilmiştir.

Önceki çalışmalarla uyumlu şekilde, *C. rosea*'nın *Fusarium* türlerine karşı belirgin antagonistik aktivite gösterdiği bilinmektedir (Sun ve ark., 2020; Nagaraj ve ark., 2023). Nagaraj ve ark. (2023), *C. rosea* izolatlarının in vitro ortamda *F. oxysporum* f. sp. *lycopersici* misel gelişiminde

%59.4 ile %71.6 arasında azalma sağladığını bildirmiştir; bu sonuçlar, mevcut çalışmada elde edilen %48.7-50.99 inhibisyon oranlarıyla karşılaştırılabilir düzeydedir. Son yıllarda yapılan genomik, transkriptomik ve metabolomik analizler içeren karşılaştırmalı omik çalışmalar, örneğin *F. graminearum* ile etkileşimde, *C. rosea*'nın hücre duvarı parçalayıcı enzimler (CWDE'ler), ikincil metabolitler ve taşıyıcı proteinler gibi çoklu moleküler mekanizmalarla antagonistik yanıt verdiğini ortaya koymuştur (Demissie ve ark., 2020; Sun ve ark., 2020; Bahadoor ve ark., 2023).

Öte yandan fonksiyonel genetik çalışmalar, *S. sclerotiorum*'a karşı mikoparazitizmde Chi67-1 gibi kitinaz genlerinin önemli rol oynadığını göstermiştir. Chi67-1 geni aşırı eksprese edilen *C. rosea* transformantlarının önemli bir kısmında, *S. sclerotiorum* sklerotlarına karşı parazitlenme oranının yaklaşık %50 daha yüksek olduğu ve en iyi transformantta kitinaz aktivitesinin 2,4 kat arttığı belirlenmiştir (Sun ve ark., 2015, 2017). Bu bulgular, *F. oxysporum*'un hücre duvarı bileşenlerine yönelik enzimatik degradasyonun, *C. rosea*'nın yüksek antagonistik etkinliğinde rol oynayan temel mekanizmalardan biri olabileceğini düşündürmektedir (Sun ve ark., 2020).

S. sclerotiorum açısından ise, elde edilen inhibisyon oranları (%39.11-43.7) *Fusarium* türlerine kıyasla daha düşük olmakla birlikte, anlamlı antagonistik etkinlik düzeyindedir. Özellikle dikkat çeken bir bulgu, CR14 izolatının *S. sclerotiorum*'un sklerot üretimini tamamen baskılamış olmasıdır. Sklerotlar, toprak kökenli patojenlerin uzun vadede canlılığını sürdürmesini sağlayan ve tarla koşullarında hastalık salgınlarının tekrarlamasında kritik rol oynayan kalıcı inokulum kaynaklarıdır (Purdy, 1979; Smolińska ve Kowalska, 2018). Rodríguez ve ark. (2011), *C. rosea*'nın sklerotları yoğun bir şekilde kolonize ederek canlılıklarını önemli ölçüde azalttığını bildirmiştir. Mevcut çalışmada da CR14 uygulamasında sklerotların gelişemediği veya gelişse bile fiziksel temas ile bu yapıların kolaylıkla parçalandığı ve morfolojik olarak bozulmuş yapılar sergilediği gözlemlenmiştir. Bu bulgu, *C. rosea*'nın sadece misel gelişimini baskılamakla kalmayıp, sklerot canlılığını düşürerek toprak inokulum yoğunluğunu azaltma potansiyeline sahip olduğunu göstermektedir.

Dual kültür testlerinde, *S. sclerotiorum* ve *S. minor* kolonilerinde, *C. rosea*'ya yakın bölgelerde tipik beyaz kolonilerden yeşilimsi-kahverengiye dönüşen belirgin bir pigmentasyon değişimi gözlenmiştir. Kontrol gruplarında bu renk değişimi görülmemiştir. Bu gözlem, *C. rosea* ile etkileşim bölgesindeki patojen hiflerinin fizyolojik stres altında olduğunu düşündürmektedir. Benzer şekilde, son çalışmalarda antagonistik etkileşimler sırasında patojen hiflerinde pigment birikiminin ve oksidatif stres göstergelerinin (örneğin ROS birikimi, melanizasyon) arttığı bildirilmiştir (Butler ve ark., 2009; Liang ve ark., 2018; Ayaz ve ark., 2024). Bu bulgular, *C. rosea'*nın çok yönlü antagonistik mekanizmalarının (doğrudan mikoparazitizm, antifungal metabolit üretimi, hücre duvarı degradasyonu) birlikte etki gösterdiğini desteklemektedir (Sun ve ark., 2020).

Mevcut çalışmada, *S. minor* üzerinde elde edilen inhibisyon oranlarının (%26.0-31.5) hem *F. oxysporum* hem de *S. sclerotiorum*'a kıyasla önemli ölçüde düşük olması dikkat çekicidir. Literatürde, Sclerotinia türlerinin biyolojik kontrol ajanlarına karşı hassasiyetlerinin, popülasyonlar ve izolatlar arasında değişkenlik gösterebildiği rapor edilmiştir (Nicot ve ark., 2019; Smolińska ve Kowalska, 2018). Sclerotinia türlerinde oksalik asit üretiminin patojeniteyle yakın ilişkili olduğu ve bazı *S. minor* izolatlarının da yüksek düzeyde oksalik asit üretebildiği bildirilmiştir; ancak oksalik asit miktarları hem türler hem de izolatlar arasında geniş varyasyon göstermektedir (Mihajlović ve ark., 2024; Bolton ve ark., 2006). Sclerotinia türlerinde sklerotial melanin, UV ışığı, sıcaklık dalgalanmaları ve diğer çevresel streslere karşı dayanıklılığı artıran; dolayısıyla sklerotların mikrobiyal antagonistler ve biyolojik kontrol etmenleri tarafından kolonize edilmesini güçleştirebilen önemli bir koruyucu faktör olarak

değerlendirilmektedir (Butler ve ark., 2009; Ordóñez-Valencia ve ark., 2015; Bolton ve ark., 2006; Chitrampalam ve ark., 2011; Rabeendran ve ark., 2006). *S. minor*'ın küçük ve yoğun melanize sklerotlarının, rind tabakasının histolojik organizasyonunun ve sklerotların farklı gelişim aşamalarındaki duyarlılıklarının da biyolojik kontrol ajanlarının penetrasyonunu güçleştirerek antagonistik etkinliği sınırlayabileceği öne sürülmektedir (Bullock ve ark., 1980; Rey ve ark., 2005).

Sonuç olarak, *C. rosea* izolatlarının in vitro koşullarda özellikle *F. oxysporum* f. sp. *lactucae*'nin misel gelişimini baskılama ve *S. sclerotiorum*'da sklerot oluşumunu engelleme kapasiteleri, bu türün entegre hastalık yönetimi açısından önemli potansiyel taşıdığını ortaya koymaktadır. CR14 izolatının özellikle sklerot inhibisyonundaki performansı, bu suşun marulda beyaz çürüklük ve Fusarium solgunluk hastalıklarının yönetiminde kullanılabilir bir biyolojik kontrol ajanı olarak geliştirilmesi açısından umut vericidir. Ancak in vitro ortamda elde edilen bu bulguların, sera ve tarla koşullarında gerçekleştirilecek daha kapsamlı araştırmalarla doğrulanması gerekmektedir. Gelecek çalışmalarda, *C. rosea* izolatlarının formülasyon geliştirme, raf ömrü, çevresel koşullara adaptasyon ve tarla koşullarında etkinliği üzerine odaklanılması, bu biyokontrol ajanının ticari uygulamalarının yaygınlaşmasına katkı sağlayacaktır.

ABSTRACT

Ornamental plant cultivation is a rapidly growing agricultural sector worldwide, with the market expected to reach $50 billion in 2025. Root-knot nematodes (RKN), root lesion nematodes, and viral vector nematodes are major pests causing significant yield and quality losses in ornamental plant production. Plant-parasitic nematodes (PPN) account for approximately 14% of global agricultural losses, with ornamental plants experiencing around 11% loss due to nematode infestation. *Meloidogyne* spp. (root-knot nematodes), *Aphelenchoides* spp. (foliar nematodes), *Ditylenchus dipsaci* (stem and bulb nematode), and viral vector nematodes such as *Xiphinema*, *Longidorus*, *Trichodorus*, and *Paratrichodorus* are among the most common damaging species in ornamental crops. Root-knot nematodes cause galling in roots, foliar nematodes produce necrotic lesions on leaves, stem and bulb nematodes induce rot in bulbs and stems, while viral vector nematodes transmit diseases causing mosaic, ring spot, and necrosis symptoms. Studies conducted in Turkey on important cut flowers such as gerbera, carnation, and roses have revealed the widespread occurrence of various nematode species. Traditional control methods include hot water treatment, soil fumigation, and nematicide application; however, environmental and economic concerns have led to the banning of many effective fumigants and nematicides, necessitating the development of alternative management strategies. The use of resistant varieties, biological control, and integrated pest management approaches have become critical for ensuring sustainable and profitable ornamental plant production.

Keywords: Plant-parasitic nematodes, Ornamental plants, Nematode management

1.GİRİŞ

Süs bitkileri yetiştiriciliği, dünya genelinde hızla gelişen ve milyarlarca dolarlık ticaret hacmine sahip bir tarımsal üretim koludur. Bu sektör; peyzaj düzenlemeleri, iç ve dış mekân bitkilendirme uygulamaları, çevre estetiği ve yeşil alan tasarımı gibi çok çeşitli kullanım alanlarına sahiptir (Salachna, 2022). Son yıllarda çiçek ve süs bitkileri pazarı önemli ölçüde büyüme göstermiş olup 2024 yılında 46,31 milyar dolar olan pazar büyüklüğünün 2025 yılında %8,4'lük büyüme oranı ile 50,17 milyar dolara ulaşacağı öngörülmektedir (Anonymous, 2025). Bu ekonomik büyüme, süs bitkileri üretiminin istihdam yaratma ve kırsal kalkınmaya katkı sağlama potansiyelini de artırmaktadır (Martinho, 2012).

Süs bitkileri üretiminde verim ve kaliteyi olumsuz etkileyen başlıca kısıtlayıcı unsurlar arasında biyotik ve abiyotik stres faktörleri önemli bir yer tutmaktadır. Sıcaklık ekstremleri, su stresi ve besin yetersizlikleri gibi abiyotik etmenler ile virüsler, bakteriler, funguslar, böcekler ve nematodlar gibi biyotik etmenler bitkilerin gelişimini sınırlamaktadır (Lal ve ark., 2023). Bu biyotik stres unsurları arasında, çoğu toprak kökenli mikroskobik olan ve zararı çoğu zaman fark edilmeden ilerleyen bitki paraziti nematodlar (BPN), süs bitkileri üretiminde önemli ekonomik kayıplara neden olmaktadırlar. Özellikle kök sistemine zarar vererek bitkinin su ve besin alımını engelleyen BPN'ler, üretim sürecinde dikkate alınması gereken başlıca zararlılardan biridir (Howland ve Quintanilla, 2023).

Bitki paraziti nematodlar (BPN), tarımı yapılan bitki türlerinin tamamında zarar yapabilmeleri ve yabancı otların büyük kısmını enfekte edebilmeleri nedeniyle tarımsal üretimdeki en büyük tehditlerden biri durumundadır. Amerikan Fitopatoloji Derneği'ne (APS) göre, küresel ölçekte tarımsal verim kayıplarının %14'ü BPN'lardan kaynaklanırken bunun yıllık maddi karşılığının yaklaşık 125 milyar dolar olduğu tahmin edilmektedir (Chitwood, 2003). Nematodlardan kaynaklanan ekonomik kayıplarda BPN türünün virülensi ve coğrafi dağılımı ile bitkisel ürünün ekonomik değeri etkili olmaktadır. Dünyada en çok zarara neden olan nematod türünün konukçu spektrumu çok geniş olan kök ur nematodları (*Meloidogyne* spp.) olduğu ve bunu sırasıyla kist nematodları (*Heterodera* ve *Globodera* spp.), kök lezyon nematodları (*Pratylenchus* spp.), kök oyucu nematod (*Radopholus similis*) ve soğan sak nematodu (*Ditylenchus dipsaci*)'nun izlediği bildirilmiştir (Jones ve ark., 2013). Mücadele yapılmayan alanlarda kök ur nematodları %100 e varan kayıplara neden olurken, kist nematodları ve kök ur nematodlarının birçok ülkede ortalama % 90'lara varan hasarlara neden olduğu (Meagher, 1972; Maqbool ve Zarina, 1988; Nicol ve ark., 2011) soğan sak nematodunun ise %80'e kadar zarar verdiği tespit edilmiştir (Sturhan ve Brzeski, 1991).

BPN'ler sebzeler, meyveler, çiçek ve süs bitkileri, baharat ve çeşniler, tıbbi ve aromatik bitkiler ve yumrulu bitkiler gibi başlıca bahçe bitkilerinde ciddi şekilde zarar yapmakta olup bu çok değerli ürünlerin birçoğunda verimin azalmasına ve hatta ölümüne neden olmaktadırlar (Ravichandra, 2014). Yapılan çalışmalar sonucunda bahçe bitkilerindeki BPN kaynaklı verim kaybının yaklaşık %13,5 süs bitkilerindeki kaybın ise %11,1 olduğu tahmin edilmektedir (Ravichandra, 2014). Tarımsal üretim üzerinde böylesine önemli bir etkiye sahip olan BPN'nin yaygınlığı, zarar seviyeleri ve mücadele olanakları üzerine birçok çalışma yapılmasına karşın dünya genelinde yaklaşık 70 milyar dolarlık bir endüstri olan süs bitkileri ile ilgili olarak yapılan çalışmalar daha sınırlı düzeydedir (Madhavan ve ark., 2021). Son yapılan araştırmalara göre süs bitkilerinde Dünya genelinde sorun oluşturan bitki paraziti nematodlar; *Meloidogyne* spp., *Ditylenchus* spp., *Aphelenchoides* spp., *Paratylenchus* spp., *Pratylenchus* spp., *Helicotylenchus* spp., *Radopholus* spp., *Xiphinema* spp., *Trichodorus* spp., *Paratrichodorus* spp., *Rotylenchulus* spp. ve *Longidorus* spp. olarak bildirilmiştir (Howland ve Quintanilla, 2023). *Ditylenchus* ve *Aphelenchoides* cinslerinin özellikle soğan ve yaprak parazitleri olarak;

Meloidogyne, *Radopholus*, *Pratylenchus*, *Heterodera*, *Xiphinema*, *Longidorus*, *Paratrichodorus*, *Criconemoides*, *Belonolaimus* ve *Hoplolaimus* spp. cinslerinin ise kök parazitleri olarak ekonomik anlamda zarar yapan türleri içerdiği bildirilmiştir (Bridge ve Starr, 2007).

Bu durum Türkiye açısından değerlendirildiğinde de benzer bir durum görülmektedir. Yüksel (1974) tarafından İstanbul'da begonyada *Meloidogyne hapla*'nın tespit edildiği çalışma süs bitkilerindeki ilk çalışma durumundadır. Antalya ili Gerbaera (*Gerbera jamesonii* L.) ve Karanfil (*Dianthus caryophyllus* L.) yetiştirilen alanlarda yürütülen çalışma sonucunda *Meloidogyne* spp., *Helicotylenchus* spp., *Aphelencoides* spp., *Xiphinema* spp., *Pratylenchus* spp., *Longidorus* spp. yaygınlıkları sırasıyla %21,02, 10,24, 4,05, %0,06, %0,44 ve 0,01 olarak belirlenmiştir. Aynı çalışmada üç farklı gerbera çeşidinde *M. incognita* üreme oranının 1,9 ila 2,7 arasında değiştiği, 14 farklı karanfil çeşidinde ise üç çeşitte üreme görülmezken diğer çeşitlerde ise üreme oranının 0,8 ila 3,9 arasında değiştiği ve ayrıca *A. besseyi* zararı sonucunda gerbera çeşitlerinde %20 ila %40 arasında değişen oranlarda bitki ölümü görüldüğü bildirilmiştir (Yarba, 2019). Antalya ili örtü altı alanlarda yapılan çalışmada ise karanfil, gerbera ve lisyantus kesme çiçeklerinde yapılan çalışma sonucunda *Pratylenchus thornei, P. neglectus, Meloidogyne incognita, M. javanica, M. arenaria* ve *M. hapla* yaygınlığı sırasıyla %98,73, %88,60, %65,82, %34,17, %22,78 ve %5,06 olarak belirlenmiştir (Sert Çelik ve ark., 2019). Yalova ili sera alanlarında yetiştiriciliği yapılan 6 farklı kesme çiçek çeşidi gül, şebboy, krizantem, hüsnü yusuf, Lisianthus ve frezyada zarar yapan bitki paraziti nematodların tespit edildiği çalışma sonucunda *Meliodogyne incognita, M. hapla, Aphelenchus avenae, Aphelenchoides* sp., *Trophurus imperialis, Longidorus moesicus, Pratylenchus vulnus, Paratylenchus hamatus, Rotylenchus arasbaranensis* türleri tespit edilmiştir (Çelik, 2019). Dört farklı karanfil çeşidinin kök-ur nematodlarına dayanıklılık durumlarının araştırıldığı çalışmada ise *Meloidogyne incognita, M. javanica* ve *M. arenaria* türlerine Turbo çeşidinin dayanıklı, Betsy ve Glaciar çeşitlerinin hassas, Nirvana çeşidinin ise *M. incognita, M. javanica*'ya orta dayanıklı *M. arenaria*'ya ise tam dayanıklı olduğu belirlenmiştir (Sert Çelik ve ark., 2022).

2. NEMATODLARIN ZARAR VERDİĞİ BAŞLICA SÜS BİTKİLERİ

Krosandra, sümbülteber, krizantem, gül, yasemin, orkide, glayöl, karanfil, gerbera, antoryum, zambak, kadife çiçeği ve aster gibi türler, yaygın olarak yetiştirilen başlıca geleneksel ve ticari süs bitkileri arasında yer almaktadır. Dünya genelinde birçok nematod türünün çeşitli süs bitkileriyle ilişkili olduğu bildirilmiş olsa da (Tablo 1), bazı bitkiler üzerinde yapılan çalışmalar halen yetersizdir. Çiçekçiliğin dünya genelinde büyük bir endüstri haline gelmesiyle birlikte, nematodlar süs bitkileri de dahil olmak üzere sera ve tarla koşullarında yetiştirilen ürünlerdeki en önemli üretim kısıtlarından biri haline gelmiştir. (Ravichandra, 2014).

Tablo 1. Önemli süs bitkilerinde zarar yapan başlıca bitki paraziti nematod türleri (Ravichandra, 2014)

Bitki	**Nematod**
Çiçekli bitkiler	
Asparagus sprengeri	*Helicotylenchus cavenessi*
Asterler	*Aphelenchoides ritzemabosi*
Begonya	*Meloidogyne incognita*
Cineraria hybrida	*Helicotylenchus* spp.
Karanfil	*R. reniformis, M. Arenaria, M. Hapla, M. Javanica, M. İncognita, Ditylenchus dipsaci, Heterodera trifolii, Criconemella curvata, Pratylenchus dianthus, Paratylenchus curvitatus, Tylenchus, Macroposthonia curvata*
Krizantem	*Aphelenchoides ritzemabosi, Helicotylenchus* sp., *Meloidogyne* spp., *Pratylenchus penetrans, R. reniformis*
Crossandra	*M. incognita, Pratylenchus delattrei, P. africans*
Dahlia	*A. ritzenabosi, Ditylenchus destructor*
Glayöl	*Meloidogyne* spp., *Helicotylenchus rotundicaudatus, Scutellonema brachyurum,*
Hemerocallis	*H. rotundicaudatus*
Hibiscus rosa-sinensis	*Helicotylenchus varicaudatus*
Sümbül ve Lale	*Ditylenchus*
Yasemin	*M. incognita, A. besseyi*
Zambak	*Pratylenchus penetrans*
Orkideler	*A. ritzemabosi*
Phlox	*X. vuittenezi*
Gül	*Pratylenchus vulnus, M. Hapla, Helicotylenchus labiata, H. Dihystera, H. 1942anus, Hoplolaimus galeatus, X. Diversicaudatum, Pratylenchus penetrans, Hemicycliophora typical, Longidorus macrosoma*
Ada çayı	*A. ritzemabosi*
Zinnia elegans	*A. ritzemabosi*
Eğrelti otları	
Asplenium nidus	*A. ritzemabosi*
Aucuba japonica	*M. arenaria*
Buxus microphylla	*M. arenaria*
B. sempervirens	*M. arenaria, Pratylenchus vulnus, Criconemella xenoplax*
Camellia japonica	*Tylenchorhynchus claytoni*
Gardenia jasminoides	*M. arenaria*
Ilex cornuta	*C. xenoplax, T. Claytoni*
I. crenata compacta	*M. arenaria*
Juniperus conferta	*Criconemella xenoplax*
J. excelsa	*Pratylenchus vulnus*
J. horizontalis	*P. vulnus*
Photinia ve *Rhododendron indicum*	*T. claytoni*
Struthiopteris orientalis	*M. arenaria*
Tuberose	*M.*spp.
Odunsu bitkiler	
Abenda grandiflora	*M. hapla*
Kaktüs	*M. incognita, Cactodera cacti, Heterodera cacti*
Cornus florida	*M. hapla*
Croton	*H. cacti*
Ctenatha	*Helicotylenchus dihystera*
Ficus elastica	*Pratylenchus coffeae*
Hippeastrum vittatum	*Pratylenchus coffeae*
Hoya carnosa	*Scutellonema brachyurus*
Momordica	*P. coffeae*
Palmiye	*Helicotylenchus dihystera*

2.1. Süs Bitkilerinde Bitki Paraziti Nematodların Toprak Üstü Belirtileri

Bitki paraziti nematodların zararı sonucunda türe bağlı olarak değişmekle beraber genellikle bitki gelişiminde gerileme, yoğun bulaşıklıklarda arazinin belli yerlerinde çökmeler, gövdelerde deformasyon ve incelme ve yüzey solgunluğu, ısıya karşı olağandışı hassasiyet, yapraklarda sararma, kızarıklık ve yaprak dökülmesi, yavaş büyüme ve erken solma (su stresi) gibi belirtiler arazi içerisinde düzensiz desenler halinde kendini gösterir. Ayrıca, odunsu süs bitkilerinde yaprak dökülmesi ve dallarda yaprak kaybı da gözlemlenebilir (Sigariova ve Karpliyk, 2015; Ravichandra, 2014). Bu semptomlar spesifik değildir ve toprağın düşük verimliliği, bitki besin maddesi eksikliği, kuraklık veya aşırı nem gibi abiyotik faktörlerden kaynaklanabileceği gibi böcekler, viruslar, funguslar veya bakteriler gibi biyotik faktörlerden de kaynaklanabilir (Hubin, 2013; Kiryanova ve Krall, 1969; Matveeva, 1989).

2.2. Süs Bitkilerinde Nematod Hasarının Toprak Altı Belirtileri

Bitki paraziti nematodların süs bitkilerinde toprak altı aksamda oluşturduğu zararlar genellikle hücre ve dokuların mekanik olarak deformasyona uğraması ve bunun sonucu olarak bitkide fizyolojik süreçlerin bozulması, fungal ve bakteriyel patojenlere giriş kapısı oluşturmaları, virüs vektörü nematodların sağlıklı bitkilere virüs bulaştırması sonucunda viral enfeksiyonların yayılması ve bitkinin mikotik funguslarla olan simbiyotik ilişkilerinin bozulması gibi çeşitli şekillerde ortaya çıkar (Hubin, 2013). Bitki paraziti nematodların bir kısmı yaşamlarını toprakta sürdürürken, bazıları ise doğrudan bitki dokularının içinde hareketli veya sabit olarak bulunurlar. Örneğin, *Pratylenchus* cinsi süs bitkilerinin kök dokularında hareketli endoparazit olarak zarar yaparken *Ditylenchus* cinsi ise soğan, gövde ve yapraklarda hareketli endoparazit olarak zarar yapmaktadırlar. *Meloidogyne* ve *Heterodera* cinslerinde yer alan türler ise sabit endoparazit olarak sınıflandırılır ve bu türler yaşam çemberlerinin büyük kısmını kök içinde sabit olarak geçirirler. Öte yandan, *Rotylenchus*, *Tylenchorhynchus*, *Helicotylenchus* ve *Paratylenchus* gibi cinslerde yer alan türler ise toprakta yaşayan ve kök sistemindeki hücre içeriklerini emerek beslenen ektoparazit nematodlar arasında yer alırlar (Sigariova ve Karpliyk, 2015).

Endoparazitik nematodlar, konukçu bitki dokuları içinde hareket ederken mekanik zarara yol açar; bu durum dokularda tahribata, nekrotik lekelere ve bireysel hücre ölümlerine neden olur (Kiryanova ve Krall, 1969). Ayrıca, nematodların salgıladığı sindirim enzimleri bitki dokularını parçalayarak metabolik aktivitelerin ve homeostazın bozulmasına yol açar. Bu etkiler, bitkinin hasar gören dokularında büyüme ve gelişme geriliği, kök, gövde ve yaprak deformasyonları ile sonuçlanabilir. Şiddetli durumlarda ise bitkinin bazı bölümlerinin tamamen işlevini yitirmesi ya da bitkinin ölümü söz konusu olabilir. Genellikle tomurcuk oluşumu gecikir, çiçeklenme süreci bozulur; bazı çiçekler deforme olurken sayılarında da azalma gözlenir. Bu durum, özellikle çiçekli süs bitkilerinde, ürün kalitesini ciddi şekilde düşürür ve ticari açıdan istenmeyen sonuçlara yol açar (Sigariova ve Karpliyk, 2015).

Diğer birçok kültür bitkisinde olduğu gibi süs bitkileri açısından en türlerin başında gelen kök ur nematodlarının beslenmeleri sonucunda oluşan dev hücreler nedeniyle bitki köklerinde popülasyon yoğunluğuna, türe ve konukçuya bağlı olarak değişen şekil ve büyüklüklerde urlanmalar meydana gelmektedir. Çimen ve birçok süs bitkisinde zarar yapan *Belonolaimus longicaudatus*, *Paratrichodorus minör* ve *Dolichodorus* spp. ise kök uçlarında zarar yaparak uçları deforme ederler (Şekil 1). *Radopholus similis*, *Pratylenchus* spp., *Hoplolaimus* spp. zararı sonucunda ise köklerde renk değişimleri görülürken nematodun beslenmesi ve bunun sonucu olarak oluşan yaralanmaların fungal veya bakteriyel etmenlerin zararına imkan vermesiyle kök dokularının yumaşaması ve kararması gibi belirtiler de oluşur (Ravichandra, 2014).

Şekil 1. *Belonolaimus longicaudatus* tarafından zarar gören ve görmeyen bermuda çim alanı ve kökleri

3. SÜS BİTKİLERİNDE GÖRÜLEN ÖNEMLİ BİTKİ PARAZİTİ NEMATODLAR

3.1.Kök-ur Nematodları (*Meloidogyne* spp.)

Bütün dünyada dağılım gösteren, geniş konukçu dizisine sahip obligat parazitler olan kök-ur nematodları (*Meloidogyne* spp.) (KUN) bilimsel ve ekonomik önemleri açısından en çok zarar yapan 10 bitki paraziti arasında ilk sırayı almaktadır (Jones ve ark., 2013). Bitkilerin köklerinde irili-ufaklı ur oluşturmaları ile tanınabilen kök-ur nematodlarının 5500'den fazla konukçusu olduğu bilinmekte olup neredeyse her tarımsal üründe ve çoğu yabancı ot türünde zarar yapabilmektedirler (Hussey ve Janssen, 2002; Elling, 2013; Trudgill ve Blok, 2001). Konukçu bitkilerin köklerinde sabit endoparazit olan kök-ur nematodlarının zararı soncu oluşan dev hücreler nedeniyle köklerde urlanmalar oluşturmaktadırlar (Şekil 2). Özellikle sulama imkânının olduğu sıcak bölgelerde, sebze ve meyve üretimi yapılan alanlarda daha zararlı olan KUN'ları Akdeniz havzasında zarar yapan önemli zararlıların başında gelmekte olup domates ve patates gibi ürünlerde %25 ila %100 arasında değişen oranlarda zarar yapabilmektedir (Conceição ve ark., 2009, Boydston ve ark., 2007). Kök-ur nematodları, dünya genelinde yaklaşık olarak yıllık % 5'lik bir verim kaybına neden olmaktadır ve bitki paraziti nematodlardan kaynaklanan yıllık yaklaşık 100 milyar € maddi kaybın büyük kısmını oluşturmaktadırlar (Abad ve ark., 2003; Agrios, 2005; Sasser ve Freckman, 1987). Kök-ur nematodlarının doğrudan zararları yanında, köke girerken açtıkları yaralardan mikroorganizmaların girişine imkan sağlamaları ile dolaylı zararlara da neden olmaktadırlar (Stirling, 1991).

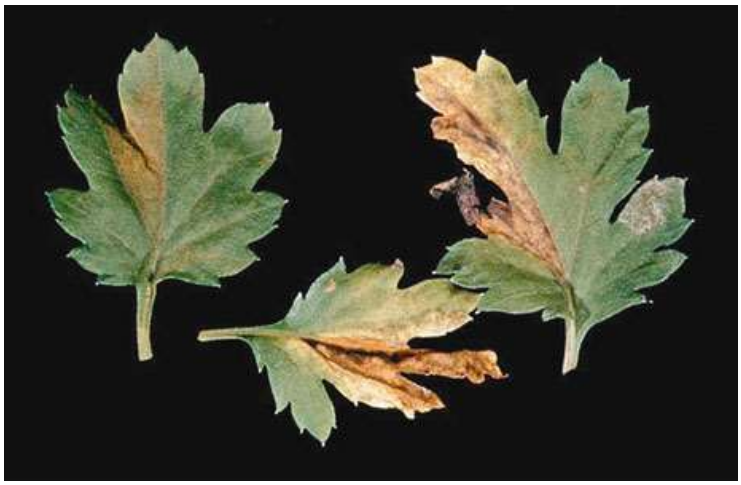
Şekil 2. Kök-ur nematodunun Lisianthus köklerindeki urlanmalar (McGovern, 2018)

Dünya'da 2020 yılına kadar *Meloidogyne* cinsine ait toplam 105 tür tespit edilmiştir (Ghaderi ve Karssen, 2020). Dünyada saptanan KUN'ları içerisinde *M. incognita, M. javanica, M. arenaria, M. chitwoodi, M. fallax* ve *M. hapla* türleri en yaygın türler olup bu cinsin %95'den fazlasını oluşturmaktadır (Adam ve ark., 2007). *Meloidogyne arenaria, M. incognita* ve *M. javanica* sıcak iklimlerde en yaygın türler durumundadır. Soğuk iklimlerde ise, *M. hapla* ve *M. naasi* açık alanda yetiştirilen ürünlerde önemli türler durumundayken, 1990'lardan bu yana *M. chitwoodi* ve *M. fallax* özellikle patates ve sebze üretiminde yaygın hale gelmiştir (Wesemael ve ark., 2011). Türkiye'de bugüne kadar yapılan çalışmalarda farklı bölgelerde ve farklı kültür bitkilerinde *M. arenaria, M. artiellia, M. chitwoodi, M. exigua, M. hapla, M. incognita, M. javanica, M. luci, M. thamesi* olmak üzere toplam 9 tür tespit edilmiştir (Yüksel 1966, Yüksel 1967, Elekçioğlu 1992, Kepenekci ve ark., 2002, Özarslandan ve ark., 2009, Gerič Stare ve ark., 2017; İmren ve ark., 2014).

Kök-ur nematodu türleri arasında, *Meloidogyne hapla*, Amerika Birleşik Devletleri'nin kuzeyinde ve Kanada'da çok yıllık süs bitkilerinin en önemli zararlıları arasında yer alırken (LaMondia, 1996), Amerika Birleşik Devletleri'nin güneyinde ise çeşitli tropikal kök-ur nematodu türleri süs bitkilerini zarar yapmaktadırlar (Brito ve ark., 2010).

Kök-ur nematodu zararı sonucunda oluşan belirtiler arasında köklerde ur oluşumu, kolayca zayıf gelişim gösteren, solan ve bodurlaşan bitkiler, kloroz gibi bitki besin maddesi eksikliklerinde yaygın olan diğer belirtiler yer alır (Şekil 3). Tarlada yetiştirilen çıplak köklü süs bitkilerinde popülasyon yoğunluğuna bağlı olarak önemli ölçüde verim kayıpları görülebilmekte olup %20'nin üzerinde verim kayıpları oluşabilmektedir (Lindberg ve ark., 2018). Kesme yeşillik bitkilerinde, kök-ur nematodu zararı sonucunda yaprakların ve gövdelerin yeniden büyümesi yavaşlayabilmektedir (Baidoo ve ark., 2017). Ayrıca kök-ur nematodu zararı sonucunda oluşan köklerdeki urlanmalar, süs bitkilerinin satışını ve dağıtımını engelleyerek karı daha da azaltabilmektedir. *Meloidogyne javanica*' nın, krizantem bitkilerinin köklerinde urlara, bitkilerde ciddi bir şekilde bodurluğa ve kloroza neden olduğu belirlenmiştir (Agudelo ve ark., 2006). *M. İncognita*' nın, gerberada %31.1'e kadar verim kaybına yol açtığı bildirilmiştir (Manju ve Subramanian, 2015). Nematod enfeksiyonlarının çiçek üretimi üzerinde de olumsuz etkileri olduğu belirlenmiş olup glayölde, *Meloidogyne incognita* enfeksiyonunun şiddetli olduğu durumlarda hiç çiçek oluşmadığı bildirilmiş ayrıca histolojik analizlerde kök dokusunda dev hücre oluşumları ve vasküler doku deformasyonları belirlenmiştir (Assumi ve ark., 2017). Büyük, etli köklere sahip çok yıllık otsu bitkilerde, özellikle düşük popülasyona sahip alanlarda kök-ur nematodu urlanmaları kolayca göze çarpmayabilmekte ve fark edilmesi zor olabilmekte olup bu durum ihracatta karantina zararlısı olmaları nedeniyle sorunlara neden olabilmektedir (Howland ve Quintanilla, 2023).

Mevcut yönetim stratejileri bu önemli zararlıyla mücadelede sınırlıdır ve genellikle nematodları öldürmek için çoğaltım materyallerinin sıcak suya daldırıldığı sıcak su uygulaması (Powell ve Riedel, 1978; Inserra ve ark., 1995; Daughtrey ve Benson, 2005) ve son derece maliyetli ve çevre için toksik olan ekim öncesi toprak fümigasyonundan oluşmaktadır. Toprak fumigasyonu ve nematisitler KUN ile mücadelede en etkili yöntem olmakla beraber gerek Avrupa Birliği gerekse de ülkemiz mevzuatlarında yapılan değişiklikler sonucunda piyasada yaygın olarak kullanılan 1,3-Dichloropropene, Aldicarp, Carbofuran, Cadusafos, Ethoprophos gibi pekçok fumigant ve non-fumigant nematisitin kullanımı yasaklanmıştır (Anonim 2020). Bu durum biyolojik nematisitler ve organik değişiklikler gibi daha az zarar veren mücadele yöntemlerine doğru bir kayma olmasına neden olmuştur (Zasada ve ark., 2010).



Şekil 3. *Meloidogyne hapla* ile bulaşık (A) ve sağlıklı (B) sarı zambak kökleri (Howland ve Quintanilla, 2023)

3.2.Yaprak Nematodları (*Aphelenchoides* spp.)

Yaprak nematodları, *Aphelenchoides* spp., yıldız çiçeği, orkide ve krizantem gibi birçok süs bitkisi de dahil olmak üzere 700'den fazla bitki türünden oluşan geniş bir konukçu dizisine sahip bitki paraziti nematodlardır (Handoo, 1998; Jagdale ve Grewal, 2006; Kohl, 2011; Mitiku, 2018; Smitamana ve McGovern, 2018). Süs bitkisi endüstrisi için ekonomik öneme sahip üç ana tür *A. fragariae*, *A. ritzemabosi* ve *A. besseyi*'dir. Yaprak nematodları esas olarak yaprakların içinde beslenen endoparazitlerdir, ancak çevresel koşullara bağlı olarak yaprak nematodları bazı bitkilerin yapraklarında ve çiçek tomurcuklarında dıştan da beslenebilirler. Bu nematodlar çoğunlukla toprakta kışı geçirir ve su film tabakası sayesinde bitki gövdelerinin dışından yapraklara doğru göç ederler. Enfekte üretim materyalleri yoluyla kolayca temiz alanlara yayılabilirlerken, yağmur veya sulama suyuyla da yakın mesafedeki temiz bitkilere taşınırlar. Yaprak nematodu beslenmesinden kaynaklanan belirtiler yapraklarda ana yaprak damarlarına paralel uzanan klorotik, köşeli lezyonlardır ve beslenme devam ederse bu belirtiler nekrotik hale gelebilirler (Şekil 4). Bu durum yaprakların kuru, parçalanmış bir görünüme sahip olmasına neden olurken şiddetli enfeksiyonlarda tüm yaprağı öldürerek yaprak dökülmesine neden olabilir (Jagdale ve Grewal, 2006; Kohl, 2011; Mitiku, 2018; Phani ve ark., 2021). *A. subtenuis*'in nergis bitkilerinde neden olduğu enfeksiyonlar, soğanlarda doğrudan zarara, yaprakların erken sararmasına ve verim düşüşüne neden olmaktadır (Chekanai ve ark., 2024). *A. ritzemabosi*, krizantem yapraklarında damarlar arası nekroz, yapraklarda renk değişimi, şekil bozuklukları, sürgün deformasyonları, bodur büyüme ve çiçek veriminde azalma gibi semptomlara neden olmaktadır (Deimi ve ark., 2007). Glayöl bitkilerinin *Aphelenchoides ritzemabosi* ile enfeksiyonu sonucunda damarlar arası nekrotik lekeler, yaprak deformasyonu ve kıvrılması, sürgünlerde zayıf gelişim ve bodurluk, çiçek oluşumunda bozulmalar gözlenmiştir. Bu belirtiler nemli koşullarda daha şiddetli olup, özellikle damarla sınırlı koyu renkli lezyonların tanı için tipik olduğu belirlenmiştir (Basterrechea, 2005). *A. ritzemabosi* ile enfekte olan zambaklarda da yapraklarda sarıdan bronz renge geçiş, kahverengileşme, ancak dökülmeme; gövdede bodurlaşma ve çiçeklenme kaybı, ilerleyen aşamada ise geriye doğru ölme belirtileri gözlenmiştir. Bu da foliar nematodların yapraklarda sistemik yayılım göstererek bitki gelişimini tamamen engelleyebileceğini göstermektedir (Eoun, 1977).

Aphelenchoides türlerinin bulaşık kurumuş yaprak döküntülerinde ve hareketsiz bitki taçlarında

uzun yıllar hayatta kalabilmesi ve temiz alanlara kolaylıkla taşınabilmesi nedeniyle yaprak nematodlarının mücadelesi zordur (Jagdale ve Grewal, 2006; El-Saadony ve ark., 2021). Bununla birlikte, yaprak nematodlarının mücadelesinde üstten sulama yerine damla sulama kullanılması ve enfekte bitkilerle temas eden alet ve ekipmanların, saksıların ve toprağın fırınlama veya buharlama yoluyla ısıl işleme tabi tutularak sanitasyonu önem arz etmektedir (Mitiku, 2018). Diğer uygulamalar arasında bulaşık bitkilere sıcak su uygulaması (Jagdale ve Grewal, 2004; Kohl, 2011; Mitiku, 2018); hümik asit kullanımı (Nagachandrabose ve Baidoo, 2021) ve bazı bitki türleri açısından dayanıklı çeşitlerin kullanımı (Kohl, 2011; Mitiku, 2018; El-Saadony ve ark., 2021) yer almaktadır.

Şekil 4. Yaprak nematodlarının krizantem yapraklarında oluşturdukları karakteristik büyük v şeklindeki lezyonlar (Horst, 2008)

3.3.Soğan-sak Nematodu (*Ditylenchus dipsaci*)

Polifag bir tür olan ve 450'den fazla bitki türünde zarar yapan *Ditylenchus dipsaci* kardelen (*Galanthus* spp.), süsen (*Iris* spp.), sümbül (*Hyacinth* spp.), sümbülcük (*Scilla* spp.), nergis (*Narcissus* spp.), soğan (*Allium* spp.), alev çiçği (*Phlox* spp.) dahil olmak üzere birçok süs bitkisinde zarar yapmaktadır (Agrios 2005; Slootweg, 1960). Soğan sak nematodunun genel belirtileri arasında yapraklarda ve gövdelerde şişme ve bükülme, gövde tabanlarında, soğanda, yumrularda ve rizomlarda nekroz veya çürüme yer alırken yoğun bulaşıklıklarda fide ölümü de meydana gelebilir. Lalede, toprak üstü kısımlar birleşebilen açık sarıdan beyaza lekeler veya şişlikler sergiler ve beyaz, düzensiz kenarlarla epidermiste çatlamalar meydana gelir. Lale çiçeklerinde özellikle karakteristik semptomlar arasında siğil büyümelerine dönüşen şişlikler yer alır ve genellikle gövde enfeksiyon bölgesinin üzerindeki taç yaprağının bir kısmı tamamen veya kısmen yeşil kalır. Etkilenen soğanlar depolama sırasında sık sık kurur ve ikincil olarak Penicillium ve akarlardan etkilenir (van Aartrijk ve ark., 2000). *D. dipsaci* ile enfekteli nergis bitkilerinde bodurlaşma, yaprak deformasyonları, renk değişimleri ve çiçeklenme oranında düşüş görülmektedir. Enfekteli soğanların iç dokularında ise çürüme ve kabuk altında nematod birikimi gözlemlenmiştir (Borazancı ve Çınarlı, 1996). *D. dipsaci*, glayöl bitkisinin soğanlarında ciddi ekonomik kayıplara neden olabilmektedir. Nematod enfeksiyonu bitkide deformasyonlara, yapraklarda sararma, kıvrılma, bodurluk gibi gelişim bozukluklarına ve çiçeklenmenin azalmasına yol açmaktadır. Enfekte soğanlarda çürüme ve dış yüzeyde doku yumuşaması görülebilir. Bu belirtiler çoğunlukla vejetatif dönemde ortaya çıkarken, ilerleyen enfeksiyonlar bitkinin ölmesine kadar varan sonuçlar doğurabilir (Tenente, 1996).

Ditylenchus dipsaci, soğanlarda, gövdelerde ve yapraklarda hareketli endoparazit olarak zarar yapmaktadır. Olumsuz çevre şartları altında dormant evresine girme yeteneğine sahip olan *D.*

dipsaci, yalnızca yoğun soğan çürümesi gibi elverişsiz koşullar sırasında toprağa girmektedir. Bitki dokusundan dışarı çıkan nematod kurumuş soğanların taban plakalarının etrafında nematod yumağı şeklinde grimsi beyaz, pamuksu kütleler halinde birikir ve bu kütleler sayesinde birkaç yıl boyunca uykuda kalabilirler. Bununla birlikte, *D. dipsaci*, bazıları sınırlı bir konukçu aralığına sahip olan 20'den fazla biyolojik ırka sahiptir (Anonymous, 2017). Nematod, enfekte üretim materyalinin yanı sıra su, rüzgar ve makinelerle taşınan kontamine toprak, sulama suyu ve rüzgar gibi faktörlerle yayılır (van Aartrijk ve ark., 2000). Mücadelesinde temiz üretim materyalinin kullanılması konukçusu olmayan bitkilerle münavebe yapılması, konukçusu olan yabancı otlarla mücadele edilmesi önem arz etmektedir. Sıcak su uygulamasında da başarılı sonuçlar elde edilmiştir (van Dam, 2013). Fumigasyon uygulamasından etkili sonuçlar elde edilirken aldicarb veya oxamyl gibi nematisitlerin çoklu tarla uygulaması, enfekte lale soğanlarının sayısını önemli ölçüde azaltmış, ancak yüksek derecede enfekte soğanlarda *D. dipsaci*'ye karşı tam etkili olmamıştır (Weststeijn ve De Rooy 1974; Windrich 1985).

3.4.Virüs Vektörü Nematodlar

Nematodlarla taşınan viruslar, nepoviruslar ve tobraviruslar olarak 2 farklı gruba ayrılırlar. Partikülleri çok düzlemli olan nepoviruslar, Cadman (1963) tarafından nematode transmission and POlyhedral particle shape'den isimlendirilmiştir. 1971 yılında da çubuk şeklinde partikülleri olan ve nematodlar tarafından taşınabilen tobra viruslar ise TOBacco RAttle virusun ilk harfleri alınarak oluşturulmuştur (Harrison et al. 1971). Pratikte bütün nematodlar, virusla bulaşık bitkilerde beslenirler ve virus parçalarını vücutlarına alırlar. Ancak 30'dan fazla familyaya bağlı yaklaşık 200 cinse ait 4100'den fazla bitki paraziti nematod türü bilinmesine karşın virüsleri taşıyan türler, bitkilerdeki parazit nematodların sayısının %1'inden fazlasını oluşturmaz. Virüs vektörü yaklaşık 44 tür bulunmakta olup bunlar, Dorylaimida takımının Longidoridae ve Trichodoridae familyalarına dahildir (Abdalreda ve Mohammed, 2022). Yapılan çalışmalar sonucunda nepovirusların sadece Longidoridae familyası tarafından, tobravirusların ise sadece Trichodoridae familyası tarafından taşındığı belirlenmiştir. Beslenmeleri sırasında vektörü oldukları virüsleri temiz bitkilere bulaşmasını sağlayan Longidorid ve Trichodorid nematodlarının her ikisi de, hem tek hem de çok yıllık bitkilerin köklerinde ektoparazittirler ve virus transferine ek olarak, üründe doğrudan zarara da neden olular (Weischer 1993).

Nepo virüsleri *Xiphinema* (kamalı nematodlar) ve *Longidorus* (iğne nematodları) cinslerinde yer alan bazı türler tarafından taşınmaktadırlar. *Xiphinema* ve *Longidorus* cinsleri 1,5-13 mm arasında değişen boyları ile en uzun bitki paraziti nematodları arasındadırlar ve beslenmeleri için kökün derinlerine girmelerini sağlayan uzun stiletleri vardır (Trudgill ve ark., 1991; Weischer, 1993). Konukçuları arasında çok yıllık ve odunsu bitkiler, sebzeler, meyveler ve süs bitkileri yer almaktadır (Weischer, 1993; Martelli ve Taylor, 1989). Sardunya, petunya ve lale gibi süs bitkileri için başlıca NEPO virüsleri domates halka lekesi virüsü (ToRSV), tütün halka lekesi virüsü (TRSV), Arabis mozaik virüsü (ArMV) ve domates siyah halka (TBRV) virüsüdür (Engelmann ve Hamacher, 2008). Çok sayıda NEPO virüsü olmasına rağmen, genel semptomlar arasında belirgin halka ve mozaik çizgili desenler, klorotik beneklenme, beneklenme, yaprak kıvrılması ve nekroz, bodur bitkiler ve genel bitki düşüşü yer alır (Şekil 5).

Şekil 5. Zambakta Arabis mosaic virüs enfeksiyonu sonucu oluşan mozaik ve nekrotik çizgiler ve noktalar (Chastagner ve ark., 2018)

TOBRA virüsleri ise 0,5-1,5 mm boyları ile bitki paraziti nematodlar arasında orta büyüklükte olan nematodlar gurubuna giren ve kıvrık bir stilete sahip kalın nematodlar olan *Trichodorus* ve *Paratrichodorus* türleri (küt kök nematodları) tarafından bulaştırılırlar (Abdalreda ve Mohammed, 2022). Kök ucundan ektoparazit olarak beslenerek kök uçlarının şişmesine ve güdükleşmesine neden olurlar (Taylor, 1972). Başlıca virüsler petunya, şakayık, lale ve zambak gibi bitkileri etkileyebilen Tobacco mosaic virus (TMV), Tobacco rattle virus (TRV), Pea early-browning virus (PEBV) ve Pepperringspot virus (PepRSV)'dür (Taylor, 1972; Handoo, 1998; Engelmann and Hamacher, 2008; Macfarlane, 2010;Khan, 2015). TOBRA virüslerinin genel belirtileri arasında yapraklarda klorotik ve nekrotik lekeler veya şeritler, mozaik, beneklenme, çiçek taç yapraklarında açık veya koyu renkli benekler, oval lezyonlar, çiçek malformasyonu ve bodur bitkiler yer alır (Engelmann ve Hamacher, 2008; Madhavan ve ark., 2021) (Şekil 6).

Şekil 6. Tobacco rattle virüsünün şakayık yapraklarında neden olduğu halka lekeleri (Garfinkel ve Chastagner, 2018)

Virüsün yayılmasını ve bulaşmasını önlemek için bu nematodların yönetimi, yalnızca virüssüz ekim malzemelerinin kullanılmasını, hijyenik önlemleri ve alet ve ekipmanların dezenfeksiyonunu, termoterapiyi, inokulumun yayılmasını önlemeye yardımcı olmak için virüsle enfekte olmuş bitkilerin yok edilmesini ve bitkilerin düzenli olarak analiz edilmesini içerir (Taylor, 1972; Engelmann and Hamacher, 2008; Adaskaveg ve Caprile, 2009; Madhavan et al., 2021). Yabancı ot kontrolü, nematodlar için alternatif konukçular olarak hizmet edebildikleri ve virüs rezervuarları olarak hareket edebildikleri için özellikle önemlidir.

Örneğin, karahindiba, *Taraxacum officinale* ve diğer geniş yapraklı yabani otlar virüsleri barındırabilir ve nematodlar bu bitkilerle beslenmeleri esnasında aldıkları virüsleri daha sonra aynı tarladaki süs bitkilerine bulaştırabilirler (Adaskaveg ve Caprile, 2009). Nematod vektörünü kontrol etmek için fumigantlar bir yönetim seçeneği olarak ekim öncesi kullanılabilir. Ayrıca hem nematoda hem de virüse dayanıklı çeşitlerin kullanılması hem etkili hem de çevre dostu mücadele yöntemleri arasındadır (Howland ve Quintanilla, 2023). Örneğin, lalelerde 'Cantata', 'Juan', 'MadameLefeber' ve 'Princeps' gibi TBV'ye dayanıklı birkaç çeşit bulunmaktadır (Madhavan ve ark., 2021).

3.5.Diğer Bitki Paraziti Nematodlar

Süs bitkilerinde zarar yapan birçok bitki paraziti nematod türü bulunmaktadır. Diğer önemli bitki paraziti nematodlardan biri konukçuları arasında nergis zambağı (Christie ve Birchfield, 1958; Nong ve Weber, 1965), eğrelti otları (Rhoades, 1968) ve kauçuk bitkileri gibi yapraklı bitkiler (Pinochet ve Duarte, 1986) dahil olmak üzere 400'den fazla bitki türünü barındıran ve hareketli endoparazit olan *Pratylenchus* spp. (kök lezyon nematodları) türleridir. Süs bitkilerinde lezyon nematodu beslenmesinin belirtileri arasında kök ve sürgünlerde bodurlaşma, klorotik yapraklar, yapraklarda renk değişikliği, solgunluk, kök şişmesi, kahverengi lezyonlar, tüm kök sistemlerinin tahrip olması ve ciddi verim kaybı yer almaktadır (Christie ve Birchfield, 1958; Rhoades, 1968; Mitiku, 2018). Belirtiler ayrıca bitki köklerinde nekrotik lezyonları da içerebilir ve bu durum hastalık komplekslerine neden olan bakteri ve fungusların ikincil enfeksiyonlara neden olabilir (Howland ve Quintanilla, 2023). Zambak (Lilium cv. Stargaze) bitkilerinde *Pratylenchus crenatus* ve *P. zeae* türleri tespit edilmiş, yumrular ve köklerde lezyonlara yol açtığı bildirilmiştir (Oliveira ve ark., 2012). Antoryum ve karabiberde ciddi seviyede zarar yapan ve 350'den fazla konukçusu bulunan *Radopholus similis* (oyuk nematodu) bir başka önemli hareketli endoparazit nematod türüdür (Haegeman ve ark., 2010; Khan, 2015). *Radopholus similis* kök ve gövdelerde beslenmesi sonucunda kök çürümesine, ciddi bitki bodurluğa ve kloroza neden olur ve bitki ölümlerine neden olabilir (Borgohain, 2016; Wang ve ark., 2016). Nematod, antoryum rizomlarında da damar demetlerini bozarak köklerde nekroz ve anatomik değişikliklere neden olabileceği gibi yeni tarlaların ekiminde kullanılan antoryum kamışlarında fark edilebilir herhangi bir belirti oluşturmayarak bu nematodun yayılmasına da neden olabilmektedir (Vovlas ve ark., 2003; Sipes ve Myers, 2018). *Rotylenchulus reniformis* (reniform nematod) bitki köklerine kısmen nüfuz eden yarı endoparazitik bir nematoddur. Bu nematodlar gündüz zambağı gibi bazı süs bitkilerinde hiçbir bitki belirtisi oluşturmazken pamuk gibi ürünler için yıkıcı parazitler olabilirler (Inserra ve ark., 1998; Koenning ve ark., 2004). *Paratylenchus* spp. (pin nematodu) gündüz zambağı gibi süs bitkilerinde yaygın olarak bulunmasına karşın bugüne kadar antoryumda zarar yapan *P. shenzhenensis* (Howland ve ark., 2022; Howland ve Quintanilla, 2023; Wang ve ark., 2016) dışında süs bitkilerinde bu nematod türü hakkında çok az araştırma yapılmıştır. *Paratylenchus* spp. enfeksiyonunun belirtileri arasında bodurluk, düşük kaliteli bitkiler ve verim azalması yer almaktadır (Howland ve Quintanilla, 2023).

4. BİTKİ PARAZİTİ NEMATODLARIN MÜCADELESİ

Süs bitkilerinde önemli derecede zarar yapan bitki paraziti nematodlar bunun sonucu olarak süs bitkileri endüstrisi açısından milyonlarca dolar kayıplara neden olmaktadırlar. Mevcut mücadele stratejilerinin çok etkili olmaması nedeniyle süs bitkilerinde bitki paraziti nematodların mücadelesi bazı zorluklar içermektedir. Bu durum özellikle etkinliği yüksek birçok nematisitin yasaklanması, belirti göstermeyen üretim materyalleri nedeniyle önemli türlerin hızla yayılması ve genel bilgi eksikliğinden kaynaklanmaktadır. Özellikle de gündüz zambağı ve iris gibi birkaç yıl boyunca sadece tarlada yetiştirilen süs bitkileri için, mevcut

yönetim stratejileri sıcak su uygulamaları ve dikim öncesi fümigasyondan oluşmaktadır. Sıcak su uygulamaları *D. dipsaci*, *A. fragariae* ve *R. similis* gibi endoparazit bitki paraziti nematodlara karşı kullanılabilmektedir ve dikim materyaline sıcak su uygulaması tohum, çiçek soğanı, yumru, rizom ve köklerin nematodlar açısından kontrolünde çok etkili olabilmektedir (Whitehead 1998). Genel olarak sıcak su uygulaması çıplak köklü bitkiler, yumrular gibi üretim materyallerinin büyük bir sıcak su tankına daldırılması ve ardından ikincil su tanklarında soğutulması şeklinde yapılmaktadır. Ancak sıcak su uygulaması endoparazitik nematodlara etkili olabilirken toprakta yaşayan ektoparazit nematodlara karşı kullanılamamaktadır. Ektoparazitik nematodlarla bulaşık olan toprağa ısıl işlem görmüş bitkilerin ekilmesi zararı engellemeyecektir. Ayrıca sıcak su uygulamasında süre ya da sıcaklık seviyesindeki hatalar bitki ölümlerine, canlılığın azalmasına neden olabileceği gibi nematodların canlılığını korumasıyla da sonuçlanabilir (Rhoades, 1964; Jagdale ve Grewal, 2004; Tsang ve ark., 2004; Howland ve ark., 2022). Bu nedenle sıcak su uygulamalarında, hedef materyali istenilen süre ve sıcaklıkta tutulabilmesini sağlayan tanklar ve ekipmanlar gerekmektedir (Sikora, 2005). Bitkileri sadece sıcak su yerine nematisitlere daldırmak alternatif bir yönetim stratejisidir. Kök-ur nematodlarına yönelik olarak gündüz zambağı fidelerinin dikimden önce fluopyram solüsyonuna daldırılması sonucunda kontrol ve Telone II fümigasyonuna kıyasla daha yüksek biyokütleye sahip bitkiler elde edilirken kök-ur nematodu zararının orta düzeyde kontrolü sağlanmıştır (Howland ve ark., 2022). Bununla birlikte, nematisitlerin çok yıllık bitkilerde ekim öncesi daldırma veya hasat sonrası uygulama olarak kullanımına yönelik olarak daha fazla çalışmaya ihtiyaç duyulmaktadır (Howland ve Quintanilla, 2023).

Bir diğer önemli mücadele stratejisi olan toprak fumigasyonu, fitotoksik olduğu için bitkiler topraktayken değil, yalnızca ekimden önce uygulanabilmektedir (Noling, 2008). Bu durum özellikle çok yıllık süs bitkilerinde nematodların yetersiz kontrolüyle sonuçlanmaktadır. Ayrıca fumigant nematisitlerin yüksek maliyet ve çevre riski taşıması nedeniyle bitkinin arazide olduğu dönemde de uygulanılabilen kontakt veya sistemik nematisitlerin kullanımı daha avantajlı durmaktadır (Zasada ve ark., 2010). Ancak Aldicarp, Carbofuran, Cadusafos, Ethoprophos gibi pekçok non-fumigant nematisitin kullanımı da yasaklanmıştır (Anonim 2020). Bununla beraber daha düşük çevresel etkiye sahip ve umut verici kontrol seviyelerine sahip fluensulfone, tioxazafen ve fluopyram gibi yeni nematisitlerin ruhsatlandırılması olumlu bir gelişmedir (Daughtrey ve Benson, 2005; Phani ve ark., 2021; Howland ve ark., 2022).

Dünya çapında yaklaşık yüz bin süs bitkisi türü ve bunların yabani akrabaları olduğu tahmin edilmesine karşın süs bitkilerinin bitki paraziti nematodlara konukçuluk durumlarının belirlenmesine yönelik çalışmalar son derece sınırlı kalmıştır (Howland ve Quintanilla, 2023; Long ve ark., 2018). Örneğin, 83.000'den fazla kayıtlı gündüz zambağı çeşidi olmasına karşın sadece birkaç çeşidin *M. Hapla*'ya konukçuluk durumu belirlenmiş durumdadır (Howland ve Quintanilla, 2023).

Birçok bitki türü açısından en önemli mücadele aracı nematodlara dayanıklı bitki kullanılmasıdır (Sikora ve ark., 2005). Yüksek etkinlik sağlaması, kullanımının kolaylığı, ekstra bir maliyet gerektirmemesi ve çevreye yan etkisinin bulunmaması dayanıklı çeşit kullanımının en önemli kazanımlarıdır. Bununla beraber birçok bitki türünde çoğu nematoda karşı dayanıklı çeşit bulunmamaktadır. Süs bitkilerinde de benzer bir durum söz konusudur.

Yapılan çalışmada üç farklı gerbera çeşidinde *M. İncognita* üreme oranının 1,9 ila 2,7 arasında değiştiği, 14 farklı karanfil çeşidinde ise üç çeşitte üreme görülmezken diğer çeşitlerde ise üreme oranının 0,8 ila 3,9 arasında değiştiği belirlenmiştir (Yarba, 2019). Bir diğer çalışmada ise dört farklı karanfil çeşidinin kök-ur nematodlarına dayanıklılık durumları belirlenmiş ve *M. İncognita, M. Javanica ve M. Arenaria* türlerine Turbo çeşidinin dayanıklı, Betsy ve Glaciar

çeşitlerinin hassas, Nirvana çeşidinin ise *M. İncognita*, *M. Javanica*'ya orta dayanıklı, *M. Arenaria*'ya ise tam dayanıklı olduğu ortaya konmuştur (Sert Çelik ve ark., 2022). Görüldüğü üzere yapılan çalışmalarda sonuçlar elde edilmesine rağmen süs bitkilerinde bitki paraziti nematodlara yönelik olarak yürütülen çalışmalar çok sınırlı düzeyde kalmış durumdadır. Önemli bir genetik çeşitliliğe sahip olan süs bitkilerinde dayanıklılık çalışmalarına ağırlık verilmesi son derece önemlidir.

Başarılı bir nematod mücadelesi yönetimi için hedef tür veya türlerimize, hedef alanımıza ve sahip olduğumuz teknik ve ekonomik imkanlara bağlı olarak kullanabileceğimiz kontrol metodolojilerinin hepsinin bir arada uygun şekilde kullanımını gerekmektedir. Bitki paraziti nematodların zararını azaltmaya yönelik olarak çevresel olarak sürdürülebilir yönetim stratejileri geliştirmenin en uygun yolu mücadelenin entegre zararlı yönetimi kapsamında sağlanmasıdır. Gelecekte süs bitkilerinde bitki paraziti nematodlardan kaynaklanan kayıpların azaltılmasına yönelik olarak yapılacak çalışmaların bu hedefler doğrultusunda oluşturulması etkili, çevreyle dost ve sürdürülebilir mücadele programlarının oluşturulması açısından büyük önem arz etmektedir.

5. SONUÇ

Dünya genelinde milyarlarca dolarlık ticaret hacmine sahip süs bitkileri sektörü, bitki paraziti nematodlar (BPN) nedeniyle ciddi tehdit altındadır. Kök-ur nematodları (*Meloidogyne* spp.), yaprak nematodları (*Aphelenchoides* spp.), soğan sak nematodu (*Ditylenchus dipsaci*) ve virüs vektörü nematodlar, süs bitkilerinde önemli ekonomik kayıplara yol açmaktadır. Bu zararlılar sadece doğrudan verim kaybına değil; kalite düşüşü, ihracatta karantina engelleri ve ikincil enfeksiyonlara da neden olmaktadır.

Mücadeledeki temel kısıtlar; zararlıların üretim materyaliyle hızla yayılması, belirtilerin diğer stres faktörleriyle karıştırılması ve etkili kimyasalların yasaklanmasıdır. Bu durum, sürdürülebilir yönetim yöntemlerinin geliştirilmesini zorunlu kılmaktadır.

Süs bitkilerinde nematod kaynaklı kayıpların minimize edilmesi için "Entegre Zararlı Yönetimi (IPM)" prensiplerinin benimsenmesi zorunludur. Gelecek araştırmaların; yerel nematod türlerinin belirlenmesi, dayanıklı çeşit ıslahı ve çevre dostu biyolojik mücadele ajanlarının etkinliğinin artırılması üzerine yoğunlaşması, sektörün sürdürülebilirliği açısından kritik öneme sahiptir.

ÖZET

Makine tasarımında malzeme seçimi yapıdan beklenen mekanik ve kimyasal özelliklere göre yapılır ancak bir malzeme her zaman istenen tüm özellikleri karşılamayabilir. Bu durumda farklı malzemelerin bir arada kullanılması iyi bir çözümdür ve aynı zamanda maliyeti düşürmeye önemli katkı sağlar. Ancak farklı malzemelerin bir arada kullanılmasında birleştirme sorunları ortaya çıkabilir. Özellikle endüstride yaygın bir üretim yöntemi olan kaynaklı imalat ile birleştirilmiş parçalarda malzemelerin mekanik veya kimyasal özelliğinde bir kayıp söz konusu olabilir. Bu sebeple farklı malzemelerin kaynaklı birleştirmelerinde kullanılan telin ve kaynak parametrelerinin kaynaklı bağlantının dayanımına etkisi incelenmelidir. Bu çalışmada farklı mekanik özelliklere sahip yüksek dayanımlı yapı çeliği S690QL ve normal dayanımlı yapı çeliği olan S355J2+N malzemelerinin kaynaklı birleştirilmesinde G4Si1 telinin çok pasolu uygulanması ile elde edilen kaynaklı bağlantının çekme mukavemeti, kaynak bölgesinin darbe dayanımı ve sertlik değerleri üzerinden bir performans değerlendirmesi yapılmıştır. 30 mm kalınlığındaki plakaların ilgili standartlara uygun olarak hazırlanmış test numuneleri ile yapılan deneylerde 535,8 MPa çekme dayanımı elde edilmiştir ve bağlantının S355J2+N malzeme tarafından koptuğu gözlemlenmiştir. Kaynak dikişinin çentikli darbe enerjisi 58,8 J olarak ölçülmüştür. Kaynak dikişinin merkezinde sertlik değeri ortalama 211 HV olup kaynak dikişinin yüzeylerine yakın bölgelerde alınan ölçümlerde sertlik değerlerinin 182-185 HV bandında olduğu görülmüştür. Kaynaklı bağlantının mekanik performansının normal dayanımlı yapı çeliği olan S355J2+N malzemeye yakın olduğu sonucuna varılmıştır.

Anahtar Kelimeler: GMAW, SG3, Çekme dayanımı, Kaynak parametreleri

MECHANICAL PERFORMANCE ASSESSMENT FOR MULTIPASS WELDING OF DISSIMILAR S690QL AND S355J2+N MATERIALS USING G4SI1 FILLER WIRE

ABSTRACT

In machine design, material selection is dictated by the required mechanical and chemical properties expected from the structure; however, a single material may not always meet all desired specifications. In such cases, the integration of dissimilar materials constitutes an effective solution and significantly contributes to cost reduction. Nevertheless, the concurrent use of different materials can lead to joining issues. Specifically, in components assembled using welded manufacturing, a common production method in industry, a potential loss in the mechanical or chemical properties of the materials may occur. For this reason, the effect of the filler wire and welding parameters utilized in the welding of dissimilar materials on the joint strength needs to be thoroughly investigated. In this study, a performance evaluation was conducted based on the tensile strength, weld zone impact toughness, and hardness of the welded joint implemented by the multi-pass application of G4Si1 filler wire when joining high-strength structural steel S690QL and normal-strength structural steel S355J2+N, which possess differing mechanical properties. The experiments, conducted using test specimens prepared in accordance with relevant standards from 30 mm thick plates, yielded a tensile strength of 535.8 MPa. It was observed that the joint fractured through the S355J2+N base material side. The notched impact energy of the weld bead was 58.8 J. The average hardness value at the center of the weld bead was 211 HV, while measurements taken in the regions near the weld bead surfaces indicated a hardness in the 182-185 HV range. It was concluded that the mechanical performance of the welded joint closely approaches that of the normal-strength structural steel S355J2+N.

Keywords: GMAW, SG3, Tensile strength, Welding parameters

1. INTRODUCTION

Material selection within machine design is governed by the requisite mechanical and chemical attributes demanded by the structure; however, it is frequently the case that a single material fails to satisfy all intended properties. In this context, the integration of dissimilar materials constitutes an optimal solution and provides a substantial advantage in terms of cost reduction. Nonetheless, the utilization of varied materials introduces inherent joining challenges. Specifically, components assembled via welding fabrication are susceptible to a resulting compromise in the materials' mechanical or chemical integrity.

S690QL steel is a High-Strength Low-Alloy (HSLA) steel that offers superior performance in terms of yield strength, weldability, and corrosion resistance compared to mild steel (Qiang et al., 2012). HSLA steels are favored in sectors such as the shipbuilding, marine engineering, bridge construction, mining, and the automotive industry (Vaikar et al., 2022; Ye et al., 2023). The combination of structural steels with dissimilar materials constitutes a favorable practice within the industry to lower costs. Studies have been conducted on the combined use of HSLA steels with various structural steels. Sorger et al. (2018) investigated the microstructure and fatigue properties of S690 and S355 steel plates joined by the Friction Stir Welding (FSW) method. Šmak et al. (2017) conducted a study on the Gas Metal Arc Welding (GMAW) of S355J0 steel and Weldox 700 (the trade name for the S700 steel product) using the standard Autrod 12.51 wire electrode. Astuti et al. (2023) evaluated the effects of the flame straightening process on the hardness of dissimilar S355J2+N and S690Q steel joints, which were welded using the GMAW method with a single V-groove. In their study, microstructural changes were investigated after the joints were subjected to the flame straightening treatment. Szusta et al. (2023) investigated the influence of both welding parameters and plate thickness on the strength of welded overlay joints utilizing S355 and Strenx 700 steels for agricultural machinery applications. Brätz et al. (2023) conducted a comprehensive study on the weldability and load-carrying capacity of multi-layer GMAW butt joints, focusing on the welding of S690, S700, and S960 high-strength structural (HSS) steels to S355 normal-strength structural steel. As part of the investigation, 10 mm and 20 mm thick plates made of S355 and S690 steels were examined to reveal the influence of the filler metal and heat input on the load-carrying capacity of the welded joints. In this study, the mechanical performance of multi-pass welded S690QL and S355J2+N materials was evaluated by examining the tensile strength, Charpy V-Notch (CVN) impact toughness, and hardness of the welded joint. This welding was performed using the GMAW method, a technique widely employed in industry, with G4Si1 filler wire. A multi-pass welding procedure was implemented for the joining of the 30 mm thick plates.

2. MATERIALS AND METHODS

2.1. Materials used and welding process

This study investigated the performance of G4Si1 (conforming to AWS A5.18/ER70S-6 and EN ISO 14341-A/G 46 3 M G4Si1 specifications) filler material when utilized in the GMAW welding of S355J2+N and S690QL steels. The chemical composition and mechanical properties of the base materials and the G4Si1 filler wire are detailed in Tables 2.1 and 2.2. The certified chemical composition data for the filler material were obtained from the manufacturer.

Table 2.1. Chemical composition (wt.%) of materials and filler wire

%	Fe	C	Si	Mn	P	S	Ni	Cr	V	Mo	Al	Cu
S690QL	Base	0.013	0.030	1.18	0.009	0.001	0.10	0.25	0.030	0.146	0.54	0.01
S355J2+N	Base	0.070	0.019	1.39	0.021	0.024	0.14	0.12	0.042	0.021	0.020	0.46
G4Si1	Base	0.08	1.00	1.70								

Table 2.2. Mechanical properties of base plates and filler wire

	S690QL	S355J2+N	G4Si1
Yield Strength, MPa	779	403	470
Tensile Strength, MPa	823	479	570
Toughness, J	235 (-40°C)	60 (20°C)	60 (-30°C)
Elongation, %	18	25	25

Plates measuring 200x350mm with a 30 mm thickness were prepared by grinding to form a 60° double-bevel groove for welding. The GMAW process was carried out manually in the flat (PA) position using reverse polarity (DC+). Shielding gas protection was provided by a mixture of 18% CO_2 and 82% Ar, maintained at a flow rate of 12 dm^3/min. A 1.2 mm diameter filler wire was employed. Arc stability was maintained throughout the process, resulting in a weld seam free of discontinuity. The interpass temperature was limited to 250 °C. Specific welding parameters for each pass are shown in Table 2.3.

Table 2.3. Welding parameters of GMAW process

Run	Current (A)	Voltage (V)	WS (mm/min)
Root pass	140-150	16-18	185
Hot passes	235-260	25-27	245-293
Fill passes	240-280	26-27	275-301
Cover pass	240-250	24-26	284

WS: Welding speed

2.2. Mechanical tests

Samples extracted from the welded plates underwent comprehensive mechanical testing, including tensile, Charpy impact, and Vickers hardness testing, with all relevant dimensions and measurement points (HMPs) shown in Fig. 2.1. Three tensile tests were performed according to the ISO 4136 standard (ISO, 2022a). For impact toughness evaluation, nine Charpy V-Notch samples were prepared (three each from the weld metal, the S355J2+N-HAZ, and the S690QL-HAZ) and according to ISO 9016 standard (ISO, 2022b). The Vickers hardness profile (HV10) was established by taking three repetitions at the S355J2+N base, its HAZ, the weld zone (WZ), the S690QL-HAZ, and the S690QL base, in line with ISO 9015 (ISO, 2016).

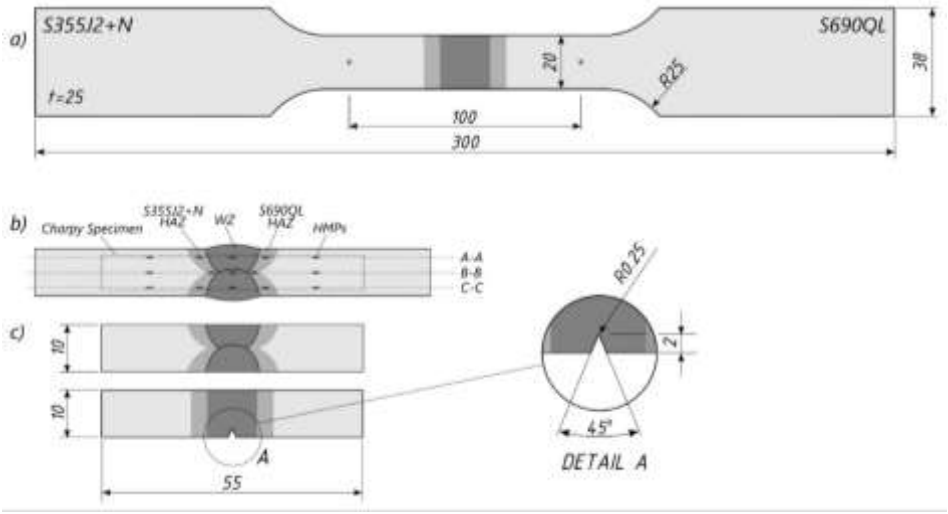

Fig. 2.1. Dimensions of specimens and Hardness measurement points. (a) tensile test specimen, (b) hardness specimen and (c) Charpy test specimen

3. RESULTS AND DISCUSSION

Fig. 3.1 provides a macrograph revealing the structure of the weldment cross-section. The image shows the layered application of the welding passes, defining both the weld zone (WZ) and the heat-affected zones (HAZs) surrounding the fusion line. The overall welding quality was satisfactory, exhibiting no discontinuities.

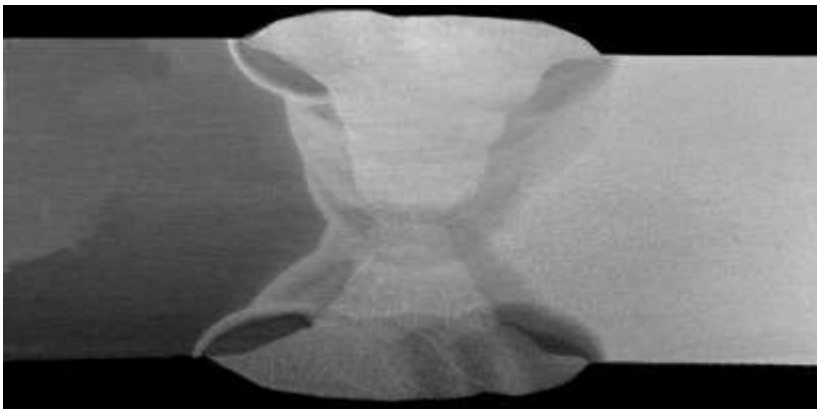

Fig. 3.1. Macrograph of welded specimen

The CVN results of the specimens were shown in Fig. 3.2. Significant differences were observed in the impact toughness values of the base materials, which were also reflected by a marked contrast in the characteristics of their respective HAZs. Specifically, CVN tests conducted on specimens extracted from the S690QL-HAZ exhibited an average absorbed energy of 280 J. In contrast, the value recorded for the S355J2+N side was considerably lower, measuring 54.4 J. The energy absorption capability of the weld metal itself closely resembled that of the S355J2+N base material, with an average measured value of 58.8 J. These obtained values surpass the minimum requirement of 27 J specified for the S355J2 steel grade at -20 °C according to the EN 10025-2 (EN 10025-2, 2004) standard.

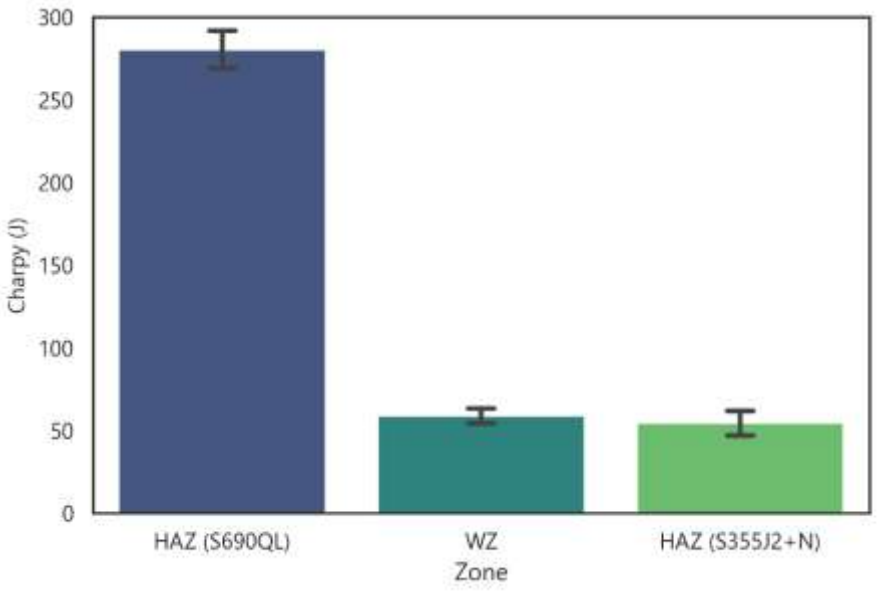

Fig. 3.2. CVN test results

Fig. 3.3 presents the hardness measurement values obtained from different regions of the welded joint. These regions are indicated in the figure as front side A-A, center B-B, and bottom side C-C. The S690QL base metal exhibited the highest hardness value, averaging 284 HV. In contrast, the hardness of the S355J2+N base metal averaged 168 HV. As shown in the figure, the hardness across the welded joint decreased smoothly from the high-strength steel side toward the normal-strength structural steel side. Hardness measurements taken from the front and bottom sides of the specimen showed a similar profile. Measurements taken from the center (B-B) indicated that the hardness in the center regions of the S690QL-HAZ was lower compared to the surface, while the hardness in the weld metal and the S355J2+N-HAZ was higher compared to the surface. This demonstrates the effect of multi-pass welding on the hardness profile.

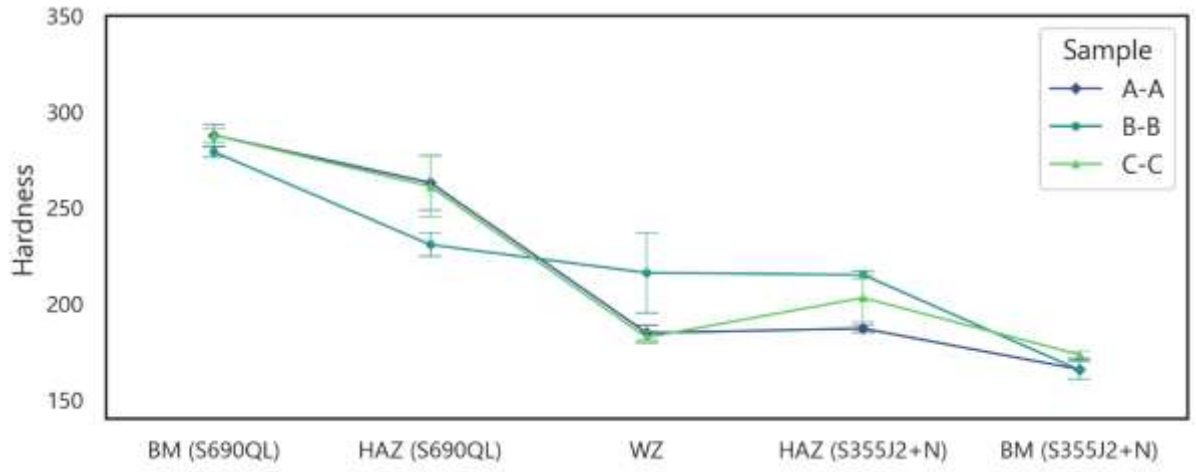

Fig. 3.3. Hardness of welded specimens (A-A: Front side, B-B: Center, C-C: Bottom side)

Table 3.1 shows the results of the tensile tests. Utilizing the selected wire and welding parameters, the welded joint achieved an average tensile strength of 535.8 MPa. All three test specimens, which exhibited an elongation of approximately 13-14%, fractured in the S355J2+N

base metal region. The resulting tensile strength of the welded joint is higher than that of the S355J2+N base material itself.

Table 3.1. Results of tensile tests

Sample	Rp0.2 (MPa)	Rm (MPa)	Elongation (%)	LoF
T1	382.9	535.4	13.6	Base (S355J2+N)

4. CONCLUSION

The mechanical properties of GMAW-welded S690QL and S355J2+N materials using G4Si1 filler wire were investigated in this study. The main outcomes could be drawn as follows:

- The tensile strength of the welded joint was measured at an average of 535.8 MPa, a value that exceeds the strength of the S355J2+N, which has the lowest strength between the two joined materials.
- The impact toughness values obtained in the weld metal and the S355J2+N-HAZ were 58.8 J and 54.4 J, respectively, both of which are higher than the expected minimum value for the S355J2+N.
- As a consequence of the multi-pass welding process, the hardness value in the S690QL-HAZ at the center of the weld cross-section was lower compared to the surface. Conversely, higher hardness values than those observed on the surface were obtained in the weld metal and the S355J2+N-HAZ regions.

ÖZET

Altın madenciliğinde siyanür kullanımı, cevherden metal kazanımında sağladığı yüksek verimlilik nedeniyle dünya genelinde yaygın olarak tercih edilmekte; ancak siyanürün toksik özellikleri nedeniyle çevresel sürdürülebilirlik bağlamında sürekli tartışılmaktadır. Bu nedenle siyanürlü proses atıklarının etkin bir şekilde yönetilmesi, çevresel risklerin azaltılması ve yasal gerekliliklere uyum açısından kritik öneme sahiptir. Bu çalışmada, bir altın madeni sülfür tesisinde oluşan siyanürlü proses atıklarının detoksifikasyon, nötralizasyon ve depolama süreçleri bütünsel olarak değerlendirilmiştir. Özellikle zayıf asit ayrılabilir siyanür (WAD_CN) ve serbest siyanür (Free_CN) fraksiyonlarının arıtım sürecindeki değişimleri incelenmiş; ayrıca pH kontrolü ve bakır (Cu) konsantrasyonlarındaki dalgalanmalar da çevresel performans göstergeleri kapsamında analiz edilmiştir. Proses çıkışında Free_CN^- 15,30 ppm düzeyindeyken detoksifikasyon sonrasında <2,00 ppm'e kadar düşmüş, WAD_CN konsantrasyonu ise 182,30 ppm'den <2,00 ppm seviyesine gerilemiştir. Bu kayda değer azalma, kullanılan detoksifikasyon kimyasallarının ve proses optimizasyonunun etkinliğini ortaya koymaktadır. Arıtma süreci boyunca pH değeri kontrol altında tutulmuş, atık depolama tesisi (TSF) çıkışında pH 9,73'ten 8,19'a doğru düzenli bir düşüş elde edilmiştir. TSF çevresindeki

yeraltı suyu izleme kuyularında siyanür tespit edilmemesi ise taşınım ve sızıntı riskinin başarılı şekilde minimize edildiğini göstermektedir. Sonuçlar, incelenen altın madeninde siyanür yönetim zincirinin hem arıtım verimliliği hem de çevresel güvenlik açısından etkili şekilde işlediğini ve sürdürülebilir maden atık yönetimi açısından iyi bir uygulama örneği sunduğunu ortaya koymaktadır.

Anahtar Kelimeler: Altın madenciliği, Siyanür yönetimi, Zayıf asit ayrılabilir siyanür, Serbest siyanür, Çevresel performans.

ENVIRONMENTAL MANAGEMENT AND CYANIDE REMOVAL OF GOLD MINE CYANIDE-BEARING WASTES

ABSTRACT

The use of cyanide in gold mining remains one of the most debated issues in terms of environmental sustainability, despite its proven efficiency in metal recovery. Effective management of cyanide-bearing process residues is therefore essential to minimize ecological risks and ensure compliance with environmental regulations. In this study, the environmental management performance of cyanide-contaminated process effluents generated in a gold mine sulfide processing plant was comprehensively evaluated. Particular emphasis was placed on the behavior of weak acid dissociable cyanide (WAD_CN) and free cyanide (Free_CN) during detoxification and neutralization, as well as on the variations in pH and copper (Cu) concentrations as indicators of treatment efficiency. At the process outlet, Free_CN^- was measured at 15.30 ppm and was reduced to <2.00 ppm after detoxification. Similarly, WAD_CN, initially 182.30 ppm, decreased to <2.00 ppm following treatment. These substantial reductions demonstrate the effectiveness of the applied detoxification reagents and operational controls. Throughout the treatment chain, pH levels were carefully regulated, with a controlled decrease from 9.73 to 8.19 at the tailings storage facility (TSF) discharge point. Monitoring results from groundwater wells surrounding the TSF revealed no detectable cyanide, indicating that migration and leaching risks were successfully mitigated. Overall, the findings indicate that the cyanide management practices implemented at the investigated gold mine operate with high efficiency in terms of both process safety and environmental protection. The study provides a strong example of effective cyanide detoxification and environmentally responsible tailings management within modern gold mining operations.

Keywords: Gold mining, Cyanide management, Weak acid dissociable cyanide, Free cyanide, Environmental performance.

1. GİRİŞ

Altın madenciliğinde siyanür liçi yöntemi, düşük tenörlü cevherlerden ekonomik olarak altın kazanımını sağlayan en yaygın yöntemdir (Adams, 2016). Ancak siyanür; toksisitesi, taşkınlar sonrası su kaynaklarına karışma riski ve ekotoksik etkileri nedeniyle çevresel açıdan en tartışmalı reaktiflerden biri olarak değerlendirilmektedir (Hilson ve Monhemius, 2006; Kohio vd., 2025). Siyanür yönetimindeki yetersizlikler sonucu ortaya çıkan kazalar - örneğin 2000 Baia Mare (Romanya) taşkını ya da 2015 Bento Rodrigues (Brezilya) felaketi - çevresel madencilik literatüründe sıkça anılmakta ve risk farkındalığını artırmaktadır (Rico vd., 2008; Azam ve Li, 2010; Kemp vd., 2021). Bu olaylar, TSF (Tailings Storage Facility - Atık Depolama Tesisi) güvenliğinin ve proses atıklarının etkin arıtımının hem bilimsel hem de toplumsal düzeyde daha dikkatle değerlendirilmesine neden olmuştur.

Son yıllarda sürdürülebilir madencilik yaklaşımı, yalnızca metal kazanım süreçlerini değil, aynı zamanda atık yönetimi, çevresel izleme ve risk azaltma stratejilerini de içeren daha geniş bir çerçeveye dönüşmüştür (Hudson-Edwards vd., 2011). Bu kapsamda Sorumlu Yatırım İlkeleri (PRI), Uluslararası Madencilik ve Metaller Konseyi (ICMM) ve Birleşmiş Milletler Çevre Programı (UNEP) tarafından Küresel Atık Barajı İncelemesi (Global Tailings Review - GTR) başlatılmıştır. GTR'nin temel görevi, mevcut endüstriyel uygulamaları değerlendirmek, geçmiş baraj kazalarından edinilen dersleri analiz etmek ve bu doğrultuda Küresel Atık Yönetimi Standardı'nı (GTR Standardı) geliştirmektir. Güvenli atık tesisi yönetimine yeni bir ölçüt getirmesi hedeflenen standart, Kasım 2019'da taslak olarak yayımlanmış ve nihai sürümü Ağustos 2020'de kamuoyuyla paylaşılmıştır (Kemp vd., 2021). Brumadinho, Mariana ve Mount Polley gibi büyük ölçekli felaketler sonrasında maden atıkları yönetiminde siyanür bileşiklerinin izlenmesi küresel standartların merkezine yerleşmiş; GISTM (Global Industry Standard on Tailings Management) ile "sıfır zarar" ilkesi uluslararası düzeyde benimsenmiştir.

Altın madenciliğinde zayıf asit ayrılabilir siyanür (WAD_CN) ve serbest siyanür (Free CN^-) giderimi, hem küresel hem de Türkiye özelinde çevresel yönetimin en kritik unsurlarından biri olarak kabul edilmektedir. Free CN^- akut toksisite potansiyeli nedeniyle ekosistemler için doğrudan tehdit oluştururken; WAD_CN, bakır, çinko ve nikel gibi zayıf komplekslerden zaman içinde siyanür salabilmesi nedeniyle orta ve uzun vadeli çevresel risklere yol açabilmektedir. Kuyucak ve Akcil (2013), altın madenciliği kaynaklı atık akımlarında özellikle WAD_CN ve Free CN^- türlerinin düzenleyici limitlerin belirleyicisi olduğunu; bu bileşiklerin doğal bozunmaya dirençli olması ve metal kompleksleşmesi yoluyla çevresel taşınıma açık bulunması nedeniyle özel önem taşıdığını belirtmektedir.

Türkiye'de altın madenciliği faaliyetleri, SKKY (Su Kirliliği Kontrolü Yönetmeliği) ve AB uyum mevzuatı çerçevesinde WAD_CN için <1 mg/L, Free CN^- için ise daha düşük limitleri sağlamakla yükümlüdür. Ülkede yeraltı suyu güvenliği, sızıntı kontrolü ve atık barajı bütünlüğüne ilişkin tartışmalarda siyanür yönetimi toplumsal kabulün şekillenmesinde belirleyici bir faktör haline gelmiştir. Ayrıca 6331 sayılı İSG Kanunu ve ÇED (Çevrese Etki Değerlendirmesi) mevzuatı kapsamında, siyanürlü proses sularının detoksifikasyon ve nötralizasyon aşamalarından geçirilmesi zorunlu olup işletmelerin WAD_CN ve Free CN^- giderim performansını sahaya özgü verilerle raporlaması gerekmektedir.

Bu çalışmada, Türkiye'deki bir altın madeninde uygulanan siyanür yönetim zincirinin performansı saha ölçümlerine dayanarak değerlendirilmekte, literatürde yer alan benzer uygulamalarla karşılaştırılmakta ve elde edilen bulgular sürdürülebilir madencilik bağlamında tartışılmaktadır.

2. MALZEME VE YÖNTEM

2.1. Çalışma Sahası

Bu çalışma, Türkiye'de faaliyet gösteren büyük ölçekli bir altın madeni sülfür tesisinde yürütülmüş olup, bölge ülkenin en yüksek altın üretim merkezlerinden biri olarak bilinmektedir. Cevherin sülfürlü yapısı nedeniyle işletmede altın kazanımı siyanür liçi ile gerçekleştirilmektedir ve bu süreç sonrasında WAD_CN ve Free CN^- bakımından zengin siyanürlü proses atıkları oluşmaktadır. Atıkların depolanmasında geleneksel TSF sistemi kullanılmakta; tabanda geçirimsiz jeosentetik membranlar ve kompakte kil tabakalarından oluşan çok katmanlı bir sızdırmazlık altyapısı bulunmaktadır. Bu tasarım, ICMM (2020) ve Avrupa Birliği madencilik direktiflerinde belirtilen modern güvenlik standartlarıyla uyumludur.

İşletmede siyanürlü proses sularının çevresel etkilerini azaltmak amacıyla üç aşamalı bir siyanür yönetim zinciri uygulanmaktadır. İlk aşama olan detoksifikasyon, SO_2/Hava Prosesi veya hidrojen peroksit gibi oksidanlarla siyanürün daha az toksik siyanat (CNO^-) formuna dönüştürülmesini sağlamakta ve böylece WAD_CN ile Free CN^- konsantrasyonlarında belirgin düşüş yaratmaktadır. Bunu izleyen nötralizasyon aşamasında, pH kontrollü olarak 9,7 seviyesinden yaklaşık 8,2'ye düşürülmekte ve böylece HCN volatilizasyonu (buharlaşması) önlenmektedir. Son aşama olan TSF depolama sürecinde, çok katmanlı sızdırmazlık sistemi sayesinde arıtılmış proses atıkları güvenli biçimde depolanmakta; düzenli piezometre ölçümleriyle olası sızıntılar izlenmektedir.

Bu bütüncül sistem, "kaynakta azaltım → proses içi kontrol → nihai depolama güvenliği" yaklaşımıyla sürdürülebilir madencilik ilkelerine uygun bir model sunmakta ve siyanür yönetiminin hem çevresel hem de operasyonel açıdan etkin biçimde yürütülmesine olanak sağlamaktadır.

2.2. Örnekleme Noktaları ve İzlenen Parametreler

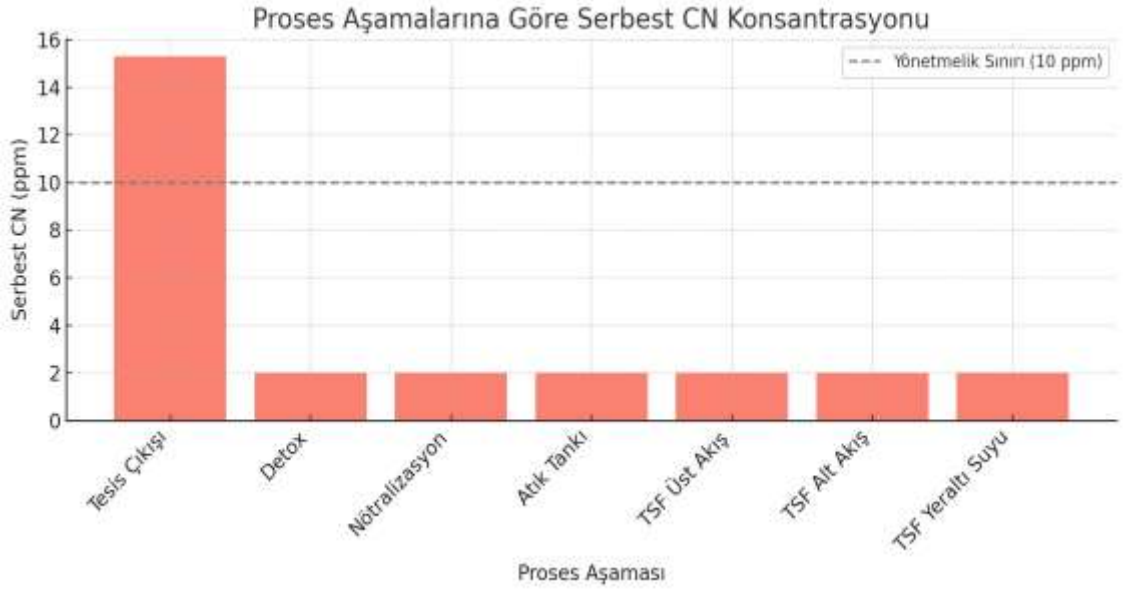
Bu çalışmada toplanan numuneler steril cam şişelere alınarak soğuk zincir koşullarında laboratuvara taşınmış ve analizler uluslararası kabul görmüş "Standard Methods" protokollerine göre gerçekleştirilmiştir (APHA, 2017). WAD_CN ve Free CN^- analizleri bu standartlara uygun olarak yapılmış, pH ölçümleri saha koşullarında kalibre edilmiş taşınabilir pH metre ile belirlenmiştir. Ayrıca bakır (Cu) konsantrasyonları, yüksek duyarlılığı ve düşük tespit sınırı nedeniyle çevresel madencilik araştırmalarında yaygın kullanılan ICP-OES (Inductively Coupled Plasma - Optical Emission Spectrometry) yöntemi ile ölçülmüştür.

Örnekleme dört kritik noktadan yapılmıştır. İlk nokta olan Proses Çıkışı, altın liçi işlemi sonrasında siyanürlü atık suyun en yüksek konsantrasyonlara sahip olduğu bölgeyi temsil etmektedir. İkinci nokta, siyanürün oksidatif kimyasal arıtımdan geçirildiği Detoks Çıkışı olup, burada siyanürün büyük bölümü daha az toksik türlere dönüşmektedir. Üçüncü örnekleme noktası olan TSF Çıkışı, atık depolama tesisine giriş sonrası bekletilen suyun kontrol noktasıdır ve depolama sisteminin çevresel güvenilirliğine ilişkin önemli veriler sunmaktadır. Dördüncü nokta ise Yeraltı Suyu İzleme Kuyularıdır; TSF çevresinde bulunan piezometrelerden alınan bu numuneler, olası sızıntıların yeraltı suyu kalitesine etkisini değerlendirmek amacıyla kullanılmıştır. Bu yaklaşım ile hem proses zinciri hem de çevresel alıcı ortam bütüncül bir şekilde incelenmiştir.

Çalışmada dört temel parametre izlenmiştir. WAD_CN, metallere komplekslenmiş siyanür fraksiyonunu temsil etmekte olup ekotoksik etkiler açısından en kritik bileşenlerden biridir. Free CN^-, HCN ve CN^- iyonlarını içeren ve akut toksisiteyi belirlemede kullanılan serbest siyanür formudur. pH, siyanürün uçucu HCN formuna dönüşüm riskinin yönetilmesinde temel bir parametre olup uluslararası standartlarda 9 - 10 aralığının korunması önerilmektedir (Freitas

ve Horta, 2023). Cu (bakır) ise siyanürle kompleks oluşturan başlıca metallerdendir ve hem proses kararlılığı hem de su kalitesi açısından çalışmada düzenli olarak izlenmiştir. Parametre seçimi WHO (2022) içme suyu standartları ve ICMM çevresel gereklilikleriyle uyumlu yapıdadır.

3. BULGULAR

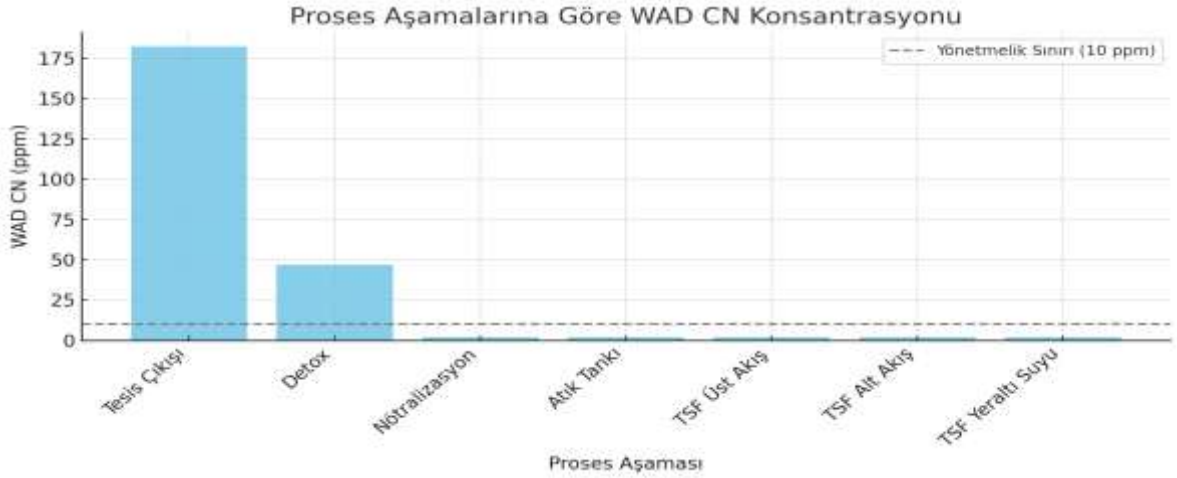


3.1. Siyanür Konsantrasyonlarının Azalması ve pH değişimleri

WAD_CN ve Free CN^- konsantrasyonlarının proses adımlarına göre değişimi Tablo 1'de verilmiştir.

Tablo 1. Kritik parametrelerin proses adımlarına göre değişimi.

Parametre	Proses Çıkışı	Detoks Çıkışı	TSF Çıkışı
Free CN^- (ppm)	15,30	<2,00	<2,00
WAD_CN (ppm)	182,30	<2,00	<2,00
pH	9,73	–	8,19

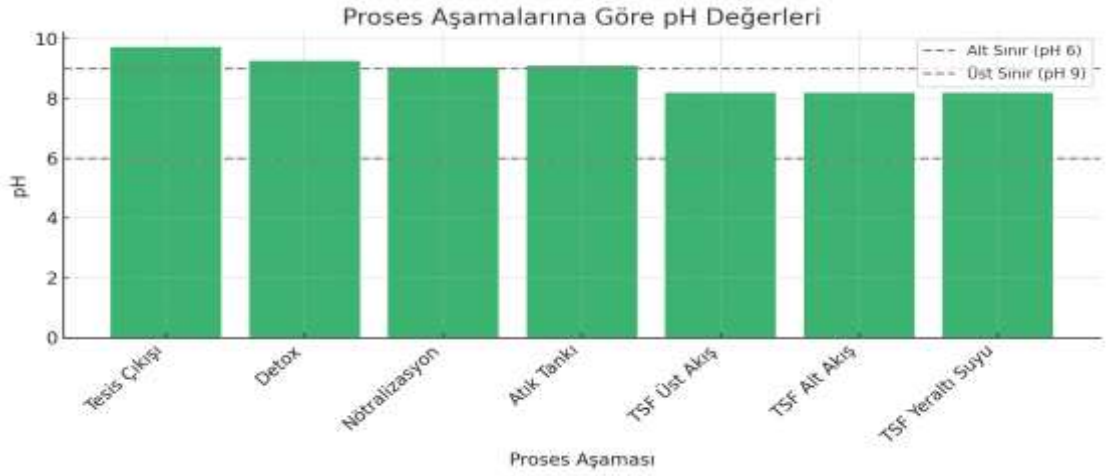


Free CN^- konsantrasyonu, detoksifikasyon aşamasında hızlı bir düşüş göstermiş ve TSF çıkışında <2 ppm seviyesinde sabitlenmiştir (Şekil 2).

Şekil 2. Free CN^- konsantrasyonlarının proses adımlarına göre değişimi.

Şekil 2'de Free CN^- değerinin detoksifikasyon sonrasında belirgin şekilde azaldığı ve TSF çıkışında uluslararası sınır değerlerin altında stabil kaldığı görülmektedir. Benzer şekilde WAD_CN değerleri, proses çıkışındaki 182,30 ppm seviyesinden detoks sonrası dramatik biçimde azalarak TSF çıkışında <2 ppm düzeyine gerilemiştir (Şekil 3).

Şekil 3, WAD_CN konsantrasyonlarının proses boyunca iki log mertebesine yakın bir azalma gösterdiğini ve TSF çıkışında çevresel standartlarla uyumlu seviyelere indiğini ortaya koymaktadır. Bu sonuçlar, detoksifikasyon ve nötralizasyon adımlarının siyanürlü proses atıkları üzerinde yüksek etkinlik sağladığını göstermektedir.

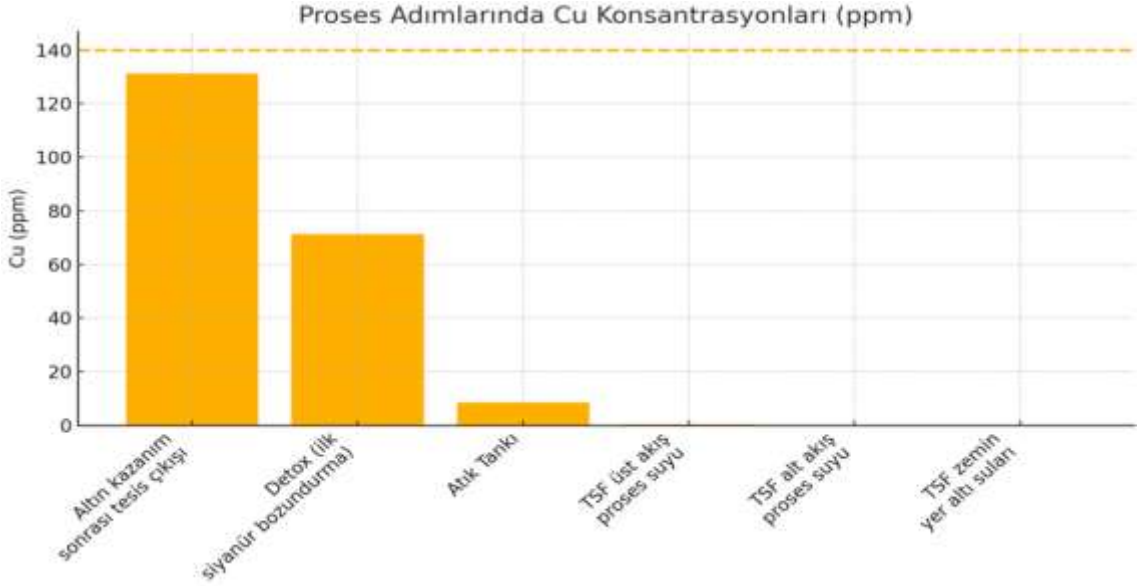


Şekil 3. WAD_CN konsantrasyonlarının proses adımlarına göre değişimi.

Altın Madeni'nde yapılan analizler, siyanür yönetim zincirinin (detoksifikasyon → nötralizasyon → TSF) etkinliğini açıkça kanıtlamaktadır. Saha bulguları, altın madenciliğinde çevresel güvenliğin yalnızca arıtma verimliliğine değil, aynı zamanda sürekli izleme ve kontrol mekanizmalarına bağlı olduğunu göstermektedir (Hudson-Edwards vd., 2011).

Çalışma sahasından elde edilen siyanür giderim oranları, Kanada'daki Musselwhite Madeni ve Avustralya'daki Fosterville Madeni gibi modern tesislerde rapor edilen sonuçlarla uyumludur. Bu tesislerde de WAD_CN konsantrasyonları <2 ppm düzeyine indirilmektedir (Adams, 2016; Vaca-Escobar vd., 2024). Avrupa Birliği'nin 2020 direktifleri, TSF çıkışında WAD_CN değerinin 10 ppm altında tutulmasını önermektedir. Sahada ölçülen değerlerin bu sınırın oldukça altında kalması, işletmenin çevresel standartlara uyum sağladığını göstermektedir.

pH değerleri proses çıkışında 9,73, TSF çıkışında ise 8,19 olarak ölçülmüştür (Şekil 4). Bu değerler, uluslararası literatürde önerilen 8-10 aralığı (Mudder ve Botz, 2004; ICMM, 2020) ile uyumludur. Kontrollü pH yönetimi, hem siyanürün çözeltide kalmasını sağlamış hem de HCN gazı volatilizasyonu riskini azaltmıştır.



Şekil 4. Proses adımlarına göre pH değişimi

Siyanürlü proses atıklarında pH yönetimi kritik öneme sahiptir. pH 9-10 aralığında tutulduğunda HCN gazı oluşumu minimuma indirilmektedir (Lottermoser, 2010). Madende pH'ın 9,73'ten 8,19'a kontrollü düşüşü, siyanürlü suların çevresel salım riski olmadan TSF'ye

verilmesini sağlamıştır. Bu uygulama, ICMM (2020) tarafından önerilen "pH bariyeri" yaklaşımıyla uyumludur.

3.2. Bakır (Cu) Konsantrasyon Profili

Proses adımlarına göre bakır konsantrasyonlarının değişimi Şekil 5'te verilmiştir. Bulgular, Cu'nun proses boyunca dalgalanma gösterdiğini ancak TSF çıkışında çevresel limitlerin altında kaldığını ortaya koymuştur.

Şekil 5. Cu konsantrasyonlarının proses adımlarına göre değişimi.

TSF çevresindeki izleme kuyularından alınan yeraltı suyu numunelerinde siyanür, tespit sınırının altında bulunmuştur. Bu bulgu, TSF tabanında uygulanan jeosentetik sızdırmazlık sistemlerinin ve düzenli izleme programlarının etkili olduğunu göstermektedir.

Siyanürle kompleks oluşturabilen metallerden özellikle Cu, proses verimliliğini ve çevresel riskleri doğrudan etkilemektedir. Çalışma sahasında Cu konsantrasyonlarının TSF çıkışında düşük düzeyde kalması, detoksifikasyon sürecinde metal-siyanür komplekslerinin etkili şekilde parçalandığını göstermektedir. Benzer şekilde Yunanistan'daki Skouries Projesi için rapor edilen bulgular da detoksifikasyon sonrası Cu'nun tespit sınırının altında kaldığını ortaya koymuştur (Alexander vd., 2018; Ilyas ve Lee, 2018).

TSF çevresindeki piezometre kuyularında siyanür tespit edilmemiştir. Bu sonuç, TSF tabanındaki çok katmanlı jeosentetik sistemlerin başarılı bir şekilde işlev gördüğünü göstermektedir. Literatürde, sızdırmazlık sistemlerinin zayıf olduğu barajlarda (örneğin Baia Mare kazası, 2000) siyanürün hızla yeraltı sularına taşındığı bildirilmiştir (Rico vd., 2008). Çalışma sahasında bu riskin ortadan kaldırılması, baraj tasarımının uluslararası standartlara uygun olduğunun göstergesidir.

4. SONUÇLAR

Proses çıkışında yüksek düzeyde ölçülen WAD_CN (182,30 ppm) ve Free CN^- (15,30 ppm) konsantrasyonları, uygulanan detoksifikasyon işlemi sonrasında <2,00 ppm seviyesine düşürülmüştür. Bu değerler, Avrupa Birliği Direktifleri ve ICMM tarafından belirlenen uluslararası standartların öngördüğü limitlerin oldukça altındadır. Proses boyunca pH'ın 9,73'ten TSF çıkışında 8,19 seviyesine inmesi, hidrojen siyanür (HCN) volatilizasyonu riskini

ortadan kaldırırken, bu pH aralığının ICMM (2020) tarafından önerilen 8–10 güvenlik aralığıyla tamamen uyumlu olduğu görülmektedir.

Ayrıca proses süreci boyunca bakır (Cu) konsantrasyonunda belirgin bir düşüş gözlenmiş ve TSF çıkışındaki değerler çevresel limitlerin altında kalmıştır. Bu durum, metal-siyanür komplekslerinin detoksifikasyon aşamalarında etkin şekilde parçalandığını göstermektedir. TSF çevresinde yer alan piezometre kuyularında siyanür, tespit sınırının altında bulunmuş; bu bulgu, tesisin kullandığı çok katmanlı jeosentetik sızdırmazlık sistemlerinin yüksek etkinliğini ortaya koymuştur.

Sonuç olarak, madende uygulanan detoksifikasyon-nötralizasyon-TSF bütünleşik yönetim zinciri, siyanürlü proses atıklarının çevresel açıdan güvenli ve kontrol edilebilir şekilde yönetilmesini sağlamaktadır. Elde edilen bulgular, uluslararası uygulamalarla uyumlu, sürdürülebilir ve güvenilir bir siyanür yönetim modeli sunduğunu doğrulamaktadır.

Çalışma yalnızca tek saha ile sınırlıdır; farklı jeokimyasal koşullara sahip diğer altın işletmelerinde benzer analizler yapılmalıdır. Ölçümler belirli dönemleri kapsamaktadır; mevsimsel değişim ve ekstrem yağış koşullarının etkileri ayrıca değerlendirilmelidir. Bu çalışmada biyolojik izleme yapılmamıştır. Gelecek araştırmalarda, sucul ekosistem göstergeleri (besin ağlarının temeli olarak önemli bir rol oynayan mikroskobik, tek hücreli organizmalar) ile siyanür kalıntılarının etkileri incelenmelidir.

ÖZET

Atık barajlarında sedde çekirdeği veya kil örtü malzemesi olarak kullanılacak zeminlerin uygunluğunun belirlenmesi, tesislerin uzun dönemli performansı ve çevresel güvenliği açısından kritik bir gerekliliktir. Bu tür yapılarda kullanılacak kil malzemelerinin düşük geçirgenlik göstermesi, yeterli plastisiteye sahip olması ve sahada yeterli derecede sıkıştırılabilirlik özellikleri sunması beklenir. Bu çalışmada, İstanbul bölgesindeki farklı jeolojik birimlerden temin edilen kil numuneleri üzerinde Atterberg limitleri, standart Proktor sıkıştırma deneyleri ve düşen seviyeli geçirgenlik testleri gerçekleştirilmiştir. Yapılan deneysel değerlendirmeler sonucunda, yüksek plastisiteli (CH) ve orta plastisiteli (CI) kil sınıflarındaki numunelerin plastisite indisi değerlerinin ($PI \geq 15$) atık depolama yapılarında aranan minimum gereksinimleri sağladığı belirlenmiştir. Bu numuneler, optimum su muhtevası ve maksimum kuru birim hacim ağırlığı değerleri açısından da uygun sıkıştırılabilirlik davranışı sergilemiş; laboratuvar koşullarında elde edilen düşük hidrolik geçirgenlik katsayıları ($k \approx 10^{-9}$-10^{-10} m/s) ile sedde çekirdeği ve kil astarı uygulamalarında kullanılabilir nitelikte bulunmuştur. Buna karşın, orta plastisiteli silt (MI) sınıfındaki bir numunenin plastisite özelliklerinin sınıra yakın değerlerde olduğu, sıkıştırma sonrası elde edilen geçirgenlik değerlerinin ise kabul edilebilir seviyelerin üzerinde ($k > 10^{-9}$ m/s) kaldığı tespit edilmiştir. Bu durum, söz konusu malzemenin tek başına bir kil çekirdeği veya kil astarı olarak kullanılmasının riskli olabileceğini göstermektedir. Elde edilen tüm deneysel veriler, uluslararası kılavuzlar ve tasarım dokümanlarında önerilen sınır değerlerle uyumluluk göstermekte; çalışma, malzeme seçiminde plastisite, kompaksiyon davranışı ve geçirgenlik parametrelerinin birlikte değerlendirilmesinin zorunluluğunu ortaya koymaktadır. Ayrıca saha kompaksiyon kontrolünün baraj güvenliği açısından vazgeçilmez bir unsur olduğu vurgulanmaktadır.

Anahtar Kelimeler: Atık barajı, Kil astarı, Geçirgenlik, Atterberg limitleri, Proktor deneyi.

EVALUATION OF GEOTECHNICAL PROPERTIES OF CLAY MATERIALS FOR USE IN TAILINGS STORAGE FACILITIES

ABSTRACT

Determining the suitability of soils to be used as core material or clay liner in tailings storage facilities is essential for ensuring the long-term performance and environmental safety of these structures. Clay materials selected for such applications are required to exhibit low hydraulic conductivity, adequate plasticity, and favorable compaction characteristics. In this study, clay samples collected from various geological units within the Istanbul region were subjected to Atterberg limits tests, Standard Proctor compaction tests, and falling-head permeability experiments. Experimental evaluations indicated that samples classified as high-plasticity clays (CH) and medium-plasticity clays (CI) meet the minimum design requirements for tailings dam construction. These samples possessed plasticity index (PI $\geq$ 15) values consistent with international guidelines, demonstrated appropriate compaction behavior in terms of optimum moisture content and maximum dry density, and yielded low hydraulic conductivity coefficients ($k \approx 10^{-9}$-10^{-10} m/s), confirming their suitability for use as core or clay liner materials.

Conversely, one sample classified as a medium-plasticity silt (MI) exhibited borderline plasticity characteristics and produced permeability values exceeding acceptable limits ($k > 10^{-9}$ m/s) even after compaction. This finding suggests that the silt material may pose risks if used alone as a core or liner without stabilization or blending with higher-plasticity clays. Overall, the experimental results align well with threshold values recommended by international design manuals and regulatory documents. The study highlights the critical importance of simultaneously evaluating plasticity, compaction response, and hydraulic conductivity during material selection. It also emphasizes that proper field compaction control remains indispensable for ensuring the structural integrity and environmental performance of tailings dam containment systems.

Keywords: Tailings dam, Clay liner, Permeability, Atterberg limits, Proctor compaction.

1. GİRİŞ

Cevher zenginleştirme tesisi atıklarının güvenli yönetimi, son on yılda meydana gelen yıkıcı kazalar ve artan yasal/toplumsal baskılar nedeniyle küresel ölçekte kritik bir mühendislik alanı hâline gelmiştir. UNEP'in "Safety is No Accident" raporu (2017), 2014 Mount Polley ve 2019 Brumadinho felaketlerinin ardından, atık depolama tesislerinde (TSF) tasarım-işletme-kapatma süreçlerinin bütüncül şekilde yeniden ele alınmasını zorunlu kılmıştır. Bu bağlamda oluşturulan Küresel Atık Yönetimi Standardı (ICMM, 2020), tüm TSF'lerde "sıfır zarar ilkesi"ni benimsemiş, düşük geçirimli bariyerlerin (kil çekirdek, kil kaplama, kil astar) tasarım ve kalite kontrolünde izlenebilir süreci zorunlu hâle getirmiştir (Al-Mahbashi vd., 2021; Karademir, 2022).

Cevher zenginleştirme tesisi atıkları; sülfür mineralleri, ağır metaller, kullanılan kimyasallar ve yüksek iyonik kuvvetli çözeltiler içermeleri nedeniyle, çevresel açıdan son derece agresif bir karakter sergilemektedirler. 2020 sonrası literatür, özellikle ağır metal taşınımına ilişkin risklerin hidrolik iletkenlik kadar kimyasal etkileşim süreçleriyle (iyon değişimi, flokülasyon, dispersiyon, şişme-çökelme davranışı) belirlendiğini göstermektedir (Hamdi ve Srasra, 2013; Özçoban vd., 2017; Widomski vd., 2021; Liu vd., 2023; Guduru vd., 2024). Bu nedenle, TSF alt yapılarında kullanılan doğal zeminlerin yalnızca düşük permeabilite sağlaması yeterli değildir; aynı zamanda kimyasal dayanım ve adsorpsiyon kapasitesinin de değerlendirilmesi gerekmektedir.

Son yıllarda araştırmalar, yüksek iyonik özellikli çözeltilerin kompakte kil astarların yapısal bütünlüğünü bozabileceğini ve hidrolik iletkenliği artırabileceğini göstermiştir (Xu vd., 2018; Ma vd., 2023). Örneğin, Cu(II) içeren yüksek konsantrasyonlu atık çözeltileri, killerde çift tabaka sıkışması ve flokülasyon etkisiyle permeabilitenin artmasına neden olabilmektedir. Bu nedenle birçok çalışma, kil astarların performansını geliştirmek amacıyla doğal zeolit (ör. klinoptilolit), organik polimerler (Na-PAA) ve yan ürün katkıları (uçucu kül, red mud, laterit) gibi malzeme modifikasyonlarının etkilerini incelemiştir (Kalkan, 2023; Zhang vd., 2025; Wang vd., 2025). Bu yeni nesil katkılar sayesinde hem hidrolik iletkenlik düşürülmekte hem de ağır metal adsorpsiyon kapasitesi artırılmaktadır. 2025 yılında yayımlanan kapsamlı bir çalışma, klinoptilolit ve Na-PAA ile zenginleştirilmiş kompakte kil astarların, Cu(II) içeren çözeltiler altında %78'e varan hidrolik iletkenlik azalması ve %65'e varan ağır metal adsorpsiyon kapasitesi artışı sağladığını ortaya koymuştur (Bi vd., 2025). Benzer şekilde, Zambiya'da yürütülen bir araştırma, doğal killerin 10^{-10} m/s mertebesindeki geçirimsizlikleri sayesinde TSF astarları için uygun bir ekonomik alternatif sunabileceğini göstermiştir (Brobbey vd., 2024).

Bununla birlikte, literatürün işaret ettiği önemli bir boşluk, kompakte kil astarların performansının saha koşullarındaki uzun dönemli davranışıdır. Yüksek iyonik kuvvet, değişken pH, redoks koşulları ve konsolidasyon basıncı gibi etkiler altında, laboratuvar performansı ile saha performansı arasında ciddi farklılıklar olabilmektedir. Bu nedenle, ICMM (2020), ANCOLD (2019), MAC/CDA (2021) ve TS EN 13491 gibi kılavuzlar, TSF tasarımında yalnızca laboratuvar deneylerine değil, saha kompaksiyon kontrolüne, mineralojik analizlere, kimyasal dayanım testlerine ve hidrolik iletkenliğin zaman-bağımlı izlenmesine vurgu yapmaktadır.

Sonuç olarak, güncel literatür açıkça göstermektedir ki:

- Kil astarların performansı yalnızca permeabilite ile ölçülemez; kimyasal dayanım ve adsorpsiyon kapasitesi kritik belirleyicilerdir.

- Cevher zenginleştirme tesisi atıkları, yüksek iyonik yükleri nedeniyle klasik kil astarların yapısını bozabilmekte; modifiye astarlar giderek zorunlu hâle gelmektedir.
- Doğal ve modifiye killer, jeomembranlarla birlikte hibrit bariyer sistemlerinde giderek daha fazla önerilmektedir.
- Sürdürülebilir madencilik için TSF bariyer tasarımı, reaktif taşınım modelleri ve uzun dönemli performans değerlendirmesi gerektirir.

Bu bağlamda çalışmanın amacı, laboratuvar ortamında elde edilen Atterberg limitleri, Proktor kompaksiyon parametreleri ve düşen seviyeli permeabilite test sonuçlarına dayanarak, inceleme konusu killerin cevher zenginleştirme tesisi atık barajlarında kompakte kil astar malzemesi olarak mühendislik açıdan uygunluğunu çok boyutlu şekilde değerlendirmektir.

2. MALZEME VE YÖNTEM

2.1. Çalışma Malzemeleri ve Numune Hazırlığı

Bu çalışmada, İstanbul ilindeki farklı jeolojik birimlerden temin edilen, atık depolama tesislerinde kullanılabilecek kil kökenli zeminlerin teknik uygunluğunu belirlemek amacıyla farklı plastisite ve mineralojik bileşime sahip 13 adet doğal kil numunesi değerlendirilmiştir. Numuneler laboratuvara getirildikten sonra etüv kurusu şartında hazırlanmış, tüm deneylerde standartlarda tarif edilen tane iriliği, su muhtevası ve numune hazırlanma prosedürleri esas alınmıştır.

Her bir kil numunesi için üç temel deney grubu uygulanmıştır:

1. Atterberg Kıvam Limitleri Deneyi (TS 1900-1; ASTM D4318)
2. Zemin Sıkıştırma (Proktor) Deneyi (TS 1900-1; ASTM D698)
3. Düşen Seviyeli Yöntem ile Hidrolik Geçirgenlik Tayini (TSE CEN ISO/TS 17892-11; DIN 18130; ASTM D5084 referanslı yöntem)

Bu deneyler, numunelerin plastisite davranışını, kompaksiyon özelliklerini ve hidrolik iletkenliğini bütüncül bir yaklaşımla değerlendirmek üzere gerçekleştirilmiştir. Deneylerde kullanılan cihazlardan bazıları Şekil 1'de verilmiştir.

(a) (b) (c)

Şekil 1. Deneylerde kullanılan cihazlar. (a-Proktor deney seti, b-Düşen seviyeli permeabilite deney seti, c-Likit limit cihazı).

2.2. Atterberg Limitleri ve Zemin Sınıflandırması

Her numune için likit limit (LL), plastik limit (PL) ve büzülme limiti (BL) deneyleri TS 1900-1 standardına uygun şekilde yapılmış; plastisite indisi PI = LL - PL bağıntısıyla hesaplanmıştır. Elde edilen değerler, numunelerin USCS sınıflandırmasına göre CH (yüksek plastisiteli kil), CI (orta plastisiteli kil) ve MI (orta plastisiteli silt) sınıflarına ayrılmasında kullanılmıştır. TSF tasarım literatüründe önerilen PI ≥ 15 sınırı (ICMM-GISTM, ANCOLD, MAC/CDA) malzeme uygunluğu için temel kriter olarak dikkate alınmıştır.

2.3. Zemin Sıkıştırma (Proktor) Deneyi

Numunelerin optimum sıkıştırma özellikleri, TS 1900-1 ve ASTM D698 Standart Proktor yöntemine göre belirlenmiştir. Her bir kil numunesi için, optimum su muhtevası (w_{opt}) ve maksimum kuru birim hacim ağırlığı ($\gamma_{d,max}$) kompaksiyon eğrilerinden elde edilmiştir.

TSF uygulamalarında yaygın olarak kullanılan ≥%95 $\gamma_{d,max}$ ve w_{opt} ± %2 saha kriterleri göz önünde bulundurularak geçirgenlik deneylerinde kullanılacak numuneler aynı kompaksiyon hedeflerinde hazırlanmıştır.

2.4. Hidrolik Geçirgenlik (Permeabilite) Deneyleri

Numunelerin doygun koşullar altındaki su geçirgenlikleri, Düşen Seviyeli (Falling-Head) yöntem kullanılarak, TSE CEN ISO/TS 17892-11 ve DIN 18130 standartlarına uygun biçimde belirlenmiştir.

Deney sürecinde, numuneler proktor yoğunluklarına göre sıkıştırılmış, esnek membranlı hücre içerisinde doygunlaştırılmış ve hidrolik iletkenlik (permeabilite) katsayısı (k), klasik düşen seviye denklemiyle (Denklem 1) hesaplanmıştır.

$$k = 2{,}3 * a * L / (A*t) * \log(h_2/h_1) \quad (1)$$

Burada ;

k: Hidrolik iletkenlik (permeabilite) katsayısı (m/s)

A: Numunenin Yüzey Alanı (m^2)

a: Hortum Alanı (m^2)

L: Numune Yüksekliği (m)

h_1: İlk Okuma (mm)

h_2: Son Okuma (mm)

t: Süre (saniye)

TSF tasarım kriterlerinde kabul edilen eşik değerler:

- Kil astarlarda: $k \leq 1\times10^{-9}$ m/s
- TSF kil çekirdeklerinde: $k \approx 10^{-9} – 10^{-8}$ m/s

olarak dikkate alınmıştır.

2.5. Veri Analizi ve Uygunluk Değerlendirme Yaklaşımı

Her deney sonucunun TSF tasarım kriterlerine uygunluğu, aşağıdaki üç temel parametreye göre yapılmıştır:

1. Plastisite Uygunluğu ($PI \geq 15$)
2. Kompaksiyon Uygunluğu ($\geq$%95 $\gamma_{d,max}$ ve w_{opt} aralığı)
3. Geçirgenlik Uygunluğu ($k \leq 10^{-9}$ m/s)

Bu üç kriter birlikte ele alınarak numunelerin “kil çekirdek”, “kil astar” veya “uygun değil/koşullu” kategorilerine yerleştirilmesi için karar matrisi altyapısı oluşturulmuştur.

3. BULGULAR

Bu bölümde, kil numunelerine ait Atterberg limitleri, kompaksiyon parametreleri ve geçirgenlik deney sonuçları bütüncül olarak değerlendirilmiştir. Deneysel bulgular, Tablo 1’de sunulan veriler üzerinden yorumlanmıştır.

Tablo 1. Kil numunelerine ait Atterberg limitleri, kompaksiyon parametreleri ve geçirgenlik sonuçları.

No	LL	PL	BL	PI	Sınıf	$\gamma_{d,max}$ (g/cm³)	w_{opt} (%)	k (m/s)
1	68,0	25,7	15,0	42,3	CH	1,43	25,5	$7,27\times10^{-10}$
2	53,0	27,0	18,0	26,0	CH	1,48	27,2	$1,15\times10^{-9}$
3	45,0	29,7	23,0	15,3	MI	1,56	16,6	$1,22\times10^{-9}$
4	43,0	25,4	19,0	17,6	CI	1,63	18,6	$1,16\times10^{-9}$
5	75,0	30,7	18,0	44,3	CH	1,50	24,6	$6,04\times10^{-10}$
6	57,0	28,1	18,0	28,9	CH	1,47	26,0	$1,24\times10^{-9}$
7	53,0	27,9	19,0	25,1	CH	1,48	27,3	$2,87\times10^{-10}$
8	69,0	33,4	17,0	38,6	CH	1,35	33,2	$3,31\times10^{-10}$
9	51,0	24,2	16,0	26,8	CH	1,46	25,2	$2,35\times10^{-10}$
10	56,0	25,6	17,0	30,4	CH	1,47	24,2	$2,39\times10^{-10}$
11	57,1	28,4	18,0	28,7	CH	1,39	27,1	$2,47\times10^{-10}$
12	55,3	27,9	18,0	27,4	CH	1,42	26,0	$2,59\times10^{-10}$
13	54,1	25,0	17,0	29,1	CH	1,51	26,5	$3,24\times10^{-10}$

Açıklamalar: LL: Likit Limit, PL: Plastik Limit, BL: Büzülme Limiti, PI: Plastisite İndisi, $\gamma_{d,max}$: Maksimum Kuru Birim Hacim Ağırlığı, W_{opt}: Optimum Su Muhtevası, k: Hidrolik İletkenlik, CH: Yüksek plastisiteli kil; CI: Orta plastisiteli kil; MI: Orta plastisiteli silt.

3.1. Atterberg Limitleri ve Zemin Sınıflandırması

Numunelerin likit limit (LL), plastik limit (PL) ve plastisite indisi (PI) değerleri Tablo 1'de verilmiştir. Bu sonuçlara göre; 13 numunenin 11'i CH (yüksek plastisiteli kil) sınıfında, 1'i CI (orta plastisiteli kil) sınıfında ve 1 numune de MI (orta plastisiteli silt) sınıfındadır.

Plastisite indisleri:

- CH killer için PI = 25-44 aralığındadır.
- CI sınıfındaki numune (No: 4) PI = 17,6 ile minimum mühendislik eşiğine yakındır.
- MI sınıfındaki numune (No: 3) PI = 15,3 ile sadece sınır değerin üzerindedir.

TSF kil çekirdeği ve astarı için literatürde önerilen PI ≥ 15 kriteri incelendiğinde 12 numunenin uygun olduğu açıkça görülmektedir. Sadece MI sınıfında olan bir numunenin düşük plastisite nedeniyle sınır değerde uygunluk gösterdiği görülmüştür. Bu sonuçlar, yüksek PI değerine sahip killerin çatlama ve iç erozyon direnci açısından daha avantajlı olduğunu desteklemektedir.

3.2. Kompaksiyon Davranışı (w_{opt} - $\gamma_{d,max}$)

Deney sonuçlarına göre maksimum kuru birim hacim ağırlıkları ($\gamma_{d,max}$) 1,35 – 1,63 g/cm³ arasında değişmektedir. wopt değerleri de CH killerde %24 - 33 aralığında, MI numunesinde

%16,6, CI numunesinde ise %18,6 olarak belirlenmiştir. Bu dağılım, plastisite arttıkça optimum su içeriğinin artması şeklindeki klasik davranışı doğrulamaktadır.

TSF uygulamalarında kritik olan ≥%95 $\gamma_{d,max}$ ve w_{opt} ± %2 saha şartları göz önüne alındığında: tüm numuneler sıkıştırılabilirlik açısından kabul edilebilir mühendislik özellikleri göstermektedir. MI numunesi düşük su içeriği ile silt karakteri sergilemekte olup kompakte edildiğinde geçirgenlik yönünden daha riskli bir davranış gösterebilir.

3.3. Hidrolik Geçirgenlik (k) Sonuçları

Düşen seviyeli permeabilite deneyleri sonucunda numunelerin k değerleri $2{,}35\times10^{-10}$ m/s ile 1×10^{-9} m/s arasında değişmektedir. TSF tasarım kriterleri açısından $k \leq 1\times10^{-9}$ m/s olan tüm numuneler kil astarında kullanılabilir niteliktedir. CH grubu killerin çoğu $k \leq 5\times10^{-10}$ m/s mertebesinde olup yüksek mühendislik performansı göstermektedir. MI sınıfındaki numune ise PI değerine paralel olarak üst sınırda bir geçirgenlik sergilemektedir.

4. SONUÇLAR

Bu çalışma kapsamında değerlendirilen kil numunelerinin Atterberg limitleri, kompaksiyon davranışları ve hidrolik geçirgenlik özellikleri birlikte ele alındığında, zeminlerin atık barajlarında (TSF) kompakte kil çekirdeği veya kil astarı olarak kullanılabilirliklerini belirleyen mühendislik kriterleri açısından önemli bulgular elde edilmiştir. Bulgular, hem klasik geoteknik prensiplerle hem de güncel uluslararası standartlarla büyük ölçüde uyumludur.

Plastisite, kompaksiyon ve geçirgenlik özellikleri birlikte değerlendirildiğinde; yüksek uygunluk kategorisindeki killer (CH), $PI \geq 25$, $k \leq 5\times10^{-10}$ m/s (çoğunluk), w_{opt} - $\gamma_{d,max}$ değerleri saha şartlarıyla uyumlu olduğu için TSF kil çekirdek ve astar uygulamaları için yüksek uygunluk göstermektedir. Koşullu uygunluk sınıfına giren killer (CI), PI = 17,6 (sınır üstü), $k = 1\times10^{-9}$ m/s (üst eşik) olduğundan astar olarak kullanılabilir, çekirdek için projeye bağlı olarak değerlendirilmelidir. Sınırda uygunluk sınıfına giren zemin numuneleri (MI), PI = 15,3 (minimum eşik), $k = 1\times10^{-9}$ m/s (üst eşik), Silt karakteri özelliği olduğundan tek başına çekirdek/astar için önerilmez; katkı veya karışım gerektirir.

Her ne kadar laboratuvar sonuçları TSF uygulamaları için güçlü bir uygunluk gösterse de literatürde sıkça belirtilen bazı uzun dönem performans riskleri göz önünde bulundurulmalıdır:

- Islanma-kuruma döngüleri kil matrisinde mikro çatlaklara neden olabilir.
- Yüksek iyonik konsantrasyonlu atık çözeltileri (Cu^{2+}, Fe^{3+}, SO_4^{2-} vb.) çift tabakayı sıkıştırarak permeabiliteyi artırabilir.
- Drenaj gradyanı yüksek çekirdek bölümlerinde iç erozyon riski artabilir.

Bu nedenle, uygun malzemenin seçilmesine ek olarak TSF tasarımında: (i) filtre zonlarının doğru yerleştirilmesi, (ii) saha kompaksiyon kontrolü, (iii) uzun dönem hidrolik izleme programları tasarımın ayrılmaz bir parçası olmalıdır.

ÖZET

Su bazlı biyo-poliüretanlar için geliştirilen biyo-poliester polioller, sürdürülebilir malzeme üretimine önemli bir katkı sağlamaktadır. Poliüretanlar (PU'lar), yüksek mekanik dayanım, kimyasal direnç ve düşük sıcaklıklarda esneklik gibi üstün özelliklerinden dolayı endüstriyel uygulamalarda yaygın olarak kullanılmaktadır. Ancak geleneksel olarak solvent bazlı sistemlerin kullanımı, çevresel ve sağlık riskleri oluşturduğundan, özellikle uçucu organik bileşik (VOC) emisyonlarının artması, alternatif çözücü sistemlerin geliştirilmesini zorunlu hale getirmiştir. Bu doğrultuda, su bazlı PU dispersiyonları (WPUD), çevreye daha dost bir seçenek olarak öne çıkmakta ve son yıllarda yapılan araştırmalarda su bazlı sistemler üzerine yoğunlaşılmaktadır. Bu çalışmada, biyo-poliester poliollerin sentezi, doğal kaynaklardan elde edilen sebasik asit (SA) ve süksinik asit (SUA) gibi biyolojik kökenli diasitler kullanılarak gerçekleştirilmiştir. Poliollerin lineer yapısının oluşturulmasında dietilen glikol (DEG) ve 1,6 heksandiol (HDO) gibi alifatik dioller tercih edilmiştir. Kondenzasyon polimerizasyonu, vakum altında ve herhangi bir çözücü kullanılmadan, sıcaklık kontrollü cam bir reaktörde mekanik karıştırma ile yürütülmüştür. Sentez sırasında, asit grubunun tüketimini artırmak amacıyla glikolün 1:1,15 mol oranında fazlası eklenmiştir. Elde edilen poliester poliollerin yapısal karakterizasyonu Fourier dönüşümlü kızılötesi spektroskopi (FTIR) ile doğrulanmış; C=O ve C-O ester bantlarının varlığı ile poliester oluşumu teyit edilmiştir. Moleküler ağırlık parametreleri ise jel geçirgenlik kromatografisi (GPC) ile belirlenmiş ve polidispersite indeksi (PDI) değerleri polimerin moleküler ağırlığı dağılımını yansıtmıştır. Ayrıca, sentez tepkimesi ilerlemesi asit sayısı takibiyle izlenmiştir. Araştırmada kullanılan biyolojik kökenli hammaddeler ve solventsiz tepkime ortamı, süreç boyunca çevre dostu bir yaklaşımın benimsendiğini göstermektedir. Sonuç olarak, elde edilen biyo-poliester polioller hem sürdürülebilirlik hem de fonksiyonellik açısından su bazlı biyo-PU uygulamalarında ileri teknolojilere katkı sunmaktadır. Bu çalışmanın, çevreye duyarlı PU üretiminde biyobazlı hammaddelerin daha etkin kullanımı için yol gösterici nitelik taşıdığı ve yeni nesil su bazlı PU sistemlerinin geliştirilmesinde önemli bir referans olacağı söylenebilir.

Anahtar Kelimeler: Biyo poliol, Sebasik Asit, Süksinik Asit, Su Bazlı Poliüretan

GİRİŞ

Su bazlı poliüretanlar (WPU'lar), poliüretan parçacıklarının sürekli bir sulu faz içinde dağıtıldığı kolloidal dispersiyonlardır. Bu sistemlerin ana bileşenleri mükemmel kolloidal stabilite gösterir ve suda kolayca dağılır, bu da diğer kolloidal parçacıklar veya katkı maddeleriyle daha fazla fonksiyonelleştirmeyi kolaylaştırır (Honarkar, 2018).

WPU sentezinde polioller, temel öncüller olarak hizmet eder ve polimerin nihai özelliklerini belirlemede belirleyici bir rol oynar. Yaygın olarak kullanılan polioller arasında polieter, polyester ve polikarbonat türleri bulunur. Polieter bazlı WPU'lar esneklikleri, hidrolitik stabiliteleri ve uygun maliyetleriyle bilinirler, ancak oksijene ve ışığa duyarlılıkları nedeniyle uzun vadeli dayanıklılıkları ve çözücü dirençleri sınırlıdır. Polyester bazlı WPU'lar ise üstün yağ ve çözücü direnci sunar, ancak hidrolitik koşullar altında daha az kararlı olma eğilimindedirler. Polikarbonat bazlı polioller, mükemmel mekanik mukavemet ve hidrolize, yağa ve çevresel bozulmaya karşı direnç sağlar, ancak diğer ikisine kıyasla nispeten pahalıdırlar (Mehravar vd., 2019; Cakić vd., 2013).

Farklı poliol türleri arasında polyester polioller, mükemmel termal kararlılık, alev geciktiricilik ve solvent direncine sahip PU malzemelerin üretiminde önemli bir rol oynar. Polieter bazlı sistemlere kıyasla hidrolize karşı daha az dirençli olmalarına rağmen, polyester polioller yüksek performanslı PU elastomerlere, esnek köpüklere, yapıştırıcılara ve kaplamalara önemli ölçüde katkıda bulunur. Ayrıca, polyesterler, yenilenebilir ve sürdürülebilir malzemelere yönelik artan küresel vurguyla uyumlu olarak, biyobazlı poliüretanların sentezi için umut verici öncüller olarak kabul edilir (Mahmood vd., 2016; Ionescu, 2005; Choffat vd., 2023).

Geleneksel olarak oligomerik polioller fosil bazlı hammaddelerden sentezlenir. Ancak, bu yenilenemeyen kaynakların tükenmesi ve artan sera gazı emisyonları, biyobazlı poliollerin sürdürülebilir alternatifler olarak geliştirilmesini teşvik etmiştir. Sebasik asit (SA) türevi polyester polioller en çok incelenen örnekler arasındadır. SA, öncelikle bol miktarda bulunan, ucuz ve yenilenebilir bir hammadde olan hint yağından elde edilir. Uzun alifatik zincir yapısı sayesinde SA bazlı polyesterler, PU malzemelerin mekanik, termal ve yapışkan performansını artıran yüksek kristallik ve erime noktalarına sahiptir (Mokhtari vd., 2018; Li vd., 2020; Umare vd., 2007). Son çalışmalar ayrıca SA'nın polikarbonat bazlı reaktif poliüretan sıcak eriyen yapıştırıcılarda biyoasit bileşeni olarak başarılı bir şekilde kullanıldığını bildirmiştir (Sun vd., 2023). Bir diğer önemli yenilenebilir monomer ise şekerlerin fermantasyonu yoluyla üretilebilen süksinik asittir (SUA). Özellikle diğer yenilenebilir monomerlerle birleştirildiğinde, tamamen biyobazlı malzemelerin sentezlenmesi için ideal bir biyo-yapı taşıdır (Jacquel vd., 2011; Jiang vd., 2017).

Bu çalışmada, SA ve SUA gibi yenilenebilir diasitler kullanılarak biyobazlı polyester polioller sentezlenmiştir. Lineer polimer omurgasını oluşturmak için dietilen glikol (DEG) ve 1,6-heksandiol (HDO) dahil olmak üzere alifatik dioller seçilmiştir. Elde edilen poliollerin kimyasal yapıları Fourier dönüşümlü kızılötesi spektroskopisi (FTIR) ile doğrulanırken, moleküler ağırlık parametreleri jel geçirgenlik kromatografisi (GPC) kullanılarak belirlenmiştir. Sentezlenen polimerlerin moleküler ağırlık dağılımını değerlendirmek için polidispersite indeksi (PDI) değerleri kullanılmıştır. Bu çalışma sürdürülebilir su bazlı poliüretan sistemlerinin hazırlanmasına uygun biyobazlı polyester poliollerin geliştirilmesi ve karakterizasyonu ile çevre dostu polimer malzemelerin ilerlemesine katkıda bulunmayı amaçlamaktadır.

MATERYAL ve YÖNTEM

Materyal

Çalışma kapsamında, Sebasik asit (ticari derece, >= %99,0), süksinik asit(teknik derece, >= %99,0), dietilen glikol (ticari derece, >= %95,0-99,0), 1,6-heksandiol (ticari derece, >= %95,0-99,0), ve butil stannoik asit (ticari derece, >= %95,0-99,0) belirtilen saflıklarda kullanılmıştır.

Poliollerin Sentezi

Sentez tepkimesi için kullanılan sistem, geri soğutuculu, mekanik karıştırıcılı, ısıtma ve soğutmanın birlikte kullanılabildiği, vakum ortamında, sıcaklık kontrollü bir cam polimerizasyon reaktöründen oluşmaktadır. Hazırlanan dört farklı Poliester Poliol (PEO) Tablo 1'deki gibi adlandırılmış olup, Karboksil: Hidroksil (COOH:OH) oranları 1:1,15 olarak sabit tutulmuştur.

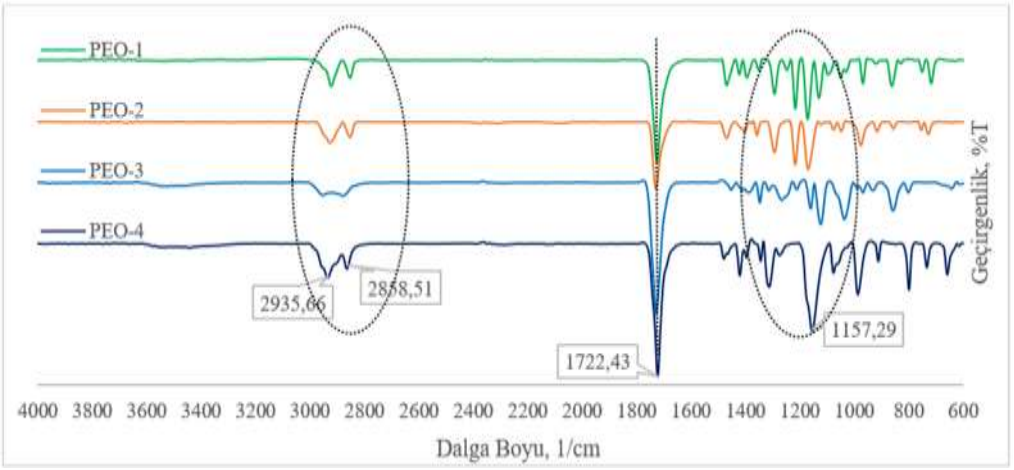
Tablo 1. Poliester Poliollerin Bileşimleri.

Örnek Kodu	Örnek Bileşimi	COOH:OH
PEO-1	SA:DEG	1:1,15
PEO-2	SA:HDO	1:1,15
PEO-3	SUA:DEG	1:1,15
PEO-4	SUA:HDO	1:1,15

Karakterizasyon

Katı madde yüzdesi, ASTM D2369'a göre numunenin 110°C'de 1 saat ısıtılmasıyla belirlendi. Sentezlenen polyester poliollerin asit sayısı, ASTM D4662 test yöntemine göre ölçüldü. Numunelerin kimyasal yapısı, 4000–600 cm^{-1} ölçüm aralığına sahip bir Shimadzu Corp. Iraffinity-1S FTIR Spektrometresi üzerinde zayıflatılmış toplam yansıma cihazı kullanılarak FTIR spektrometrisi kullanılarak incelendi.

Moleküler ağırlık parametreleri (¯Mw ve ¯Mn) ve polidispersite indeksi (PDI; ¯Mw/¯Mn), bir Tosoh EcoSEC HLC-8320GPC sistemi kullanılarak belirlendi. Ayırma işlemi için, TSKgel 5000HXL, G4000HXL ve G3000HXL kolonlarıyla birlikte bir TSKgel HXL-L koruyucu kolon kullanıldı. Sistem hem kırılma indisi hem de UV-Vis dedektörleriyle donatılmış olup, GPC düzeneğine bir Waters-Wyatt Technology WTREOS-15 çok açılı ışık saçılım dedektörü de bağlanmıştır. HPLC sınıfı tetrahidrofuran, seyreltici olarak ve polimer çözeltilerinin hazırlanmasında kullanılmıştır.



BULGULAR ve TARTIŞMA

Sentezlenen poliester poliollerin % katı madde miktarı, asit sayısı ölçümleri Tablo 2'de özet olarak verilmiştir. Buna göre poliester poliollerin tamamı %1'den az oranda su içermektedir. Vakum altında gerçekleşen reaksiyonlar su çıkışı gerçekleşmeyene kadar sürdürülmüştür. Sentez sonrası ölçülen asit sayıları sebasik asit kullanılan poliolllerde (PEO-1 ve PEO-2) 12 mgKOH/g olarak ölçülürken, süksinik asit kullanılan poliollerde (PEO-3 ve PEO-4) sırasıyla 9 ve 3 mgKOH/g olarak ölçülmüştür.

Tablo 2. Poliester Poliollerin Özellikleri.

Örnek Kodu	Fiziksel Görünüm (@25°C)	Katı Madde (%)	Asit Sayısı (mgKOH/g)
PEO-1	Katı	99,3	12
PEO-2	Katı	99,0	12
PEO-3	Sıvı	99,7	9
PEO-4	Katı	99,4	2

Şekil 1. Sentezlenen polyester poliollerin FTIR spektrumunu göstermektedir. Elde edilen FTIR sonuçlarına göre, polyester poliollerdeki alifatik düz zincir titreşimlerinin (–CH_2–) karakteristik tepe noktaları sırasıyla 2800–3000 cm^{-1}'de görülmektedir (Saltan ve Akat, 2021). PEO spektrumlarında 1722 cm^{-1}'de görülen absorpsiyon bandı ve 1157 cm^{-1} civarındaki bir diğer tepe noktası, esterin fonksiyonel grupları (–COOH) ve (C–O) grupları olan karboksil grubunun karakteristik absorpsiyon tepe noktası olan (C=O)'ya atfedilebilir (Tang vd., 2006). 1100–1200 cm^{-1} aralığındaki çoklu emilim tepe noktası, kullanılan poliollerden türetilen ester gruplarından kaynaklanan (C(O)-O-C) gerilme titreşimiyle ilişkilidir (Parcheta vd., 2020).

Şekil 1. Polyester poliollerin FTIR Spektrumu.

GPC analizleri sonucunda PEO-3 poliolü ile yapılan sentezler haricinde birbirine yakın sonuçlar elde edilmiştir. Bu da hedeflenen yapıların sentezlendiğini kanıtlamaktadır. SA'nın kullanıldığı PEO-1 ve PEO-3 poliollerinin molekül ağırlığı SUA'nın kullanıldığı poliollerden yüksek değerlerde ölçülmüştür (Tablo 3). PDI'ı 1,05-1,2 olarak ölçülen POE numuneleri monodispers (tek molekül ağırlıklı) yapıdadır.

Tablo 3. Poliester Poliollerin Moleküler Özellikleri.

Örnek Kodu	Mw (g/mol)	Mn (g/mol)	PDI (Mw/Mn)
PEO-1	3266	2857	1,143
PEO-2	2983	2823	1,056
PEO-3	7141	5975	1,195
PEO-4	3351	3013	1,112

SONUÇLAR

Bu çalışmada, biyo-POE'lerin sentezi, SA ve SUA gibi biyolojik kaynaklı diasitler kullanılarak gerçekleştirilmiştir. POE'lerin yapısının oluşturulmasında DEG ve HDO gibi alifatik dioller kullanılmıştır. Elde edilen poliester poliollerin yapısal karakterizasyonu FTIR ile doğrulanmış; 1722 cm^{-1}'de görülen absorpsiyon bandı ve 1157 cm^{-1} civarındaki bir diğer tepe noktası, C=O ve C-O ester bantlarının varlığı ile poliester oluşumu teyit edilmiştir. Moleküler ağırlık parametreleri GPC ile belirlenmiş ve PDI değerlerinde poliollerin moleküler ağırlığı dağılımının monodispers olduğu görülmüştür. Özetle, geliştirilen biyo-poliester polioller, hem sürdürülebilirlik hedeflerine hizmet etmekte hem de su bazlı biyo-PU uygulamalarında işlevsellik açısından ileri düzey çözümler sunmaktadır.

KATKI

Bu bildiri, birinci sırada yer alan yazarın Kocaeli Üniversitesi, Fen Bilimleri Enstitüsü'nde hazırladığı yayımlanmamış doktora tezinden üretilmiştir. Ayrıca çalışma, 1002-A/224Z160 TÜBİTAK projesi kapsamında hazırlanmış ve desteklenmiştir.

ABSTRACT

One of the most critical components determining the performance of coolants used in the engine cooling system is the corrosion inhibitor. While water and ethylene glycol provide effective heat transfer, they alone cannot prevent corrosion and wear on metal surfaces. Therefore, the use of suitable corrosion inhibitors is essential for the long-term efficiency and durability of the cooling system. In this study, the effectiveness of Organic Acid Technology (OAT)-based additives was investigated. The most commonly used OAT component is 2-ethylhexanoic acid. However, 2-ethylhexanoic acid has the GHS08 (health hazard) pictogram according to the harmonized classification and labelling system, which indicates that the substance is hazardous and may also damage the unborn child. Therefore, this study aims to investigate new carboxylic acid corrosion inhibitors that are more suitable for human health and the environment. In this context, isononanoic acid and a polycarboxylic acid were selected to be evaluated as new type corrosion inhibitors for engine cooling fluids. Separate formulations were prepared and tested individually for 2-ethylhexanoic acid, isononanoic acid and polycarboxylic acid to evaluate their corrosion protection performance. The results showed that all additives provided good corrosion protection. Among the developed corrosion inhibitor additives, the isononanoic acid and polycarboxylic acid-based additives stand out in terms of sustainability and environmental impact.

Keywords: Engine coolant, corrosion inhibitor, ethylene glycol, organic acid, non-hazardous additive.

INTRODUCTION

Antifreeze is a water-based coolant used in gasoline and diesel engines. All coolants are typically made from water, a base fluid such as ethylene glycol or propylene glycol, and various corrosion-inhibiting additives. Coolants serve three main functions: first, to remove heat from hot engine components to prevent overheating during operation; second, to prevent the coolant from freezing when the vehicle is not in use in cold climates; and third, to protect the metal components of the engine block and cooling system from corrosion. Automotive radiators are made of parts containing various metals that are electrochemically incompatible, such as aluminium, cast iron, copper, brass, and solder. Ethylene glycol or propylene glycol in the antifreeze tends to corrode these metals under high temperature and ventilation conditions in internal combustion engines. Therefore, corrosion inhibitors added to antifreeze are of great importance.

Automotive coolants are generally classified into three main technologies: Inorganic Additive Technology (IAT), Organic Acid Technology (OAT) and Hybrid Organic Acid Technology (HOAT). IAT coolants use traditional inorganic additives such as silicates and phosphates to protect engine metals, but they lose their effectiveness more quickly and must be replaced more often. OAT coolants use organic acids like carboxylates and 2-ethylhexanoic acid (2-EHA), providing longer-lasting protection, especially for modern aluminium radiators, although they are not suitable for older systems with **brass or soldered** parts. HOAT coolants combine both inorganic and organic additives, offering a balanced protection system and are commonly used in many recent vehicles. Finally, all information regarding the types of coolants is presented in Table 1.

Table 1. Coolant Type and Colour Chart [1].

TYPE	INHIBITOR TECHNOLOGY	COLOR	VEHICLES
IAT (Inorganic Additive Technology)	Silicates	Green	Older Vehicles
OAT (Organic Acid Technology)	Organic Acids	Orange	GM, Saab, VW
HOAT (Hybrid OAT)	Silicates & Organic Acids	Yellow	Ford, Chrysler, European
HOAT (Hybrid OAT, Phosphate-free)	NAP Free	Turquoise	BMW, Volvo, Tesla, Mini, others
P-HOAT (Phosphated HOAT)	Phosphates & Organic Acids	Pink / Blue	Toyota, Nissan, Honda, Hyundai, KIA & other Asian vehicles
Si-OAT (Silicated HOAT)	Silicates & Organic Acids	Purple	Mercedes-Benz, Audi, VW, Porsche, others

Water glycol-based cooling systems are prone to chemical and galvanic corrosion due to the presence of different metal alloys. Therefore, not only the antifreeze function but also the use of appropriate corrosion inhibitors is critical. Studies have shown that inhibitor packages

significantly reduce the corrosion rate on metals [2]. Chen et al. (2015) have developed organic acid-based antifreeze coolants to improve both corrosion protection and environmental compatibility in water–glycol cooling systems. These coolants not only inhibit metal corrosion effectively but also reduce the formation of deposits and sludge, enhancing system performance and longevity [3].

2-ethylhexanoic acid has the GHS08 (health hazard) pictogram according to the harmonized classification and labelling (ATP20) system, which indicates that the substance is hazardous and may also damage the unborn child. In contrast, isononanoic and polycarboxylic acid do not have such a hazard pictogram [4]. Therefore, they are more sustainable alternatives. The purpose of the study is to investigate new carboxylic acid corrosion inhibitors that are more suitable for human health. In this context, isononanoic acid and a polycarboxylic acid were selected to be evaluated as new type corrosion inhibitors for engine cooling fluids instead of 2-ethylhexanoic acid.

MATERIALS AND METHOD

Materials

In this study, 2-ethylhexanoic acid, isononanoic acid, and polycarboxylic acid were selected as additive components to evaluate their different corrosion-inhibiting performances. The other main component of the coolant formulation was monoethylene glycol with a purity of ≥99.9 wt%. In addition, NaOH (48 wt%) was used as a buffering agent.

Methods

All tests were performed in accordance with the relevant ASTM and DIN standards. The pH values of the samples were measured using a Mettler Toledo SD20 pH meter according to ASTM D 1287 [5]. Filter paper corrosion tests were carried out in accordance with the DIN 51360 standard [6]. Glassware corrosion tests were conducted according to ASTM D 1384 [7], and the results were evaluated against the tolerance limits specified in ASTM D 3306 [8].

Figure 1 shows an example of filter paper corrosion testing.

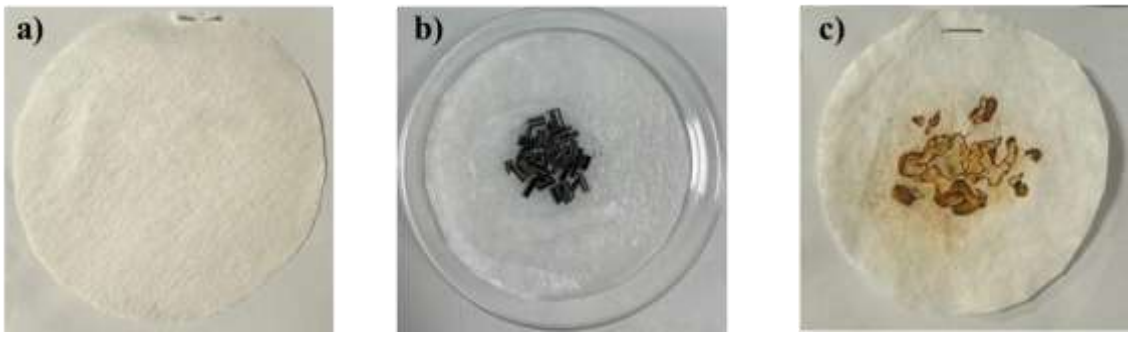

Figure 1. Filter paper corrosion test a) Filter paper before test, b) During Test and c) After testing (Corrosion present), DIN 51360.

Additionally, glassware corrosion testing has been performed on aluminium, cast iron, steel, copper, brass, and solder using a corrosion tester. The glassware corrosion tester and plates are shown in Figure 2.

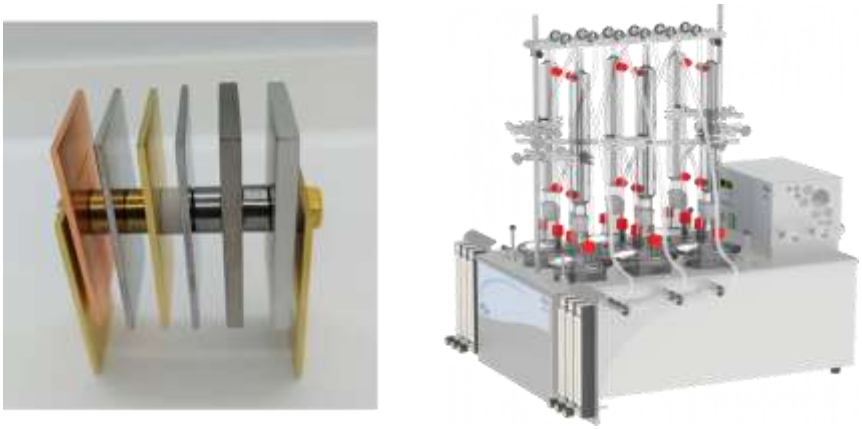

Figure 2. Corrosion test for engine coolants in glassware, ASTM D 1384.

Experiment

The experimental work utilized the compounds 2-ethylhexanoic acid, isononanoic acid, and polycarboxylic acid. First part, each compound was separately neutralized with sodium hydroxide (NaOH) to prepare stock solutions, which were stirred until homogeneous. Afterwards, the filter paper corrosion test was applied to these samples. In the second part, these stock solutions were subsequently diluted with water and subjected to a filter paper corrosion test to evaluate their inhibitory performance. Based on the results, the additive formulations demonstrating the highest corrosion resistance were identified. In the third part, these optimized formulations were then incorporated into antifreeze solutions. The antifreeze samples were prepared at three different concentrations 100%, 50%, and 33% (v/v) and evaluated through a series of tests, including filter paper corrosion, glassware corrosion, and other relevant performance assessments.

The structures of corrosion inhibitor components are given in Figure 3.

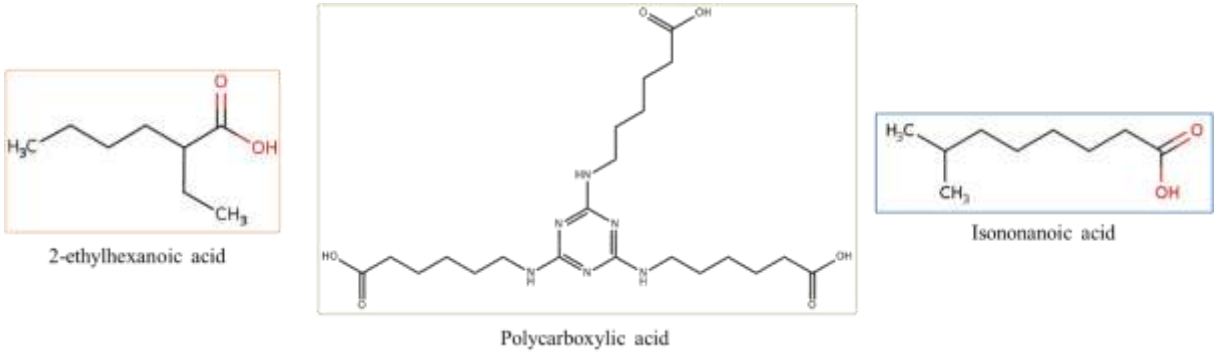

Figure 3. Molecular structures of the components that constitute the corrosion inhibitor

RESULTS AND DISCUSSION

To prevent potential corrosion in the final antifreeze formulation, pH and corrosion tests were performed on the diluted form of the 10% stock solution. Table 2 presents the pH and corrosion test results of the diluted 10% 2-ethylhexanoic acid stock solution. The filter paper corrosion test results for the 1% and 2% ratios of the stock solution are given in Figure 4. According to the results, 2-ethylhexanoic acid has shown good corrosion inhibition performance as is known.

Table 2. Test results for the diluted 10% 2-ethylhexanoic acid stock solution

Dilution Rates	pH	Filter Paper corrosion Test (24 hours)
%5 stock 2-EHA + water	13.16	No corrosion
%4 stock 2-EHA + water	13.1	No corrosion
%3 stock 2-EHA + water	13	No corrosion
%2 stock 2-EHA + water	12.85	Corrosion present
%1 stock 2-EHA + water	12.61	Corrosion present

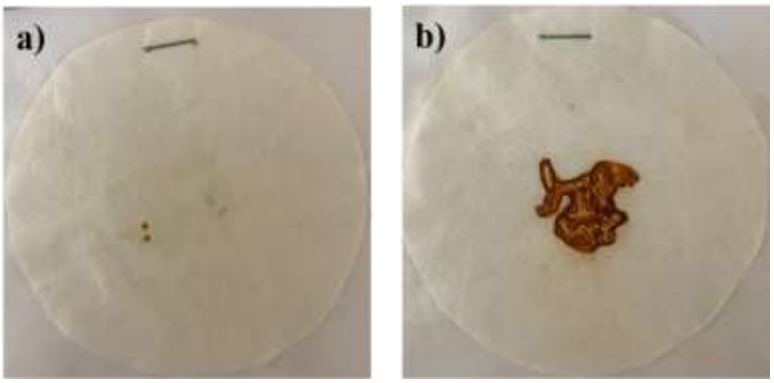

Figure 4. Corrosion test images for the a) 1% and b) 2% dilutions of the stock solution

The optimal ratios were selected, and water-diluted 2-ethylhexanoic acid-based additive formulations were prepared accordingly. The results of these formulations are presented in Table 3 and Figure 5, demonstrating their respective properties and performance.

Table 3. Dilution results of 2-ethylhexanoic acid-based additive

	pH	Filter Paper Corrosion Test (24 hours)
100% additive	9.23	No corrosion
50% diluted additive	9.19	No corrosion
33% diluted additive	9.11	No corrosion

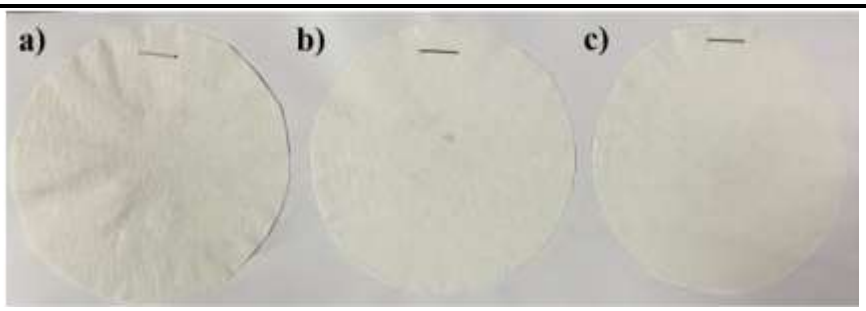

Figure 5. Filter paper corrosion test images for the a) 100% b) 50% and c) 33% dilutions of the additive

Subsequently, the study progressed to the final antifreeze formulation, and the corresponding test results are presented in Table 4 and Figure 6. The results indicate that the 2-ethylhexanoic acid-based additive can be used as a corrosion-inhibiting component in antifreezes.

Table 4. 2-ethylhexanoic acid-based antifreeze results

Antifreeze Ratio	pH	Filter Paper Corrosion Test (24 hours)
100% Antifreeze	7.7	No corrosion
50% Antifreeze	7.47	No corrosion
33% Antifreeze	7.51	No corrosion

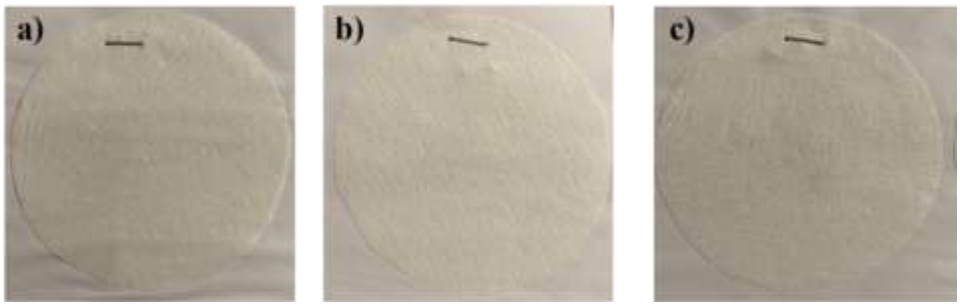

Figure 6. Filter paper corrosion test images for the a) 100% b) 50% and c) 33% antifreeze

To evaluate the corrosion inhibition performance of isononanoic acid and determine suitable dilution ratios, pH measurements and corrosion tests were carried out on various dilutions prepared from the 10% stock solution. Table 5 presents the pH values and corrosion test results of the 10% isononanoic acid stock solution diluted at different ratios. The results indicate that isononanoic acid provides effective corrosion inhibition as an additive, except at the 1% dilution ratio. The filter paper corrosion test result for the 1% dilution is shown in Figure 7.

Table 5. Test results for the diluted 10% Isononanoic acid stock solution

Dilution Rates	pH	Filter Paper corrosion Test (24 hours)
%5 stock Isononanoic acid + water	6.98	No corrosion
%4 stock Isononanoic acid + water	6.81	No corrosion
%3 stock Isononanoic acid + water	6.63	No corrosion
%2 stock Isononanoic acid + water	6.55	No corrosion
%1 stock Isononanoic acid + water	6.52	Corrosion present

Figure 7. Corrosion test images for the 1% dilution of the stock solution

After determining the optimal ratios, water-diluted isononanoic acid-based additive formulations were prepared accordingly. The results of these formulations, presented in Table 6 and Figure 8, indicate that isononanoic acid-based additive exhibits corrosion-inhibiting properties.

Table 6. Dilution results of Isononanoic acid-based additive

	pH	**Filter Paper Corrosion Test (24 hours)**
100% additive	9.37	No corrosion
50% diluted additive	9.18	No corrosion
33% diluted additive	9.11	No corrosion

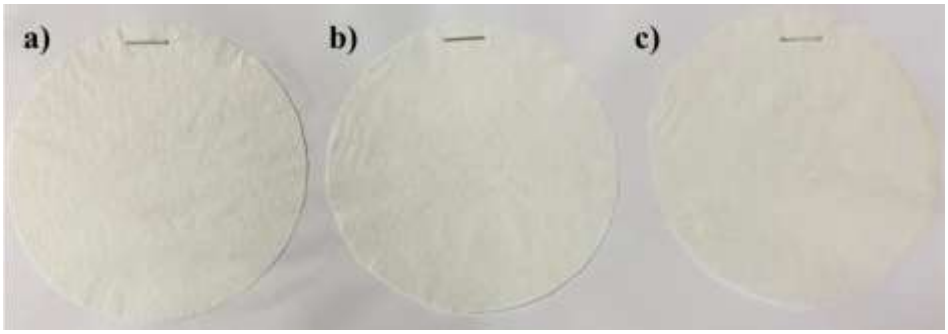

Figure 8. Filter paper corrosion test images for the a) 100% b) 50% and c) 33% dilutions of the additive

Subsequently, the study progressed to the final antifreeze formulation, and the corresponding test results are presented in Table 7 and Figure 9. The results indicate that the isononanoic acid-based additive can be used as a corrosion-inhibiting component in antifreezes.

Table 7. Isononanoic acid-based antifreeze results

Antifreeze Ratio	pH	Filter Paper Corrosion Test (24 hours)
100% Antifreeze	7.41	No corrosion
50% Antifreeze	7.6	No corrosion
33% Antifreeze	7.67	No corrosion

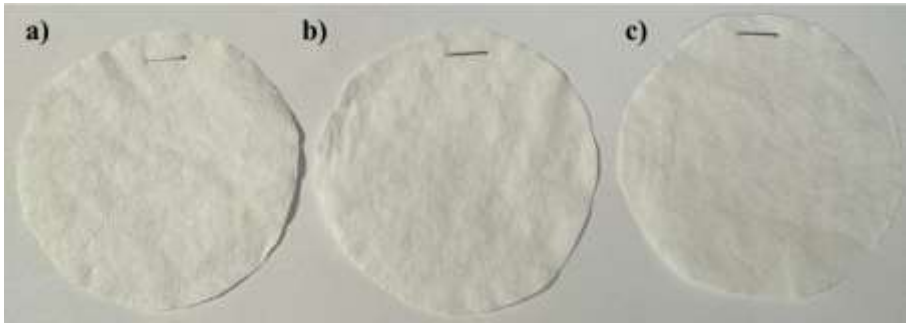

Figure 9. Filter paper corrosion test images for the a) 100% b) 50% and c) 33% antifreeze

Similarly, a formulation containing a lower ratio of the polycarboxylic acid additive was examined, and it exhibited excellent corrosion protection performance despite the reduced dosage. The results are presented in Table 8.

Table 8. 2% Polycarboxylic acid-based stock results

Dilution Rate	pH	Filter Paper Corrosion Test (24 hours)
%2 Polycarboxylic acid stock	8.02	No corrosion

The optimal ratio was selected, and water-diluted polycarboxylic acid-based additive formulations were prepared accordingly. The results are shown in Table 9 and Figure 10.

Table 9. Dilution results of Polycarboxylic acid-based additive

	pH	Filter Paper Corrosion Test (24 hours)
100% additive	8.02	No corrosion
50% diluted additive	7.99	No corrosion
33% diluted additive	7.96	No corrosion

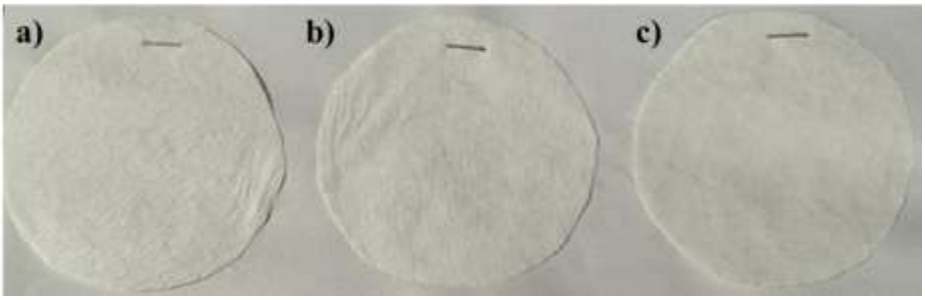

Figure 10. Filter paper corrosion test images for the a) 100% b) 50% and c) 33% dilutions of the additive

Following this step, the research advanced to the preparation of the final antifreeze formulation, with the relevant test outcomes provided in Table 10 and Figure 11. These findings demonstrate that the polycarboxylic acid-based additive is suitable for use as a corrosion-inhibiting agent in antifreeze applications.

Table 10. Polycarboxylic acid-based antifreeze results

Antifreeze Ratio	pH	Filter Paper Corrosion Test (24 hours)
100% Antifreeze	7.71	No corrosion
50% Antifreeze	7.98	No corrosion
33% Antifreeze	8.02	No corrosion

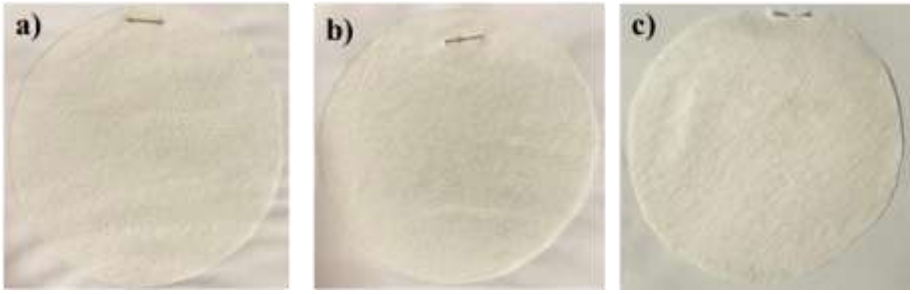

Figure 11. Filter paper corrosion test images for the a) 100% b) 50% and c) 33% antifreeze

In the final phase of the study, a glassware corrosion test, simulating actual operating conditions and involving components of a cooling engine, was conducted in accordance with the ASTM D 1384 standard. Metal parts from an automotive radiator were subjected to this test. The ASTM D 3306 method defines the maximum limit weight loss of metal parts due to corrosion. Negative results indicate the formation of a protective layer on the surface. The lower the weight loss of the metal coupons, the higher the anticorrosion performance. As shown in Table 11, the 2-ethylhexanoic acid-based antifreeze successfully passed this test.

Table 11. 2-ethylhexanoic acid-based antifireeze glasware corrosion results

ASTM D 1384 Test			**ASTM D 3306 Limit**

Cast Aluminum (A23190)	-0.0153	-0.4	30 max

CONCLUSION

In summary, the corrosion tests showed that all developed additives possess excellent corrosion-inhibiting properties. The filtration corrosion tests and glassware corrosion tests conducted in this study demonstrated that the developed additives exhibit stable performance and good compatibility with antifreeze formulations used in the automotive industry. The positive outcomes obtained from these tests support the suitability of the additives for key metals commonly found in automotive radiators, such as aluminium, cast iron, copper, brass, and solder.

Although 2-ethylhexanoic acid remains an effective component in antifreeze formulations, recent safety assessments highlight the need to explore safer alternatives. Since 2-EHA is classified under certain risk categories within the ECHA Hazard Classification and Labelling

System, evaluating alternative substances that are not classified as hazardous under ECHA has gained importance. In this context, the findings indicate that isononanoic acid and polycarboxylic acid represent potential alternatives to 2-ethylhexanoic acid, as they are not classified as hazardous and offer a more favourable safety profile.

Overall, the results of this study provide a scientific basis for transitioning to new-generation antifreeze additives that ensure both effective corrosion protection and improved safety, offering valuable guidance for future development efforts.

ABSTRACT

It is known that ester-based additives reduce friction and protect surfaces from wear under boundary lubrication conditions due to their strong surface affinity. These properties contribute to extending the operational life of machine components. In this study, the effects of different ester types, such as Methyl Oleate, 2-Ethylhexyl Oleate, Pentaerythritol Monooleate (PEMO), Trimethylolpropane Trioleate (TMPTO), Diisotridecyl Adipate (DTDA), Zinc Dialkyldithiophosphate (ZDDP) and Triphenyl Phosphorothionate (TPPT) on the improvement of boundary lubrication characteristics were investigated using a linear oscillation SRV (Schwingung, Reibung, Verschleiss) tribometer. For this purpose, all ester types were blended into the Group I mineral base oil at 10 wt%. However, TPPT was used at 5 wt% due to its limited miscibility. The viscosity of all formulations was kept within a similar range to ensure a fair comparison. According to the lubrication regime graph, only the first 10 minutes of the SRV friction curves were considered in the evaluation. The results revealed that Diisotridecyl Adipate and phosphate esters significantly enhance boundary lubrication performance by reducing friction between the metal ball and disc. In contrast, monoesters exhibited limited or even adverse effects on friction behavior. Overall, this study demonstrates the critical importance of ester type selection for optimizing boundary lubrication performance and shows that the molecular structure of the esters has a significant influence on boundary lubrication mechanisms.

Keywords: Lubrication, boundary lubrication, ester additives, tribology, friction

1. INTRODUCTION

Tribology is the science that studies the interactions of surfaces in contact and in relative motion. Generally, tribology includes three key topics: friction, wear and lubrication. Friction is the resistance to relative motion, wear is the loss of material due to that motion, and lubrication Additionally, wear leads to material loss and decreased mechanical performance. Lubrication is the use of a fluid or in some cases a solid to minimize friction and wear. (Mischler S.)

In modern engineering systems, machines operate at increasingly higher speeds, causing contacting surfaces to experience severe friction and substantial wear. Elevated friction leads to unnecessary energy losses and negatively affects the durability and service life of critical components. The resulting decline in performance within production systems also poses significant risks to operational reliability and quality consistency. Therefore, in high-technology applications, controlling friction and wear has become essential for improving overall efficiency and ensuring long-term system stability. (T, 2021)

Tribological data is commonly presented in the form of a Stribeck curve.(Meyer F.) The Stribeck curve is a graph of the friction coefficients according to the Hersey number (Bearing number) (Spikes H., 1997). The Hersey number is a dimensionless number of rotational velocity, external force, and viscosity of the lubricant. It divides the frictional properties of a rotor and bearing system into three lubricating regions of hydrodynamic, mixed, and boundary lubrications. (Hong G., 2022)

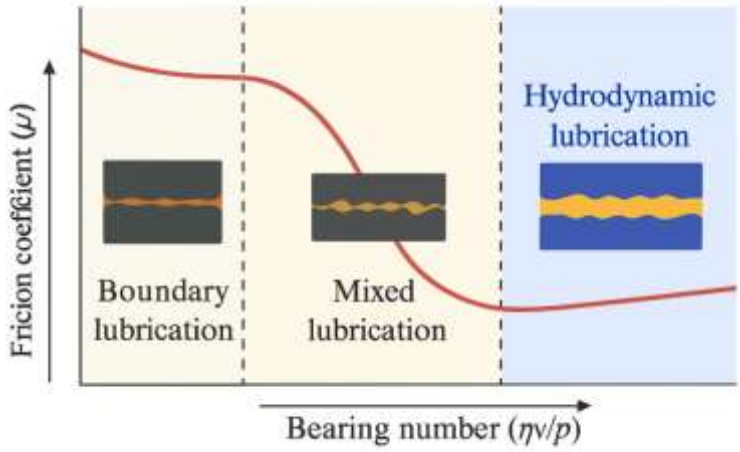

Figure 1. Streibeck curve (Li S., 2023)

At sufficiently high sliding speeds, the lubricant is drawn into the contact and forms a pressurized fluid layer that completely separates the two surfaces; film thickness increases with viscosity and speed, and decreases with load. Wear is negligible in this case, and this condition is referred to as hydrodynamic lubrication.

When the speed is lower or the load is higher, the fluid film becomes thin enough to approach the surface roughness. Part of the load is still carried by the fluid layer, but some asperity contact occurs, leading to limited wear; this regime is known as mixed lubrication.

At very low speeds and high loads, a continuous fluid film cannot be sustained, and the full load is transmitted through direct asperity contact. Significant wear takes place, although adsorbed lubricant molecules may still offer partial protection; this situation is called boundary lubrication. (Mischler S.) Since the lubricant film can no longer prevent direct surface

interactions, chemical additives become the primary mechanism for reducing friction and wear. In other words, the performance of the system becomes highly dependent on how effectively the lubricant molecules can adsorb onto the surface and form protective boundary layers.

Ester-based additives play a particularly important role under these conditions. Due to their polar functional groups, esters exhibit strong affinity for metallic surfaces, enabling them to adsorb and create a stable, coherent film that reduces metal-to-metal contact. This adsorbed layer can lower the coefficient of friction and serve as a sacrificial barrier, preventing direct asperity interactions and minimizing wear.

In addition to their surface activity, esters offer several inherent advantages for boundary lubrication. Their molecular structure typically provides good thermal stability, allowing them to retain lubricity at elevated temperatures where many hydrocarbon-based components begin to degrade. Furthermore, esters are often characterized by high biodegradability, making them attractive for environmentally conscious formulations, especially in applications where lubricant loss to the environment is likely. Their tunable viscosity and strong solvency also improve additive compatibility and overall formulation stability.

Recent studies report that monoesters, diesters, and polyol esters have all been evaluated as boundary lubrication agents, with several works employing SRV-type oscillating tribometers to assess their friction and wear behavior. These findings consistently show that ester-based structures can significantly enhance boundary lubrication through strong surface adsorption and stable film formation. In this context, Mofidi M. conducted SRV oscillation tests under a 100 N load to evaluate the friction and wear behavior of different ester classes, including monoesters, diesters, and polyol esters. His findings demonstrated clear differences in film formation and surface protection among these ester types, further emphasizing that ester chemistry plays a decisive role in boundary lubrication performance. (M., 2007)

Fox et al. investigated the boundary lubrication effects of free fatty acids by doping sunflower oil with stearic, oleic, and linoleic acids. They found that saturated stearic acid delivered the strongest friction- and wear-reducing performance, while the unsaturated acids showed noticeably weaker improvement under boundary conditions. (Fox N.J., 2003)

In the present study, the boundary lubrication performance of various ester structures was systematically examined by blending into a mineral base oil and evaluating their friction-reducing capabilities during the initial stages of SRV oscillation testing.

2. EXPERIMENTAL METHOD

In this study, Group I mineral oils SN-500 (Heavy Neutral) and SN-900 (Bright Stock) are mixed to be used as base fluids. Their physicochemical properties were given in Table 1.

Table 1. Physicochemical properties of base fluids.

Test Parameter	**Test Method**	**SN-500**	**SN-900**
Kinematic Viscosity (40°C, cSt)	ASTM D 445	99,773	504,8
Kinematic Viscosity (100°C, cSt)	ASTM D 445	10,84	30,42
Viscosity Index	ASTM D 2270	91	88
Flash Point (°C)	ASTM D 92	256	316
Pour Point (°C)	ASTM D 97	-6	-6

To investigate the influence of different ester structures on boundary lubrication performance, various ester types including Methyl Oleate, 2-Ethylhexyl Oleate, Pentaerythritol Monooleate (PEMO), Trimethylolpropane Trioleate (TMPTO), and Diisotridecyl Adipate (DTDA) were individually blended with the base oil mixture at predetermined ratios given in Table 1. Each formulation includes a single ester type along with SN-500 and SN-900 as base oils. To ensure a consistent comparison of tribological behavior across the ester-containing blends, all formulations were adjusted to achieve the same target viscosity level.

As a formulation describtion, the ester mass fractions and the final blend viscosities are provided in Table 2. All experiments were conducted with a 10 wt% ester addition, except for TPPT. This exception is due to the solid nature of TPPT, which did not allow adequate miscibility at the 10% level.

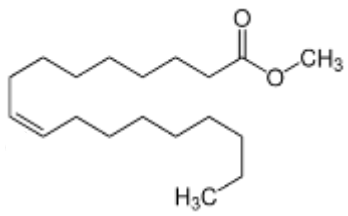

Table 2. Formulation Table

Product No	**Additives**	**Ester Ratio %by mass**	**Kinematic Viscosity of Final Blend (40°C, cSt)**
Pr. 1	Methyl Oleate	10	150
Pr. 2	2-Ethylhexyl Oleate	10	150
Pr. 3	PEMO	10	150
Pr. 4	TMPTO	10	150
Pr. 5	Diisotridecyl Adipate	10	150

High Frequency Linear Oscillation – SRV (Schwingung, Reibung, Verschleiss)

SRV instrument, shown in Figure 2, is a well versatile laboratory machine that aims to evaluate friction and wear characteristics of lubricants in many different operative conditions by using couplings of different geometry and materials. In this work, the selected coupling is stainless steel cylinder on disk, and the procedure is ASTM D 6425.

The test values of the method are shown in Table 4.

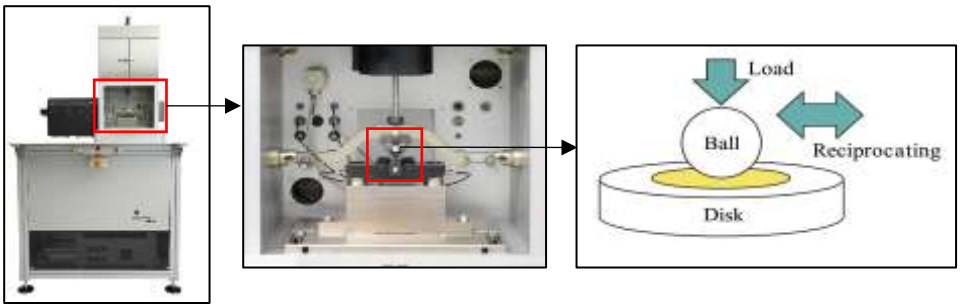

Figure 2. Optimol SRV tribometer

Table 4. ASTM D 6425 Method for determination of friction and wear properties

Test Parameters	**Test Conditions**
Temperature	50°C
Constant Load	300 N
Stroke	1 mm
Frequency	50 Hz
Time	120 min.
Ball Type	Steel-10mm

The SRV friction curves of the products will be evaluated as presented in Figure 2. As known from the Stribeck curve, the boundary lubrication regime corresponds to the initial stage in which the lubricant film is not yet able to fully separate the two metal surfaces. Since metal-to-metal contact is predominant in this region, the maximum friction values are observed here. The improvements provided by different ester types are therefore identified by whether they reduce the f_{max} value.

RESULTS

The boundary lubrication performance and friction coefficients of the formulations were evaluated using the ASTM D6425 method on an SRV tribometer. A complete 120-minute measurement table is presented in Figure 3. In addition, Figure 3 represents a Stribeck-type interpretation of the SRV test results, which models the coefficient of friction over time according to the lubrication regime. Since the boundary lubrication regime corresponds to approximately the first 30 minutes of all experiments, only this region of the friction curves was considered in the performance assessment and is depicted accordingly.

Table 5. Result table

Product No	Sample Name	SRV wear (f_{max})
*	KV 150 @40˚C Mineral Base Oil	0,582
Pr. 1	Mineral Base Oil + Methyl Oleate	0,625
Pr. 2	Mineral Base Oil + 2-Ethylhexyl Oleate	0,582
Pr. 3	Mineral Base Oil + Pentaerythritol Monooleate (PEMO)	0,582
Pr. 4	Mineral Base Oil +Trimethylolpropane Trioleate (TMPTO)	0,377
Pr. 5	Mineral Base Oil + Diisotridecyl Adipate	0,186
Pr. 6	Mineral Base Oil + Zinc Dialkyldithiophosphate (ZDDP)	0,155
Pr. 7	Mineral Base Oil + Triphenyl Phosphorothionate (TPPT)	0,210

Table 6. Result graphic

The experimental results revealed clear performance differences among the ester-containing formulations.

- Formulations containing simple mono esters showed the weakest anti-wear performance under boundary lubrication conditions.
- The addition of an ester does not automatically guarantee improved friction or wear performance; its effectiveness strongly depends on molecular structure.
- As the ester chain length increases and the molecular architecture becomes more complex, boundary lubrication behavior generally improves.
- Reactive anti-wear additives such as TPPT and ZDDP provided substantially superior protection, outperforming all ester-based formulations.
- In future studies, the wear scars will be further examined using a 3D optical microscope to quantitatively assess wear diameter, depth, and overall surface topography, enabling a more comprehensive correlation between ester structure and wear behavior.

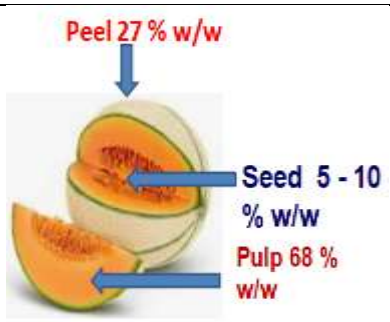
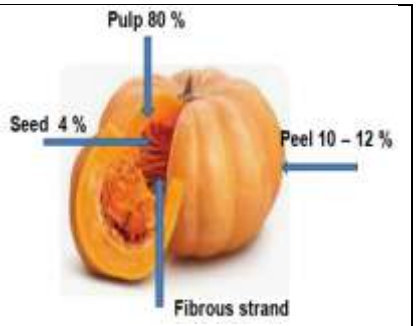
ABSTRACT



Melons (*Cucumis melo* L.) are a diverse group of fruits belonging to the *Cucurbitaceae* family known for their juicy flesh, sweet flavor and variety of uses due to their nutritional and bioactive properties. Melon crop wastes and processing residues are estimated at 58% to 62% of the fresh mass, including peel, rind, seed, fibrus strand and leftover pulp / pomace, present numerous opportunities for valorization of theses considered as discardable residues. These contain a wide range of phytochemicals, including carotenoids, polyphenols, tocopherols, vitamins, minerals, and dietary fiber. These compounds also exhibit antioxidant, anticancer, anti-inflammatory, anti-diabetic, antimicrobial and functional food properties. These by-products besides significant nutritional benefits present new market opportunities for the food, bakery and beverages as well as for other industrial, commercial, pharmaceutical, **nutraceutical** and cosmetic industries generating the framework of a circular - bio -economy. India produces about 1.3 to 1.5 million tones. Melons come in various shapes, sizes, and colors, each with its own unique taste and nutritional profile.In this paper, we intend to highlight the significance of watermelon, muskmelon, and pumpkin, emphasizing their nutritional, agricultural, and economic importance. These crops are often underappreciated and underutilized despite their high potential, and our objective is to explore their value, promote their wider use, and encourage further research and development in their cultivation and processing.

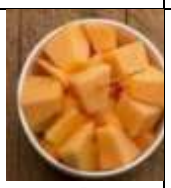
Keywords: Melon fruits, Watermelon, Muskmelon, Pumpkin, Wastes and processing residues, Food bakery and dairy products, Bakery Products, Commercial products, Industrial products



Major Melon Wastes and Processing By – products:

Average proportion of watermelon wastes

Average proportion of muskmelon wastes



Average proportion of pumpkin wastes

Average Composition of Melon Fruits

Fruit	Peel % of total weight	Rind % of total weight	Seed % of total weight	Pomace (solid residue) % flesh	Edible pulp pulp % of fruit weight	Fibrous strand / funiculi % w/w	Juice % edible flesh
Watermelon	3 - 9	21 - 27	1.5	5 - 10	60 -70	--	55 – 57 of total weight or 92 % of flesh weight
Muskmelon	27	-	5 -10	20 -	68	--	20 of total weight / 90 % of edible flesh
Pumpkin	10 - 12%	-	3.5 – 4.5	10 -25	79 - 83	0.5 – 1.5	42 – 56 % of total weight / 87-91% of edible flesh

Wastes and Processing Residues from Melon Fruits (Edible wastes 30.48%)

 Watermelon Total wastes 33 8 %	 Pulp 66%	 Rind 30%	 Peel 3%	 Seed ! %	 Dehusked seed	 Seed husk
 Muskmelon	 Pulp	----	 Peel	 Seeds	 Dehusked seeds	 Seed husk
 Pumpkin	 Pulp	 Rind	 Peel	 Seed	 Dehusked seeds	 Seed husk

Reprocessed Products from Melon Wastes and Processing Residues

Pumpkin

Pumpkin: Pumpkin by-products comprise various parts, such as seeds, peels, and pulp residues, with their bioactive composition and many potential benefits poorly explored by the food industry. Pumpkin and their by-products contain a wide range of phytochemicals, including carotenoids, polyphenols, tocopherols, vitamins, minerals, and dietary fibers. These

compounds in pumpkin by-products exhibit antioxidant, anticancer, anti-inflammatory, anti-diabetic, and antimicrobial properties

 **Peel**	 **Peel powder**	 **Peel extract**	 **seed**	 **Dehulled seed**
 **Seed husk**	 **Seed powder**	 **Seed oil**(51–62.5%),	 **Pomace**	 **Pomace powder**
 **Seed husk churi**	 **Pumpkin strands**			

Melon seed peeling / de - hulling: The seed kernel from the outer shells / husk is separated by impact - based and wet processing techniques. In mpact-based shelling seeds are collided with a stationary object or rotating impeller where impact force is generated, to crack the shells. In wet dehulling, seeds are water soaked to soften the hulls, followed by mechanical dehulling using using a combination of friction, impact, or pressure. Some of the commercially available machines are shown pictorially below

Utilization of melon wastes and processing by products for food, bakery, pastry, dairy, beverages, commercial, industrial, pharmaceutical and cosmetic products: :

Food products: Extruded snacks (10 – 20%), roasted seeds, chewy snacks food, jams, jelly, pies, dehydrated slices, roasted nuts, puttu (steamed rice cake), snacks (brown rice 90% and seed powder 10 %), chappathi (Indian flat bread). noodles , gluten-free noodles (up to 50 % flour), gluten free pasta (up to 50 % flour), cereal bars, puree, pickle, dosa , halwa , preserve, candy, sweets, confectionery, etc.

Dairy products: Enriched yogurt, cheese, ice cream, curd, flavoured milk, butter cream, dairy beverages, sweets, etc.

Commercial products: Dried peel, paste, peel powder, peel flour, peel extract, dried rind, rind powder, rind flour. flesh , flesh powder, seed, seed powder, seed flour, seed oil, pomace, pomace / leftover pulp / powder, pomace flour, syrup, dietary fiber, animal feed, compost, etc.

Industrial products: Bio ethanol, animal feed , coloring agent in pasta and flour mixes, peel extract, seed oil extract, seed meal, low-cost sorbent to remove dyes, pectin,, edible coating, bio degradable packaging film, nutrient-rich soil amendments, bioplastics, biocomposites, edible coatings, biodegradable foams, activated carbon materials, etc.

Beverages: Soup, syrup, enriched milk, melon seed powder milk, etc.

Bakery products: Bread, bread mix, functional melon waste biscuits, cake, , cookies (10 – 40%), muffins, smoothies, sandwiches, (rind waste up to 20 % cake) , biscuits up to 15 % peel powder in breads, cake, seed flour/ seed residues after oil 10 % in bread, , fortified bread (15 – 25%), seed oil baking and cooking, buns, burgers, waffles, crackers, and doughnuts , etc.

Pharmaceutical products: Bioactive compounds (carotenoids, tocopherols, phytosterols, phenolic compounds, and various vitamins and minerals), . cucurbit in bioactive compound, seed oil, seed extract as anti-inflammatory effects, seed extract as trypsin inhibitor, antioxidant activity.

Cosmeceuticals: seed oil, pulp. face mask, skin care, etc.

Wastes and By products	Utilization
Watermelon Peel	cookies, bread, and muffins, crackers, jam, pickle, smoothies,
Watermelon Peel powder	**Nutritionally enhanced bakery goods, biscuit 50 %, muffins 100 % (biscuit 50 %, muffins 100 %,2024),**
Watermelon rind	Tutti frutti, candy,jam, preserves, fruit butter, chutney, stir fried, pcickle, baked goods like cookies. racker, breads, noodles,
Watermelon rind powder	**Cake 10 – 20 %, biscuit 10 – 20 %, biscuit 50 %, muffins 100 %, cookies 20 - 30%,**
Watermelon seed powder	**Bakery products (10 - 15 % in pasta, 5 – 10% cake)**
Watermelon seed powder	**Bakery products (10 - 15 % in pasta, 5 – 10% in cake and bread)**
Watermelon pomace	Bakery products (cookies and cakes), pasta 15 % w/w, enriched beverages (juices , smoothies,), natural colorant , flavor enhancer, cosmetics,
Watermelon pomace powder:	**Bakery products (10 - 15 % in pasta, 5 – 10% cake). Pickles , Preserves, Curries and Stir-fries, Fruit Butters, pectin, animal feed, biosorbent, cosmetics,**
Muskmelon peel	**Pectin, yogurt,** fruit-flavored milk, 10 – 20 % bakery products,
Muskmelon peel powder	**jams, jellies, and baked goods; biodegradable films, bio coatings, prebiotic supplements; flavor, nutrients, and potentially extending shelf life in dairy products; adding nutritional and functional properties in bakery products,**
Muskmelon seeds	**Fortified breads, cake, melon seed-based beverage, sausages,** cheese or yogurt, **seed meal** bioplastics, biodegradable films, biocomposites, edible coatings, and biodegradable foams, trypsin inhibitor.
Muskmelon seed flour	to enhance the nutritional and functional properties of bread, cake (40%), cookies, muffins, buns, burgers, waffles, crackers, doughnuts, food preservation enhancer, plant-based milk, enzymes. biodegradable film, packaging paper, edible coatings, biodegradable foams. bioethanol, glucose, proteins, enzymes, flavour compounds,
Muskmelon pomace	Enrichment of bakery and pastry goods (bread, cakes, cookies, muffins, crackers, and biscuits, etc) in terms of fiber, texture, flavor, anti oxidants; confectionery products to enhance flavor and improve texture; as a natural texturizer and stabilizer in dairy products; natural colourants; natural flavouring agents; biodegradable films for packaging; dairy products. ice cream, yogurt, paneer, milkshakes; natural glow and skin health as cosmetics;
Muskmelon pomace flour	Flavour and aroma in dairy products - lavored milk, cheese, dairy-based desserts, ice cream, yogurt, milkshakes, paneer ; natural glow and skin health as cosmetics;
Pumpkin peel	Pectin, food products, cosmetics , pharmaceuticals, mayonnaise sause 0.02 – 0.1 %, (गाढ़ा, मलाईदार सॉस)_, natural food colorants , preservatives. Animal feed, snacks, soups, bakeries, and beverages, bio degradable packaging, natural colourants, bio-adsorben, yogurt, 2 – 4 %, biscuit 5 – 15 %, and 10 – 40 %, baked ball 5%, Jam 0.2 – 0.4 %, yogurt 2 – 4 %
Pumpkin peel powder	Natural colorant, dietary fiber, nutrient enrichmer, bread, cakes, and cookies, sensory enhancers, cosmetic skinc are, skin ourishment, cosmetic additives. Biscuit 20% and baked muffins, , yogurt 2 – 4 %, Butter cake and chiffon cake 20%, and chiffon cake; sandwich bread, bread, sweet bread and cookies 10 %, pumpkin powder (10, 20, 30, 40 and 50%) in sandwich bread, sweet bread, butter cake, chiffon cake and cookies. Bread made with 5% pumpkin peel flour,
Pumpkin seed	salads, baked goods, and snacks , Bakery and pastry goods, biscuits, nacks, bread, muffins, crackers, cookies, cakes, cereal bars
Pumpkin seed powder	dressings, soups, and baked goods, snacks, bread, muffins, crackers, cookies, cakes, cereal bars, cream milk, ice cream,
Pumpkin pomace	Jam, jelly, syrup, puree, bread, gluten free noodles and pasts 25%, sausage 30%, cheese, fortified pastry goods , fortified bakery goods, dietary fiber, animal feed
Pumpkin hull flour	bread 2.5% and 5%,
Pumpkin strands	It is part of pomace

GREENHOUSE POTENTIAL OF KONYA PROVINCE AND DIFFERENT GREENHOUSE PRACTICES*

ABSTRACT

In parallel with the rapid increase in the world population, ensuring healthy and balanced nutrition for humanity has become one of the most critical issues. For a healthy life, it is essential that the foods consumed are grown under safe and hygienic conditions. The Covid-19 pandemic has once again demonstrated to the entire world the importance of agricultural production and the necessity of maintaining agricultural activities under sustainable and healthy conditions. This process has contributed to the expansion of greenhouse production and greenhouse enterprises in the province of Konya. This study was conducted in 2025 to investigate the greenhouse cultivation potential of Konya Province—where greenhouse enterprises have been rapidly established in recent years—and to examine selected greenhouse enterprises recently founded in the region. Konya ranks 29th in Türkiye with a greenhouse area of 1,036 decares. Following the Covid-19 pandemic, greenhouse cultivation areas in Konya increased by 50.58% (TÜİK, 2025). The research findings reveal that the number of greenhouse enterprises in Konya Province has increased rapidly with the Covid-19 pandemic. Considering the agricultural and livestock production potential of the Konya Region, it is evident that this growth will continue. It is recommended that newly established greenhouse enterprises in the region be designed in accordance with the cultivated crop types and local environmental conditions to ensure efficient and sustainable production.

Keywords: Konya, Greenhouse Enterprise, Sustainable Agriculture.

*This study is produced from the master's thesis of Muhammed Işık.

INTRODUCTION

Greenhouse structures play a critical role in modern agricultural production by enabling the cultivation of crops under controlled environmental conditions during periods when natural climatic factors are unsuitable for plant growth. Defined as steel- or wood-framed structures covered with glass or plastic, greenhouses provide all environmental parameters required for plant development regardless of external conditions, thereby allowing continuous production for seedling cultivation, crop production, research, and demonstration purposes (Demir, 2001; Baytorun, 2016).

Greenhouse cultivation significantly contributes to the agricultural economy in Türkiye by increasing productivity per unit area, reducing unemployment rates, improving rural welfare, and ensuring the efficient use of limited agricultural land. Greenhouse enterprises not only offer year-round employment opportunities for farmers but also support the emergence of new industrial sectors involved in the production of greenhouse equipment. Compared to open-field agriculture, greenhouses yield two to three times higher output, shorten growing periods, enable multiple harvests from the same plot within a year, and ensure stable labor distribution in small-scale agricultural operations (Anonymous, 2018a).

Globally, approximately 800,000 hectares are devoted to greenhouse cultivation, with Mediterranean countries accounting for a substantial share of this area. Of these protected cultivation areas, 85% consist of plastic-covered greenhouses and 15% of glass-covered structures (Silleli et al., 2020). Türkiye ranks fourth globally and second in Europe after Spain in terms of greenhouse production area (Ministry of Agriculture and Forestry, 2019). The country's total greenhouse area amounts to 776,110 decares, comprising 58.4% plastic greenhouses, 7.21% glass greenhouses, 21.04% low tunnels, and 13.40% high tunnels (TÜİK, 2024).

Rapid population growth in Türkiye, advancements in export markets, increasing awareness of healthy nutrition, and the recognized importance of fruit and vegetable consumption have all accelerated innovation in agriculture. This surge in consumer demand has led to a rapid expansion of greenhouse cultivation alongside traditional open-field production, resulting in the establishment of numerous new greenhouse enterprises (Saltuk, 2014).

In recent years, the COVID-19 pandemic has caused significant global disruption, resulting in loss of life, economic instability, and sector-wide crises. At the same time, the pandemic highlighted the critical importance of food security and balanced nutrition. Consequently, governmental and societal support for agriculture has intensified, accompanied by a pronounced global increase in greenhouse construction. Greenhouse cultivation has expanded even in regions previously considered unsuitable. Thus, evaluating the structural characteristics, operational capacities, and development potential of greenhouses in regions with extensive agricultural land such as Konya Province has become increasingly important.

Konya, which ranks 29th among Turkish provinces in greenhouse cultivation area, has experienced significant growth in greenhouse activities, particularly following the COVID-19 pandemic. This study aims to assess the greenhouse cultivation potential of Konya Province and to examine the structural and operational characteristics of representative greenhouse enterprises established in the region.

GREENHOUSE CULTIVATION IN THE WORLD

Plant production is carried out worldwide using two primary methods: open-field cultivation and protected cultivation. Activities conducted in protected areas have given rise to greenhouse cultivation. The historical origins of greenhouse cultivation date back to the Roman Empire,

with the earliest documented examples appearing around 30 A.D. during the reign of Emperor Tiberius (Anonymous, 2015). In historical practice, instead of glass or plastic coverings commonly used today, pits excavated on mountain slopes facing south were covered with thin cloth polished with oil or beeswax, or with semi-transparent mica sheets, known as *specularium*. The main motivation behind this practice was Emperor Tiberius's desire to consume cucumbers out of season (Üçışık Erbilen & Şahin, 2011). In 1599, the first greenhouse was constructed in Leiden, the Netherlands, for the purpose of cultivating tropical medicinal plants (Anonymous, 2007a; 2010). In this greenhouse, *Tamarindus indica*, a species of the Fabaceae family native to Egypt and India, was cultivated (Üçışık Erbilen & Şahin, 2011).

Globally, greenhouse cultivation began in Italy during the Roman period, and structures built up to the 16th and 17th centuries are considered the earliest examples of greenhouse agriculture. Following the Industrial Revolution, greenhouse construction in the United States and Europe accelerated rapidly after the First World War. Today, it is known that greenhouses have a wide global distribution, characterized by diverse ecological conditions and highly varied, continuously developing greenhouse technologies (Yağanoğlu, 2014).

Greenhouse cultivation worldwide can be classified into three categories based on climatic zones: cool climate, temperate climate, and countries with dual climatic characteristics. Countries within the cool climate zone include the Netherlands, the United Kingdom, Denmark, Germany, Romania, Bulgaria, and Russia. Countries in the temperate climate zone include Türkiye, Spain, France, Japan, Italy, Greece, and Israel. The United States is the leading country representing the dual-climate category, with the common feature of cultivating in both glass and plastic greenhouses. Among the countries in the cool climate zone, the Netherlands stands out with 10,000 hectares of glass-covered greenhouse area and advanced cultivation techniques (Anonymous, 2022a).

Although the first greenhouses were established in Europe, greenhouses built for commercial production emerged in the United States during the 18th century (Bayraktar, 1964). The first greenhouse in the United States was constructed in 1737 by a wealthy merchant in Boston. Beginning in 1825, protected cultivation activities developed rapidly, and today they are practiced throughout nearly all regions of the country, from Alaska to California (Üçışık Erbilen & Şahin, 2011).

Greenhouse cultivation expanded significantly beginning in the 18th century. In the Netherlands, greenhouses were initially used to protect endemic plants brought from tropical climates and to overwinter them. Later, greenhouses were used to cultivate fruits, vegetables, flowers, and herbs that could not grow and develop during cold seasons.

A major breakthrough in greenhouse cultivation occurred in the 1960s when plastic coverings were first introduced in Japan (Jensen & Malter, 1995). Plastic-covered greenhouses gradually replaced glass-covered ones due to their lower cost and spread from North America to Europe. Today, protected cultivation is practiced across wide areas in many countries, including Canada, Romania, Spain, and Japan. The regions where greenhouse cultivation is most successfully implemented lie between 30° and 40° north and south latitudes and in Mediterranean Basin countries (China, South Korea, Spain, Japan, Türkiye, India, Italy, Mexico, the Netherlands, France, and the United States). Until the mid-20th century, greenhouses were classified according to the types of plants cultivated inside them (e.g., cucumber, tomato, carnation, flower, and pot-plant greenhouses). Today, greenhouse prevalence and technology are continually increasing, and greenhouses are constructed in various designs (Figures 1 and 2). Greenhouses constructed under contemporary conditions can

be used to cultivate different plant species thanks to advanced control systems (Baytorun, 2016).

GREENHOUSE CULTİVATİON İN TÜRKİYE

Türkiye holds a significant position in global vegetable and fruit production due to its favorable ecological characteristics. However, modern greenhouse production in the country began in the 1940s along the Mediterranean coastal belt, and has shown marked development since the 1970s. Although greenhouse cultivation can be practiced in various regions of the country, the availability of suitable environmental conditions, economic factors, transportation and marketing possibilities are determinants that either limit or enhance the prevalence of greenhouse enterprises. In addition, in regions that are less suitable for greenhouse cultivation but are located close to major consumption centers, the reduction in transportation costs may outweigh the increase in heating expenses, making greenhouse establishment a viable option. In this context, technical measures such as utilizing solar energy to reduce heating costs and benefiting from geothermal resources (hot water, boiling water, and steam) constitute important strategies that could significantly contribute to the expansion of greenhouse enterprise areas in Türkiye (Anonymous, 2023).

The plastic greenhouse area in Türkiye is 452,907 decares. Antalya, the most important center of greenhouse cultivation in the country, possesses 245,109 decares of plastic greenhouse area. Following Antalya, Mersin ranks second with 99,633 decares. The plastic greenhouse area in Konya is 520 decares. With technological advancements, increasing emphasis has been placed on modern and well-equipped greenhouse structures. Among the commonly used greenhouse types in Türkiye, steel-frame plastic-covered greenhouses are predominantly preferred (Figure 3). Due to developments in plastic covering materials, the use of glass-covered greenhouses has decreased compared to past decades, owing to cost and service-life considerations. Because of the high rate and duration of sunshine in Antalya Province, 79% of all glass-covered greenhouses in Türkiye are located in this region (TÜİK, 2024) (Figure 4).

Protected cultivation practices in Türkiye began in the 1940s with the establishment of glass-covered greenhouses in Antalya. Between 1940 and 1960, greenhouse development remained limited (Tüzel et al., 2005). The most significant period of advancement in greenhouse cultivation began in the 1970s, primarily due to the replacement of glass covering with polyethylene (PE) material, which is lighter, more economical, and easier to apply (Öneş, 1986; Çolak, 2002). There were notable increases in greenhouse areas between 1975 and 1985, and a growth rate of 64.5% was recorded between 1990 and 1997 (Tüzel & Eltez, 1997; Sevgican, 2000). Although a short-term decline occurred in 2001 as a result of the economic crisis, the upward trend in greenhouse area has continued in subsequent years.

Cold winter conditions adversely affect field cultivation under current climatic circumstances, thereby increasing the importance of greenhouse production. The total protected cultivation area in Türkiye increased from 660,265 decares in 2015 to 776,110 decares in 2024. During this period, the glass greenhouse area decreased from 79,977 decares to 55,949 decares, while the plastic greenhouse area expanded from 306,074 decares to 452,907 decares. Low-tunnel and high-tunnel areas were recorded as 161,541 decares and 112,674 decares in 2015, and 163,276 decares and 103,978 decares, respectively, in 2024. Thus, as of 2024, the total greenhouse area in Türkiye has reached 776,110 decares (TÜİK, 2024) (Table 1.1).

Table 1.1. Annual Change in Covered (Protected) Agricultural Areas in Turkey (TÜİK, 2024)

Year	Total (da)	Glass Greenhouse (da)	Plastic Greenhouse (da)	High Tunnel (da)	Low Tunnel (da)
2015	660 265	79 977	306 074	112 674	161 541
2016	691 724	80 137	328 745	112 974	169 867
2017	752 168	85 749	355 121	119 899	191 399
2018	772 091	78 110	368 527	114 232	211 222
2019	789 604	75 495	378 670	111 038	224 400
2020	805 159	80 779	401 795	104 258	218 326
2021	854 600	76 213	464 973	100 756	212 657
2022	810 881	59 633	471 284	110 426	169 538
2023	764 206	55 312	448 510	117 743	142 642
2024	776 110	55 949	452 907	103 978	163 276

The Mediterranean Region, which has the most suitable climatic conditions in Turkey, possesses the highest proportion of protected cultivation areas, accounting for 84%. It is followed by the Aegean Region (9.4%), the Black Sea Region (4.8%), and the Marmara Region (1.7%). Within the Mediterranean Region, Antalya ranks first with 37.90% of protected cultivation areas, followed by Mersin with 40.84%, while Adana ranks third with 22.81% and 16.85% (Table 1.2).

Table 1.2. Selected Provinces in Turkey with Protected Cultivation Areas (Ministry of Agriculture and Forestry, 2024)

Province	Glass Greenhouse Area (da)	Plastic Greenhouse Area (da)	Total Greenhouse Area (da)	Low Tunnel Area (da)	High Tunnel Area (da)	Total Protected Cultivation Area (da)

GREENHOUSE CULTİVATİON İN KONYA

In recent years, a remarkable increase has been observed in protected cultivation areas in Konya, particularly following the Covid-19 pandemic. Greenhouse enterprises utilizing geothermal heating have become increasingly common in the districts of Ilgın, Hüyük, and Karatay where geothermal resources are concentrated as well as in Tuzlukçu, Seydişehir, and Cihanbeyli, where new geothermal sources have recently been identified. The use of geothermal

water and the efficient utilization of waste heat derived from these resources enable the establishment of protected cultivation facilities and contribute to the use of low-cost energy alternatives. Furthermore, the extensive agricultural land available in Konya positively supports this expansion. Consequently, the number of technologically advanced greenhouses with large production areas and geothermal-based heating systems has increased significantly in the region.

REPRESENTATİVE GREENHOUSE EXAMPLES İN KONYA

Within the scope of this study, five greenhouse enterprises established in recent years in the Konya Region selected for their high level of technological integration and representativeness were examined as case examples.

BUTTERFLY VALLEY GREENHOUSE

One of the world's most distinctive exhibition-type greenhouses is the Butterfly Valley located in Konya Province. Designed as a modern exhibition facility built in the form of a butterfly when viewed from above, this greenhouse was established for the display of tropical butterfly species as well as selected plant varieties. Butterfly Valley is situated within a valley surrounded by tulip gardens and hosts a wide range of recreational and educational activities (TÜİK, 2021e) (Figure 1).

Figure 1. Perspective View of the Butterfly Valley Greenhouse, Konya, Türkiye (Anonymous, 2025a)

NUMBER 2 GREENHOUSE ENTERPRİSE

Located in the Çumra district of Konya, the greenhouse enterprise owned by Konya Şeker Ltd. Şti. is established on a total area of 60,000 m², of which 38,500 m² consists of fully controlled, steel-constructed Venlo-type glass greenhouses where tomato cultivation is carried out. The tomatoes are grown using soilless culture techniques in gutter systems. Steam generated during the processing of sugar beet at the Konya Sugar Factory is utilized for heating the greenhouses.

The greenhouse, designed as a narrow-span Venlo type, has a sidewall height of 6.00 m. In addition to tomato production, crops such as cucumber, banana, cocoa, date palm, and raspberry species that cannot naturally be grown under Konya's climatic conditions are cultivated in these greenhouses. Moreover, banana cultivation is carried out in plastic greenhouses within the enterprise, and tropical fish production is also conducted in plastic greenhouse structures.

The enterprise employs systems that ensure water and energy savings, enabling fully controlled production conditions and efficient use of water and fertilizers.

Figure 2. Perspective View of Greenhouse Enterprise No. 1, Çumra, Konya, Türkiye (Anonymous, 2025b)

Figure 2. Interior View of the Greenhouses in Greenhouse Enterprise No. 1 (Anonymous, 2025c)

NUMBER 2 GREENHOUSE ENTERPRİSE

The greenhouse enterprise located in the Cihanbeyli district of Konya is established on an area of 7,072 hectares, with 110,000 m² allocated to tomato cultivation in steel-constructed plastic greenhouses designed with a gothic roof structure. In Greenhouse Enterprise No. 2, geothermal hot water is used for heating, and as shown in Figure 3, soilless cultivation techniques are applied. The enterprise plans to carry out production using a modern, fully automated, soilless greenhouse system.

Figure 3. Perspective View of Greenhouse Enterprise No. 2, Cihanbeyli, Konya, Türkiye (Anonymous, 2025d)

Figure 4. Interior View of the Greenhouses in Greenhouse Enterprise No. 2 (Anonymous, 2025e)

NUMBER 3 GREENHOUSE ENTERPRİSE

The greenhouse enterprise established in the Meram district of Konya operates on an area of 3,250 m², where seedling production is carried out in a steel-constructed greenhouse covered with polycarbonate panels. The facility has an annual production capacity of 12 million seedlings. It produces healthy and high-yield vegetable and ornamental plant seedlings to support growers in Konya in obtaining higher-quality products.

Greenhouse Enterprise No. 3 was established with the financial support of the Konya Plain Project (KOP) Regional Development Administration, Meram Municipality, Karatay Chamber of Agriculture, and the Central Konya Vegetable Producers Union.

Şekil 6 **.** 3 Nolu Seracılık İşletmesinde Bulunan Seraların İçerisinden Görünüm (Anonim, 2025g)

NUMBER 4 GREENHOUSE ENTERPRİSE

The greenhouse enterprise established in the Tuzlukçu district of Konya Province covers an area of 100,000 m², where year-round production is carried out in steel-construction greenhouses. In these facilities, tomato cultivation is conducted using soilless farming techniques. To ensure optimal greenhouse microclimate conditions in the Konya region, the enterprise utilizes seven geothermal sources located within the area, while also incorporating renewable energy systems (such as solar energy) to support heating.

Figure 7. Interior View of the Greenhouses in the 4th Greenhouse Enterprise (Anonymous, 2025ı)

CONCLUSION

The findings of this study demonstrate that the rapid increase in the global population, coupled with the impacts of the Covid-19 pandemic, has significantly heightened the need for reliable, balanced, and healthy nutrition. Achieving this goal depends fundamentally on the use of high-quality seeds developed under controlled conditions and the cultivation of crops in environments that ensure plant health and optimal growth. Greenhouse cultivation has therefore emerged as a critical production system, as it enables the controlled manipulation of environmental factors, the cultivation of species with diverse ecological requirements, and the consistent production of high-quality agricultural outputs.

Greenhouses also provide unique opportunities for biodiversity conservation and exhibition by allowing the cultivation of plants and organisms originating from various ecological zones. The ability to produce year-round not only accelerates plant breeding programs but also facilitates multiple cropping cycles, thereby increasing overall productivity. In this regard, Konya Province possesses considerable potential for greenhouse-based agriculture, as evidenced by the rapid establishment of technologically advanced greenhouse enterprises supported by abundant geothermal resources and expansive agricultural lands.

For the sustainable expansion of greenhouse cultivation in the region, it is essential that future greenhouse structures be designed with close attention to local climatic and environmental conditions as well as the technical requirements of modern controlled-environment agriculture. Based on the analysis conducted, it is recommended that greenhouse enterprises—and their associated technical and auxiliary units—be systematically evaluated, that operational constraints be identified through comprehensive field studies, and that targeted and region-specific solutions be developed to improve efficiency, sustainability, and technological integration.

Özet

Artan dünya nüfusu, iklim değişikliği ve doğal kaynakların sınırlılığı, bitkisel üretimde daha verimli, kaliteli ve stres koşullarına dayanıklı çeşitlerin geliştirilmesini zorunlu kılmaktadır. Geleneksel bitki ıslahı yöntemleri uzun zaman gerektirmesi ve çevresel faktörlerden yoğun biçimde etkilenmesi nedeniyle bu ihtiyaçlara sınırlı hızda cevap verebilmektedir. Moleküler biyoloji ve biyoteknolojide yaşanan gelişmeler, bitki genomunun doğrudan ve hedefe yönelik olarak düzenlenmesine olanak sağlayan yeni yaklaşımların ortaya çıkmasına zemin hazırlamıştır. Bu yaklaşımlar arasında CRISPR-Cas9 genom düzenleme teknolojisi, yüksek özgüllüğü, görece düşük maliyeti ve uygulama kolaylığı sayesinde bitki ıslahında devrim niteliğinde bir araç olarak öne çıkmaktadır. Bu derlemede CRISPR-Cas9 teknolojisinin temel çalışma prensibi, bitki ıslahında kullanım alanları, sağladığı avantajlar, karşılaşılan sınırlılıklar ve gelecekteki potansiyeli sade ve bilimsel bir çerçevede ele alınmıştır.

Anahtar Kelimeler: CRISPR-Cas9, genom düzenleme, bitki ıslahı, biyoteknoloji

TARGETED GENE EDITING IN PLANT BREEDING USING CRISPR–Cas9

Abstract

The increasing global population, climate change, and the limited availability of natural resources necessitate the development of crop varieties that are more productive, high-quality, and resilient to stress conditions. Conventional plant breeding methods often require long periods of time and are strongly influenced by environmental factors, which limits their ability to respond rapidly to these demands. Advances in molecular biology and biotechnology have paved the way for novel approaches that enable direct and targeted modification of plant genomes. Among these approaches, CRISPR–Cas9 genome editing technology has emerged as a revolutionary tool in plant breeding due to its high specificity, relatively low cost, and ease of application. This review addresses the basic working principle of CRISPR–Cas9 technology, its applications in plant breeding, the advantages it offers, the limitations encountered, and its future potential within a clear and scientific framework.

Keywords: CRISPR-Cas9, genome editing, plant breeding, biotechnology

1. Giriş

Bitki ıslahı, tarımsal üretimin sürdürülebilirliği ve insanlığın artan gıda ihtiyacının karşılanmasında tarih boyunca temel bir rol üstlenmiştir. Tarımın ilk dönemlerinden itibaren insanlar, yüksek verimli, çevre koşullarına daha iyi uyum sağlayabilen ve tüketim açısından tercih edilen bitkileri seçerek üretimde kullanmıştır. Seleksiyon, melezleme ve adaptasyona dayalı klasik bitki ıslahı yöntemleri sayesinde günümüzde yaygın olarak yetiştirilen birçok tarım bitkisi geliştirilmiştir. Ancak bu yöntemler, büyük ölçüde uzun zaman gerektirmesi ve çevresel faktörlerin etkisine açık olması nedeniyle modern tarımın artan taleplerini karşılamada yetersiz kalabilmektedir (Doğan, 2024).

Günümüzde dünya nüfusundaki hızlı artış, iklim değişikliğine bağlı olarak ortaya çıkan kuraklık, sıcaklık stresi ve tuzluluk gibi abiyotik stresler ile hastalık ve zararlı baskısındaki artış, bitkisel üretimi doğrudan tehdit etmektedir. Bununla birlikte su ve toprak gibi doğal kaynakların giderek azalması ve tüketicilerin ürün kalitesi, besin değeri ve gıda güvenliği konularındaki beklentilerinin yükselmesi, bitki ıslahında daha hızlı, etkin ve hassas yaklaşımların geliştirilmesini zorunlu hale getirmiştir. Bu koşullar altında, klasik ıslah yöntemlerinin moleküler ve biyoteknolojik yaklaşımlarla desteklenmesi kaçınılmaz olmuştur.

Moleküler markör teknolojileri, genetik haritalama çalışmaları ve yeni nesil genom dizileme yöntemleri, bitkilerde verim, kalite ve stres toleransı gibi özelliklerin genetik temellerinin daha ayrıntılı bir şekilde ortaya konmasını sağlamıştır. Bu gelişmeler, istenilen özelliklerden sorumlu genlerin veya gen bölgelerinin tanımlanmasına olanak tanımış ve bitki ıslahında daha hedefe yönelik stratejilerin uygulanmasının önünü açmıştır. Bu bağlamda, genetik değişikliklerin rastgele değil, belirli hedefler doğrultusunda gerçekleştirilmesini sağlayan genom düzenleme teknolojileri, modern bitki ıslahının önemli araçları haline gelmiştir (Yücel, 2023).

Zinc parmak nükleazları (ZFN) ve Transkripsiyon Aktivatör Benzeri Efektör Nükleazlar (TALEN) gibi erken dönem genom düzenleme sistemleri, hedef DNA bölgelerinde kontrollü değişiklikler yapılabileceğini göstermesi açısından önemli birer kilometre taşı olmuştur. Ancak bu sistemlerin tasarım ve uygulama süreçlerinin karmaşık olması, yüksek maliyet gerektirmesi ve her hedef gen için ayrı protein mühendisliği ihtiyacı doğurması, kullanım alanlarını sınırlamıştır (Tufan, 2019).

Bu sınırlılıkların aşılmasında CRISPR-Cas9 genom düzenleme sistemi önemli bir dönüm noktası olmuştur. Basit tasarımı, kolay uygulanabilirliği ve yüksek hedef özgüllüğü sayesinde CRISPR-Cas9, bitki genomunda istenilen bölgelerin hızlı ve etkin bir şekilde düzenlenmesine olanak tanımaktadır. Ayrıca aynı anda birden fazla genin düzenlenebilmesi, bu teknolojiyi özellikle kompleks özelliklerin kontrol edildiği bitki ıslahı çalışmalarında son derece cazip hale getirmiştir. Bu özellikleriyle CRISPR-Cas9, klasik ve moleküler ıslah yaklaşımlarını tamamlayan, modern bitki ıslahında yeni bir dönemin kapılarını aralayan güçlü bir araç olarak öne çıkmaktadır (Akbudak ve Kontbay, 2017).

2. CRISPR-Cas9 Teknolojisi

CRISPR-Cas9 teknolojisi, bakterilerin ve arkelerin virüs kaynaklı genetik saldırılara karşı geliştirdiği doğal bir bağışıklık sisteminden uyarlanmıştır. Bu sistem, mikroorganizmaların daha önce karşılaştıkları virüslerin genetik bilgilerini tanımasını ve bu yabancı DNA'yı etkisiz hale getirmesini sağlamaktadır. Bitki biyoteknolojisinde kullanılan CRISPR-Cas9 sistemi ise bu doğal mekanizmanın kontrollü ve hedefe yönelik biçimde yeniden tasarlanmış bir versiyonudur. CRISPR-Cas9 sistemi temel olarak iki ana bileşenden oluşmaktadır: kılavuz RNA (single guide RNA; sgRNA) ve Cas9 endonükleaz enzimi. Kılavuz RNA, genom üzerinde düzenlenmesi hedeflenen DNA dizisine tamamlayıcı olacak şekilde tasarlanır. Bu RNA

molekülü, Cas9 enzimine hedef DNA bölgesini adeta bir "adres" gibi tanımlar. Cas9 enzimi ise kılavuz RNA tarafından belirlenen bu hedef bölgeye yönlendirilerek DNA üzerinde kesim işlemini gerçekleştirir (Samanta ve Gayen, 2016). Hedef DNA dizisinin tanınabilmesi için, kesim yapılacak bölgenin yakınında PAM (Protospacer Adjacent Motif) olarak adlandırılan kısa bir nükleotid dizisinin bulunması gerekmektedir. PAM dizisi, Cas9 enziminin DNA'yı tanıması ve bağlanması için zorunlu bir unsurdur. Bu özellik, CRISPR-Cas9 sisteminin genom üzerinde rastgele değil, yalnızca belirli ve tanımlı bölgelerde etkili olmasını sağlamaktadır. Cas9 enzimi, hedef DNA bölgesinde çift zincirli bir kırık (double-strand break) oluşturarak genom düzenleme sürecini başlatır. Bu kırık, hücre için ciddi bir hasar niteliğindedir ve bitki hücresi bu hasarı onarmak üzere kendi doğal DNA tamir mekanizmalarını devreye sokar. CRISPR-Cas9 teknolojisinin etkinliği, büyük ölçüde bu tamir mekanizmalarının sonuçlarına dayanmaktadır. Bitki hücrelerinde en sık devreye giren DNA onarım yolu, non-homologous end joining (NHEJ) mekanizmasıdır. Bu yol, kırık DNA uçlarını hızlı bir şekilde birleştirir; ancak süreç sırasında çoğunlukla küçük ekleme (insertiyon) veya silinmeler (delesyon) meydana gelir. Bu tür değişiklikler, hedef genin okuma çerçevesini bozarak genin işlevini kaybetmesine yol açabilir. Bu nedenle NHEJ mekanizması, özellikle bir genin etkisiz hale getirilmesinin amaçlandığı çalışmalarda yaygın olarak kullanılmaktadır. Alternatif bir onarım yolu olan homologous recombination (HR) mekanizması ise daha kontrollü ve hassas genetik değişikliklere olanak tanımaktadır. Bu yaklaşımda, hücreye dışarıdan verilen bir DNA şablonu kullanılarak, hedef bölgede istenilen genetik dizinin eklenmesi veya belirli nükleotid değişikliklerinin yapılması mümkün olmaktadır. Ancak bitki hücrelerinde HR mekanizmasının etkinliği genellikle NHEJ'ye kıyasla daha düşüktür ve uygulama açısından daha fazla teknik zorluk içermektedir (Liu ve ark. 2017). Sonuç olarak CRISPR-Cas9 teknolojisi, hedef DNA dizilerinde kontrollü çift zincirli kırıklar oluşturarak, bitkilerin kendi onarım mekanizmalarından yararlanılmasını esas alan bir genom düzenleme yaklaşımıdır. Bu sistem, genlerin işlevinin ortadan kaldırılması, düzenlenmesi veya yeni genetik özelliklerin kazandırılması gibi farklı amaçlarla kullanılabilmekte; bu yönüyle modern bitki ıslahında son derece esnek ve güçlü bir araç olarak değerlendirilmektedir (Shan ve ark. 2020).

3. Bitki Islahında Hedefe Yönelik Gen Düzenleme

CRISPR-Cas9 teknolojisinin bitki ıslahındaki en önemli katkısı, genetik değişikliklerin rastlantısal değil, önceden belirlenmiş hedef genler üzerinden gerçekleştirilebilmesidir. Bu yaklaşım, klasik mutasyon ıslahı yöntemlerinde görülen istenmeyen yan etkilerin büyük ölçüde önüne geçmektedir.

Hedefe yönelik gen düzenleme sayesinde: Verimle ilişkili genler doğrudan modifiye edilebilmekte, hastalık ve zararlılara duyarlılığı artıran genler etkisiz hale getirilebilmekte, abiyotik stres toleransında rol oynayan genlerin ekspresyonu düzenlenebilmektedir. Bu durum, ıslah sürecini hem hızlandırmakta hem de elde edilen genotiplerin daha öngörülebilir özellikler sergilemesini sağlamaktadır (Saini ve ark., 2023).

4. Verim ve Kalite Özelliklerinin İyileştirilmesi

Verim ve kalite, bitki ıslahının temel hedefleri arasında yer almaktadır. CRISPR-Cas9 teknolojisi, fotosentez verimliliği, tane iriliği, biyokütle üretimi ve besin içeriği gibi özelliklerin genetik kontrolünde görev alan genlerin düzenlenmesine olanak tanımaktadır. Özellikle tek veya az sayıda gen tarafından kontrol edilen kalite özelliklerinde, bu teknoloji oldukça etkili sonuçlar sunmaktadır. Besin değeri artırılmış bitkiler, düşük glütenli veya alerjen içeriği azaltılmış ürünler ve raf ömrü uzatılmış meyve-sebzeler, CRISPR-Cas9 destekli ıslah çalışmalarının dikkat çeken çıktıları arasında yer almaktadır. Bu sayede hem üretici hem de

tüketici beklentilerine daha iyi cevap veren çeşitlerin geliştirilmesi mümkün olmaktadır (Jung ve ark. 2018).

5. Biyotik ve Abiyotik Streslere Dayanıklılık

Tarımda verim kayıplarının önemli bir kısmı hastalıklar, zararlılar ve çevresel stres faktörlerinden kaynaklanmaktadır. CRISPR-Cas9 teknolojisi, bu streslere duyarlılığı artıran genlerin devre dışı bırakılması veya toleransla ilişkili genlerin düzenlenmesi yoluyla dayanıklı bitkilerin geliştirilmesine katkı sağlamaktadır. Kuraklık, tuzluluk ve yüksek sıcaklık gibi abiyotik stresler, özellikle iklim değişikliği bağlamında daha büyük bir tehdit oluşturmaktadır. Hedefe yönelik gen düzenleme, bitkilerin bu stres koşullarına adaptasyon kapasitesini artırarak sürdürülebilir tarıma önemli katkılar sunmaktadır (Hua ve ark. 2019).

6. CRISPR-Cas9 Teknolojisinin Avantajları

CRISPR-Cas9'un bitki ıslahında yaygınlaşmasının temel nedenleri arasında:

- ✓ Yüksek özgüllük ve hassasiyet,
- ✓ Görece düşük maliyet,
- ✓ Kısa sürede sonuç alınabilmesi,
- ✓ Aynı anda birden fazla genin düzenlenebilmesi,
- ✓ Transgenik olmayan ürünlerin geliştirilebilmesi yer almaktadır.

Bu avantajlar, teknolojinin hem araştırma hem de uygulama aşamalarında tercih edilmesini sağlamaktadır (Chen ve ark. 2019).

7. Dezavantajları ve Etik Boyutu

Her ne kadar CRISPR-Cas9 teknolojisi önemli avantajlar sunsa da bazı sınırlılıklar da mevcuttur. Hedef dışı etkiler, her ne kadar son yıllarda geliştirilen tasarım araçlarıyla azaltılmış olsa da hâlen dikkat edilmesi gereken bir konudur. Ayrıca bitkilerde gen transferi ve rejenerasyon süreçleri, tür ve genotipe bağlı olarak zorluklar içerebilmektedir. Regülasyon açısından ise CRISPR-Cas9 ile elde edilen ürünlerin genetiği değiştirilmiş organizmalar kapsamında değerlendirilip değerlendirilmeyeceği, ülkeden ülkeye farklılık göstermektedir. Bu durum, teknolojinin ticarileşme sürecini doğrudan etkilemektedir. CRISPR-Cas9 teknolojisinin, yeni nesil genom düzenleme sistemleriyle birlikte daha da gelişmesi beklenmektedir. Baz düzenleme ve prime editing gibi yaklaşımlar, daha hassas ve kontrollü genetik değişikliklere olanak tanımaktadır. Bu gelişmeler, bitki ıslahında hedefe yönelik gen düzenlemenin kapsamını daha da genişletecektir (Louwaars ve Jochemsen 2021). Gelecekte CRISPR-Cas9'un; dijital tarım, fenotipleme sistemleri ve yapay zekâ destekli ıslah programlarıyla entegre edilmesi, bitki ıslahında yeni bir paradigmanın oluşmasına zemin hazırlayacaktır (Zhao ve Wolt 2017).

8. Sonuç

CRISPR-Cas9 genom düzenleme teknolojisi, bitki ıslahında hedefe yönelik genetik değişikliklerin yapılmasını mümkün kılarak, klasik ıslah yaklaşımlarının hem hız hem de hassasiyet açısından önemli ölçüde ötesine geçilmesini sağlamıştır. Belirli genlerin doğrudan düzenlenebilmesi, ıslah sürecinde uzun yıllar gerektiren seleksiyon ve geriye melezleme aşamalarını büyük ölçüde kısaltmakta ve elde edilen sonuçların daha öngörülebilir olmasına katkı sunmaktadır. Bu teknoloji sayesinde verim, ürün kalitesi ve besin değeri gibi doğrudan ekonomik öneme sahip özelliklerin yanı sıra, kuraklık, tuzluluk ve yüksek sıcaklık gibi abiyotik

stresler ile hastalık ve zararlılara karşı dayanıklılık gibi özellikler daha etkin bir biçimde geliştirilebilmektedir. Özellikle tek ya da sınırlı sayıda gen tarafından kontrol edilen özelliklerde CRISPR-Cas9'un sunduğu hassas düzenleme imkânı, bitki ıslahında önemli bir avantaj oluşturmaktadır. Ayrıca aynı anda birden fazla genin düzenlenebilmesi, kompleks özelliklerin iyileştirilmesine yönelik yeni olanaklar sunmaktadır. Bununla birlikte, hedef dışı etkiler, bitkiye gen aktarımı ve rejenerasyon süreçlerindeki teknik sınırlılıklar ile düzenleyici belirsizlikler, CRISPR-Cas9 teknolojisinin yaygın uygulamaya geçişinde dikkate alınması gereken önemli hususlar arasında yer almaktadır. Bu nedenle teknolojinin etkin ve güvenli bir şekilde kullanılabilmesi için moleküler düzeyde doğrulama çalışmaları, standart protokoller ve bilimsel temelli risk değerlendirmelerinin yapılması büyük önem taşımaktadır. Sonuç olarak, uygun etik yaklaşımlar ve bilimsel temellere dayalı regülasyon çerçeveleri eşliğinde değerlendirildiğinde, CRISPR-Cas9 teknolojisinin sürdürülebilir tarım, iklim değişikliğine uyum ve küresel gıda güvenliği hedeflerine uzun vadede önemli katkılar sağlayacağı açıktır. Gelişen genom düzenleme yaklaşımları ve ıslah programlarıyla entegrasyonu sayesinde, CRISPR-Cas9'un gelecekte modern bitki ıslahının temel araçlarından biri haline gelmesi beklenmektedir.

ÖZET

Bu çalışma, mercimek (*Lens culinaris* Medik.) bitkisinin abiyotik ve biyotik stres koşullarına verdiği moleküler yanıtları, çok katmanlı omik yaklaşımlar ve sistem biyolojisi analizleri çerçevesinde kapsamlı biçimde değerlendirmektedir. Transkriptomik çalışmalar, tuzluluk, kuraklık, sıcaklık ve patojen kaynaklı streslerde iyon taşınımı (NHX1, SOS1, HKT1), ozmotik dengeleme (P5CS, BADH), protein koruma (HSP70, HSP90) ve patojen savunması (PR genleri, JA–SA sinyal yolları) gibi temel mekanizmaların aktive olduğunu göstermiştir. Yabani mercimek türlerinde NBS-LRR gibi direnç genlerinin kültür çeşitlerine göre daha yüksek düzeyde ifade edilmesi, biyotik stres toleransında önemli bir genetik kaynak potansiyeli ortaya koymaktadır. Çalışmada ayrıca WGCNA tabanlı birlikte ifade ağları incelenmiş, stresle ilişkili mTurquoise ve mYellow gibi modüllerin antioksidan savunma, hormon sinyallemesi, karbon metabolizması ve transkripsiyonel düzenleme süreçlerini eş zamanlı yönettiği belirlenmiştir. bZIP, NAC, MYB ve WRKY transkripsiyon faktörleri, stres toleransını şekillendiren başlıca "hub genler" olarak öne çıkmıştır. Çok katmanlı ağ modellemesi ve dinamik Bayesian ağ analizleri ise, stres yanıtının erken (ABA–SnRK2–DREB ekseni) ve geç (ROS temizleyici enzimler) olmak üzere iki temel aşamada gerçekleştiğini ortaya koymuştur. Transkriptom–proteom–metabolom entegrasyonu, gen ekspresyonundaki değişimlerin protein düzeyi ve metabolit birikimiyle bağlantısını doğrulamış; özellikle prolin, trehaloz ve fenolik bileşiklerin kuraklık altında belirgin şekilde arttığı gösterilmiştir. Fonksiyonel doğrulama çalışmalarında ise LcDREB2A ve LcNHX1 gibi genlerin aşırı ekspresyonunun stres dayanımını artırdığı deneysel olarak kanıtlanmıştır. Genel olarak bu çalışma, mercimekte stres toleransının karmaşık bir gen–protein–metabolit ağından oluştuğunu göstermekte ve modern ıslah programlarında kullanılabilecek kritik aday genleri, düzenleyici ağları ve biyokimyasal yolları çok yönlü bir bakış açısıyla tanımlamaktadır.

Anahtar Kelimeler: Çok katmanlı ağ modellemesi, stres toleransı, aday genler

OMICS-BASED ANALYSIS OF ABIOTIC AND BIOTIC STRESS RESPONSES AND MULTILAYER NETWORK MODELS IN *Lens culınarıs*

ABSTRACT

This study comprehensively evaluates the molecular responses of lentil (*Lens culinaris* Medik.) to abiotic and biotic stress conditions within the framework of multilayer omics approaches and systems biology analyses. Transcriptomic studies have shown that under salinity, drought, temperature, and pathogen-induced stresses, fundamental mechanisms such as ion transport (NHX1, SOS1, HKT1), osmotic adjustment (P5CS, BADH), protein protection (HSP70, HSP90), and pathogen defense (PR genes, JA–SA signaling pathways) are activated. The higher expression levels of resistance genes such as NBS-LRR in wild lentil species compared to cultivated varieties reveal an important genetic resource potential for biotic stress tolerance. The study also examined WGCNA-based co-expression networks and determined that stress-related modules such as mTurquoise and mYellow simultaneously regulate antioxidant defense, hormone signaling, carbon metabolism, and transcriptional regulation processes. Transcription factors including bZIP, NAC, MYB, and WRKY have emerged as the main hub genes shaping stress tolerance. Multilayer network modeling and dynamic Bayesian network analyses revealed that the stress response occurs in two main stages: an early stage involving the ABA–SnRK2–DREB axis and a late stage characterized by ROS-scavenging enzymes. Transcriptome–proteome–metabolome integration confirmed the association between changes in gene expression and protein levels as well as metabolite accumulation; in particular, proline, trehalose, and phenolic compounds were shown to increase markedly under drought stress. In functional validation studies, the overexpression of genes such as *LcDREB2A* and *LcNHX1* was experimentally proven to enhance stress tolerance. Overall, this study demonstrates that stress tolerance in lentil consists of a complex gene–protein–metabolite network and identifies critical candidate genes, regulatory networks, and biochemical pathways from a comprehensive perspective that can be utilized in modern breeding programs.

Keywords: Multilayer network modeling, stress tolerance, candidate genes

1. Stres-Spesifik Transkriptom Dinamikleri

Transkriptomik analizler, mercimeğin farklı stres koşullarına karşı nasıl tepki verdiğini moleküler düzeyde anlamak için güçlü bir araçtır. Bu analizler sayesinde, bitkinin stres sırasında hangi genleri aktive ettiği ya da baskıladığı, hangi biyolojik yolları kullandığı ve tolerans mekanizmasını nasıl şekillendirdiği ayrıntılı olarak ortaya konmaktadır. Farklı stres tipleri genellikle kendilerine özgü gen ifade düzenleri oluşturmaktadır. Bu nedenle RNA-Seq çalışmaları, su eksikliği, tuzluluk, sıcaklık değişimleri veya hastalık etmenleri gibi durumlarda devreye giren özel gen ağlarını tanımlamada kritik rol oynamaktadır (Zhang ve ark., 2019).

1.1.Tuz Stresi

Tuz stresine verilen moleküler yanıt, mercimekte iyon dengesinin korunması ve hücrelerin tuzluluk kaynaklı zararlardan korunması açısından kritik öneme sahiptir. Tolerant (*IG 4258*) ve hassas (*Precoz*) mercimek genotiplerinde yapılan karşılaştırmalı RNA-Seq analizleri, tuz stresinin belirli gen gruplarını güçlü biçimde aktive ettiğini göstermektedir. Bu çalışmalar, özellikle üç temel gen grubunun tuz stresine yanıt olarak yukarı yönlü ifade edildiğini ortaya koymuştur.

İyon taşınımı ve iyon dengeleme genleri: *NHX1, HKT1, SOS1*. Bu genler hücre içi sodyum ve potasyum dengesini düzenleyerek iyon homeostazını korumaktadır. Böylece tuzun hücrede toksik seviyeye ulaşmasını engellemektedir.

Osmotik koruma sağlayan genler: *P5CS, BADH*. Bu genler prolin ve betain gibi ozmoprotektanların sentezini artırarak hücrenin su kaybını azaltır ve metabolik dengeyi desteklemektedir.

Isı şok proteinleri (HSP) ve protein koruma mekanizmaları: *HSP70, HSP90*. Tuz stresinin yol açtığı protein hasarını sınırlayarak proteinlerin katlanmasını ve stabilitesini korur. Ayrıca LEA (Late Embryogenesis Abundant) protein ailelerine ait genlerin de tuzluluk ve kuraklık koşullarında belirgin şekilde arttığı gösterilmiştir. LEA proteinleri, stres altında hücre yapılarının korunmasına ve su eksikliği kaynaklı zararların azaltılmasına yardımcı olur. Bu sonuçlar genel olarak, mercimeğin tuz stresine karşı iyon düzenleme, ozmotik dengeleme ve protein koruma olmak üzere üç temel savunma stratejisi geliştirdiğini göstermektedir (Roy ve ark., 2014; Wang ve ark., 2020).

1.2.Biyotik Stres Yanıtları

Mercimek bitkisi, patojen saldırılarıyla karşılaştığında hızlı ve çok katmanlı bir savunma yanıtı geliştirir. RNA-Seq analizleri, bu savunma mekanizmalarının moleküler temelini ayrıntılı biçimde ortaya koymaktadır. Antraknoz etmeni *Colletotrichum truncatum* ile yapılan çalışmalarda, enfeksiyon sırasında iki önemli bitki savunma sinyal yolunun etkinleştiği görülmüştür: Jasmonat (JA) sinyal yolu ve Salisilik asit (SA) sinyal yolu.

Bu sinyal molekülleri, bitkide savunma yanıtını başlatan temel düzenleyicilerdir. JA ve SA sinyallemesinin eş zamanlı aktive olması, mercimeğin hem nekrotrofik hem de biyotrofik etmenlere karşı çok yönlü bir savunma stratejisi geliştirdiğini göstermektedir. Aynı çalışmalarda, enfeksiyon sırasında Pathogenesis-Related (PR) genlerinin belirgin biçimde arttığı tespit edilmiştir. PR proteinleri, bitki savunmasının ilk basamaklarında görev alır ve patojenleri doğrudan baskılayan enzimatik işlevlere sahiptir. Biyotik stres yanıtlarının anlaşılmasında yabani mercimek türlerinin incelenmesi de önemli bilgiler sağlamıştır. *Lens ervoides* ile kültüre alınmış *L. culinaris* genotiplerinin karşılaştırmalı transkriptom analizleri, yabani türlerin savunma genlerini çok daha güçlü şekilde aktive ettiğini göstermiştir. Özellikle: NBS-LRR (nucleotide-binding site–leucine-rich repeat) tipi direnç genlerinin ifade düzeyleri,

yabani türlerde kültür çeşitlerine göre 3–5 kat daha yüksektir. Bu yüksek ifade düzeyleri, yabani türlerin doğal ortamlarda daha fazla patojen baskısına maruz kalmaları nedeniyle genetik olarak daha güçlü savunma kapasitesi geliştirdiklerini göstermektedir. Bu bulgular, *L. ervoides* gibi yabani akrabaların biyotik stres toleransı için değerli genetik kaynaklar olduğunu ve mercimek ıslahında bu türlerin kullanılmasının önemini açıkça ortaya koymaktadır (Glazebrook, 2005; Sudheesh ve ark., 2016).

1.3. Çoklu Stres Etkileşimleri ve Ağ Analizi

Mercimek bitkisi doğal ortamlarda çoğu zaman tek bir stresle değil, kuraklık, tuzluluk, sıcaklık ve hastalık etmenleri gibi birden fazla stresle aynı anda karşı karşıya kalmaktadır. Bu nedenle son yıllarda yapılan transkriptom çalışmalarında, bitkinin eş zamanlı stres koşullarında nasıl bir gen ifade düzeni oluşturduğunu anlamak için sistem biyolojisi yaklaşımları kullanılmaktadır. Bu amaçla en yaygın kullanılan yöntemlerden biri, Weighted Gene Co-expression Network Analysis (WGCNA) adlı birlikte ifade ağ analizidir. WGCNA, benzer ifade paternlerine sahip genleri "modül" adı verilen kümeler halinde gruplar. Her modül, belirli biyolojik süreçlerle ilgili genleri içerir ve stres altında birlikte çalıştıkları düşünülmektedir (Langfelder ve Horvath, 2008).

2. Fonksiyonel Genomik ve Sistem Biyolojisi Entegrasyonu

Mercimek (*Lens culinaris Medik.*) gibi geniş ve karmaşık genom yapısına sahip bitkilerde, tek bir omik yaklaşımı kullanmak genellikle biyolojik süreçleri tam olarak anlamak için yeterli değildir. Bitkilerin streslere, gelişim süreçlerine veya çevresel değişikliklere nasıl yanıt verdiğini anlamak için genomik, transkriptomik, proteomik ve metabolomik gibi farklı veri katmanlarının bir arada değerlendirilmesi gerekmektedir. Bu nedenle son yıllarda fonksiyonel genomik ve sistem biyolojisi yaklaşımlarının entegrasyonu, mercimek ıslahı ve stres biyolojisi araştırmalarında yeni bir bakış açısı oluşturmuştur. Fonksiyonel genomik, genlerin hangi koşullarda nasıl ifade edildiğini, hangi proteinleri kodladığını, bu proteinlerin hangi metabolik yolları etkilediğini ve tüm bunların bitkinin fenotipine nasıl yansıdığını incelemeyi amaçlar. Bu yaklaşım, yalnızca gen varlığını belirlemekle kalmaz, aynı zamanda genlerin işlevini ve biyolojik önemini de ortaya koymaktadır. Sistem biyolojisi ise bu bilgileri daha geniş bir çerçevede değerlendirerek, gen protein metabolit etkileşimlerini dinamik ve çok katmanlı bir ağ (network) olarak ele alır. Böylece bitkinin belirli bir strese veya çevresel koşula verdiği yanıt, tekil gen davranışları üzerinden değil, tüm biyolojik sistemin ortak işleyişi üzerinden anlaşılabilir. Bu iki yaklaşım bir araya getirildiğinde, mercimekte: Stres toleransını yöneten temel genler, gen ve metabolitler arasındaki kritik bağlantılar, ağın merkezinde yer alan "hub genler" ve kompleks karakterlerin biyolojik temeli çok daha net biçimde ortaya konabilmektedir. Bu durum, modern ıslah çalışmalarında hedef gen seçimini, fonksiyonel belirteç geliştirilmesini ve moleküler düzeyde hassas ıslah stratejilerinin tasarlanmasını önemli ölçüde kolaylaştırmaktadır. Mercimek genomunda yapılan çalışmalar, transkriptomik, proteomik, ve metabolomik verilerin bir araya getirilmesinin, özellikle stres toleransı, verim ve kalite gibi kompleks karakterlerin çözümünde kritik olduğunu göstermektedir. Bitkiler çevresel streslere maruz kaldığında genlerdeki değişim yalnızca mRNA düzeyinde kalmaz. Aynı zamanda proteinlerin miktarı, yapısı ve işlevi de etkilenir. Bu nedenle transkriptomik (RNA-Seq) ve proteomik verilerin birlikte değerlendirilmesi, stres yanıtının daha bütüncül şekilde anlaşılmasını sağlar. Böyle bir entegrasyon, mRNA düzeyinde gözlenen artışların gerçekten protein düzeyine yansıyıp yansımadığını ortaya koyar. Metabolomik analizler, bitkilerin stres koşullarında ürettiği veya biriktirdiği küçük molekülleri (metabolitleri) inceleyerek, stres yanıtlarının biyokimyasal düzeyde nasıl şekillendiğini ortaya koyar. Bu analizler, gen ekspresyonunda gözlenen değişikliklerin hücresel metabolizmaya nasıl yansıdığını anlamak

açısından büyük önem taşır. Kuraklık stresine yönelik yapılan LC–MS/MS (sıvı kromatografisi–kütle spektrometrisi) temelli metabolomik çalışmalar, mercimek bitkisinin yapraklarında belirli metabolitlerin belirgin şekilde arttığını göstermektedir (Basu et al., 2023). Bu metabolitler arasında: Prolin, trehaloz, rafinoz ve fenolik bileşikler gibi stres toleransı ile ilişkili moleküller bulunmaktadır. Bu bileşikler, hücreyi kuraklığın neden olduğu oksidatif ve ozmotik zararlara karşı koruyan önemli savunma unsurlarıdır. Bu metabolitlerin artışı, transkriptom analizlerinde yukarı regüle olduğu belirlenen belirli genlerle doğrudan ilişkilidir. Dolayısıyla, gen ekspresyonu ile metabolit birikimini birlikte inceleyen gen–metabolit korelasyon analizleri, mercimekte stres toleransını belirleyen temel biyokimyasal yolların tanımlanmasında oldukça güçlü bir araçtır. Bu yaklaşımlar, ıslah programlarında hangi gen veya metabolitlerin hedeflenmesi gerektiğini belirlemede önemli avantaj sağlamaktadır (Gygi ve ark., 1999; Civelek ve Lusis, 2014; Basu ve ark., 2023).

3. Gen Etkileşim Ağları ve Önemli Düzenleyici Genler

3.1. Birlikte İfade (Co-Expression) Ağları

Mercimekte stres yanıtlarını anlamak için yalnızca tek tek genlerin ifade düzeylerini incelemek yeterli değildir. Bitki, stres koşullarında genellikle birlikte çalışan gen gruplarını devreye sokar. Bu nedenle transkriptom verilerinin ağ yapısı içinde analiz edilmesi, stres toleransını yöneten gen kümelerinin belirlenmesine olanak sağlar. Bu amaçla en sık kullanılan yöntemlerden biri Weighted Gene Co-expression Network Analysis (WGCNA) tekniğidir. WGCNA, benzer ifade düzeylerine sahip genleri "modül" adı verilen kümeler halinde toplar ve böylece stres altında birlikte çalışan gen grupları ortaya çıkarır. Mercimek için yapılan analizlerde birkaç önemli modül tanımlanmıştır:

"mTurquoise" Modülü: Bu modül, özellikle aşağıdaki gen gruplarını içermektedir:

Antioksidan savunma genleri: *SOD*, *POD*, *GST*. Bu genler, stres sırasında oluşan reaktif oksijen türlerini (ROS) temizleyerek hücreyi oksidatif hasardan korumaktadır.

mBlue Modülü: Bu modül ise hormon sinyallemesiyle ilgili genleri içermektedir: ABA (absisik asit), Etilen, Jasmonat (JA). Bu hormonlar, bitkinin stres algısı ve savunma tepkilerinin düzenlenmesinde önemli role sahiptir. Her modülün merkezinde, ağın işleyişini yönlendiren ve "hub gen" olarak adlandırılan temel düzenleyici genler bulunur. Bu hub genler genellikle transkripsiyon faktörleridir. Bu genlerin ağdaki merkezi konumu, stres toleransının düzenlenmesinde kritik rol oynadıklarını göstermektedir. Bu tür birlikte ifade ağ analizleri, mercimekte stres toleransını yöneten anahtar genleri belirlemede güçlü bir araçtır ve gelecekte ıslah çalışmalarında hedef gen seçimi için önemli bir temel sunmaktadır.

3.2. Anahtar Regülatör Transkripsiyon Faktörleri

Bitkiler stres koşullarına maruz kaldığında, çok sayıda gen aynı anda devreye girer. Bu geniş yanıtı yöneten en kritik gen gruplarından biri transkripsiyon faktörleridir. Transkripsiyon faktörleri, diğer genlerin açılıp kapanmasını kontrol ederek stres sırasında genetik yanıtın koordinasyonunu sağlar. Bu nedenle sistem biyolojisi analizlerinde TF'ler çoğunlukla ağın merkezinde yer alır ve "master regülatör" olarak adlandırılır. Mercimekte kuraklık, tuzluluk ve sıcaklık gibi stres koşullarında öne çıkan başlıca transkripsiyon faktörü aileleri şunlardır:

- bZIP (Basic Leucine Zipper) Ailesi

  Görevleri: ABA sinyallemesinin düzenlenmesi, su dengesinin kontrolü

  Örnek genler: *LcbZIP12*, *LcbZIP62*

Bu genler kuraklık ve tuzluluk streslerinde hücre içi su dengesini koruyan yolları aktive eder.

- NAC Ailesi (NAM–ATAF–CUC)

  Görevleri: Hücre duvarının dayanıklılığı, yaşlanma süreçleri, stres toleransı

  Örnek genler: *LcNAC67*, *LcNAC19*

NAC genleri özellikle kuraklık ve yüksek tuzluluk altında dayanıklılığı artıran yeniden yapılanma süreçlerini yönetir.

- MYB Ailesi

  Görevleri: Sekonder metabolit sentezi, fenolik bileşiklerin üretimi, antioksidan savunma

  Örnek genler: *LcMYB44*, *LcMYB108*

Bu genler oksidatif stresin azaltılmasında önemli rol oynayan metabolitlerin sentezini artırır.

- WRKY Ailesi

  Görevleri: Biyotik stres yanıtları, patojen savunması, PR genlerinin düzenlenmesi

  Örnek genler: *LcWRKY70*, *LcWRKY33*

WRKY faktörleri özellikle antraknoz ve Fusarium gibi hastalıklara karşı savunma yanıtını yönetir.

Bu transkripsiyon faktörleri stres sırasında yalnızca kendi işlevlerini yerine getirmekle kalmaz, aynı zamanda birbirleriyle oluşturdukları etkileşim ağları aracılığıyla çok daha geniş bir savunma mekanizmasını koordine eder. Özellikle bZIP–MYB–NAC etkileşimlerinin kuraklık toleransında "metabolik yeniden programlama" adı verilen, bitkinin tüm metabolizmasını stres koşullarına uyarlayan kilit mekanizmayı yönettiği bildirilmektedir. Dolayısıyla bu transkripsiyon faktörleri, mercimekte stres toleransının moleküler düzeyde anlaşılması ve ıslah programlarında hedef genlerin belirlenmesi açısından en kritik düzenleyici gen gruplarını oluşturmaktadır (Jakoby ve ark., 2002; Dubos ve ark., 2010; Rushton ve ark., 2010).

3.3. Sistem Biyolojisi Modelleri ve Dinamik Simülasyonlar

3.3.1. Ağ Tabanlı Modelleme

Mercimekte stres yanıtlarını anlamak için yalnızca tek tek genlerin veya metabolitlerin davranışlarını incelemek yeterli değildir. Bitki, stres sırasında genler, proteinler ve metabolitler arasında çok sayıda karşılıklı etkileşim içeren karmaşık bir biyolojik ağ oluşturur. Bu nedenle mercimek sistem biyolojisi araştırmalarında giderek daha fazla ağ tabanlı modelleme (network-driven modeling) yaklaşımı kullanılmaktadır. Bu modellerde, stres yanıtında rol oynayan tüm biyomoleküller genler, proteinler ve metabolitler birlikte ele alınır ve aralarındaki ilişkiler çok katmanlı (multi-layer) ağlar şeklinde gösterilir. Böylece stres altında hangi moleküler yolların birlikte çalıştığı ve hangi bileşenlerin ağın merkezinde yer aldığı daha net biçimde ortaya konur.

LentilDroughtNet adlı model, mercimeğin kuraklık stresine verdiği yanıtı sistem düzeyinde inceleyen kapsamlı bir ağ yapısıdır. Bu modelde: 312 gen, 58 metabolit, 45 protein arasındaki bağlantılar analiz edilmiştir. Ağın merkezinde özellikle bZIP–LEA–P5CS ekseninin yer aldığı görülmüştür. Bu eksen: bZIP → stres sinyallemesini, LEA proteinleri → hücreyi

kuruma ve su kaybına karşı korumayı, P5CS → prolin sentezini düzenleyerek ozmotik dengeyi sağlamayı kontrol eden kritik bileşenlerdir.

Bu sonuçlar, mercimekte kuraklık toleransının tek bir gen veya metabolitten ziyade birbirine bağlı çok sayıda molekülden oluşan karmaşık bir ağ tarafından yönetildiğini göstermektedir. Ağ tabanlı modelleme, bu tür karmaşık stres yanıtlarını çözmek ve gelecekte ıslah için hedeflenebilecek "anahtar bileşenleri" belirlemek açısından oldukça güçlü bir yaklaşımdır (Weckwerth ve Fiehn, 2002; Barabási ve ark., 2011; Zhu ve ark., 2013).

3.3.2. Dinamik Ağ Analizi

Bitkilerin stres koşullarına verdiği yanıtlar zamanla değişen ve birbirini takip eden aşamalardan oluşur. Bu nedenle, genlerin yalnızca bir zaman noktasındaki durumunu gösteren statik ağ analizleri, stres sürecinin tamamını açıklamak için yeterli değildir. Stres yanıtının zaman içindeki değişimini görmek için dinamik ağ modellerine ihtiyaç vardır. Bu amaçla mercimek çalışmalarında Dynamic Bayesian Network (DBN) modelleri kullanılmaktadır. DBN, farklı zaman noktalarında elde edilen gen ifade verilerini analiz ederek:

- ✓ genler arasındaki neden–sonuç ilişkilerini,
- ✓ belirli süreçlerin hangi sırayla aktive olduğunu,
- ✓ stres yanıtının erken ve geç evrelerde nasıl farklılaştığını

ayrıntılı biçimde ortaya koyar.

Mercimeğe uygulanan DBN analizleri, kuraklık ve tuzluluk gibi stres koşullarında iki önemli aşama olduğunu göstermiştir:

1. Erken stres yanıtı aşaması

Bu aşamada özellikle:

- ✓ ABA sinyal yolakları
- ✓ SnRK2 protein kinazları
- ✓ DREB transkripsiyon faktörleri

aktif durumdadır. Bu üçlü (ABA–SnRK2–DREB ekseni), bitkinin stresi algılamasını ve hızlı bir savunma yanıtı başlatmasını sağlar.

2. Geç stres yanıtı aşaması

Stres süreci ilerledikçe bitki daha çok oksidatif stresle mücadeleye odaklanır. Bu aşamada:

• ROS temizleyici (ROS-scavenging) genlerin (*SOD, CAT, APX* vb.) daha baskın hale geldiği görülür. Böylece hücrede biriken reaktif oksijen türleri azaltılarak hücre hasarı sınırlandırılır. Bu bulgular, mercimek ıslahında tüm stres sürecini tek bir aşama olarak değerlendirmek yerine, farklı stres fazlarında etkili olan genlerin ayrı ayrı hedeflenmesi gerektiğini göstermektedir. Erken yanıt genleri hızlı algılamayı, geç yanıt genleri ise uzun süreli dayanımı şekillendirdiği için her iki grup da ıslah açısından kritik öneme sahiptir (Windram ve ark., 2012; Friedman ve ark., 2000).

5.4. Fonksiyonel Gen Doğrulama Yaklaşımları

Fonksiyonel genomik entegrasyonunun son aşaması, belirlenen aday genlerin fonksiyonel validasyonudur. Mercimekte bu doğrulama şu yaklaşımlarla yapılmaktadır:

qRT-PCR: RNA-Seq ile belirlenen genlerin ifade düzeylerinin doğrulanmasında kullanılmaktadır.

Heterolog ekspresyon sistemleri (Arabidopsis, Medicago truncatula): Mercimekten izole edilen genlerin diğer model bitkilerde test edilmesi.

CRISPR/Cas9 veya VIGS (Virus-Induced Gene Silencing): Hedef genlerin susturulması veya düzenlenmesiyle fonksiyonun doğrudan test edilmesi.

Bu doğrulama adımları, sistem biyolojisi modellerinden elde edilen teorik tahminlerin deneysel olarak desteklenmesini sağlayarak mercimek ıslahında genetik hedeflerin güvenilirliğini artırmaktadır (Sakuma ve ark., 2002; Bustin ve ark., 2009).

ÖZET

Küresel enerji dönüşümü hedefleri doğrultusunda yenilenebilir enerji kaynaklarının şebekeye entegrasyonu, enerji sistemlerinde önemli bir zorluk olarak ortaya çıkmaktadır. Bu kaynaklar arasında güneş enerji santrallerinin (GES) payı hızla artmakla birlikte, meteorolojik değişkenlere bağlı kesintili üretim yapıları, şebeke kararlılığı ve yük dengeleme operasyonları açısından ciddi planlama gereksinimleri doğurmaktadır. Bu nedenle GES'lerin kısa dönemli güç üretiminin yüksek doğrulukla tahmin edilebilmesi hem teknik işletme güvenliği hem de enerji piyasalarında ekonomik verimlilik açısından kritik öneme sahiptir. Bu çalışmada, GES'lerin kısa dönem güç üretimini yüksek hassasiyetle tahmin etmek amacıyla makine öğrenmesi tabanlı sınıflandırma algoritmalarından XGBoost modeli kullanılmıştır. Modelin girdi vektörü; saatlik ortam sıcaklığı, güneş ışınımı, geçmiş fotovoltaik üretim değerleri ve ışınım kararlılığı gibi türetilmiş atmosferik özellikler kullanılarak oluşturulmuştur. Geliştirilen model, mevsimsel değişkenliğin tahmin performansı üzerindeki etkisini değerlendirmek amacıyla dört mevsim özelinde ayrı ayrı test edilmiştir. Elde edilen sonuçlar, en yüksek doğruluk seviyesinin yaz mevsiminde sağlandığını göstermekte olup, karekök ortalama hata (KOH), ortalama mutlak yüzdesel hata (OMYH) ve belirlilik katsayısı (R^2) sırasıyla 648.95 kW, %7.94 ve 0.99 olarak hesaplanmıştır. Buna karşın en düşük performans sonbahar döneminde gözlenmiş; KOH, OMYH ve R^2 değerleri sırasıyla 1332.02 kW, %10.95 ve 0.94 olarak belirlenmiştir. Yüksek R^2 değerleri ve düşük hata oranları, XGBoost modelinin GES'lerin doğrusal olmayan ve karmaşık üretim dinamiklerini başarıyla yakalayabildiğini ortaya koymaktadır. Bu bulgular, geliştirilen modelin santral operatörleri ve şebeke yöneticileri için güvenilir bir karar destek aracı olarak endüstriyel uygulamalarda etkin biçimde kullanılabileceğini göstermektedir.

SHORT-TERM POWER PRODUCTION FORECASTING USING THE XGBOOST ALGORITHM DEVELOPED FOR SOLAR POWER PLANTS

ABSTRACT

In line with global energy transition goals, the integration of renewable energy sources into power grids has become a critical challenge. Among these sources, the role of photovoltaic (PV) power plants is steadily increasing; however, their intermittency driven by meteorological conditions creates significant planning difficulties in terms of grid stability and load balancing. Therefore, achieving accurate short-term forecasting of PV generation is essential for both operational reliability and economic efficiency in energy markets. In this study, the XGBoost algorithm, a machine learning–based classification method, is employed to predict the short-term power output of PV plants with high precision. The input vector of the model consists of hourly ambient temperature, solar irradiance, historical PV output, and derived atmospheric indicators such as irradiance stability. To investigate the influence of seasonal variability on forecasting accuracy, the proposed model is evaluated separately for four distinct seasons. The results demonstrate that the highest prediction accuracy is achieved during the summer period, with a root mean square error (RMSE) of 648.95 kW, mean absolute percentage error (MAPE) of 7.94%, and coefficient of determination (R^2) of 0.99. Conversely, the lowest performance is observed in autumn, where RMSE, MAPE, and R^2 are calculated as 1332.02 kW, 10.95%, and 0.94, respectively. The high R^2 values and low error metrics confirm the strong capability of XGBoost in capturing the nonlinear and complex generation dynamics of PV systems. These findings indicate that the developed model can serve as a robust and effective decision-support tool suitable for industrial applications by grid operators and power plant managers.

Keywords: Solar Energy, Power Forecasting, Grid Stability, XGBoost, Machine Learning

1.GİRİŞ

Günümüzde, fosil yakıtların tükenmesi ve artış gösteren sera gazı emisyonları nedeniyle, yenilenebilir enerji kaynaklarının yaygınlaşması hız kazanmıştır (Taşdemir ve ark., 2024). En yaygın kullanılan yenilenebilir enerji kaynaklarından biri olan fotovoltaik enerji, enerji sistemlerinin sürekli, istikrarlı ve ekonomik çalışmasında önemli bir rol oynamaktadır (Lin ve ark., 2022). 2025 yılı Eylül ayı itibarıyla Türkiye'nin kurulu gücü 121.418 MW'a ulaşmış olup güneş enerjisinin oranı %19,9 olarak gerçekleşmiştir. 2024 yılı için elektrik üretiminin kaynaklara göre dağılımı ise Şekil 1.1'de verilmiştir (T.C. Enerji ve Tabii Kaynaklar Bakanlığı, 2025).

Şekil 1.1. 2024 yılı elektrik üretiminin kaynaklara göre dağılımı

Fotovoltaik enerji üretimindeki belirsizlik ve değişkenlik nedeniyle, büyük ölçekli fotovoltaik sistemlerin şebekeye bağlanmasında önemli zorluklar bulunmaktadır (Maghami ve ark., 2016). Fotovoltaik enerjinin dalgalanması ve kesintileri, mevcut elektrik sistemlerinde beklenmedik kayıplara neden olabilir (Liu ve ark., 2018). Ayrıca, fotovoltaik güç sistemlerinin dengesiz yapısı elektrik kesintilerine, gerilim dalgalanmalarına ve şebekede verim kayıplarına yol açabilir. Bu nedenle, fotovoltaik güç çıkışının doğru tahmini ve fotovoltaik gücün şebekeye entegrasyonunun kolaylaştırılması gibi konular, fotovoltaik güç üretiminde önemli araştırma alanları olarak ortaya çıkmıştır (Saber ve ark., 2014).

Yapay zeka teknolojisindeki gelişmelerin bir sonucu olarak, fotovoltaik güç tahmini çok kısa vadeli, kısa vadeli, orta vadeli ve uzun vadeli dönemlerde gerçekleştirilmektedir (Li ve ark., 2020). Fotovoltaik güç tahmini için kullanılan dört farklı zaman aralığı ve amaçları Tablo 1.1'de verilmiştir (Elsinga ve Van Sark, 2017).

Tablo 1.1. Farklı zamanlarda fotovoltaik güç tahmininin uygulanabilirliği

Tahmin dönemleri	Periyot	Amaçlar
Çok kısa vadeli dönem	1 saniye ile 15 dakika arası	Yük takibi, yedek kapasite planlaması, güç kalitesi
Kısa vadeli dönem	15 dakika ile 1 saat arası	Piyasa belirlenmesi, yük takibi, yedek kapasite planlaması
Orta vadeli dönem	1 saat ile 1 gün arası	Piyasa belirlenmesi, temel yük planlaması
Uzun vadeli dönem	1 gün sonra tahmin	Enerji yönetimi, güç kapasitesinin dağıtımı

İlgili literatür çalışmaları incelendiğinde; günlük fotovoltaik güç tahmini çalışmalarında YSA ile JAYA–YSA hibrit modelinin karşılaştırıldığı ve hibrit modelin daha yüksek tahmin doğruluğu sağladığının raporlandığı görülmektedir (Irmak ve ark., 2024). Fotovoltaik güç tahmini kapsamında en iyi performansın Otomatik Regresif Entegre Hareketli Ortalama (OREHO) modeli tarafından elde edildiği; modelin KOH ve OMH değerlerinin sırasıyla 821,6 W ve 699,9 W olarak hesaplandığı bildirilmektedir (Das, 2021). Meteorolojik değişkenlere ek olarak PM10 parametresinin de modele dâhil edildiği bir diğer çalışmada, PM10'un fotovoltaik güç tahmini üzerindeki etkisi değerlendirilmiştir (Irmak ve ark., 2023).

Öğretme–Öğrenme Tabanlı Optimizasyon (TLBO) algoritması ile gerçekleştirilen fotovoltaik güç tahmini çalışmalarında ise hata ölçütü olarak KOH ve OMYH kullanılmıştır (Taşdemir, 2024). Haftalık tahmin uygulamalarında bağıl nem, yağış, ortam sıcaklığı, güneşlenme süresi ve bulutluluk miktarı gibi meteorolojik değişkenlerin giriş parametreleri olarak kullanıldığı belirtilmektedir (Moreira ve ark., 2021). Ayrıca geçmiş fotovoltaik güç, ortam sıcaklığı ve güneş ışınımı verilerinin kullanıldığı bir çalışmada Genetik Algoritma (GA) ile başarılı tahmin sonuçları elde edilmiştir (Ermiş ve Taşdemir, 2025). Uzun vadeli fotovoltaik güç tahmini için Kapılı Tekrarlayan Birimler (KTB) ve Uzun Kısa Süreli Bellek (UKSB) modelleri kullanılmış; bu modeller için sırasıyla R^2=0,987, OMH (%)=8,86 ve R^2=0,986, OMH (%)=8,77 değerleri rapor edilmiştir (Khatib ve ark., 2022).

Bu çalışmada, güneş enerji santrallerinin kesintili üretim karakteristiğinin şebeke üzerindeki olumsuz etkilerini en aza indirmek ve güç üretim tahmin doğruluğunu artırmak amacıyla XGBoost algoritmasına dayalı kısa vadeli tahmin modeli geliştirilmiştir. Önerilen yaklaşımda, ham verilerin bilgi taşıma kapasitesini artırmak amacıyla özellik mühendisliği (feature engineering) süreçleri uygulanmıştır. Bu süreçte, literatürdeki yaygın meteorolojik girdilere (sıcaklık, güneş ışınımı) ek olarak, atmosferik geçirgenliğin ve bulutluluk değişimlerinin bir göstergesi olan ışınım kararlılığı ile çevresel etkenlerin sisteme kümülatif etkisini yansıtan verimlilik faktörü parametreleri türetilerek modele dahil edilmiştir. Çalışma kapsamında, mevsimsel etkilerin model performansı üzerindeki değişimini analiz etmek üzere veriler mevsimsel bazda sınıflandırılmış ve modelin başarısı dört farklı mevsim için ayrı ayrı test edilmiştir. Elde edilen sonuçlar, Karekök Ortalama Hata (KOH), Ortalama Mutlak Yüzdesel Hata (OMYH) ve Belirlilik Katsayısı (R^2) gibi istatistiksel hata metrikleri kullanılarak değerlendirilmiştir.

2. ARAŞTIRMA VE BULGULAR

2.1. XGBoost Algoritması

Tianqi Chen ve Carlos Guestrin'in 2016 yılında geliştirdiği algoritma, Gradyan Artırma (Gradient Boosting) temelli, ölçeklenebilir ve yüksek performanslı bir makine öğrenmesi yöntemidir (Chen ve Guestrin, 2016). XGBoost, karar ağaçlarını ardışık olarak eğiterek ve her adımda bir önceki modelin hatalarını düzelterek güçlü bir tahmin yapısı oluşturur. XGBoost'u diğer topluluk öğrenme yöntemlerinden ayıran ve bu çalışmada tercih edilmesini sağlayan en önemli özellik, modelin karmaşıklığını kontrol altında tutan regülasyon yeteneğidir. Bu prosedür, modelin eğitim verisine aşırı uyum sağlamasını engelleyerek genelleştirme başarısını artırır (Friedman, 2006). Modelin amaç fonksiyonu (L_Ω), eğitim hatasını ölçen kayıp fonksiyonu (L) ve karmaşıklığı cezalandıran regülasyon teriminden (Ω) oluşur ve Denklem 1 ile ifade edilir.

$$L_\Omega(F_M) = \sum_{i=1}^{N} L(y_i, F_m(X_i)) + \sum_{m=1}^{M} \Omega(f_m) \quad (1)$$

Burada N örnek sayısını, L ise tahmin edilen değer ile gerçek değer arasındaki farkı ölçen kayıp fonksiyonu temsil eder. Algoritmanın kararlılığını artıran regülasyon terimi Ω ise, yaprak (düğüm) sayısı (J) ve yaprak ağırlıklarının (W) L2 normu kullanılarak Denklem (2)'deki gibi hesaplanır.

$$\Omega(f_m) = \Upsilon Jm + \frac{1}{2}\lambda\|W\|^2 \quad (2)$$

Eşitlikteki Υ parametresi bir düğümün bölünmesi için gereken minimum kayıp fonksiyonunu kontrol ederken, λ parametresi yaprak ağırlıklarını dengeleyerek modelin varyansını düşürür. Ayrıca algoritma, optimizasyon sürecinde kayıp fonksiyonunun ikinci dereceden Taylor serisi açılımını kullanır. Bu yaklaşım, hem birinci türev (gradyan) hem de ikinci türev (Hessian) bilgisinden yararlanarak standart gradyan iniş yöntemlerine göre daha hızlı ve kararlı bir yakınsama sağlar.

2.2. Deneysel Çalışmalar

Bu çalışmada İç Anadolu Bölgesi'nde faaliyet gösteren 25 MW kurulu güce sahip bir GES'ten elde edilen saha verileri kullanılmıştır. Veri seti, 1 Mart 2024 – 28 Şubat 2025 tarih aralığını kapsamakta olup, santralin SCADA (Merkezi Gözetim, Kontrol Ve Veri Toplama Sistemi) sisteminden kaydedilen 1 saatlik fotovoltaik güç üretim (kW) değerleri ile eş zamanlı olarak meteoroloji istasyonundan alınan ortam sıcaklığı (°C) ve güneş ışınımı (W/m²) verilerini içermektedir. Ham veriler, modelin öğrenme başarısını artırmak amacıyla ön işleme sürecine tabi tutulmuştur. Bu süreçte sensör hatalarından kaynaklanan kayıp veriler, gece saatlerinde oluşan gürültülü veriler (pozitif üretim hataları) ve santral kapasitesini aşan aykırı değerler eğitim veri setinden ayıklanmıştır. Modelin girdi vektörünü güçlendirmek amacıyla özellik mühendisliği (feature engineering**)** uygulanmış, geçmiş üretim verileri, ışınım kararlılığı ve zamansal döngüsellik (günlük/mevsimsel) sisteme yeni özellikler olarak eklenmiştir. Modelin genelleme yeteneğini doğrulama amacıyla veri seti, zaman serisi bütünlüğü korunarak kronolojik sırayla %70 eğitim ve %30 test seti olarak ayrılmıştır. Tüm süreçler Python ortamında gerçekleştirilmiştir. Model performansının değerlendirilmesinde temel metrikler olarak, Karekök Ortalama Hata (KOH), Ortalama Mutlak Yüzdesel Hata (OMYH) ve Belirlilik Katsayısı (R^2) tercih edilmiştir.

Denklem 3, tahmin edilen değerler ile gerçek değerler arasındaki farkların karesel ortalamasının karekökünü ifade eder. (Ermiş ve Taşdemir, 2025).

$$\text{KOH} = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(y_i - p_i)^2} \quad (3)$$

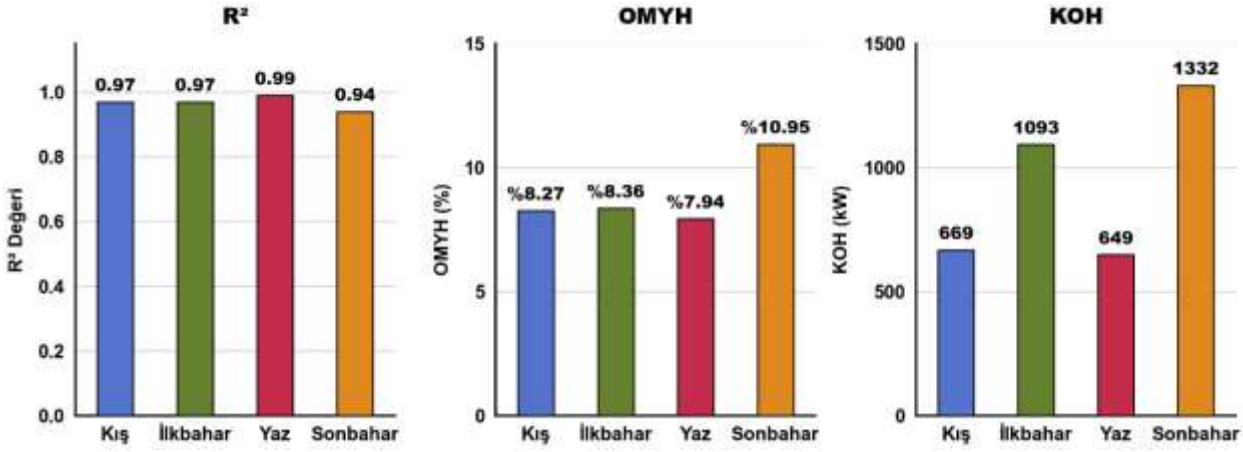
Denklem 4, hataların mutlak büyüklüğünün gerçek değerlere oranını yüzdesel olarak ifade eder. (Ermiş ve Taşdemir, 2025).

$$\text{OMYH} = \frac{1}{N}\sum_{i=1}^{N}\frac{|y_i - p_i|}{p_i} \text{ x } 100 \quad (4)$$

Denklem 5, modelin, bağımlı değişkendeki varyansı açıklama oranını gösterir.

$$R^2 = 1 - \frac{\sum_{i=1}^{n}(y_i - p_i)^2}{\sum_{i=1}^{n}(y_i - g_i)^2} \quad (5)$$

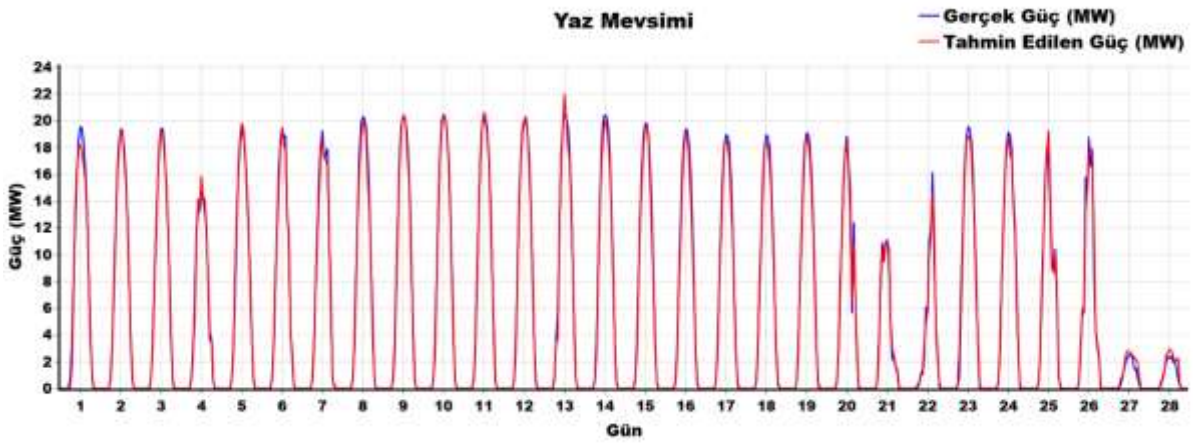
İlgili eşitliklerde; n toplam gözlem (veri) sayısını, y_i i. zaman adımındaki gerçek üretim değerini, p_i model tarafından tahmin edilen üretim değerini ve g_i $g$erçek üretim değerlerinin aritmetik ortalamasını temsil etmektedir.



2.3. Deneysel Sonuçlar

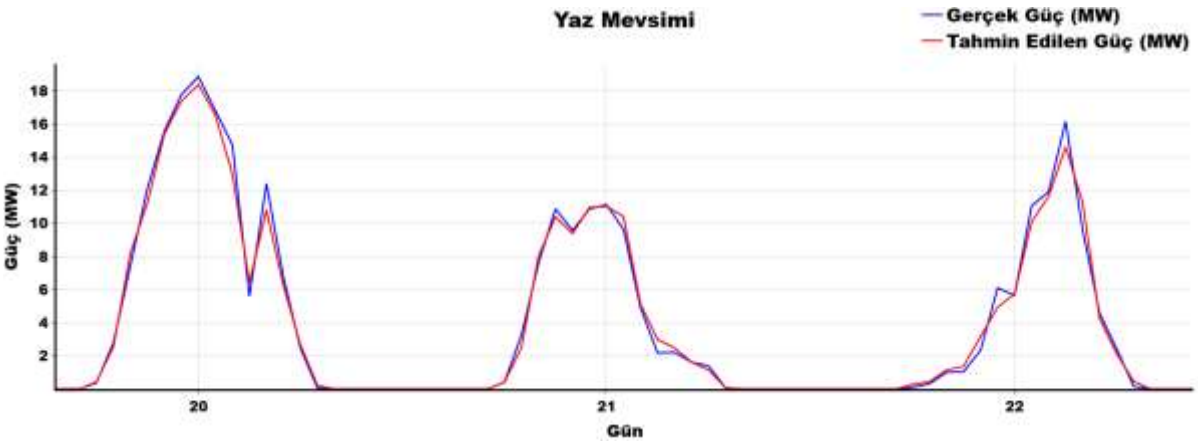
Geliştirilen XGBoost modelinin yaz, ilkbahar, kış ve sonbahar dönemlerindeki kısa dönem tahmin performansını, güvenilirliğini ve genelleme kabiliyetini değerlendiren karşılaştırmalı metrik sonuçları Tablo 2.1'de verilmiştir.

Tablo 2.1. Modelin mevsimsel performans karşılaştırması



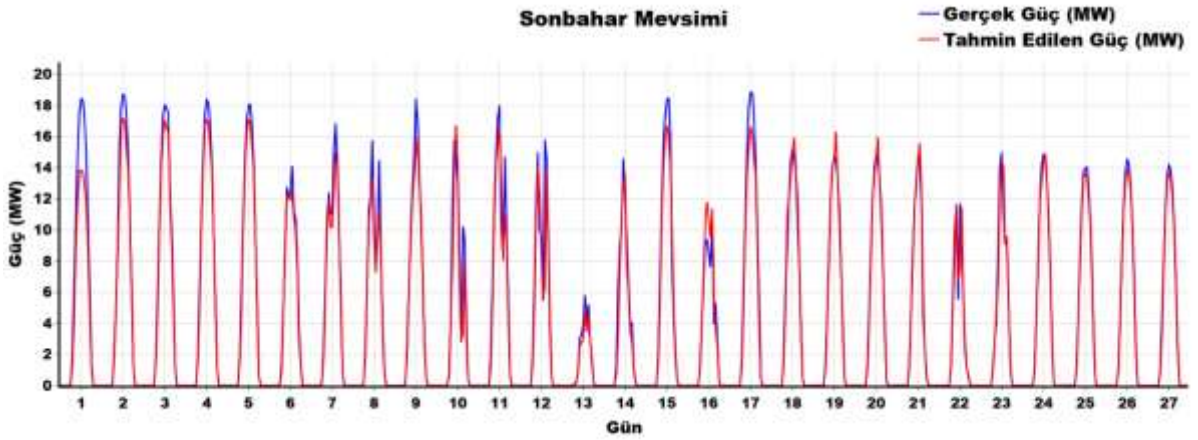
Mevsim	KOH (kW)	OMYH (%)	R^2
Yaz	648.95	7.94	0.99
İlkbahar	1093.28	8.36	0.97
Sonbahar	1332.02	10.95	0.94
Kış	668.98	8.27	0.97

Tablo 2.1'deki bulgular ve performans metriklerinin mevsimsel değişimlerinin sunulduğu Şekil 2.1 incelendiğinde, geliştirilen XGBoost modelinin tüm mevsimlerde 0.94'ün üzerinde R^2skoruna ulaşarak yüksek bir genelleme performansı sergilediği görülmektedir. KOH değerinin 648.95 kW olduğu yaz mevsimindeki 0.99'luk yüksek uyumun yanı sıra atmosferik koşulların değişkenlik gösterdiği ve KOH'un 1332.02 kW ile zirveye ulaştığı sonbahar döneminde dahi model, 0.94 seviyesindeki başarısını koruyarak verideki değişkenliği açıklama gücünü kanıtlamıştır. Mevsimsel koşullar ve KOH miktarları değişse de OMYH değerlerinin %7.94 ile %10.95 arasında düşük bir yüzdede seyretmesi, modelin farklı iklim profillerine ve güç değerlerine karşı kararlı bir yapı sergilediğini göstermektedir.



Şekil 2.1. R^2, KOH ve OMYH mevsimsel karşılaştırılması

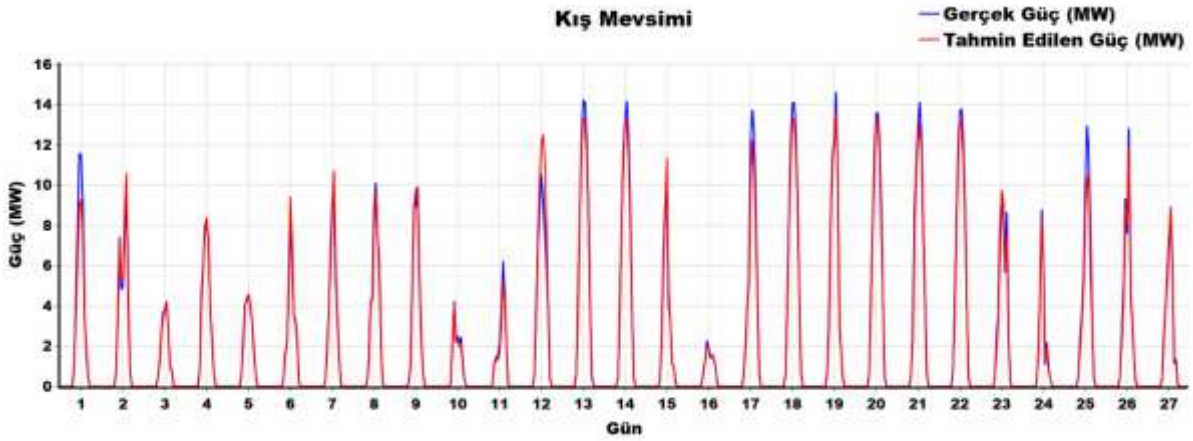
Performans metrikleri detaylı olarak incelendiğinde, mevsimsel koşullara bağlı olarak istatistiksel farklılıklar ortaya çıktığı görülmektedir. Söz konusu farklılıklar içerisinde en dikkat çekici performansa, modelin en yüksek tahmin doğruluğunu yakaladığı yaz mevsiminde ulaşılmıştır. Bu dönemde, KOH ve OMYH sırasıyla 648.95 kW ve %7.94 olarak en düşük hata oranları gözlemlenmiş aynı zamanda 0.99 ile en yüksek belirlilik katsayısı elde edilmiştir. Bu başarının altında yatan temel faktörün, yaz aylarındaki güneş ışınımı verilerinin daha düzenli ve tahmin edilebilir bir karakteristik göstermesi olduğu değerlendirilmektedir. Şekil 2.2 ve Şekil 2.3, yaz mevsimi için gözlemlenen gerçek ve tahmin edilen güç eğrileri arasındaki performansı görsel olarak teyit etmektedir.



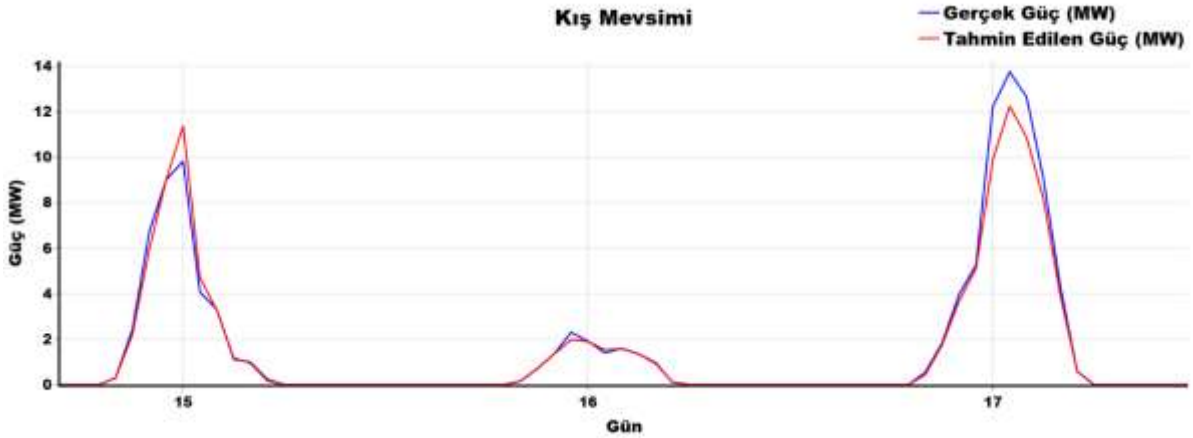
Şekil 2.2. Yaz mevsiminde gerçek ve tahmin edilen güç değişimleri

Şekil 2.3. Yaz mevsiminde kesiti alınmış gerçek ve tahmin edilen güç değişimleri

Buna karşılık, tüm mevsimler içerisinde en zorlu dönem olarak belirlenen sonbaharda, artan meteorolojik belirsizlikler ve değişken bulutluluk gibi koşullara bağlı olarak model performansı en yüksek hata değerlerine KOH = 1332.02 kW, OMYH = %10.95 ve en düşük $R^2 = 0.94$ değerine gerilemiş olsa da, Şekil 2.4 ve Şekil 2.5'te görülen yüksek dalgalanmalara karşın XGBoost algoritmasının ani bulut geçişlerinden kaynaklanan keskin değişimleri yakalamayı başarması, modelin yüksek frekanslı değişimlere karşı tahmin kabiliyetinin güçlü olduğunu ve genel trendi koruyabildiğini göstermektedir.

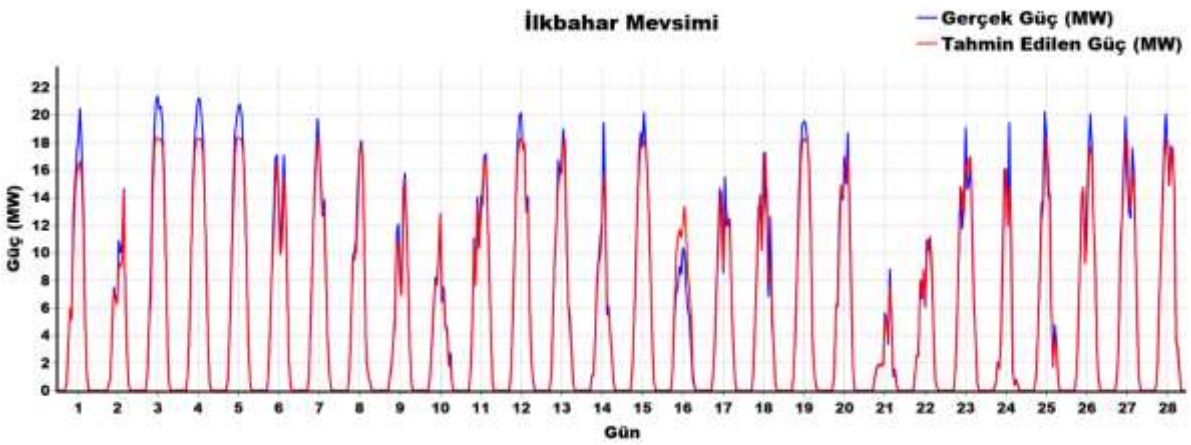


Şekil 2.4. Sonbahar mevsiminde gerçek ve tahmin edilen güç değişimleri



Şekil 2.5. Sonbahar mevsiminde kesiti alınmış gerçek ve tahmin edilen güç değişimleri

Kış mevsimi düşük ışınım seviyelerine rağmen KOH = 668.98 kW, OMYH = %8.27 ve $R^2 = 0.94$ değeri ile istikrarlı bir performans sergileyen modelin başarısının sadece yüksek üretimlerle sınırlı kalmayıp kapalı veya yağışlı günlerdeki ani değişimleri de başarıyla yakalaması, sistemin meteorolojik değişkenliğe karşı duyarlılığını kanıtlamaktadır.



Şekil 2.6. Kış mevsiminde kesiti alınmış gerçek ve tahmin edilen güç değişimleri

Şekil 2.7. Kış mevsiminde kesiti alınmış gerçek ve tahmin edilen güç değişimleri

Sonbahardan sonra en yüksek hata oranlarının gözlemlendiği KOH = 1093.28 kW, OMYH = %8.36 ve $R^2 = 0.97$ değerlerinin kaydedildiği ilkbahar mevsiminde, modelin gün ortası zirve üretim anlarını düşük tahmin etmesine karşın gün doğumu ve gün batımı süreçlerindeki çizgisel artış ve azalış dinamiklerini yüksek bir başarıyla yakaladığı Şekil 2.8 ve Şekil 2.9'da görülmektedir.

Şekil 2.8. İlkbahar mevsiminde gerçek ve tahmin edilen güç değişimleri

Şekil 2.9. İlkbahar mevsiminde kesiti alınmış gerçek ve tahmin edilen güç değişimleri

3. SONUÇ

Bu çalışmada türetilmiş veriler olan ışınım kararlılığı ve verimlilik katsayısının kullanıldığı özellik mühendisliği süreci, XGBoost algoritmasının güçlü öğrenme yapısıyla birleştirilerek güneş enerjisi üretiminin doğrusal olmayan karmaşık dinamiklerini modellemede etkili ve üstün bir performans ortaya konmuştur. Geliştirilen model, tüm mevsimsel döngülerde 0.94'ün üzerinde bir belirlilik katsayısı ve %11 in altında düşük bir ortalama mutlak yüzde hataya ulaşarak, yalnızca atmosferik koşulların durağan ve tahmin edilebilir olduğu dönemlerde değil, aynı zamanda değişkenliğin ve atmosferik belirsizliğin zirveye ulaştığı ilkbahar ve sonbahar aylarında da istikrarlı ve güvenilir bir tahmin yeteneği sergilemiştir. Özellikle bulutlanma ve ani hava olaylarının sıkça yaşandığı günlerde hata oranlarında kısmi artışlar görülse de modelin üretim profilindeki ani artış ve azalış trendlerini doğru bir şekilde takip ettiği ve verideki anlık gürültüye rağmen ana üretim sinyalini yüksek bir doğrulukla yakaladığı gerçekleştirilen grafiksel analizlerle doğrulanmıştır. Elde edilen bu yüksek tahmin başarısı, modelin sağladığı teknik doğruluğun çok ötesine geçerek enerji yönetimi ve sistem güvenliği açısından da somut ve kritik faydalar sunmaktadır. Nitekim güç üretimindeki dalgalanmaların önceden ve yüksek hassasiyetle tahmin edilmesi, şebeke operatörlerinin güç dengeleme sistemlerini ve yük tevzi işlemlerini çok daha verimli yönetmesini sağlamakta ve şebekede oluşabilecek ani güç dengesizliklerine karşı hazırlıklı olunmasına imkan tanımaktadır. Bu gelişmiş öngörü yeteneği, inverter ve trafo gibi hassas güç donanımlarının

ani yüklenmeler sonucu maruz kaldığı aşırı ısınmayı ve mekanik yıpranmayı engelleyerek sistemin bakım maliyetlerini önemli ölçüde düşürmekte ve tesisin operasyonel kullanım ömrünü uzatmaktadır. Sonuç olarak bu çalışma, önerilen yaklaşımın sadece yüksek doğruluklu bir tahmin aracı değil, aynı zamanda yenilenebilir enerji kaynaklarının elektrik şebekesine entegrasyonunu kolaylaştıran, arz güvenliğini destekleyen ve tesislerin operasyonel verimliliğini artıran stratejik bir karar destek mekanizması olduğunu kanıtlamaktadır.

ÖZET

Hastaneler, sağlık hizmeti sunarken çevre üzerinde önemli etkiler yaratabilecek atıklar üretmektedir. Bu atıklar enfekte, kimyasal, radyoaktif veya evsel nitelikte olabilmektedir. Özellikle tıbbi ve tehlikeli atıklar hem insan sağlığı hem de çevre açısından ciddi riskler taşımaktadır. Çevresel sürdürülebilirlik anlayışı, bu atıkların azaltılmasını, güvenli şekilde toplanmasını, taşınmasını, ayrıştırılmasını ve bertaraf edilmesini gerektirmektedir. Atık yönetimi süreçlerinin yasal mevzuata uygun, etkin ve çevre dostu yöntemlerle yürütülmesi sürdürülebilirliğe katkı sağlamaktadır. Ayrıca hastanelerde geri dönüşüm uygulamalarının yaygınlaştırılması, hastane personelinin eğitilmesi ve teknolojik çözümlerden faydalanılması hem çevresel etkilerin azaltılmasına hem de kaynakların verimli kullanılmasına katkıda bulunabilinecektir. Yeşil hastane uygulamaları ve enerji geri kazanım sistemleri gibi çevre dostu teknolojiler, sürdürülebilir sağlık hizmetlerinin geleceği açısından umut verici adımlar olarak değerlendirilmektedir. Sonuç olarak, hastane atıklarının etkin ve doğru yönetimi yalnızca çevrenin korunmasına değil, aynı zamanda sağlık sistemlerinin uzun vadeli sürdürülebilirliğine de hizmet eden temel bir unsurdur. Bu çalışma, çevresel sürdürülebilirliğin sağlanmasında hastane atıklarının etkisini analiz etmeyi amaçlamakta; aynı zamanda hastane kaynaklı atıkların yönetimine yönelik çözüm önerileri sunmaktadır.

Anahtar kelimeler: Sürdürülebilirlik, Yeşil Hastane, Hastane Atıkları, Atık Yönetimi.

HOSPITAL WASTE IN THE CONTEXT OF ENVIRONMENTAL SUSTAINABILITY

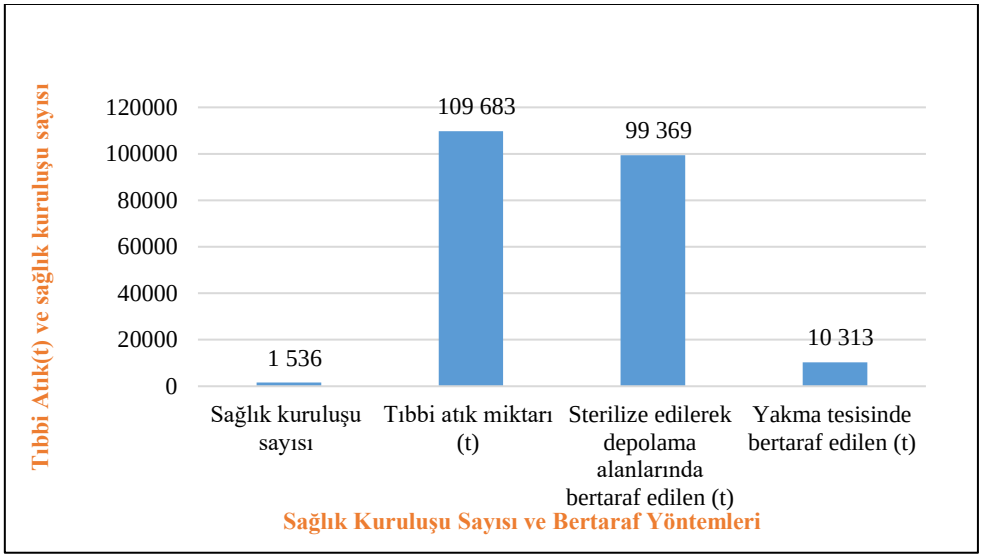
ABSTRACT

Hospitals produce waste that can have significant impacts on the environment while providing healthcare services. This waste can be infectious, chemical, radioactive, or domestic in nature. Medical and hazardous waste, in particular, poses serious risks to both human health and the environment. The concept of environmental sustainability requires that this waste be reduced, collected, transported, separated, and disposed of safely. Waste management processes that are legally compliant, effective, and environmentally friendly contribute to sustainability. Furthermore, promoting recycling practices in hospitals, training staff, and utilizing technological solutions can contribute to both reducing environmental impacts and efficient use of resources. Environmentally friendly technologies, such as green hospital practices and energy recovery systems, are considered promising steps for the future of sustainable healthcare services. In conclusion, the effective and proper management of hospital waste is a fundamental element that not only protects the environment but also serves the long-term sustainability of healthcare systems. This study aims to analyze the impact of hospital waste on ensuring environmental sustainability; it also offers solutions for managing hospital-generated waste.

Keywords: Sustainability, Green Hospital, Hospital Waste, Waste Management.

1.GİRİŞ

Dünya, canlı ve cansız varlıkların birlikte yaşadığı bir ekosistemdir ve bu varlıklar birbirleriyle sürekli etkileşim halindedir. İnsanlar binlerce yıldır bu ekosistemle iç içe yaşamlarını sürdürmüş, ancak zamanla çevre üzerinde önemli etkiler yaratmıştır. Sanayileşme ve fosil yakıt kullanımıyla atmosfere zararlı gazların salınımı artmış, bu da çevre kirliliği ve bozulmasına yol açmıştır. Günümüzde ise hızlı nüfus artışı, aşırı enerji kullanımı ve bilinçsiz kaynak tüketimi nedeniyle insan etkisi küresel boyuta ulaşmıştır(Çilhoroz & Işık, 2018).



Sağlık sektöründe, hastanelerde servis edilen ancak tüketilmeyen gıdalar önemli bir atık kaynağıdır. Bu atıklar hem finansal kayıplara hem de çevresel sorunlara yol açmaktadır. Sağlık kurumlarında gıda atıklarının etkin yönetimi; atık miktarının azaltılması, ihtiyaç sahiplerine dağıtım, hayvan besleme ve kompostlama gibi yöntemlerle sürdürülebilirliği desteklemektedir. Bu bağlamda, sağlık sektöründe çevre dostu ve sürdürülebilir gıda atık yönetimi uygulamalarının geliştirilmesi önem taşımaktadır. Atık yönetimi, küresel, bölgesel, ulusal ve yerel düzeylerde çok katmanlı bir yapıya sahiptir. Dünya üzerinde Basel Sözleşmesi (tehlikeli atıklar vb.), Stockholm Sözleşmesi (kalıcı kirleticiler vb.) ve Minamata Sözleşmesi (civa) gibi uluslararası anlaşmalar ve Dünya Sağlık Örgütü(WHO) gibi uluslararası kuruluşlar bulunmaktadır. Avrupa Birliği ise Yeşil Anlaşma, Döngüsel Ekonomi Eylem Planı ve Plastik Stratejisi gibi direktif ve stratejilerle atıkların yönetimini düzenlemektedir. Bölgesel iş birliği kapsamında ise Batı Balkanlar için ekonomik ve çevresel ortaklık programları geliştirilmiştir. Ulusal düzeyde yasalar, stratejiler, eylem planları ve yönlendirme komiteleri atık yönetiminin temelini oluştururken, yerel topluluklar da sıfır atık sivil toplum kuruluşları, iş sektörü ve bilimsel topluluklar gibi paydaşlarla bu sürece katkı sağlamaktadır. Böylece atık yönetimi, farklı seviyelerdeki iş birliği ve düzenlemelerle bütüncül bir şekilde ele alınmaktadır. Nüfus artışı ve tek kullanımlık ürünlerin yaygınlaşmasıyla sağlık kurumlarında atık miktarı artmıştır. Hastanelerde sürdürülebilirlik için tıbbi ve gıda atıklarının uygun şekilde yönetilmesi önemlidir. “Yeşil hastane” uygulamaları, geri dönüşüm ve yeniden kullanım programları ile desteklenmektedir. Ancak bütçe, bilgi eksikliği ve talep sınırlılığı gibi zorluklar sürdürülebilir gıda tedarikini etkilemektedir. Dünya Sağlık Örgütü'nün 2015 değerlendirmesine göre, sadece sağlık kuruluşların %58’i güvenli atık bertaraf sistemine sahiptir(Çatar et al., 2023).

Tıbbi atık yönetiminde, tıbbi atıkların üretiminden bertarafına kadar olan süreç oldukça karmaşık olduğunu ve bu sürecin doğru yönetimi büyük önem arz etmektedir. Hastane atıklarının sınıflandırılması Şekil 1.’de verilmiştir(Ertaş & Güden, 2019).

Şekil 1. Hastane Atıklarının Sınıflandırılması.

Hastanelerdeki farklı birimlerde oluşan atık türlerinin dağılımı, atık yönetiminin her bölüm için özel olarak ele alınması gerektiğini göstermektedir. Hastane birimlerinde atık türleri yüzdesel dağılımında klinik birimlerden ameliyathane, acil servis, yoğun bakım ve hasta servislerinde en fazla atık kâğıt (%60) ve plastik (%30–35) kaynaklıdır. Diyaliz ünitesinde ise plastik atıkların oranı %85'e kadar çıkmakta, bu da plastik atık yönetiminin burada öncelikli olduğunu göstermektedir. Laboratuvarlarda patolojik atık (%25) ve cam atık (%10) oranları dikkat çekerken, eczanelerde cam atıklar (%20) öne çıkmaktadır. Hemşire odalarında ve hasta servislerinde yine kâğıt ve plastik ağırlıklı atıklar bulunmakta; bunun yanı sıra belirli oranda yiyecek ve cam atık da oluşmaktadır. Araştırma birimlerinde kâğıt (%40), patolojik (%30) ve metal (%20) atıklar ön plandadır. Alet biriminde ise atıkların büyük çoğunluğu plastik (%90) ve metalden (%10) oluşmaktadır. Yazı işleri birimi yalnızca kâğıt (%100) atığı üretirken, kafeteryalarda en fazla yiyecek atığı (%30) oluşmakta, kâğıt ve plastik atıklar ise %20 oranındadır(Ertaş & Güden, 2019). 2020 yılında Türkiye'de tıbbi atık miktarı yaklaşık 110 bin tondur. Bu atıkların büyük çoğunluğu, yani yaklaşık 99,4 bin ton sterilize edilerek depolama alanlarında bertaraf edilmiştir. Yakma tesislerinde bertaraf edilen tıbbi atık miktarı ise yaklaşık 10,3 bin tondur. 2020 Yılı Türkiye'deki sağlık kuruluşlarının tıbbi atık miktarı ve bertaraf yöntemleri Şekil 2.'de verilmiştir(TÜİK, 2020). Atık Yönetimi Yönetmeliği (AYY)'ne göre, atık üreticileri her yıl tıbbi atık beyanlarını Çevre, Şehircilik ve İklim Değişikliği Bakanlığı (ÇŞİDB)'nın Entegre Çevre Bilgi Sistemi üzerinden yer alan Atık Beyan Sistemi (TABS) aracılığıyla yapmaktadır. Ülkemizde 2023 yılında ise yaklaşık 17 bin tesis tarafından yapılan beyanlara göre toplam 130,8 bin ton tıbbi atık oluşmuştur(ÇŞİDB, 2023).

Şekil 2. 2020 Yılı Türkiye'deki Sağlık Kuruluşlarının Tıbbi Atık Miktarı ve Bertaraf Yöntemleri.

Şekil 2.'ye göre Türkiye'de tıbbi atık yönetiminin büyük oranda sterilizasyon ve düzenli depolama yöntemine dayandığını göstermekte olup, bu yöntemin uzun vadeli sürdürülebilirliği sınırlı kalabilmektedir. Bu nedenle, çevreye duyarlı yakma sistemlerinin artırılması, atık üretiminin azaltılması ve geri dönüşüm uygulamalarının yaygınlaştırılması sağlık sektöründe çevresel sürdürülebilirlik açısından kritik öneme sahiptir.

2.ARAŞTIRMA VE BULGULAR

Hastane atıklarının bileşiminin belirlenmesi, sıfır atık konseptinin uygulanmasında kritik bir rol oynamaktadır. Plastik ve kâğıt ağırlıklı atık bileşimi, atıkların azaltılması ve geri dönüştürülmesi yoluyla hastane kalitesinin korunması ve iyileştirilmesine yönelik etkili

yönetim stratejilerinin geliştirilmesini mümkün kılmaktadır. Bir sağlık kuruluşunda sıfır atık yönetim sistemi benimsenmiş ve çeşitli çalışmalar yürütülmektedir. Atık potansiyelinin artırılması, yönetim sisteminin etkinliği ve yaygınlaştırılması için personel eğitim programlarının düzenlenmesi gerekmektedir. Ayrıca, hastanenin tüm birimlerinde tıbbi sarf malzemelerinin ihtiyaca uygun kullanımı sağlanmalı ve atıklar özelliklerine göre ayrıştırılarak geri dönüşüm süreçlerine dahil edilmelidir. Bu yaklaşım, çevresel sürdürülebilirliğin desteklenmesi, doğal kaynakların korunması ve sağlık sektörünün ekolojik ayak izinin azaltılması açısından büyük önem taşımaktadır(Öncel et al.).

Hastanelerde sağlık hizmeti sunumu sırasında oluşan tıbbi atıklar, enfeksiyon ve yaralanma riski açısından diğer atık türlerine kıyasla daha yüksek tehlike arz etmektedir. Bu nedenle, tıbbi atıkların uygun şekilde yönetilmesi hem çevresel sürdürülebilirlik hem de sağlık hizmetlerinin güvenliği ve ekonomik verimliliği açısından kritik öneme sahiptir. Yapılan bir çalışmada, bir eğitim ve araştırma hastanesinde 2019 yılı boyunca üretilen tıbbi atık miktarları, Sağlık Bakanlığı'nın Verimlilik Yerinde Değerlendirme Rehberi kapsamında değerlendirilerek, aylık başvuran hasta sayısı, yatan hasta sayısı, yatak sayısı ve diyaliz seans sayısına göre analiz edilmiştir. Çalışmaya göre, hasta başına günlük 0,17 kg, yatan hasta başına 3,48 kg, yatak başına 1,36 kg ve diyaliz seansı başına 1,19 kg tıbbi atık üretildiği tespit edilmiştir. Ayrıca, bu atıkların bertarafı için yapılan harcama 2019 yılında yaklaşık toplam 1,5 milyon TL harcama yapılmıştır. Sonuçlara göre, iyi bir tıbbi atık yönetimi ile atık miktarının ve maliyetlerin azaltılabileceğini, çevresel, ekonomik ve kurumsal sürdürülebilirliğe katkı sağlanabileceğini göstermektedir(Esen & Çalışkan, 2021).

Tıbbi atıkların yönetimi de ciddi maddi boyutlara ulaşmaktadır. 2024 yılı itibarıyla ülkemizde oluşan tıbbi atıkların toplanması, taşınması ve bertaraf edilmesine ilişkin ücretlendirmeye göre Adana ilinde Yüreğir, Sarıçam, Seyhan, Çukurova, Karaisalı, Ceyhan, Karataş, İmamoğlu, Kozan ve Yumurtalık ilçelerinde bulunan sağlık kuruluşlarından alınan tıbbi atıklar için taşıma ücreti 6,55 TL/kg + KDV, bertaraf ücreti 10,04 TL/kg + KDV olmak üzere toplam 16,59 TL/kg + KDV olarak belirlenmiştir. İl merkezine 81 km ve daha uzak mesafede bulunan Aladağ, Feke, Saimbeyli, Tufanbeyli ve Pozantı ilçelerinde ise taşıma ücreti 7,02 TL/kg + KDV, bertaraf ücreti yine 10,04 TL/kg + KDV olmak üzere toplamda 17,06 TL/kg + KDV olarak uygulanmaktadır. Ayda 0–7 kg arası tıbbi atık üreten sağlık kuruluşlarından taşıma hizmeti için 125,64 TL/ay + KDV, bertaraf hizmeti için 10,04 TL/ay + KDV olmak üzere toplam 135,68 TL/ay + KDV, ayda 8–15 kg arası atık üreten kuruluşlar için ise taşıma ücreti 251,32 TL/ay + KDV, bertaraf ücreti 10,04 TL/ay + KDV olmak üzere toplam 261,36 TL/ay + KDV olarak belirlenmiştir. Tıbbi atık üreten kuruluşlardan çıkan patolojik atıkların, özellikleri gereği yakma yöntemiyle bertaraf edilmesi zorunlu olup, Adana iline en yakın patolojik atık yakma tesisi Ankara ilinde bulunduğundan, bu atıkların Ankara'ya gönderilmektedir. Patolojik atıklar için taşıma ücreti 69,41 TL/kg + KDV olarak belirlenmiş olup, bertaraf ücreti ise Ankara Mahalli Çevre Kurulu (MÇK) tarafından ayrıca belirlenmektedir(ÇŞİDB, 2024).

Şanlıurfa bir devlet hastanesinde yapılan bir çalışmada atık üretimi ve sıfır atık yaklaşımı incelenmiştir. 2021 yılına ait veriler doğrultusunda, hastanede plastik ve kâğıt atıkların toplam miktarı 22,76 ton/yıl, tehlikeli atık miktarı 16,55 ton/yıl ve farmasötik, tıbbi ile enfekte atık miktarları ise 458,34 ton/yıl olarak hesaplanmıştır. Kişi başı enfekte atık miktarı ise 2,42 kg/yatak/gün olarak bulunmuştur. Aynı yıl plastik ve kâğıt atıklarda geri dönüşüm miktarı 22,50 ton/yıl düzeyindedir. Hastanede israfın azaltılması amacıyla çeşitli sıfır atık uygulamaları yürütülmekte olup, bu örnek üzerinden kentteki diğer sağlık kuruluşları için sıfır atık projeksiyonu yapılabileceğini önermektedir.

Hastanelerdeki faaliyetlerden kaynaklanan atık oluşumunu ölçen herhangi bir özel yöntem bulunmamaktadır. Genellikle atık kaynağı mutfak ve mutfak dışı kaynaklar olarak ayrılarak işlem yapılmaktadır. Mevcut hastanedeki toplam günlük atık oranını ve atığın özelliklerini belirlemek amacıyla her yatak başına düşen atık ağırlığının hesaplanması için Denklem1 kullanılır(Öncel et al.).

$$G_A = (T_{TA} + T_{MA})/H_G \qquad \text{Denklem 1}$$

G_A=Günlük Atık oranı(kg/yatak/gün-birim)

T_{TA}=Toplam Tıbbi atık(kg/gün-birim)

T_{MA}=Toplam Mutfak Atığı(kg/gün-birim)

H_G=Geceleyen Hasta Sayısı

Sürdürülebilirlik kavramı 1990'larda inşaat sektöründe ortaya çıkmış ve yeşil yapılar olarak gelişmiştir. Yeşil yapılar; çevreye zarar vermeyen, enerji ve suyu etkin kullanan, daha az malzeme tüketen ve sağlıklı iç ortam sağlayan yapılar olarak tanımlanır. 20. yüzyıl sonunda yapıların toplam malzeme, su ve enerji tüketimindeki yüksek payı, yeşil yapıların önemini artırmıştır. Yeşil yapılar, aşırı kaynak kullanımına ve çevre kirliliğine çözümler sunarken, ekonomik fırsatlar sağlamakta ve insan sağlığı ile verimliliğini desteklemektedir. Yeşil yapıların çevresel performansını değerlendirmek amacıyla çeşitli sertifikalandırma sistemleri geliştirilmiştir. İlk sistem İngiltere'de Building Research Establishment's Environmental Assessment Method (BREEAM- Yapı Araştırma Kurumu Çevresel Değerlendirme Yöntemi) olarak ortaya çıkmış, 1998'de ABD'de Leadership in Environmental and Energy Design (LEED- Çevre ve Enerji Tasarımında Liderlik), Avustralya'daki GREENSTAR gibi birçok sistem ortaya çıkmıştır. Bu sistemlerde enerji ve su verimliliği, iç ortam kalitesi ve yenilikçi malzeme kullanımı gibi kriterler puanlanarak yapılar değerlendirilmektedir(Çilhoroz & Işık, 2018).

Artan nüfus ve doğal kaynak kullanımı çevre sorunlarını ortaya çıkarmış, bu da yeşil yapı ve yeşil hastane kavramlarını doğurmuştur. Ankara'daki hastanelerde yapılan çalışmada, yeşil hastane kriterlerine uygunluk genel olarak %72 civarında bulunmuştur. Hastaneler su yönetimi ve sürdürülebilirlikte başarılı olurken, enerji yönetimi ve malzeme seçiminde eksiklikleri bulunmaktadır. Hastanelerde en çok üretilen atıklar yaklaşık bitkisel atık yağlar 6 bin lt, evsel atıklar 420 t ve 106 t tıbbi atıklardır. En az üretilen atık ise nükleer tıp atığı yaklaşık 6 t olarak belirlenmiştir. Kamu hastanelerinde en çok bitkisel atık yağ yaklaşık 11 bin lt, en az nükleer tıp atığı yaklaşık 10 t üretilirken, özel hastanelerde en çok bitkisel atık yağ yaklaşık 750 lt, radyoloji atık suyu ise hiç üretilmemiştir(Çilhoroz & Işık, 2018).

Tıbbi atıklar, insan sağlığı açısından diğer atıklara göre daha yüksek risk taşımakta ve son yıllarda miktarları artmaktadır. Bu atıkların ayrıştırılması, toplanması ve depolanması maliyetli olduğu için, ekonomik yükün azaltılması ve atıkların kaynağında azaltılması büyük önem taşır. Başarılı bir tıbbi atık yönetimi için iyi bir planlama ve yönetim anlayışı gereklidir. Ayrıca, Birleşmiş Milletler gibi uluslararası platformlarda tıbbi atıkların kaynağında engellenmesi veya azaltılması, mümkün olduğunda geri dönüşümünün sağlanması ve atıkların güvenli bir ortamda işlenip bertaraf edilmesi gibi tedbirler önerilmektedir.

Tıbbi atık minimizasyonu, atık yönetiminde öncelikli hedef olarak atık oluşumunun engellenmesini veya en aza indirilmesini amaçlamaktadır. Bu süreçte "Tıbbi Atıkların Oluşumu Sırasındaki Minimizasyon" aşaması, uzun ömürlü ve tek kullanımlık malzemelerin azaltılmasıyla başlar. "Geri Dönüşüm" başlığı altında, satın alma sürecinde geri dönüştürülebilir malzemelerin tercih edilmesi önerilir. "Karar Alma Süreci'nde ise kimyasal

malzemeler için Malzeme Güvenlik Bilgi Formları talep edilerek daha az tehlikeli ürünlerin seçilmesi hedeflenir. Ayrıca, "Üretimin Planlanması" aşamasında atıkların doğru tanımlanması ve tasnifi için ekipman ve eğitim sağlanması önem taşır. Tüm bu adımlar, atıkların doğru sınıflandırılması ve gereksiz tıbbi atık oluşumunun önlenmesiyle atık miktarının ciddi oranda azaltılmasını sağlamaktadır.

Kaynakta azaltımın temel amacı, malzeme üretimini kontrol altına alarak hem atık minimizasyonu sağlamak hem de maliyetleri düşürmektir. Bu kapsamda tüm hastane personelinin eğitimleri, atık azaltmaya yönelik sistemlerinin geliştirilmesi ve daha az tehlikeli maddelerin kullanılması önemli yöntemler arasında yer almaktadır. Ayırma işlemi ise atıkların cinslerine göre ayrı toplanmasını sağlayarak atık miktarının ve hacminin azalmasına katkı sağlamaktadır. Bu süreçte atık tipi, yeniden kullanım ve geri dönüşüm durumu dikkate alınmalı, tüm sağlık çalışanları ve üreticiler sürece dahil edilmelidir. Özellikle tıbbi atıkların ayrıştırılmasında, iğneler, kanla kontamine malzemeler, cerrahi atıklar ve insan ile hayvan kaynaklı atıklar titizlikle belirlenip ayrıştırılmalıdır. Geri dönüşüm ve yeniden kullanımda ise, cerrahi aletler başta olmak üzere uygun malzemeler sterilize edilerek tekrar kullanılır; sterilizasyonun doğru yapılması enfeksiyon riskini önler. Ayrıca, tehlikesiz ambalaj ve kaplar ile diyaliz suyu kapları gibi malzemeler de geri dönüşüm tesislerinde işlenmektedir.

Hastanede oluşan tıbbi atıkların bertaraf edilmesinin temel amacı, atıkların zararlı etkilerine önlem alarak ve çevre sağlığını koruyarak tehlikesiz hale getirmektir. Bertaraf yöntemleri, atığın türüne göre farklılık göstermekte olup, çeşitli kimyasal, termal teknikler uygulanmaktadır. Kimyasal bertaraf yönteminde kesici aletlerde O_3, NaOCl gibi etken maddeler kullanılarak tıbbi atıkların dezenfeksiyonu sağlanmaktadır. Termal bertaraf yöntemleri ise düşük ve yüksek ısıl işlemler olarak uygulanmakta; düşük ısıl işlemde otoklavlama ile buhar kullanılırken, yüksek ısıl işlemde yakma işlemi yapılmaktadır. Mekanik işlemler atıkların sıkıştırılması ve parçalanması gibi fiziksel yöntemlerle atık hacmini azaltmakta, ancak patojenleri yok etmemektedir. Işınlama yöntemleri elektromanyetik radyasyon kullanarak patojenleri imha eder ancak yüksek risk taşımaktadır. Biyolojik süreçte organik atıkların ayrıştırılması için sindirim enzimleri ve kompostlama yöntemleri uygulanmaktadır. Yakma ise yüksek sıcaklıkta (1000-2000°C) gerçekleşen ve kullanım süresi dolmuş tehlikeli atıkların oksidasyon yoluyla bertaraf edilmesidir; bu süreç dikkatle denetlenmelidir çünkü zararlı kimyasal reaksiyonlar oluşabilmektedir(Ertaş & Güden, 2019). Şekil 3.'te Atık yönetimi hiyerarşisi verilmiştir(Tripathi et al., 2022).

Şekil 3. Atık Yönetimi Hiyerarşisi.

Atık yönetiminde çevresel etkileri azaltmak ve kaynak verimliliğini artırmak amacıyla 3-R (Azaltma, Yeniden Kullanım ve Geri Dönüşüm) ilkelerine dayalı atık yönetimi hiyerarşine göre, atık oluşumunu önleme ve atıkların çevreye zarar vermeyecek şekilde yönetilmesini sağlama hedefini taşımaktadır. Azaltma, hiyerarşinin en üstünde yer alır ve atığın kaynağında oluşmasının engellenmesini, yeniden kullanım ömrü tamamlanmamış ürünlerin tekrar değerlendirilmesini, geri dönüşüm ise atığın işlenerek tekrar ham madde veya ürün olarak ekonomiye kazandırılmasını içermektedir. Bu sıralama, çevresel kazancın en fazla olduğu uygulamadan en az etkili olana doğru bir önceliklendirme sağlamaktadır(Tripathi et al., 2022).

Yapılan bir çalışmaya göre, hastane atıklarının yönetiminde yerinde buhar sterilizasyonu ile gazlaştırma teknolojisinin kullanımı, çevresel sürdürülebilirlik açısından etkili bir alternatif sunmaktadır. Avustralya hastanelerinde gerçekleştirilen değerlendirmede, hastane atıklarının büyük kısmını genel atıkların (%84,8), küçük bir kısmını ise klinik atıkların (%6,9) oluşturduğu belirlenmiştir. Genel atıkların çoğunluğu plastik (%74,5) ve kâğıt/karton (%13,4) gibi geri dönüştürülebilir malzemelerden oluşmaktadır. Gazlaştırma yöntemiyle bu atıkların işlenmesinin, çöp sahalarına gönderilen atık miktarını ve atık taşımacılığı ile yakma işlemlerinden kaynaklanan emisyonları %95,9 oranında azaltabileceği ortaya konmuştur. Ayrıca bu yöntem, çöp sahalarının kullanım ömrünü uzatmakta ve geri dönüşüm potansiyelini artırmaktadır. 2019/2020 verilerine göre Avustralya hastanelerinde yılda yaklaşık 230.717 ton atık üretildiği göz önünde bulundurulduğunda, bu çalışmada önerilen sistemin uygulanabilirliği ve çevresel faydaları büyük önem taşımaktadır. Bu bulgular, hastane atık yönetiminde daha döngüsel ve çevre dostu yaklaşımların benimsenmesine katkı sağlayabilir(Harris & McCabe, 2024). Tıbbi atıklar sağlık hizmetleri sırasında ortaya çıkan ve tehlikeli ile tehlikesiz olarak sınıflandırılan çeşitli materyalleri içermektedir. Bangladeş'in Dakka şehrindeki iki hastanesinde yapılan çalışmaya göre, sağlık çalışanlarının tıbbi atık yönetimi konusunda çalışanların eğitimi ve bilinçlendirilmesi gerektiğini belirtmişlerdir. Toplam atığın yaklaşık %15'inin tehlikeli olduğu ve bu atıkların uygun şekilde bertaraf edilmemesi halinde hem iş sağlığı ve güvenliği

açısından ciddi riskler oluşturduğu hem de çevre kirliliğine yol açtığı vurgulanmıştır. Özellikle sağlık çalışanlarının, kontamine iğne batması gibi yaralanmalar nedeniyle kan yoluyla bulaşan patojenlere maruz kalma riski oldukça yüksek olduğunu belirtmişlerdir. Bu durum, tıbbi atıkların doğru yönetiminin halk sağlığı ve çevre güvenliği açısından kritik önem taşıdığını göstermektedir(Islam et al., 2025).

3.SONUÇ

Hastaneler, teknolojik gelişmeler ve artan sağlık ihtiyaçları nedeniyle giderek daha fazla başvuru alan, yoğun kullanılan sağlık kurumlarıdır. Bu hizmet sürecinde çeşitli türlerde atıklar oluşur. Artan tıbbi faaliyetlere paralel olarak bu atıkların miktarı ve çeşitliliği de sürekli artmaktadır. Hastanelerde oluşan atıklar; evsel (genel) atıklar, tıbbi/patolojik/enfekte atıklar, kimyasal atıklar ve radyoaktif atıklar olmak üzere dört ana gruba ayrılır. Dünya Sağlık Örgütü'ne göre bu atıkların yaklaşık %80'i evsel, %15'i enfekte-patolojik, %1'i kesici-delici ve %4'ü farmasötik atıklardır.

Türkiye'de hastaneler, "Tıbbi Atıkların Kontrolü Yönetmeliği (TAKY)" çerçevesinde atıkları kaynağında ayrıştırmak, toplamak, depolamak ve azaltmakla yükümlüdür. Bu sürecin etkili bir şekilde yürütülebilmesi için sağlık çalışanlarının bilgi ve tutumu büyük önem taşımaktadır. TAKY ile tıbbi atıkların kontrollü bir şekilde toplanması, taşınması ve bertarafı yasal zorunluluk haline gelmiştir. Bu sürecin etkin yürütülebilmesi için, atıkların kaynağında ayrıştırılması ve kurumsal düzeyde atık yönetimi kültürünün geliştirilmesi gerekmektedir(İncesu & Evirgen, 2017).

Bangalore şehrindeki diş hekimliği eğitim hastanelerinde yapılan çalışmaya göre, artan kentleşmenin sağlık sektöründe yol açtığı olumlu gelişmelerin yanında, biyomedikal atıkların uygunsuz yönetimi çevresel ve halk sağlığı açısından ciddi tehditler oluşturmaktadır. Özellikle hastane personelinin atık yönetimi konusunda eğitimsiz olması, sorunun derinleşmesine neden olmaktadır. Personelin hastane atık yönetimi konusunda bir günlük eğitim programı uygulanmıştır. Eğitimin ardından katılımcıların bilgi düzeylerinde anlamlı iyileşmeler kaydedilmiştir. Eğitim programlarının hastane atık yönetiminde bilgi ve farkındalığı artırmada etkili olduğunu göstermektedir. Ayrıca, uygun atık yönetimi uygulamalarının yaygınlaştırılabilmesi için sağlık kuruluşlarında eğitimlerin düzenli ve sistematik olarak sunulmasının gerekliliği vurgulanmaktadır(Rudraswamy, 2014). Endonezya'daki hastanelerde yapılan çalışmaya göre, sıvı tıbbi atık yönetimi konusunda uyum düzeyini etkileyen faktörler net olarak belirlenememektedir ve bu alanda kanıta dayalı veriye ihtiyaç duyulmaktadır. 2017–2023 yılları arasındaki literatür taramasıyla yapılan bu sistematik inceleme, hastanelerde tehlikeli atık yönetimine yönelik mevcut uygulamaların değerlendirilmesini ve yönetmeliklere uyumu etkileyen belirleyicilerin haritalandırılmasını amaçlamıştır. Çalışma kapsamında incelenen makalelerden biri yönetmeliklere uyumu, diğeri ise atık yönetiminin denetimini ele almakta; ancak her iki çalışma da denetim süreçlerini yeterince ayrıntılı olarak açıklamamaktadır. Bu durum, hastane atık yönetimi süreçlerinin etkinliğini değerlendirmek ve sonuçlarını iyileştirmek için denetim mekanizmalarının güçlendirilmesi gerektiğine işaret etmektedir. Araştırma sonuçları, yönergelere uyumun sadece yasal bir zorunluluk değil, aynı zamanda halk sağlığı ve çevreyi koruma açısından da bir alışkanlık haline getirilmesi gerektiğini vurgulamaktadır. Etkin ve sürekli iyileştirme odaklı bir denetim sistemi, hastanelerdeki atık yönetim süreçlerinin sürdürülebilirliğini sağlamada kritik bir rol oynamaktadır(Kaban et al., 2025).

Turgutlu Devlet Hastanesi'nde yapılan bir çalışmaya göre, sağlık tesislerinde önemli bir sorun olarak ortaya çıkan konulardan biri tıbbi atıkların etkin yönetimidir. Sağlık kuruluşlarında oluşan atıkların büyük bir kısmını tıbbi atıklar oluşturmaktadır. Enfeksiyon kontrol ve tesis güvenliği komitelerinin aylık analizlerinde atık miktarında belirgin bir artış gözlemlenmiş, bu durum etkili bir atık yönetim planının gerekliliğini ortaya koymuştur. Bu bağlamda gerçekleştirilen çalışmada, Turgutlu İlçe Devlet Hastanesi'nde görev yapan sağlık personelinin tıbbi atık yönetimi konusundaki bilgi düzeylerini, algılarını ve uygulama yeterliliklerini değerlendirmek; elde edilen sonuçlar doğrultusunda eğitim programları oluşturmak ve maliyet etkin bir atık yönetim planı geliştirmek amaçlanmıştır(Yazgan et al., 2014). İzmir Urla Devlet Hastanesi'nde yapılan bir çalışmada, görev yapan 170 sağlık çalışanının tıbbi atıkların toplanması, taşınması, depolanması ve işleme tesisine güvenli ulaştırılması konusundaki bilgi düzeyleri incelenmiştir. Hastane çalışanlarının tıbbi atıklar konusundaki doğru bilgi oranı ortalama %86 olarak bulunmuş olup, sağlık çalışanlarına tıbbi atık yönetimi konusunda düzenli eğitim verilmesi ve belirli aralıklarla denetim yapılmasının, atık yönetimi farkındalığını artırarak uygulamaların etkinliğini yükselteceğini vurgulamaktadır(Şahin & Yiğit, 2024). Nevşehir ve Kayseri illerinde yapılan bir çalışmada, en az 20 yatak kapasitesine sahip dört özel hastane araştırılmıştır. Bu hastanelerde toplam yaklaşık 1338 personel çalışmakta olup, günlük tıbbi atık miktarı incelenmiştir. Araştırma sonuçlarına göre, iki hastanede günlük ortalama tıbbi atık miktarı 60 kg civarında iken, diğer iki hastanede yaklaşık 135 kg olarak belirlenmiştir. Bu veriler, hastanelerdeki tıbbi atık üretiminin önemli seviyelerde olduğunu göstermekte ve tıbbi atık yönetim uygulamalarının yeterince etkin ve başarılı olmadığını ortaya koymuştur. Bu sonuçlar, sağlık kurumlarında atık yönetiminin geliştirilmesi ve iyileştirilmesi gerekliliğini göstermektedir(Cingöz & Tinni, 2020).

Yeşil binalar, doğa dostu teknolojileri bünyesinde barındırarak israfı azaltmakta, ısıtma-soğutma maliyetlerini düşürerek sağlıklı çevre ortamları sağlamaktadır. Bu binaların bakımından da maliyet ve zaman tasarrufu sağlanmakta, hava kalitesini iyileştirmektedir. Ayrıca, yeşil bina standartlarına yapılan yatırımlar uzun vadede mülk değerini artırmakta, enerji verimliliği sağlamakta ve enerji yasalarına uyumu teşvik etmektedir. Amerika'da yerel ve federal düzeyde yeşil bina yapımına yönelik vergi teşvikleri de bulunmaktadır. Yeşil bina uygulamaları, yeni inşaatlar, yenilemeler, okul binaları, kentsel dönüşüm projeleri ve özellikle sağlık kuruluşlarında yaygınlaşmaktadır. Yeşil hastane" kavramı, çevre dostu yerleşim seçiminden sürdürülebilir tasarımlara, doğa dostu malzeme kullanımından inşaat ve hizmet süreçlerinde çevre duyarlılığına kadar çeşitli çevresel kriterleri karşılayan sağlık tesislerini ifade etmektedir. Bu hastaneler, geri dönüşüm uygulamalarıyla atık miktarını azaltmakta ve çevreye daha temiz hava sağlamaktadır. Yeşil hastanelerde uygulanan çevresel ve sağlık odaklı prensiplerin, tesis planlama, tasarım, inşa ve bakım süreçlerine entegre edilmesi maddi ve manevi birçok fayda sunmaktadır. Yapılan araştırmalar, yeşil hastanelerde yatan hastaların duygusal açıdan daha iyi durumda olduğunu, daha az ağrı kesici kullandığını ve daha kısa sürede taburcu edildiğini göstermektedir. Bu nedenle, sağlık kurumları için yeşil stratejilerin geliştirilmesi ve uygulanması önem taşımaktadır(Terekli et al., 2013).

Ermenek Devlet Hastanesi'nde yapılan bir araştırmada sıfır atık yönetimi uygulamaları ile toplanan tıbbi atıkların yıllara, aylara, birimlere, yatan hasta sayısına, maliyete ve atık türlerine göre dağılımı incelenmiştir. 2013–2024 yılları arasında toplam yaklaşık 139 bin kg tıbbi atık toplanmış; en fazla atık 2023 yılında yaklaşık 19 bin kg, en az atık ise 2013 yılında yaklaşık 3 bin kg olarak tespit edilmiştir. 2017–2023 yılları arasında birim bazında en fazla tıbbi atık yaklaşık 21 bin kg ile diyaliz biriminde, en az atık ise 133 kg ile palyatif ünitede oluşmuştur. 2014–2024 yılları arasında hastanede yaklaşık 29 bin hasta yatarak tedavi görmüş, hasta başına düşen en yüksek tıbbi atık oranı ise 2021 yılında yaklaşık 12 kg olarak hesaplanmıştır. 2022–

2024 yılları arasında toplanan atıkların toplam maliyeti yaklaşık 560 bin TL olarak gerçekleşmiştir(Çataltaş, 2024).

Hastane atıkların yönetimi için Dünya Sağlık Örgütü'ne (WHO) göre olması gereken önlemlerden biri atıklar hasta odalarından başlayarak toplanmalıdır. Evsel atıklar ile tıbbi atıklar asla karıştırılmamalıdır. Hastane atıkları uygun atık taşıma araçlarıyla taşınmalı, bu araçların düzenli dezenfekte edilmesi sağlanmalıdır. Tehlikeli atıklar, uzman firmalarca bertaraf edilmelidir. Radyoaktif ve kimyasal atıklar için güvenli depolama alanları oluşturulmalıdır. Hastanede atık yönetimi planları, sağlık kuruluşlarının kuruluş aşamasında tamamlanmalıdır. Hastane atık miktarları, hasta sayısına göre planlanmalı, atıklar türlerine göre ayrıştırılmalıdır. Büyük hastaneler kendi bertaraf yöntemlerini uygulayabilirken, küçük sağlık kuruluşları için ortak bertarafı sağlanmalıdır. Hastanelerin atık yönetiminde kullanılan araç ve gereçlerin, mevzuat hükümlerine uygun olması gerekmektedir. Hastane atık yönetiminde amaç, sağlık ve çevre risklerini en aza indirmektir(Ertaş & Güden, 2019).

Tıbbi atıklar, hastane ve laboratuvarlarda oluşan enfeksiyöz, kimyasal ve radyoaktif atıklardır. Sağlık kuruluşlarındaki atıkların çoğu (%75-80) evsel, sadece %5-10'u enfeksiyözdür. Atıkların kaynağında ayrılması önemlidir çünkü enfeksiyöz atıkların bertaraf maliyeti evsel atıklardan daha yüksektir. Sağlık kurumlarında tıbbi atıkların doğru yönetimi için etkili bir atık yönetimi planı ve hastane personeline düzenli eğitimler gereklidir.

Etkili hastane atık yönetiminin önemli adımlarından biri atıkların azaltılmasıdır. Geri kazanılabilir atıklar için uygun poşet eksikliği tespit edilerek çalışmalar başlatılmalıdır. Atıkların doğru kovaya atılması için sağlık personeline bilgilendirici yazılar asılmış ve eğitimler planlanmalıdır. Hastanelerde sürdürülebilir atık yönetimi için periyodik eğitimler ve yeterli bütçe gereklidir(İncesu & Evirgen, 2017).

Abstract

Lanthanum based scheelite-type oxides have recently attracted attention for their luminescence and thermal conduction properties. These studies mainly focused on the undoped $La_2Mo_3O_{12}$ for thermal conductivity and lanthanide doped (Eu, Dy, Sm etc.) $La_2Mo_3O_{12}$ for luminescence applications of the material. In this study, Ba doped (≤5%) $La_2Mo_3O_{12}$ was prepared using a co-precipitation and calcination approach. The structure of the samples was studied by XRD and SEM, and UV-Vis spectroscopy and photoluminescence measurements were carried out to investigate the optical properties. XRD results showed that single phase Ba doped samples could be synthesised with a simple approach. The samples had a monoclinic structure with space group C2/c. SEM results showed that the particle size was unaffected up to 2.5 mol% Ba doping and decreased with further doping. SEM micrographs showed that the particles had sphere-like irregular shapes with ~1 μm diameter, which was mostly unaffected by doing. SEM-EDS results revealed the homogeneous distribution of La, Mo, Ba and O elements in the samples. Optical band gap, E_g values were calculated from the UV-vis spectroscopy data using Tauc relationship given by $(\alpha hv)^n = A(hv-E_g)$. The results showed that E_g was 3.03-3.32 eV for the samples with undoped sample having the smallest and 2.5 mol% Ba doped sample having the largest E_g. The excitation and emission spectra of the samples were recorded and the results showed that the emission intensity was increased up to 2.5 mol% Ba doping and decreased with further doping due to concentration quenching effect. The results showed that Ba could be utilised similar so alkali ions to increase the photoluminescence intensity of $La_2Mo_3O_{12}$.

Keywords: $La_2Mo_3O_{12}$, Ba doping, structural properties, optical properties

Introduction

Rare earth molybdates has attracted attention due to their optical, magnetic and catalytic properties (Chen et al., 2008). In this regard, $La_2Mo_3O_{12}$ has garnered attention from researchers due to the modification of their morphology, chemical and physical properties with different production strategies and doping approaches. $La_2Mo_3O_{12}$ powders can be synthesized by solid state reaction of raw oxide powders (X. Li et al., 2020; Q. Ma et al., 2023; Parauha et al., 2020), hydrothermal method (Chen et al., 2008; F. Li et al., 2017; M.-G. Ma et al., 2014), facile cyclic microwave radiation method (Keereeta et al., 2012), co-precipitation and calcination approach (Gajraj & Mariappan, 2020; Velchuri et al., 2015) and self-energetic mechano-chemical reaction method (Krishnan & Swart, 2021). It is investigated as microwave dielectric ceramics (Pang et al., 2011), anode material for lithium ion batteries (Jiang et al., 2019), electrodes for supercapacitors (Gajraj & Mariappan, 2020; Mona et al., 2025) and phosphors (Ankoji et al., 2021; Parauha et al., 2020; Satheesh et al., 2023). Among these applications, the most prominent application appears to be as a phosphor candidate since it was reported that upon excitation by UV light, an intense red, green and blue light downconversion photoluminescence emission could be achieved with Eu^{3+}, Tb^{3+}, and Tm^{3+} ions, respectively (N. Li et al., 2014; Zhang & Yu, 2016). Moreover, wide optical band gap and low phonon energy of $La_2Mo_3O_{12}$ leads to its strong photoluminescence characteristics and in combination with its high structural, physical and chemical stability this makes it an attractive candidate for phosphor applications (Ankoji et al., 2021). Furthermore, it was shown that upconversion photoluminescence intensity of oxides could also be efficiently improved by alkali ions (Maurya et al., 2018).

In this study, undoped and Ba-doped (≤5 mol%) $La_2Mo_3O_{12}$ powders were synthesized using a co-precipitation and calcination approach. XRD and SEM results confirmed the single-phase and homogeneous nature of the powders. There was limited change in both the crystallite size and the optical band gap values with doping levels up to 2.5 mol%. Further increasing the dopant level led to a decrease in both. Upon doping with Ba, no bands corresponding to f-f transitions , which is frequently seen with lanthanide doping, was observed. However, similar to doping with alkaline ions, an increase in the photoluminescence intensity was observed with increasing Ba doping level and doping levels above 5 mol% led to a decrease in the intensity due to the quenching effect.

Materials and Methods

$La_2Mo_3O_{12}$ powders were prepared by the calcination of the co-precipitated powders by procedure illustrated in Figure 1. For the co-precipitation procedure two separate solutions were initially prepared. Solution A was prepared by dissolving $La(NO_3)_3.6H_2O$ (Merck, ≥96%) in 60 ml deionised water and solution B was prepared after dissolving $Na_2MoO_4.2H_2O$ (KİMYALAB, 99.6%) in 90 ml deionised water. Then, solution A was added to solution B dropwise over 30 minutes using a separatory funnel. Next, the final mixture was magnetically stirred for 2 hours at room temperature. Afterwards, precipitant was filtered and washed 3 times with deionised water and once with ethanol, and the product was dried in an oven at 75 °C in air overnight. Finally, the powders were calcined in air at 1100 K for 8 hours using a muffle furnace. For the Ba doped samples, the amount of $La(NO_3)_3.6H_2O$ and $Ba(NO_3)_2$ (TEKKİM, ≥99%) was adjusted according to the doping levels (0, 0.5, 1, 2.5 and 5 mol%) during the preparation of solution A and the same procedure was followed for all the samples. The samples were labelled as LMO, LMO-0.5Ba, LMO-1.0Ba, LMO-2.5Ba and LMO-5.0Ba for undoped, 0.5, 1, 2.5 and 5 mol% Ba doped samples, respectively.

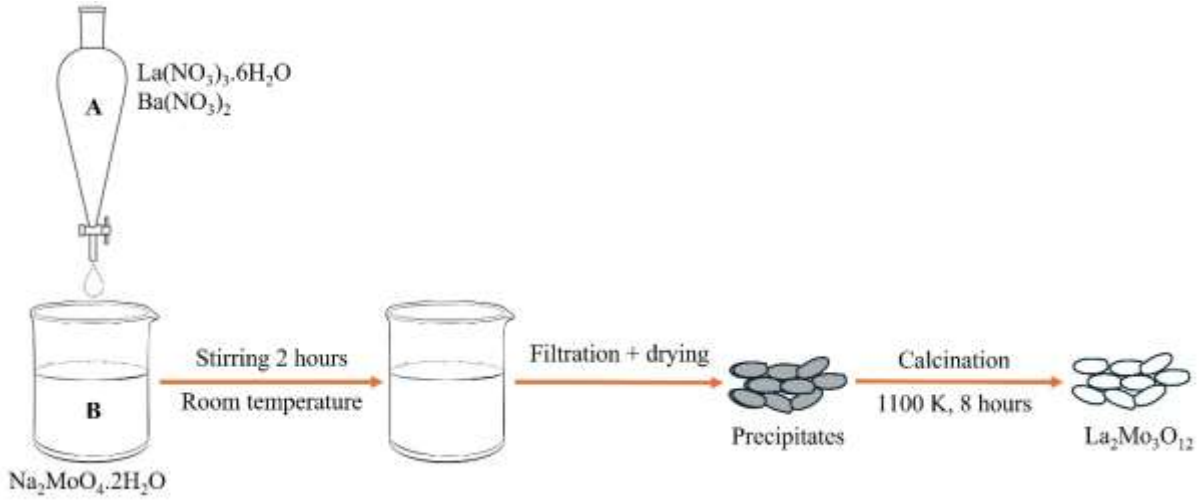

Figure 1 Schematic illustration of the preparation procedure for undoped and Ba-doped $La_2Mo_3O_{12}$ powders.

For the structural characterisation, X-ray diffraction (XRD) data was collected 20°-90° range with a step size of 0.05 °/s using a Malvern Panalytical EMPYREAN diffractometer with a Cu source ($\lambda_{Cu-K\alpha}$ = 1.540598 Å). The morphology and chemistry of the samples were analysed using Thermo Fisher Scientific Apreo S SEM fitted with X-ray spectroscopy detector (EDS). Diffuse reflectance spectrum for the samples was collected between 200-800 nm with a SHIMADZU UV-2600i UV-Vis Spectrophotometer. Finally, excitation and emission spectrums were measured with an Edinburgh Instruments FLSP920 Fluorescence Spectrometer.

Results and Discussion

XRD patterns of undoped and Ba doped $La_2Mo_3O_{12}$ (0, 0.5, 1, 2.5 and 5 mol%) powders are presented in Figure 2. The obtained patterns are in agreement with the structure of $La_2Mo_3O_{12}$ (JCPDS No. 70–1382). They have a monoclinic structure with C2/c space group and this structure is made of MoO_4 and LaO_8 tetrahedra (He et al., 2022). No additional peaks were observed upon doping with Ba, suggesting that the samples were single phase and Ba was successfully doped. The full width at half maximum (FWHM) value for the most intense XRD peaks were used to determine the change in the crystallite size with doping using Debye-Scherrer equation (see Equation 1); where, D is the crystallite size, K is a dimensionless shape factor and was taken as 0.9, B is FWHM of the peak and θ is the Bragg angle. The crystallite size of the samples is given in Table 1. The crystallite size was 41.7 nm for LMO sample and slightly increased to 42.4 nm with 2.5 mol% Ba doping. However, it decreased noticeably to 34.2 nm when Ba doping level was 5 mol%.

$$D = \frac{K\lambda}{B\cos\theta} \quad (1)$$

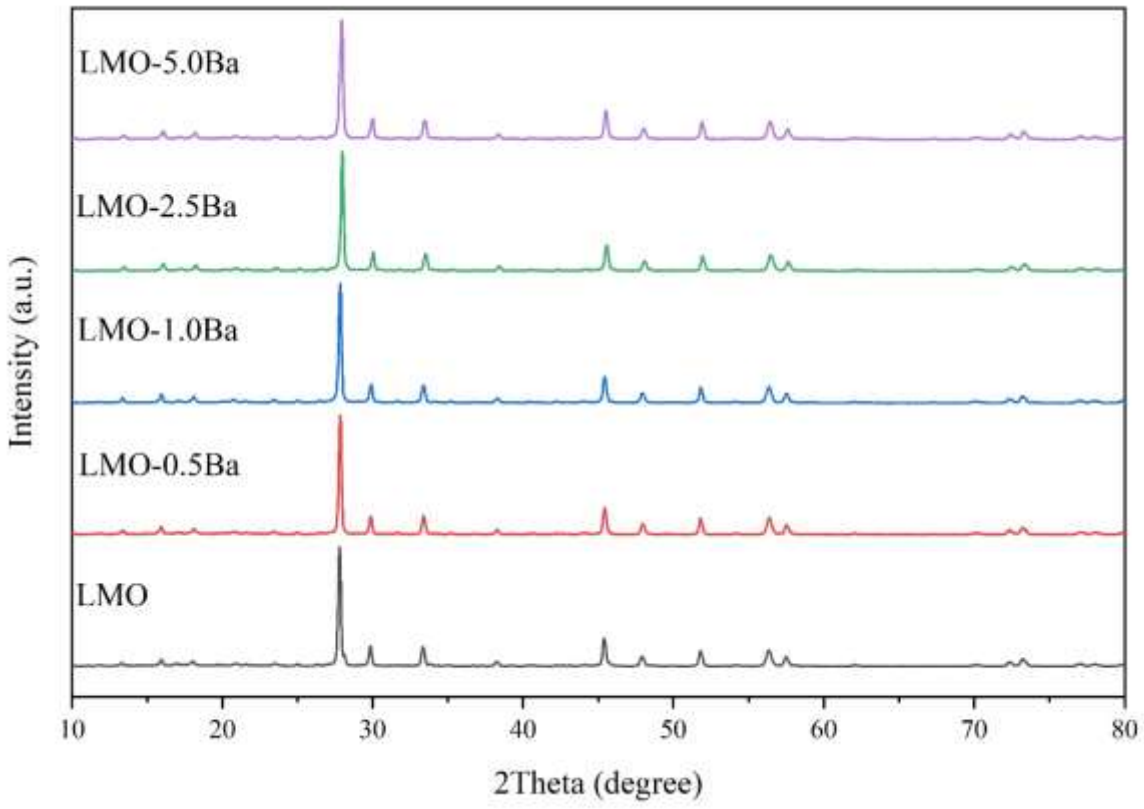

Figure 2 XRD patterns of undoped and Ba doped $La_2Mo_3O_{12}$ (0, 0.5, 1, 2.5 and 5 mol%) powders

Table 1 Crystallite sizes which were calculated using Debye-Scherrer equation for $La_2Mo_3O_{12}$ powders

Sample	Crystallite size (nm)
LMO	41.7
LMO-0.5Ba	42.7
LMO-1.0Ba	41.2
LMO-2.5Ba	42.4
LMO-5.0Ba	34.2

Figure 3 shows the evolution of the morphology for the undoped and Ba doped $La_2Mo_3O_{12}$ powders. It can be seen from the figure that all the samples were made of aggregates that are made of particles with irregular shapes. Moreover, these agglomerates consisted of both submicron and micron scale particles. The morphology of the samples is quite similar to Eu doped $La_2Mo_3O_{12}$ powder that were prepared by the solid state reaction of La_2O_3, H_2MoO_4 and Eu_2O_3 (Q. Ma et al., 2023). Such morphology is characteristic for $La_2Mo_3O_{12}$ powders that are prepared via solid state reaction of raw powders or calcination of co-precipitates at 873-1223 K range (Gajraj & Mariappan, 2020; He et al., 2022; X. Li et al., 2020; Q. Ma et al., 2023; Song et al., 2018; Tian et al., 2011).

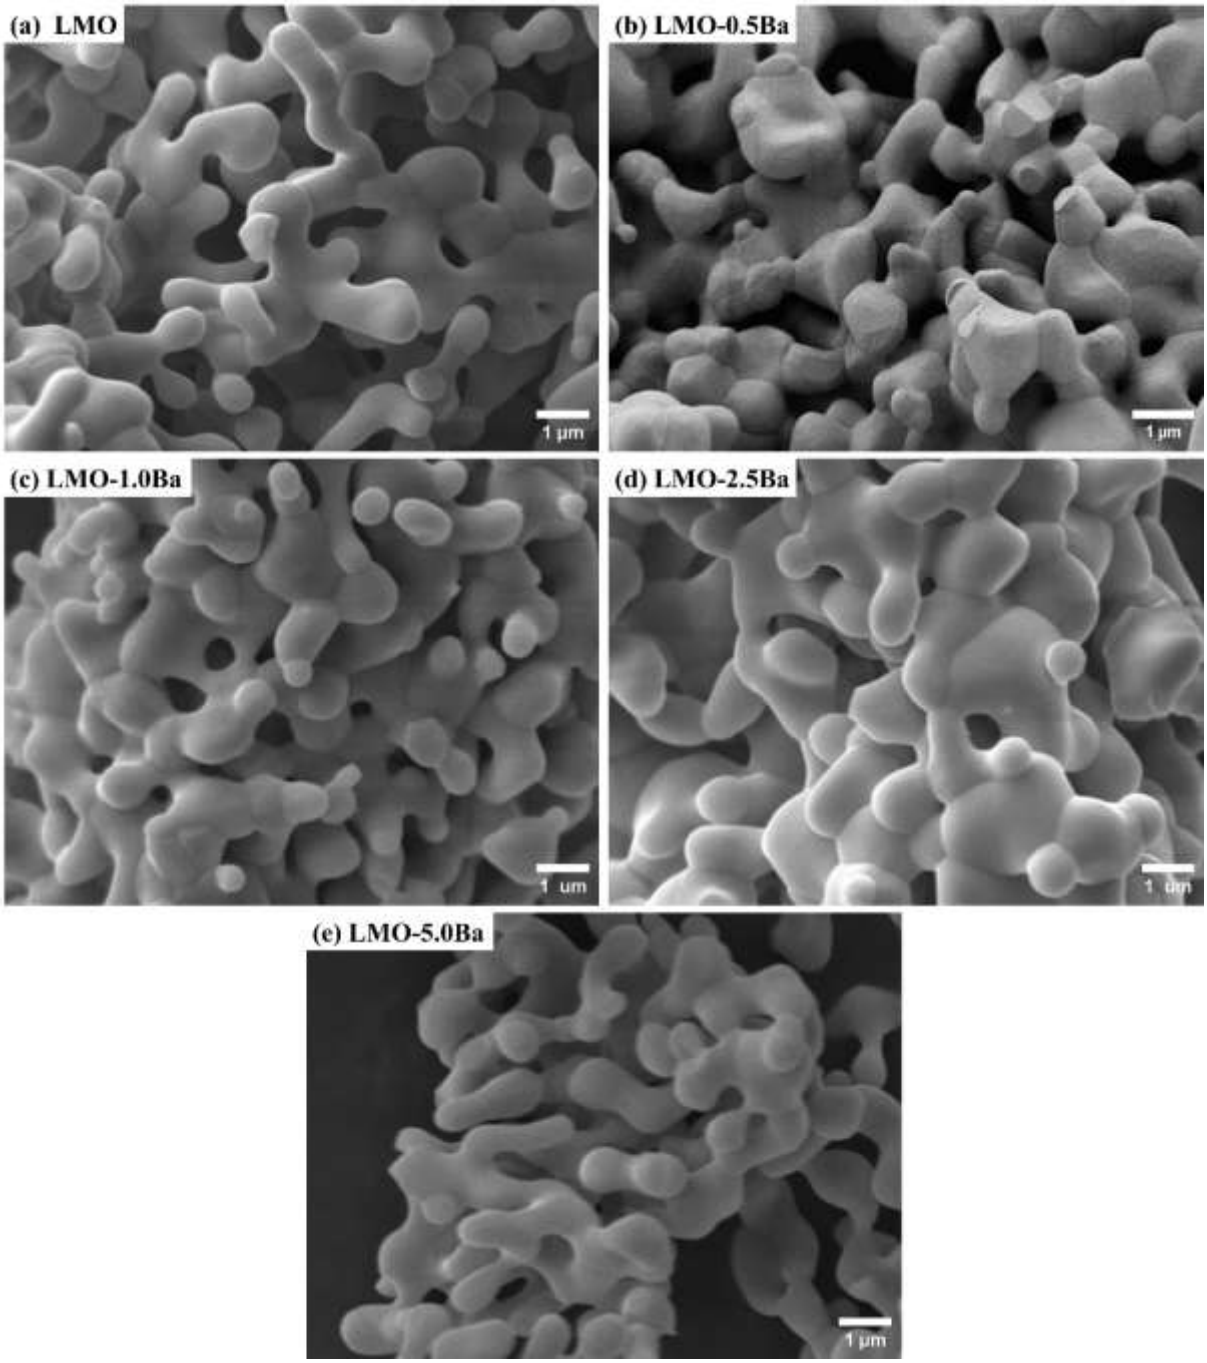

Figure 3 SEM images of $La_2Mo_3O_{12}$ powders: (a) LMO, (b) LMO-0.5Ba, (c) LMO-1.0Ba, (d) LMO-2.5Ba and (e) LMO-5.0Ba.

Figure 4 shows La, Mo and O elemental EDS maps for LMO sample. SEM-EDS mapping results showed that the sample was chemically homogeneous since La, Mo and O distribution was uniform within the sample. Moreover, uniform distribution of La, Mo, O and Ba was observed for the Ba-doped $La_2Mo_3O_{12}$ powders which suggests that the no secondary phase was present. This was in agreement with the XRD results where no peaks regarding to a secondary phase was present. Thus, it can be concluded that co-precipitation and calcination route can be utilised for the preparation of Ba-doped $La_2Mo_3O_{12}$ powders.

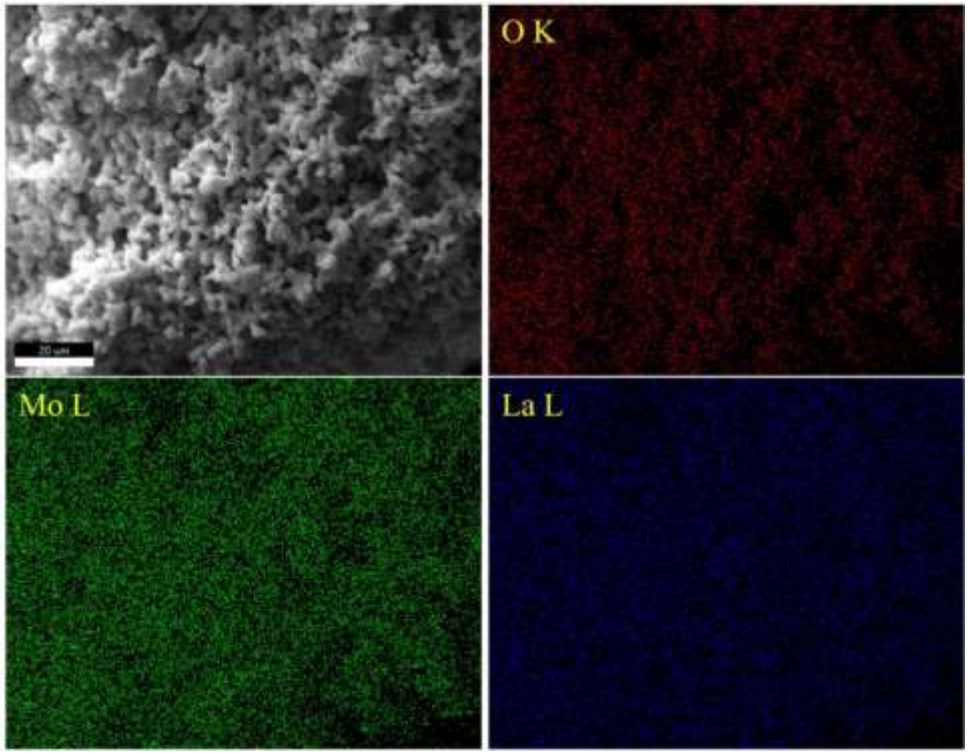

Figure 4 SEM-EDS La, Mo and O elemental maps for LMO sample.

Diffuse reflectance spectrum for the undoped and Ba doped $La_2Mo_3O_{12}$ (0, 0.5, 1, 2.5 and 5 mol%) powders are presented in Figure 5a. The reflectance spectra of the samples were quite similar with and band edge absorption near 300-330 nm, which is related to the band gap of the samples. The excitation of electrons from the valance band to the conduction band leads to this absorption edge (Hwang et al., 2003; Velchuri et al., 2015). Typically, absorption bands related to the f-f electronic transitions of lanthanide ions is observed in 400-900 nm range, but such bands are not reported for undoped $La_2Mo_3O_{12}$ since its f orbitals are unoccupied (Satheesh et al., 2023; Stankeviciute & Zalga, 2014; Velchuri et al., 2015; Wang et al., 2021). Moreover, doping with Ba did not lead to the appearance of any absorption bands suggesting that the electronic transitions observed with lanthanide doping was absent in the Ba-doped samples. Tauc relationship given by Equation 2 was used to estimate the optical band gap values for the samples. In this equation, α, $h\nu$, A, E_g represent absorption coefficient, photon energy, a material constant and the band-gap energy (eV), respectively. Moreover, n is taken as either 1/2 or 2 for indirect and direct band gap, respectively (Makuła et al., 2018).

$$(\alpha h\nu)^n = A(h\nu - E_g) \quad (2)$$

Here, n was taken as 2 for the estimation of E_g (Satheesh et al., 2023) and E_g values was determined by extrapolation of the linear section of Tauc plot as shown in Figure 5b. The estimated band gap values are also presented in Table 2. The band gap value for LMO was 3.03 eV and was lower than the reported values in literature (Masuno et al., 2024; Satheesh et al., 2023; Velchuri et al., 2015). Moreover, it slightly increased to 3.32 eV with 2.5 mol% Ba doping and increasing the dopant level to 5 mol% led to a decrease in E_g to 3.09 eV. Such behaviour is explained by Burstein-Moss effect (Burstein, 1954) and also observed for $La_2Mo_3O_{12}$ samples doped with Sm (Satheesh et al., 2023).

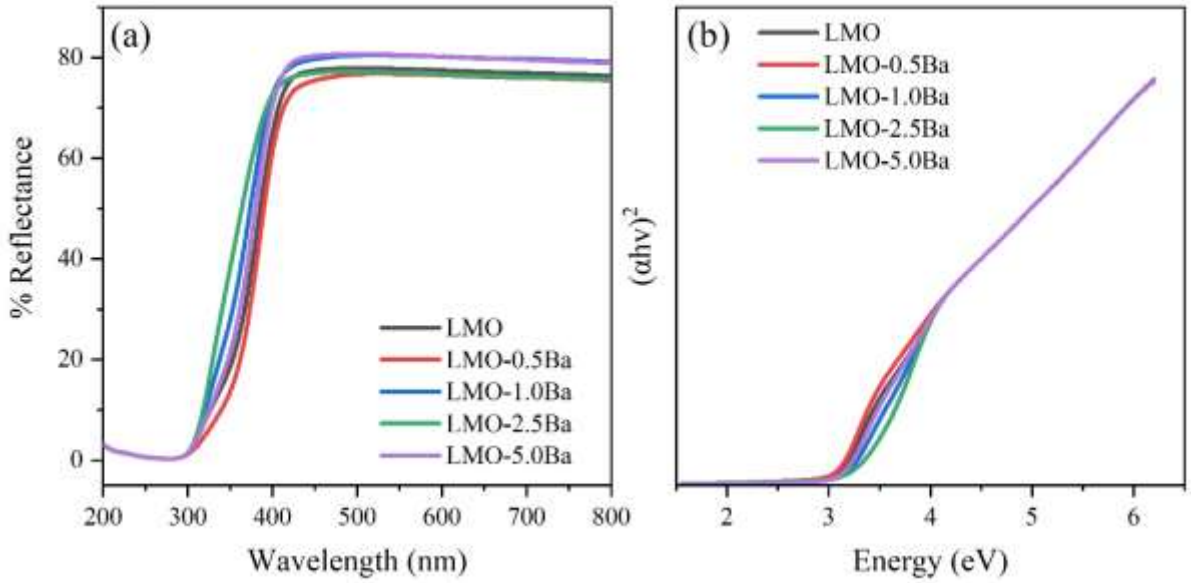

Figure 5 (a) UV-Vis diffuse reflectance spectruma and (b) Tauc plot for undoped and Ba doped $La_2Mo_3O_{12}$ (0, 0.5, 1, 2.5 and 5 mol%) powders

Table 2 optical band gap values calculated from Kubelka-Munk (KM) plot for $La_2Mo_3O_{12}$ powders

Sample	Band gap (eV)
LMO	3.03
LMO-0.5Ba	3.04
LMO-1.0Ba	3.16
LMO-2.5Ba	3.32
LMO-5.0Ba	3.09

Photoluminescence excitation and emission spectrum for undoped and Ba doped $La_2Mo_3O_{12}$ (0, 0.5, 1, 2.5 and 5 mol%) powders are presented in Figure 6a and b, respectively. The room temperature measurements were recorded at the excitation wavelength of 352 nm and the emission wavelength of 532 nm. For $La_2Mo_3O_{12}$ a broad emission band was reported from 370 to 750 nm when the excitation wavelength was 211 nm (Q. Ma et al., 2023). In the current work, a broad and weak band was observed at 250-300 nm range, which is linked to the charge transfer band (CTB) transitions of $Mo^{6+} \rightarrow O^{2-}$ (F. Li et al., 2017; Tian et al., 2009). In addition to these sharp bands located at excitation and emission wavelengths were observed. Intensity of the emission band increases with doping up to 2.5 mol% and then decreases again with increasing doping level. This behaviour is associated with concentration quenching effect (Parauha et al., 2020). The increase in the nonradiative energy transfer between the dopant ions (cross relaxation) is caused by decreasing distance between Ba ions with increasing Ba^{2+} concentration (Krishna Bharat et al., 2014). This leads to the quenching effect observed. This dopant concentration dependency of the intensity is also reported for E^{3+} (F. Li et al., 2017; Parauha et

al., 2020), Er^{3+} (X. Li et al., 2020) and Er^{3+}/Yb^{3+} (He et al., 2022) doped $La_2Mo_3O_{12}$. It appears that the doping with Ba had a similar effect with using alkali ions as dopants since increase in the photoluminescence intensity of oxides was observed with alkali ion doped $La_2Mo_3O_{12}$ and $CaZrO_3$ (X. Li et al., 2020; Maurya et al., 2018).

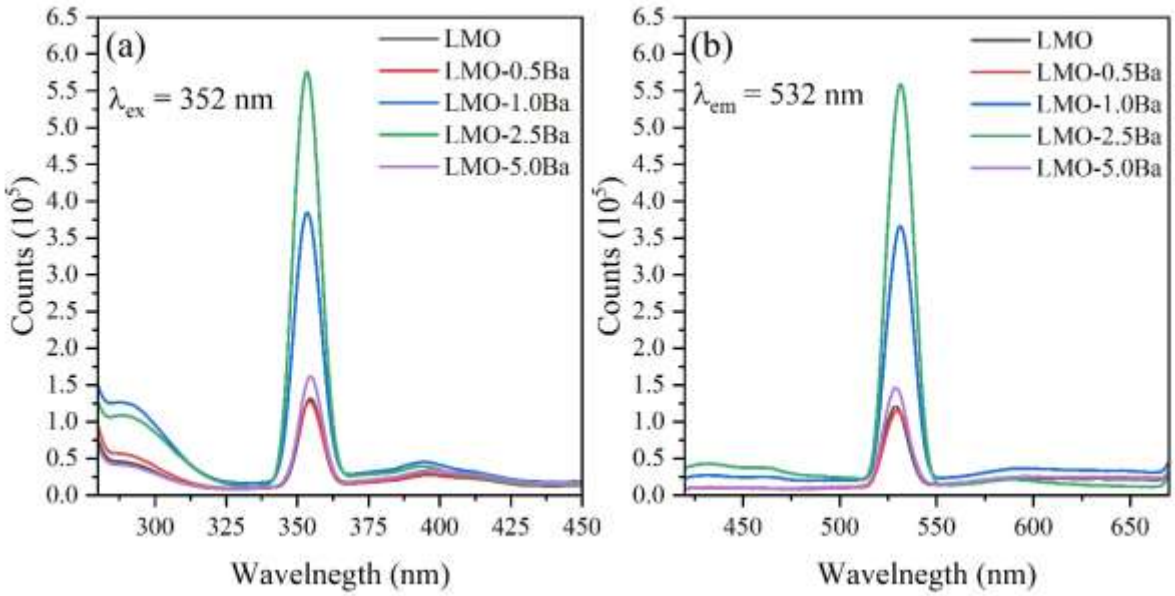

Figure 6 Photoluminescence (a) excitation and (b) emission spectra for undoped and Ba doped $La_2Mo_3O_{12}$ (0, 0.5, 1, 2.5 and 5 mol%) powders

Conclusions

In conclusion, single phase Ba-doped (≤5 mol%) $La_2Mo_3O_{12}$ powders was prepared using a simple co-precipitation and calcination route. Structural analysis confirmed the monoclinic structure with C2/c space group. ≤2.5 mol% Ba doping levels had little effect on the crystallite size while sample with ≤5 mol% Ba exhibited the lowest with 34.2 nm. A similar dependency on Ba doping level was observed for the estimated optical band gap values, and it varied 3.03-3.32 eV. The morphology of the particles was not dependent on the composition and samples consisted of aggregates that were made of particles with irregular shapes. Moreover, homogeneous distribution of La, Mo, Ba and O was also confirmed by EDS mapping. No emission band corresponding to f-f transition observed for rare earth doped $La_2Mo_3O_{12}$ was observed. But an emission peak located at 532 nm (green) was observed. Its intensity initially increased with doping up to ≤2.5 mol% Ba, however further increasing the dopant concentration led to a decrease in the intensity due to concentration quenching effect. These results demonstrated that Ba can be utilised, similar to alkali ions, to increase the photoluminescence intensity of $La_2Mo_3O_{12}$ phosphors.

Özet

Bu çalışma, Van Yüzüncü Yıl Üniversitesi Kampüsü ve çevresinden toplanan makromantar örnekleri üzerindengerçekleşmiştir. Arazi çalışması boyunca toplanan makromantar örneklerinin doğal yetişme alanlarında renkli fotoğrafları çekilmiştir. Makromantarların morfolojik ve ekolojik özellikleri kaydedilmiştir. Arazi ve laboratuvar çalışmaları sonucunda Ascomycota ve Basidiomycota bölümleri içinde yer alan 3 takım, 14 familya ve 18 cins içerisinde dağılım gösteren toplam 40 yenen makromantar türü tespit edilmiştir. Çalışma örnekleri Van Yüzüncü Yıl Üniversitesi, Eğitim Fakültesi, Biyoloji Araştırma Laboratuvarında saklanmaktadır.

Anahtar Kelimeler: Yenen makromantar, taksonomi, Van, Türkiye.

SOME EDIBLE MACROFUNGI DETECTED IN VAN YÜZÜNCÜ YIL UNIVERSITY CAMPUS AND SURROUNDING AREA (VAN, TURKEY)

Abstract

This study was conducted using macrofungi collected from the Van Yüzüncü Yıl University Campus and its surrounding area. Color photographs were taken of the natural products of the macrofungal specimens collected during the field study. The morphological and ecological characteristics of the macrofungi were established. As a result of field and laboratory studies, a total of 40 new macrofungal species were identified, distributed within three orders, 43 families, and 18 genera within the divisions Ascomycota and Basidiomycota. The study specimens are kept in the Biology Research Laboratory of the Faculty of Education, Van Yüzüncü Yıl University.

Keywords: Edible macrofungus, taxonomy, Van, Turkey.

1. GİRİŞ

Bu çalışma, 2023-2025 yılları arasında Van Yüzüncü Yıl Üniversitesi Kampüsü ve çevresinden toplanan makromantar örnekleri üzerinde yapılmıştır. Ülkemiz, eşsiz florası ve iklim şartlarından dolayı doğal olarak yetişen makromantar çeşitliliği açısından oldukça zengindir. Dolayısı ile yenen makromantarlar acısından da zengindir. Ülkemizde 2022 yılına kadar yapılan çalışmalarda 3100 kadar makromantarlar türü olduğu bildirilmiştir (Solak ve Türkoğlu, 2022). Böyle olmasına rağmen halkımız bu doğal besin kanyağından yeterince istifade edememektedir. Yenen makromantarlar, vitamin (özellikle D vitamini), protein ve karbonhidrat açısından oldukça yüksek, yağ oranı açısından da oldukça düşük olmalarının yanında lifli olmaları da önemli bir özelliktir. Sağlıklı ve dengeli bir diyetin esas besini olarak da karşımıza çıkarmaktadır. Ayrıca bunların en önemli özellikleri doğadaki çeşitli atıkları parçalayarak toprağa karışmasını sağlarlar. Böylece toprağı verimli hale getirir ve biyolojik döngüde önemli katkı sağlarlar. Çalışma alanımız karasal iklime sahip olup meteorolojik verilerine göre yıllık sıcaklık ortalaması 9 °C'dir. Yılın en soğuk ayı sıcaklık ortalaması-3,5 °C, en sıcak ayı sıcaklık ortalaması 22 °C'dir. Yağışların %39'u ilkbaharda, %27'si sonbaharda, %26'sı kışta, %7'si ise yaz mevsiminde düşer. En çok güneş gören yerlerinden biridir. Yıllık yaklaşık 400 mm yağış ile Doğu Anadolu'nun en az yağış alan yerlerinden biridir (Anonim 2025). Yörenin bitki örtüsü genelde bozkır ve çayırlıklardan oluşur. Ağaç formları ise ağaçlandırma çalışmaları sonucunda oluşan başta çam, söğüt, kavak, akasya, huş ağaçlarının yanında bazı kültür bitkileri (iğde, elma, kayısı, armut) ve çeşitli peyzaj bitkilerinden oluşmaktadır. Çalışma sonucunda yöreden Agaricomycetes ve Pezizomycetes sınıflarına ait 40 yenilebilir makrofungus türü belirlendi. Çalışmanın amacı, bölgede yenilebilir makrofungal çeşitliliğini ve yerel tüketimini belirlemek ve Türkiye mikobiyotasına katkı sağlamaktır.

Lokal bazı çalışmaların listesi; Akçay vd., (2023); Sadullahoğlu vd., (2023); Acar, (2022), Acar vd., (2021); Şelem., (2019); Demirel ve Koçak (2016); Demirel vd., (2015); Demirel ve ark., (2015); Keleş ve Şelem, (2017); Keleş ve ark., (2016); Kesici, (2015); Uzun ve ark., (2008)..

2. MATERYAL VE YÖNTEM

Çalışma materyalini Van Yüzüncü Yıl Üniversitesi Kampüsü ve Çevresinden Yetişen 2023-2025 tarihleri arasında toplanan makromantar örnekleri oluşturmaktadır. Makromantar örneklerinin doğal habitatlarında fotoğraflarının çekiminde kullanılan dijital fotoğraf makinesi, coğrafi koordinatları belirleyen GPS cihazı, mantar örneklerinin spor boyutunun ve mikroskobik yapılarının incelenmesinde, fotoğraflanmasında kullanılan ışık mikroskobu, mikrometre takımı, lam-lamel ve ilgili literatürler oluşturmaktadır. Arazi çalışmasında toplanıp ve laboratuvarda çalışmalar neticesinde elde edilen veriler ve makromantar için çıkarılan deskripsiyonlar özellikle renkli baskılı ilgili literatür (Breitenbach ve Krânzlin, 1984, 1986, 1991, 1995, 2000; Bresinsky ve Besl, 1991; Buczacki, 1989, 2012; Ellis ve Ellis, 1990; Jordan, 1995; Krânzlin, 2005; Kuo ve Methven, 2014; Moser, 1983; Phillips, 1981, 2006; Phillips ve ark., 1991) kullanılarak örneklerin teşhisi yapılmıştır. Teşhisleri yapılmış olan makrofungus örneklerinin geçerli adları Index Fungorum (www.speciesfungorum.org; erişim (2025) ile Sesli ve ark., 2020)'ye göre verilmiş olup alfabetik bir sıralama ile düzenlenmiştir. Tespit edilen yenen makromantar örnekleri dolaplara yerleştirilerek saydam plastik kutular içerisinde saklanmaktadır. Van Yüzüncü Yıl Üniversitesi, Eğitim Fakültesi, Biyoloji Araştırma Laboratuvarında saklanmaktadır.

3. BULGULAR

Arazi ve laboratuvar çalışmaları neticesinde Ascomycota ve Basidiomycota bölümlerine ait 3 takım, 14 familya ve 18 cins içinde dağılım gösteren 40 yenen makromantar türü tespit edilmiştir. Teşhisleri yapılan makromantar örneklerinin geçerli adları Index Fungorum (2025)'e göre verilmiş olup alfabetik sıraya göre dizilmişlerdir. Listede örneklerin habitatları, substratları, lokaliteleri, toplandığı tarihler ve kişisel fungaryum numaraları (örn; Tıp fakültesi morfoloji binası, çayırlık alan, 38°34′K-43°17′D, 1667m., 07.05.2025, A.K. 6754.) verilmiştir.

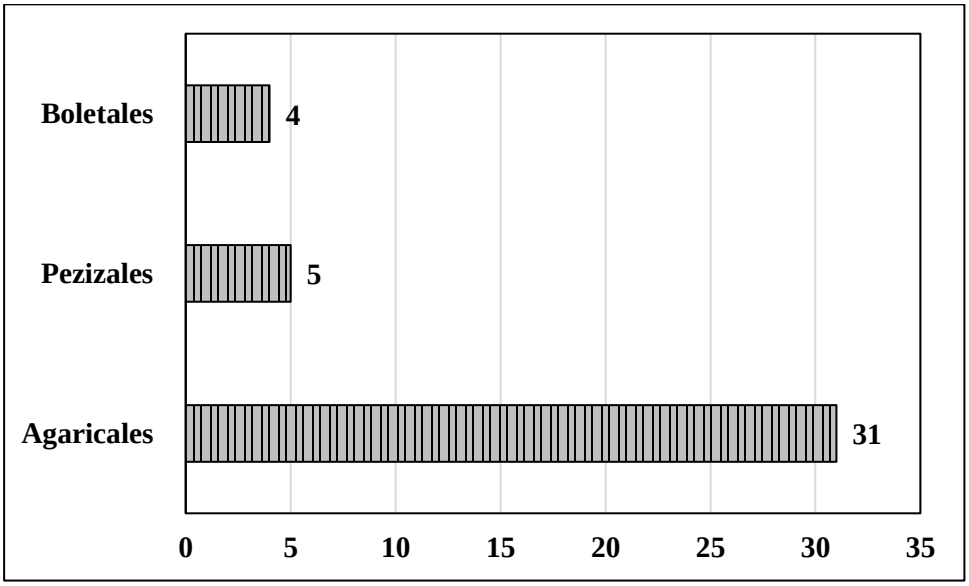
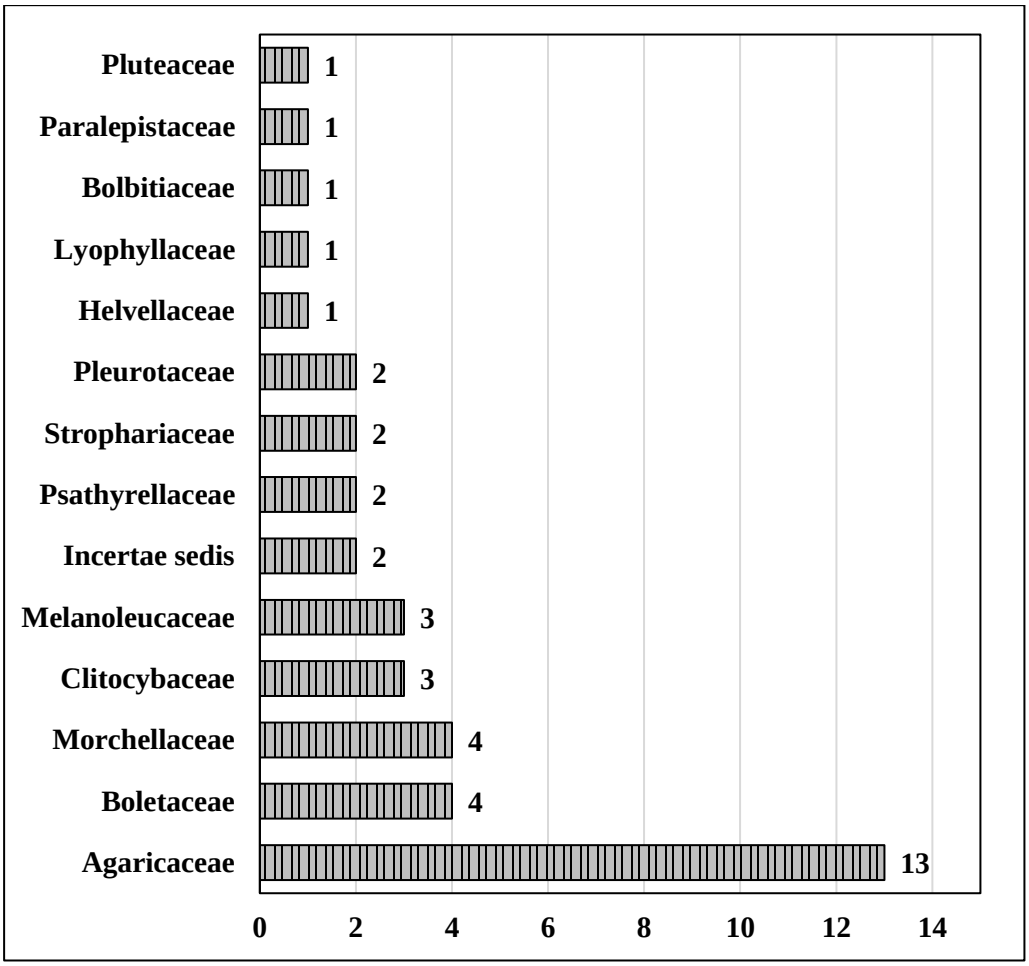
4. TARTIŞMA VE SONUÇ



Bu çalışma sonucunda, Van Yüzüncü Yıl Üniversitesi Kampüsü ve Çevresinden 2 sınıf, 3 takım, 14 familya, 18 cins'e ait 40 yenilebilir doğal makromantar türü tespit edilmiştir. Tespit edilen türlerden 5'i Ascomycota, 35'i ise Basidiomycota şubesine aittir. Yörede 40 yenilebilir makromantar bulunmasına rağmen, bunlardan yalnızca dokuzunun (*Morchella esculenta, M.*

elata, M. prava, M. vulcaris, Agaricus bisporus, A. campestris, Coprinus comatus ,P. ostreatus ve P. populinus) yörede toplanıp tüketildiği tespit edilmiştir. Faydalanma oranı %22,5 tur. Bu da ülkemiz ortalamasının çok altında olduğu düşünülmektedir. Tespit edilen makrofungusların%12,5'i Ascomycota, %87,5'i ise Basidiomycota bölümünde yer alır.



Şekil 2. Tespit edilen türlerin ait olduğu bölümlerdeki oranları

Agaricales (31 tür) takımından sonra en çok üye ile temsil edilen takımlar ise sırasıyla; Pezizales (5 tür) ve Boletales (4 tür) takımlarıdır. Dağılımın bu şekilde olması araştırma alanındaki yenen makromantar gelişimini ve çeşitliliğini etkileyen iklimi ve bitki örtüsünden bir sonucu olduğu düşünülmektedir. Araştırma yöresinde tespit edilen 40 türden 3'i Agaricales takımında yer almaktadır. Bu durum, Agaricales takımının yeryüzünde bulunan makromantarların büyük bir çoğunluğunun yer aldığı Agaricomycetes sınıfının en kalabalık takımı olması, araştırma alanının iklimsel özelliklerinden ve ekolojik yapısından da kaynaklanmaktadır

Şekil 3. Tespit edilen türlerin takımlara göre dağılımı.

Teşhisi yapılan türlerin familyalara göre dağılımı incelendiğinde en çok tür ile temsil edilen familyaların Basidiomycota bölümünde olduğu ve sırasıyla; Agarcaceae (13), Suillaceae (4), Clitocybaceae (3), Melanoleucaceae (3), Strophariaceae (2), Pleurotaceae (2 tür), Psathyrellaceae (2), Incertae (2), Bolbitiaceae (1), Lyophyllaceae (1), Paralepistaceae (1), Pluteaceae (1), olduğu görülmektedir. Ascomycota bölümünde ise 2 familyanın bulunduğu ve içerdikleri tür sayıları sırasıyla; Morchellaceae (4) ve Helvellaceae (1) familyalarıdır. Araştırma alanında tespit edilen familyalardan (5 familya) tek türü temsil etmektedir. Türlerin familyalara göre dağılımının araştırma alanının iklim özelliklerinden ve bitki örtüsünden kaynaklandığı düşünülmektedir.

Şekil 4. Tespit edilen türlerin familyalara göre dağılımı.

Araştırma alanında 40 yenilebilir makromantar türü belirlenmesine rağmen yörede sadece *Agaricus bisporus, A. campestris, Coprinus comatus, Pleurotus ostreatos, P. populinus*, ve *Morchella* cinsine ait türleri yemektedir. Arazi çalışmaları esnasında toplanan örnekler yöre halkına gösterilmesine rağmen bunlar dışında herhangi bir mantarı yemediklerini ve geri kalanların ise zehirli olarak bildiklerini ifade etmişlerdir.

Çalışmanın yürütüldüğü bölgede en fazla yenen makromantar örneği 2023 Ekim ve Kasım aylarında toplanmıştır. Bunun nedeni de yağışların bu dönemde hem bol hem de uzun sürmesinin yanında sıcaklıkların düşmesinin gecikmesi. Ayrıca çalışma alanının iklimi karasal olduğundan yaz aylarında sıcaklıkların yüksek olası ve yağışların çok az olması makromantar gelişimini durdurmaktadır. 2024 yılı ilk baharda yağışların çok az olması ve ani ısınması, son

baharda da güz yağışlarının çok geç gelmesi ile havaların ani soğuması makro mantar gelişimini olumsuz etkilemiştir. Dolayısı ile yenen makromantar gelişimi çok az olmuştur. Buradan anlıyoruz ki ilim ve ekolojik etkenler makro mantar gelişimini önemli derecede etkilemektedir. Bu yüzdendir ki makromantar çalışmaları en az iki yıl olmalı. Nedeni de şartlar birinci yıl iyi olmazsa ikinci yıl telafisi yapılabilsin.

Abstract

In this study, traditional randomized complete block design (RCBD) Model is modified from linear to intrinsically nonlinear RCBD (INRCBD) model with fixed block effect where the mean part of the INRCBD model follows a three-parameter Weibull growth function. The parameters of the formulated model are estimated using the generalized least square approach where the error variance component is estimated via Method of Likelihood Maximization (MLM). The adequacy of the fitted INRCBD-MLM model is assessed using median adequacy measures (MAM). A $7^1 \times 6^1$ treatment combination data with 3 blocks from an experiment for determining the effect of saponins on oil spillage remediation was analyzed using the INRCBD-MLM model. The MAM values obtained showed that the model is adequate in capturing large data variability, high prediction power, strong model efficiency, and consistent error prediction strength.

Keywords: Intrinsically nonlinear, Weibull growth function, RCBD, Saponins, Oil spillage remediation

1. Introduction

Experiments are conducted by researchers across nearly all fields of study, typically to learn more about a specific process or system. In simple terms, an experiment is a trial. A designed experiment, on the other hand, involves a structured test or series of tests where intentional modifications are made to the predictor variables of a process or system, which allows observation to determine the causes/effects of the response variable(s) (David *et al*., 2013). The randomized complete block design (RCBD) is a commonly used design in agricultural (and other) experiments where experimental units are organized into blocks and/or replicates (Grant, 2010). In standard RCBD, block effects can be either fixed or random depending on the experiment type. Random block effects are used when samples come from a population with specific properties, allowing conclusions beyond the specific blocks studied. Fixed blocks are used when block levels are specific and of particular interest, limiting conclusions to the blocks in the study. (Dixon, 2016).

Nonlinear models extend traditional linear approaches to capture complex variable relationships. Within RCBD frameworks, they use polynomial, exponential, or logarithmic forms while maintaining basic structure (Montgomery, 2017). Recent research has shown promising applications of nonlinear RCBD models. David & Ikwuoche (2024a) created and compared a split-plot design using Chapman-Richards and Johnson-Schumacher functions, with parameters estimated through EGLS and variance components (VCs) via Method of Likelihood Maximization (MLM) and Residual Likelihood Maximization Technique (RLMT). Other linear and INSPD models and their theoretical formulation and estimation were studied by David *et al*. (2013), David & Adehi (2014), David *et al*. (2016), (2018), (2019), (2022a), (2022b), David & Ikwuoche (2022), David *et al*. (2023a), (2023b), and David & Ali (2024b). Vilas-Boas *et al*. (2023) applied various growth functions including Gompertz, logistic, and Weibull models, using least squares estimation and evaluating fit through adjusted R^2, residual standard deviation, and AIC. Indrajaya *et al*. (2024) tested twenty nonlinear RCBD models, assessing performance using coefficient of determination (R^2), root mean square error, absolute percentage error, and information criteria.

In this research, a fixed block effect INRCBD model is formulated with its mean part tailored by a three-parameter Weibull growth function. The Method of Estimated Generalized Least Squares (MEGLS) parameter estimation with VC estimated via MLM and RLMT. In assessing the fitted model, the resistant R^2, resistant predicted-R^2, Resistant Modelling Efficiency Predictor (RMEF), and Median Square Error Prediction (MedSEP).

2. Methodology

The Weibull-RCBD (WRCBD) model is formulated to accommodate the fixed block effect as an additive factor outside the nonlinear mean part of the model. Now, let $f(x_{ijk}, \theta)$ be a three parameter Weibull growth function and y_{ijk} be a traditional linear RCBD model given in Equation (1) and (2) as;

$$f\left(x_{ijk},\theta\right)=\alpha_{ijk}\times\exp\left[-\left(\frac{x_{ijk}}{\delta}\right)^{\lambda}\right] \tag{1}$$

$$y_{ijk}=\mu+\xi_i+\beta_j+\left(\xi\beta\right)_{ij}+\gamma_k+\varepsilon_{ijk}\,. \tag{2}$$

Therefore, the WRCBD model is given as;

$$y_{ijk} = \left(\alpha + \xi_i + \beta_j + (\xi\beta)_{ij}\right)\exp\left[-\left(\frac{x_{ijk}}{\delta}\right)^{\lambda}\right] + \gamma_k + \varepsilon_{ijk} \quad (3)$$

where, α_{ijk} is the asymptote and it is tailored as $\alpha_{ijk} = \alpha + \xi_i + \beta_j + (\xi\beta)_{ij}$, γ_k is the additive fixed block effect, x_{ijk} is the mean covariate effect in the ith block at the jth factor A and k^{th} factor B. Also, δ_{jk} and λ_{jk} are the Weibull scale and shape parameters, respectively, ε_{ijk} is the model error with mean zero and constant variance σ^2. Note that $E[\varepsilon_{ijk}] = 0$ and Cov $[\varepsilon_{ijk}] = \sigma^2\mathbf{I}$.

2.1. Model Parameter Estimation

The EGLS is obtained by minimizing the objective function when the covariance matrix of y is known.

$$(y - f(X, \theta))^t \Sigma^{-1} (y - f(X, \theta)) \quad (4)$$

where, θ is the model parameters and Σ is the known covariance matrix from the model.

Let Equation (3) becomes

$$y_{ijk} = f(x_{ijk}, \theta) + \gamma_k + \varepsilon_{ijk} \quad (5)$$

Going by Cholesky decomposition, Equation (5) becomes

$$L^{-1}y_{ijk} = L^{-1}f(x_{ijk}, \theta) + L^{-1}\gamma_k + L^{-1}\varepsilon_{ijk} \quad (6)$$

Let the LHS of (6) be $\mathbf{T}_{ijk}$ and the RHS be $Z(x_{ijk}, \theta^*) + Q_k + \eta_{ijk}$. Then Equation (6) becomes

$$\mathbf{T}_{ijk} = Z(x_{ijk}, \theta^*) + Q_k + \eta_{ijk} \quad (7)$$

where, $E[\eta_{ijk}] = 0$ and $\Sigma[\eta_{ijk}] = \sigma^2\mathbf{I}$. Thus, a transformation of the GLS model to OLS has been achieved and Equation (7) is to be solved using OLS estimator as follows.

$$L(\theta^*) = \sum_i^a \sum_j^b \sum_k^c \eta_{ijk}^2 = \sum_i^a \sum_j^b \sum_k^c \left[T_{ijk} - Z(x_{ijk}, \theta^*) - Q_k\right]^2 \quad (8)$$

Minimize Equation (8) w.r.t θ^*, equate to zero, and simplify to get

$$\frac{\partial L(\theta^*)}{\partial \theta_p^*} = \sum_i^a \sum_j^b \sum_k^c \left[T_{ijk} - Z(x_{ijk}, \theta^*) - Q_k\right]\left[\frac{\partial Z(x_{ijk}, \theta^*)}{\partial \theta_p^*}\right]_{\theta^* = \hat{\theta}^*} = 0 \quad (9)$$

At this point, Equation (9) has no closed form solution but can be solved using the Gauss-Newton method with Taylor series expansion of $Z(x_{ijk}, \theta^*)$ at first order (for details see David *et al*., 2018).

2.2 Results

The data used for this study is obtained from an experiment conducted by Dr. R. B. Donatus which was part of his Ph.D. research on investigating greener saponins options against commercial synthetic surfactants. Four plants extracts (Hydroxylated Balanite Aegyptiaca Root Extract, Hydroxylated Securica Longepedunlata Root Extract, Hydroxylated Saponins Quillaja Extract at 25-30%, and Hydroxylated Saponins Quillaja Root Extract) and three synthetic surfactants (Sodium Dodecyl Sulphate, TWEEN 80, and HSPDE) were used at six concentration levels, 0.1mm, 0.2mm, 0.3mm, 0.4mm, 0.5mm, and 1.0mm. The experiment was to compare the plant extracts to the synthetic surfactants' effects on crude oil spill remediation considering humans and aquatic lives in the environment. The parameter estimates from the analysis using PROC NLMIXED in SAS 9.4 software is presented.

Table 1: WRCBD Model Estimates

Parameter	Estimate	Std Error	*t*-Value	p-value
α	34.28	0.4152	82.57	**<0.0001**
β_1	1.87	0.1284	14.59	**<0.0001**
β_2	0.43	0.0876	4.93	**<0.0001**
δ	0.62	0.0534	11.67	**<0.0001**
λ	1.25	0.0923	13.49	**<0.0001**
B_1	0.00	0.0000	-	-
B_2	0.12	0.0567	2.18	**0.0312**
B_3	4.22	0.0567	74.38	**<0.0001**
σ^2	0.0234	0.0045	5.20	**<0.0001**

From the results in Table 1, it can be observed that all the parameter estimates are significant at 5%. Also, the experimental factors contributed positive effect on crude oil spill remediation. At block one, B_1, it is seen to be redundant while block two, B_2 and block three, B_3 are significant at 5%. the error variance is also significant at 5%.

Table 2: Median Adequacy Measures Results

Models	r_r^2	*Pred-* r_r^2	RMEF	MedSep
WRCBD Fixed (MLE)	0.9756	0.9734	0.9721	0.0247

The model adequacy measures values presented in Table 2 clearly shows that the estimated model produced large resistant-R^2 (r_r^2) value of 97.56%, resistant predicted-R^2 (*Pred-* r_r^2) value of 97.34%, RMEF value of 97.21%, and a small MedSEP value of 0.0247. This indicates that the model can explain a large proportion of variation in the data, better prediction power, highly efficient, and low prediction error.

2.3 Conclusion

In this research, a Weibull RCBD model was formulated and used in the analysis of saponins effect on oil spill remediation. The parameters of the model are estimated using the method of EGLS with the variance component estimated using MLM. The results obtained showed that the formulated model icaptured a large variation proportion in the data with the ability of low prediction error and it is highly efficient based on the MAM values obtained.

ORCID: 0000-0002-6546-5891

ÖZET

Üzümsü meyveler (*Rubus, Vaccinium, Fragaria, Aronia* spp.) yüksek besin değerleri ve artan ticari öneme sahip meyve türleridir. Fidan üretimi yetiştiricilik taleplerinin karşılanması bakımından önemlidir. Bu türlerin doku kültürü ile fidan üretimi etkili bir şekilde yürütülmektedir. Mikroçoğaltımda sterilizasyon protokolünün belirlenmesi en kritik sorunlardan birini oluşturmaktadır. Sterilizasyon başarısı; eksplant tipine, kullanılan kimyasallara ve uygulama süresine bağlı olarak önemli ölçüde değişmektedir. NaOCl birçok üzümsü türünde temel sterilant olarak etkilidir. $HgCl_2$ yüksek etkinliğine rağmen fitotoksisite riski nedeniyle dikkat edilmesi gerekmektedir. $AgNO_3$ ve H_2O_2 alternatif sterilantlar olarak başarılı sonuçlar vermiştir. Tween-20'nin yüzey gerilimini azaltıcı etkisi, tüm protokollerde dezenfektan etkinliğini artırmıştır. Genel olarak, çok aşamalı sterilizasyon protokolleri (EtOH + NaOCl veya kısa süreli $HgCl_2$ kombinasyonları) üzümsü meyvelerde en düşük kontaminasyon ve en yüksek eksplant canlılığı sağlayan yaklaşımlar olarak öne çıkmaktadır.

Anahtar Kelimeler: Üzümsü meyveler, sterilizasyon, NaOCl, EtOH, $HgCl_2$

STERILIZATION STRATEGIES IN TISSUE CULTURE OF BERRY FRUITS

ABSTRACT

Berry fruits (Rubus, Vaccinium, Fragaria, Aronia spp.) are fruit species with high nutritional value and increasing commercial importance. Seedling production is crucial for meeting cultivation demands. Seedling production of these species is effectively carried out through tissue culture. Determining the sterilization protocol in micropropagation is one of the most critical problems. Sterilization success varies significantly depending on the explant type, the chemicals used, and the application time. NaOCl is effective as a primary sterilant in many berry species. $HgCl_2$, despite its high effectiveness, requires caution due to the risk of phytotoxicity. $AgNO_3$ and H_2O_2 have yielded successful results as alternative sterilants. The surface tension-reducing effect of Tween-20 increased disinfectant effectiveness in all protocols. In general, multi-stage sterilization protocols (combinations of EtOH + NaOCl or short-term $HgCl_2$) stand out as approaches that provide the lowest contamination and highest explant viability in berry fruits.

Keywords: Berry fruits, sterilization, NaOCl, EtOH, $HgCl_2$

1. GİRİŞ

Üzümsü meyveler, doğal antioksidan kaynakları olmaları ve tüketici tarafından sevilerek tercih edilmeleri nedeniyle son yıllarda talebi artan önemli meyve gruplarındandır. Farklı ürünlere işlenebilmeleri sayesinde gıda endüstrisinde de geniş bir kullanım potansiyeline sahiptirler. Üretim alanlarının gelişmesi, bu türlerde fidan üretimine olan ihtiyacı artırmış; geleneksel çelik ve daldırma gibi vejetatif yöntemlerin yanında, doku kültürü ile üretilen fidanlar giderek daha fazla önem kazanmıştır. Doku kültürü, iklim koşullarından bağımsız, kontrollü ve steril ortamlarda sağlıklı bitki materyali üretme olanağı sunduğu için ahududu (*Rubus idaeus* L.), böğürtlen (*Rubus fruticosus* L.) ve *Vaccinium* cinsine ait türlerde (mavi yemiş, turna yemişi vb.) bir örnek ve hastalıksız fidan üretiminde önemli bir araç haline gelmiş; aynı zamanda büyük bir endüstri oluşturmuştur (Debnath ve Ghosh, 2022; Topçu 2022; Correia vd., 2024). Mikroçoğaltım üzümsü meyve türlerinde etkinliği kabul edilen ve in vitro koşullarda genetik stabilitenin korunduğu bir yöntem olarak bildirilmiştir (Gajdošová vd. 2006).

Doku kültüründe yüzeysel ve içsel kaynaklı enfeksiyonlar, kültür kayıplarının en önemli nedenleri arasında yer almaktadır. Çoğaltım materyallerinin üretimindeki başarı, eksplantların yüzey sterilizasyonunun doğru ve etkili bir şekilde yapılmasına bağlıdır. Yüzey sterilizasyonunda yaygın olarak kullanılan kimyasal maddeler arasında etanol, sodyum hipoklorit, kalsiyum hipoklorit, cıva klorür ve gümüş nitrat bulunmaktadır. Bu maddeler tek başına veya ardışık olarak uygulanmaktadır (Madhuri vd., 2021). Sterilizasyon sırasında Tween 20 eklenmesi, yüzey gerilimini azaltarak dezenfektanın eksplant yüzeyine daha iyi yayılmasını sağlamakta ve böylece etkinliği artırmaktadır (Sigma-Aldrich, 2025).

Etanol (EtOH), fitotoksik etkisi nedeniyle kısa süreli uygulanan, hızlı etki gösteren bir ön sterilizasyon maddesidir. Klor bazlı maddeler güçlü oksitleyici özellikleri sayesinde uygun süre ve dozlarda oldukça etkili sonuçlar vermektedir. Cıva klorür ($HgCl_2$) ve gümüş nitrat ($AgNO_3$) gibi maddeler ise yüksek toksisiteleri nedeniyle dikkatli kullanılmalıdır. Dezenfektan seçimi yapılırken tür ve eksplant tipine uygun optimum konsantrasyon ve sürelerin belirlenmesi, sterilizasyon başarısının temelini oluşturmaktadır. Bu çalışmada, üzümsü meyve türlerinin doku kültüründe kullanılan sterilizasyon aşamaları ele alınmıştır.

2. ÜZÜMSÜ MEYVELERDE KULLANILAN STERİLİZASYON MADDELERİ

NaOCl, güçlü oksitleyici etkisiyle mikrobiyal proteinleri ve nükleik asitlerin yapısını bozmakta, $HgCl_2$ peptit bağlarını oksitleyerek mikrobiyal proteinleri denatüre etmektedir (Das vd., 2012; Pathi vd., 2013). $HgCl_2$ mikroflora kaynaklı kontaminasyonu azaltmada etkili olmakla birlikte, önemli doku toksisitesine yol açmaktadır. NaOCl'nin dezenfektan etkisi $HgCl_2$'ye kıyasla daha düşüktür. İki sterilant art arda iki aşamalı sterilizasyon olarak uygulandığında daha etkili sonuç alınmaktadır (Dodake et al. 2020; Madhuri et al., 2021).

Etanolün lipit çözündürücü ve hızlı etkili yapısı, eksplant yüzeyindeki kutikulanın geçirgenliğini artırarak NaOCl'nin oksitleyici etkisinin daha etkin bir şekilde dokuya nüfuz etmesini sağlamaktadır. Bu durum, tek aşamalı sterilizasyon protokollerine kıyasla daha düşük kontaminasyon oranları ve daha yüksek asepsi düzeyleri ile sonuçlanmaktadır. NaOCl süresi sabit tutularak, etanol uygulama süresinin artırılması kontaminasyon oranını önemli düzeyde düşürmekte, aynı zamanda eksplant canlılığını koruyarak indüksiyon başarısını artırmaktadır (Wang vd., 2023). Hassas türlerde ve kontaminasyon riski yüksek materyallerde tercih edilebileceği vurgulanmaktadır (Dodake vd., 2020; Madhuri vd., 2021). Tablo 1'de sterilizasyon aşamaları özetlenmiştir.

Tablo 1. Üzümsü Meyvelerin İn Vitro Sterilizasyon Protokolleri

Materyal ve Kaynak	**Protokol**
Tür: Yaban mersini, böğürtlen **Eksplant:** Yan tomurcuklar, boğum **Kaynak:** Makarov vd., 2021.	**a.** Klor içermeyen ekolojik bir sterilizasyon maddesi ve sodyum hipoklorit bazlı ağartıcı "Belizna", 15 ve 20 dakika uygulanmıştır. Her iki sürede etkili olmuştur. **b.** Eksplantların en yüksek canlılığı, %0,1'lik cıva klorür çözeltisi ile sterilizasyonunda 15 dakika canlılığın korunmasında ve sterilizasyonda etkili olmuş, 20 dakika süreli uygulamada eksplant kayıpları olmuştur.
Tür: Böğürtlen çeşitleri (Rubus L.) ('Natchez', 'Black Magic', 'Osage' ve 'Heaven Can Wait') **Eksplant:** Aksiller tomurcuklu boğum kısımları **Kaynak:** Malakhova vd., 2025.	**Ön işlem:** Sabunlu suya daldırma ve 30 dakika çalkalama; **Sterilizasyon:** %70 etanol + %1 sodyum hipoklorit+%0,05 Tween-20 (Farklı konsantrasyonlar ve süreler) **SONUÇ:** 2 dakika %70 etanol + 15 dakika %1 NaOCl tüm çeşitler arasında en etkili sterilizasyon olmuştur. Etanol ön işlemi içermeyen yöntemlerde kontaminasyon yüksek olmuştur.
Tür: Yaban mersini (*Vaccinium corymbosum* cv. Berkeley), ahududu (*Rubus idaeus* cvs Gradina ve Willamette); böğürtlen (*Rubus sp*. cv. Smoothstem) **Eksplant:** Tek tomurcuklu boğum kısımları **Kaynak:** Gonzalez vd. 2000).	**Ön sterilizasyon:** 30 saniye %70 etanol+%1 Tween-20'de ön sterilizasyon; 15 dakika %0,1 (a/h) benomil çözeltisine daldırılma; **Sterilizasyon:** %0,5 (h/h) sodyum hipoklorit çözeltisinde 20 dakika bekletme + steril, damıtılmış su ile dört kez çalkalama. **Sonuç:** Etkili
Tür: Tilki üzümü (*Vaccinium vitis-idaea* L.) (Koralle, Kostromichka ve Kostromskaya Rozovaya çeşitleri); Kamçatka yaban mersini (*Vaccinium praestans* Lamb.) (Sakhalin ve Kuril çeşitleri) **Eksplant**: Sürgün ucu/boğum **Kaynak:** Chudetsky vd. 2022.	**Sterilizasyon:** Domestos deterjan çözeltileri (su ile 1:3 oranında seyreltilmiş), gümüş nitrat (%0.2), aşındırıcı süblimat (%0.2), Lysoformin 3000 (%5) ve klor içermeyen Ecosterilizer (%5) kullanılmıştır. Sterilizasyon süreleri 5, 10, 15 ve 20 dakika olarak belirlenmiştir. **Sonuç:** %0.2 $AgNO_3$ ile 10 dakika sterilizasyon süresi eksplantların en yüksek hayatta kalma oranını vermiş ve etkili olmuştur (Tilki üzümü %72; yaban mersini %96).
Tür: Yaban mersini (*Vaccinium corymbosum* L.) var. 'Blue ribbon' **Exsplant:** Saksılı 6 aylık bitkilerden boğum ve koltukaltı tomurcukları **Kaynak:** Taku vd., 2025.	**Ön Sterilizasyon:** Çift damıtılmış su ile yıkama + 3-5 damla Tween-20 içeren %2'lik fungisit çözeltisi (Carbendazim) ile muamele + çift damıtılmış su ile iyice durulama **Yüzey Sterilizasyonu:** HgCl2 (0.2%) 2 dk.; HgCl2 (0.2%) 4 dk. NaOCl (4.0%) 2 dk. NaOCl (4.0%) 4 dk. NaOCl (4.0%) 2 dk. + HgCl2 (0.1%) 2 dk. NaOCl (4.0%) 2 dk. + HgCl2 (0.1%) 4 dk. NaOCl (4.0%) 4 dk. + HgCl2 (0.1%) 2 dk. NaOCl (4.0%) 4 dk. + HgCl2 (0.1%) 4 dk.
Tür: Çilek, ahududu, yaban mersini, kekreyemiş **Eksplant:** Aksilar tomurcuklar **Kaynak:** Georgieva vd., 2016.	**Ön sterilizasyon:** Musluk suyuyla yıkama; 1-2 damla Tween 20 ilave edilerek 15 dakika sürekli çalkalama; **Sterilizasyon:** Çilek: %96 etanol (30 s.)+ %0.1 $HgCl_2$ (3 dk.); steril su ile üç kez durulama Ahududu: %70 etanol (60 s.)+ %0.1 $HgCl_2$ (5 dk.); steril su ile üç kez durulama Yaban mersini ve kekreyemiş: %70 etanol (30 s.); %0.1 $HgCl_2$ (3 dk.); steril su ile üç kez durulama
Tür: Aronya (*Aronia melanocarpa* (Michaux) Elliot) **Eksplant:** Sürgün ucu **Kaynak:** Kaya vd. 2024.	**NaOCl tabanlı karışımlar** %1 NaOCl %5 NaOCl + %3 H_2O_2 %3 NaOCl + %70 Etanol (C_2H_5OH) %7 NaOCl + %80 Etanol (C_2H_5OH) **$HgCl_2$ tabanlı karışımlar**

	%1 $HgCl_2$ + %3 H_2O_2 %0.1 $HgCl_2$ + %70 Etanol (C_2H_5OH) %0.5 $HgCl_2$ + %80 Etanol (C_2H_5OH) %0.1 $HgCl_2$ + %5 NaOCl **H_2O_2 tabanlı karışımlar** %5 H_2O_2 + %70 Etanol (C_2H_5OH) %7 H_2O_2 + %70 Etanol (C_2H_5OH) %3 H_2O_2 + %5 NaOCl **Sonuç:** %5 NaOCl ve %3 $H2O_2$'nin (her biri 10 dakika) en düşük kontaminasyon oranı
Tür: Yaban mersini 'ZY09 genotipi' Eksplant: 10 cm uzunluğundaki tepe segmentleri eksplant olarak kullanılmıştır. İkinci adımda, sterilize edilmiş eksplantlar tomurcuk oluşumunu indüklemek için birincil kültür ortamına yerleştirilmiş ve in vitro kurulum tamamlanmıştır. **Kaynak:** Wang vd. 2023.	**Ön sterilizasyon:** 30 dakika musluk suyu altında yıkama; **Sterilizasyon:** %75 etanol (0, 30 veya 60 sn) + %4 NaOC (5,10 veya 15 dk.) + steril su ile üç kez (2 dk.) **Sonuç:** Etanol (30 s) + NaClO (15 dk): Kontaminasyon yok, bitkiler sağlıklı. Etanol (60 s) + NaClO (5 dk): %93 kontaminasyon.
Tür: Böğürtlen (*Rubus fruticosus* L.) 'Triple Crown' çeşidi **Eksplant:** Boğum ve sürgün eksplantları **Kaynak:** AbdAlla vd. 2015.	**Ön sterilizasyon:** Bir saat musluk suyuyla yıkama; **Sterilizasyon:** %30 ve %40 (hacim/hacim) sodyum hipoklorit (%5.2) (20 ve 30 dakika); steril, damıtılmış su ile 5 kez yıkama **Sonuç:** %40 sodyum hipoklorit, 30 dk. %90 başarı
Tür: Çilek (Senga Sengana çeşidi) **Eksplant:** Sürgün uçları ve boğumlar **Kaynak:** Jan vd. 2013.	**Ön sterilizasyon:** 5 dakika Tween 20 deterjanı ile yıkama+ 4-5 kez suyla durulama **Sterilizasyon** **Civa klorür Tabanlı Karışımlar** Civa klorür (%0.1) (2 dk) Civa klorür (%0.1) (3 dk) Civa klorür (%0.1) (4 dk) Civa klorür (%0.1) + etanol (%1.5) (3 dk. + 30 s) Civa klorür (%0.1) + etanol (%1.5) (4 dk. + 30 s) Civa klorür (%0.1) + etanol (%1.5) (2 dk.+30 s) **Sodyum hipoklorit Tabanlı Karışımlar** Sodyum hipoklorit (%1.5) (10 dk) Sodyum hipoklorit (%1.5) + etanol (%1.5) (10 dk. + 30 s) Sodyum hipoklorit (%1.5) (15 dk.) Sodyum hipoklorit (%1.5) (20) Sodyum hipoklorit (%1.5)+etanol (%1.5) (15 dk.+ 30 s) Sodyum hipoklorit (%1.5)+ etanol (%1.5)(20 dk.+ 30 s). Tüm uygulamalar için steril damıtılmış suda 5 dakika durulama **Sonuç:** **a.** %1,5 sodyum hipoklorit (20 dk.)+%70 etanol (30 s.): nekroz ve doku hasarı, yaşama oranı düşük. **b.** %0,1 Civa klorür (4 dk.)+%70 etanol (30 s.): Yaşama oranı %32, nekroz ve kontaminasyon düşük
Tür: Ahududu (Meeker ve Willamette çeşitleri) **Eksplant**: Aksilar tomurcuklar **Kaynak:** Anđelić vd. 2024.	**Kombinasyonlar** **Etanol (%70)+NaOCl** 70% EtOH (1 min)+ 10% NaOCl (15 dk.) 70% EtOH (1 min)+ 10% NaOCl (20 dk.) **Etanol (%70)+Civa klorür ($HgCl_2$ %0.1** 70% EtOH (30 s) + 0.1% $HgCl_2$ (3 dk) 70% EtOH (30 s) + 0.1% $HgCl_2$ (4 dk) 70% EtOH (30 s) +0.1% $HgCl_2$ (5 dk) **Etanol OH (1 dakika) + $HgCl_2$ %0.1** 70% EtOH (1 dk) + 0.1% $HgCl_2$ (3 dk) 70% EtOH (1 dk)+ 0.1% $HgCl_2$ (4 dk) **Sonuç:** 70% EtOH (1 dk.)+ 10% NaOCl (20 dk.)

Tür: Mavi yemiş (*Vaccinium corymbosum* L.) **Eksplant:** Sürgün ucu ve boğum **Kaynak:** Rymkhanova vd. 2025.	**Ön Sterilizasyon:** Sabunlu suyla yıkama ve durulma. **Sterilizasyon:** %0.1'lik civa klorür (3-10 dk.); steril damıtılmış suyla üç kez durulama.

3. SONUÇ

Kültürlerin oluşturulmasındaki başarı büyük ölçüde sterilizasyon maddesinin seçimine, konsantrasyonunun ve maruz kalma süresinin hassas ayarlanmasına bağlıdır. Sterilizasyon maddesinin konsantrasyonu ve maruz kalma süresi mikrobiyal kontaminasyon seviyelerini, eksplant ölüm oranlarını ve hayatta kalma oranlarını önemli ölçüde etkilemektedir. Çalışmalar ardışık sterilizasyon uygulamalarının doku kültürü uygulamalarında güvenilir ve etkili bir yöntem olduğunu ortaya koymaktadır.

ÖZET

Ayva (*Cydonia oblonga*) çeliklerinin köklenme başarısı genotip, hormon uygulamaları, çelik alma zamanı ve yetiştirme ortamına bağlı olarak büyük değişkenlik göstermektedir. Literatürde odun çeliklerinin yaygın olarak kullanıldığı, IBA ve NAA'nın ise en sık denenen hormonlar olduğu görülmektedir. Köklenmesi orta düzeydedir. Genotipe özgü yeni araştırmalara ihtiyaç duyulmaktadır.

Anahtar Kelimeler: *Cydonia oblonga*, köklenme, çelik, hormon

FACTORS INFLUENCING ROOTING SUCCESS IN QUINCE (*Cydonia oblonga*) CUTTINGS

ABSTRACT

The rooting success of quince (Cydonia oblonga) cuttings varies greatly depending on genotype, hormone applications, cutting time, and growing medium. Literature shows that woody cuttings are commonly used, and IBA and NAA are the most frequently tested hormones. Rooting success is moderate. New genotype-specific research is needed.

Keywords: *Cydonia oblonga*, rooting, cutting, hormone

1. GİRİŞ

Ayva (*Cydonia oblonga* Mill.), çeşit ve anaç olarak kullanılan önemli bir yumuşak çekirdekli meyve türüdür (Nečas vd., 2016; Şahin, 2021). Armut ve yenidünya yetiştiriciliğinde, yine ayva yetiştiriciliğinde anaç olarak birçok klonu ve çeşidi talep görmektedir (Rufato 2004; Atay 2011). Anaç ıslahında eğilimler klonlanmış ayva anaçlarının kullanılması yönündedir (Rufato vd., 2004). Üzerine aşılı çeşitlerde verim ve kaliteyi artırması tercih edilme nedenleri arasındadır (. Aynı zamanda ayva kökenli klon anaçların bodurluk sağlaması bahçe sistemleri açısından avantaj oluşturmaktadır.

Ayva çelik, daldırma ve doku kültürü gibi yöntemlerle vegetatif olarak üretilebilmektedir (Aziz 2024). Ayva çeliklerinin köklenme oranları büyük farklılıklar göstermektedir (Rufato vd., 2004). Ayvanın genotipine, uygulanan yönteme, kullanılan hormon tipi ve dozuna bağlı olarak köklenme başarısı ve kök kalitesi değişmektedir (Browning ve Watkins, 1991; Atay ve ark., 2011). Bu çalışmada ayva çeşit, genotip ve anaçlarının çelikleri ile çoğaltılması konusundaki çalışmalar derlenmiştir.

2. ÇELİKLE ÇOĞALTMA ÜZERİNE ÇALIŞMALAR

Çelik tipi olarak odun çeliklerinin tercih edildiği görülmektedir. Çelik alma zamanı geç sonbahar-kış periyodu olarak öne çıkmaktadır. Köklendirme hormonu olarak IBA ve NAA etkili hormonlardır. Yine IBA ve NAA içerikli ticari preparatların da kullanıldığı görülmektedir (Tablo 1). Çelikle çoğaltımı yapılan anaçlar arasında Quince A başta olmak üzere BA 29 ve Quince C anaçları yer almaktadır.

Tablo 1. Ayva (*Cydonia oblanga* L.) çeliklerinin köklenme durumları

Aziz vd. 2024.	**Materyal:** Ayva (*Cydonia oblonga* Mill.) **Çelik tipi:** Odun çelikleri **Hormon:** IBA (0, 1000, 2000 ve 3000 mg/l) **Köklendirme Ortamı:** Nehir kumu, nehir kumu/turba yosunu ve perlit/turba yosunu **Sonuç:** IBA köklenme oranı ve kök karakterini etkilememiştir. En yüksek köklenme yüzdesi (%62,50), kök ve sürgün kalitesi kontrol çeliklerinde elde edilmiştir. En iyi köklenme ortamı (%64,58) nehir kumunda gerçekleşmiştir. Diğer ortamlarda hormon uygulanmaksızın yeterli bulunmuştur.
Milagres vd., 2023	**Materyal:** Ayva anaçları (Adams, BA-29, EMA, EMC ve Sydo) **Amaç:** Adventif köklenmenin artırılması **Sonuç:** BA-29'da düşük köklenme
Nečas vd., 2016.	**Materyal:** Cydomalus (elma ve ayva melezi) **Hormon:** %1 Racine (%2.5 NAA), %0.5 Rhizopon AA (%2,5 IBA) ve %50 etanol çözeltisinde %0.25 IBA. **Yöntem:** Hormon etkisi; hormon ve ısıtma etkisi birlikte denendi. **Sonuç:** **1.Hormon çeşitlerinin etkileri** Rhizopon AA+ ısıtma köklenme iyi Ortalama %36.9 köklenme; Cydomalus (%73,9) **2. Dönemler karşılaştırıldı** BA29 için Mart en iyi dönem; Mart ve Aralık ayları arasındaki köklenme farkı %43,9. Cydomalus için Aralık en iyi dönem; Aralık ve Mart ayları arasında %18,7. **3. Hormon+ısı etkisi karşılaştırıldı** Isıtma olumsuz etkiledi. +5°C'de saklama ve %50 etanol çözeltisinde %0,25 IBA ile muamele etkili oldu.
Atay vd. 2011	**Materyal:** Ege-2, Ege-22 ve Eşme ayva çeşitleri **Çelik tipi:** Odun çeliği **Dönem:** Şubat

	Hormon: 1000 ppm IBA **Yöntem:** 5 s uygulama; Şubat-Nisan kuma gömerek bekletme; Nisan perlit+torf karışımına, siyah plastik malçlı yastığa dikim. **Sonuç:** Ege 2: %64; Ege 22:%40; Eşme: %25 köklenme
Necas, Kosina, 2008	**Materyal:** *Malus communis* × *Cydonia oblonga* melezi 'Cydomalus' Ayva anaçları (BA 29, Sydo, MA ve S1) **Çelik tipi:** Odun çeliği **Dönem:** Ocak-Şubat **Hormon:** %1 Racine (%2,5 NAA) ve %0,5 Rhizopon AA (%2,5 IBA) **Yöntem:** Çeliklerin yarısı, kallus oluşana kadar 25-35 gün 21°C'de, diğer yarısı 5°C'de muhafaza edilmiştir. **Sonuç:** Kallus oluşumu açısından en iyi performansı 'Cydomalus' (%100) ve 'S1' (%67) anaçları göstermiştir. Sydo', 'Adams', 'Mansan', 'Shinseiki' ve 'BA 29' çeşitlerinde köklenme oluşumu başarısız olmuştur. Kök gelişimi için uygun bir yetiştirme ortamı belirlenmesi önerilmiştir.
Giacobbo vd. 2007.	**Materyal:** Ayva (*Cydonia oblonga* Mill.) cv. EMC **Amaç:** IBA uygulaması ve kök aşılama yönteminin köklenmeye etkilerinin incelenmesi **Çelik tipi:** Odun çelikleri **Yöntem: 1.**IBA konsantrasyonu (0; 1000; 2000 ve 3000 mg/l) test edilmiştir. **2.**Kök aşılama yapılmış veya yapılmamış çelikler test edilmiştir. Köklenme ortamı: Vermikülit; Plantmax®; veya Plantmax® + vermikülit, 1:1 (v/v). **Sonuç:** Kök uzunluğu için IBA eşik değeri 1534 mg/l; Köklü çelik yüzdesi için IBA eşik değeri 2119 mg/l Plantmax®+vermikülit substratı + kök aşılama en fazla kök sayısı ve daha kısa sürgün uzunluğu oluşturdu Vermikülitte köklendirenlerde en yüksek adaptasyon %93,75 olmuştur.)
Rossi vd. 2004.	**Materyal:** Mela, Radanelli, Portugal 1611, Orange, Inta, Vranja ve Quince C anaçları **Dönem:** Kasım **Çelik tipi:** Yeşil çelik **Hormon:** 3000 mg/l IBA **Köklendirme ortamı:** Vermikülit **Sonuç:** Radanelli, Portugal 1611, Orange ve Inta çeşitlerinde köklenme oranı ≥%50; Diğer çeşitlerin köklenme potansiyeli düşük, Vranja çeşidinde köklenme yok
Hepaksoy ve Ünal, 1995.	**Materyal:** Ayva çeşitleri (Kirli, Limon, Ören, Söbü, Şeker Gevrek Turgutlu, Quince A anacı **Çelik tipi:** Odun çeliği **Sonuç:** Quince A (38%); Şeker Gevrek (0.67%) köklenme
Yousif vd. 1989.	**Materyal:** Haweja Asfahani ayva çeşitleri **Materyal:** 6 yaşlı ağaçlardan alınan çelikler **Dönem:** Ekim-Ocak arasında 21 günlük periyotlarda çelik alma **Hormon:** 0-2000 ppm aralığında IBA konsantrasyonu **Yöntem:** 2 ay 3 ± 2°C'de nemli spagnum turbada saklama **Sonuç:** 20 Kasım çelikleri + 500 ppm IBA en iyi köklenme oranı Haweja çeşidinde köklenme daha yüksek.

3. SONUÇ

Ayvanın genotipe bağlı olarak verdiği cevaplar oldukça değişkendir. Literatür sonuçlarına göre köklenme başarısı orta derecede kolay olarak sınıflandırılabilir. Ayvanın çelikle köklendirilmesi üzerine sınırlı sayıda çalışma olduğu açıkça görülmektedir. Bu çalışmalardan elde edilen sonuçlar, ayva anaçları ve çeşitlerinde çelikle çoğaltma üzerinde yeni çalışmalarla köklenme başarısının artırılmasının gerektiği ortaya koymaktadır.
