2. **Güçlendirilmiş Yerel Kalkınma:** Yerel kooperatifler, zorunlu rehberlik ve yerel tedarik zinciri ile turizm gelirleri yerelde kalacak, istihdam artacak ve sosyo-ekonomik refah yükselecektir. Bu, aynı zamanda yerel halkın parkı bir tehdit değil, bir değer olarak görmesini teşvik edecek ve koruma çabalarına desteklerini artıracaktır.

3. **Yüksek Kaliteli Ziyaretçi Deneyimi:** Sürdürülebilir altyapı, eğitimli rehberler ve hedefe yönelik pazarlama ile ziyaretçilere unutulmaz, nitelikli, eğitici ve sorumlu bir seyahat deneyimi sunulacak, böylece destinasyonun itibarı ve tekrar ziyaret oranları artacaktır.

Politika ve Uygulama Önerileri:

Bu modelin hayata geçirilebilmesi için aşağıdaki adımların atılması kritik öneme sahiptir:

- **Acil Eylem:** Kazakistan Çevre Bakanlığı öncülüğünde, KKMP için "2025-2030 Ekoturizm Master Planı" acilen hazırlanmalı ve bu plan, önerilen modeli temel almalıdır.

- **Mevzuat Düzenlemesi:** Yerel halkın turizm gelirlerinden adil pay almasını ve karar süreçlerine katılımını güvence altına alan, ayrıca sürdürülebilir altyapı standartlarını zorunlu kılan yasal düzenlemeler yapılmalıdır.

- **Kamu-Özel-Sektör İşbirliği (KÖS):** Altyapı yatırımları ve hizmet geliştirme için KÖS modelleri teşvik edilmeli, özel sektör yatırımları sürdürülebilirlik kriterlerine bağlanmalıdır.

- **Kapasite Geliştirme Programı:** Yerel halk ve park personeli için sürekli ve kapsamlı bir eğitim programı (dil, girişimcilik, rehberlik, dijital pazarlama) ulusal ve uluslararası fonlarla desteklenmelidir.

Bu çalışmanın, Kazakistan'daki karar vericiler, park yöneticileri, yerel yönetimler, sivil toplum kuruluşları ve yerel paydaşlar için somut bir eylem rehberi ve tartışma belgesi olması umulmaktadır. Katon-Karagay Milli Parkı'nın, Orta Asya'nın önde gelen, sürdürülebilirliği ile rol model bir ekoturizm merkezine dönüşmesi, ancak bu tür bütünleşik yaklaşımların benimsenmesi ve kararlılıkla uygulanmasıyla mümkün olacaktır.

Gelecek Çalışmalar için Öneriler: Bu çalışma, teorik bir model sunmakla birlikte, pratikteki geçerliliğini test etmek amacıyla gelecek araştırmalara ihtiyaç duymaktadır:

1. **Birincil Saha Araştırması:** Önerilen modelin bileşenlerine yönelik yerel halk, ziyaretçiler, tur operatörleri ve park yöneticileriyle derinlemesine mülakatlar ve anketler yapılarak modelin uygulanabilirliği, öncelikleri ve potansiyel engelleri detaylıca incelenmelidir.

2. **Karşılaştırmalı Analiz:** Model, benzer özelliklere sahip diğer korunan alanlarda (örneğin, Nepal'deki Sagarmatha Milli Parkı veya Tanzanya'daki Serengeti) uygulanan başarılı modellerle karşılaştırmalı olarak analiz edilerek zenginleştirilebilir.

3. **Ekonomik Fizibilite Çalışması:** Önerilen altyapı yatırımları ve işletme modellerinin ekonomik fizibilitesi ayrıntılı bir şekilde hesaplanmalıdır.

4. **İklim Değişikliği Etki Analizi:** İklim değişikliğinin parkın ekosistemleri ve turizm potansiyeli üzerindeki spesifik etkileri modellenerek, modele uyum stratejileri entegre edilmelidir.

ÖZET

Havacılık sektörü, küresel CO_2 emisyonlarının yaklaşık %2–3'ünü oluşturmaktadır. Ancak, sektörün iklim değişikliği üzerindeki toplam etkisinin sadece bu doğrudan emisyonlardan değil, aynı zamanda diğer atmosferik etkilerden dolayı yaklaşık iki kat daha fazla olduğu belirtilmektedir. Bu yönüyle havacılık, karayolu taşımacılığının ardından ulaşım sektöründe iklim değişikliğine en fazla katkıda bulunan ikinci alan olarak değerlendirilir. Bu çerçevede havacılık sektörü, artan çevresel baskılar ve sürdürülebilir kalkınma hedefleri doğrultusunda çevresel, sosyal ve yönetişim (ÇSY) performansını iyileştirmeye yönelik stratejiler geliştirmektedir. Hava yolu şirketleri için sürdürülebilirlik, çevresel etkilerin azaltılmasını ifade etmenin yanı sıra sosyal sorumluluk, kurumsal yönetim ve operasyonel verimlilik alanlarında dengeli bir gelişimi de gerektirmektedir. Bu kapsamda, sektördeki sürdürülebilirlik performansının bütüncül ve analitik biçimde değerlendirilmesi, stratejik karar alma süreçleri açısından kritik bir önem taşımaktadır. Bu çalışmada, 5 uluslararası hava yolu şirketinin (Türk Hava Yolları, Lufthansa Hava Yolları, Copa Hava Yolları, Singapore Hava Yolları ve Qatar Hava Yolları) 2020–2023 yılları arasındaki sürdürülebilirlik performansları çok kriterli karar verme (ÇKKV) yaklaşımlarıyla analiz edilmiştir. Analiz kapsamında çevresel, sosyal ve yönetişim olmak üzere üç ana kriter altında 9 alt kriter değerlendirmeye alınmıştır. Kriter ağırlıkları, öznel yargılardan ziyade nesnel verilere dayanan MEREC yöntemiyle belirlenmiş; elde edilen ağırlıklar MABAC ve MARCOS yöntemlerine entegre edilerek yıllara göre şirket sıralamaları belirlenmiştir. Lufthansa Hava Yolları 2020–2023 yılları içerisinde hem MABAC hem de MARCOS yöntemleri açısından en yüksek sürdürülebilirlik performansını gösteren hava yolu şirketi olmuştur. Ayrıca, yıllar arasındaki sıralama farklılıkları, hava yolu şirketlerinin sürdürülebilirlik stratejilerinde dönemsel değişikliklerin etkili olduğunu göstermektedir. Çalışma, havacılık sektöründe ÇSY performansını bütüncül bir yaklaşımla değerlendiren entegre bir ÇKKV modeli sunmaktadır. Ayrıca, farklı ağırlıklandırma yöntemlerinin duyarlılık etkisini ortaya koyarak karar vericilere daha sağlam bir analitik temel sağlamaktadır.

Anahtar Kelimeler: Sürdürülebilirlik, Havacılık sektörü, ÇSY, Çok kriterli karar verme (ÇKKV), Duyarlılık analizi.

EVALUATION OF SUSTAINABILITY PERFORMANCE IN AIRLINA COMPANIES USING MEREC-BASED MABAC AND MARCOS APPROACHES

ABSTRACT

The aviation sector accounts for approximately 2–3% of global CO_2 emissions. However, it is reported that the sector's total impact on climate change is approximately twice as high, due not only to these direct emissions but also to other atmospheric impacts. In this respect, aviation is considered the second-largest contributor to climate change in the transportation sector, after road transport. In this context, the aviation sector is developing strategies to improve its environmental, social, and governance (ESG) performance in line with increasing environmental pressures and sustainable development goals. For airline companies, sustainability not only implies reducing environmental impacts but also requires balanced development in social responsibility, corporate governance, and operational efficiency. In this context, a holistic and analytical assessment of the sector's sustainability performance is critical for strategic decision-making processes. In this study, the sustainability performance of five international airlines (Turkish Airlines, Lufthansa Airlines, Copa Airlines, Singapore Airlines, and Qatar Airways) between 2020 and 2023 was analyzed using multi-criteria decision-making (MCDM) approaches. Within the scope of the analysis, nine sub-criteria were evaluated under three main criteria: environmental, social, and governance. Criteria weights were determined using the MEREC method, which relies on objective data rather than subjective judgments. The resulting weights were integrated with the MABAC and MARCOS methods to determine company rankings by year. Lufthansa Airlines achieved the highest sustainability performance between 2020 and 2023, based on both the MABAC and MARCOS methods. Furthermore, the differences in rankings between years indicate that seasonal changes are influential in airlines' sustainability strategies. The study presents an integrated MCDM model that evaluates ESG performance in the aviation sector with a holistic approach. It also provides decision-makers with a more robust analytical basis by demonstrating the sensitivity impact of different weighting methods.

Keywords: Sustainability, Aviation sector, ESG, Multi-Criteria Decision Making (MCDM), Sensitivity analysis.

1. GİRİŞ

Sürdürülebilirlik, var olan bir şeyin ya da bir durumun sürdürülmesi, daimi olma yeteneği olarak adlandırılan ve farklı alanlardaki ilişkileri birbiri ile uyumlu kılmak zorunluluğuna işaret eden bir kavramdır. İngilizce karşılığı "sustainability" olan sürdürülebilirlik kavramı (Şen vd., 2018) literatürde genellikle bugünün ihtiyaçlarını, gelecek nesillerin kendi ihtiyaçlarını karşılama kapasitesini tehlikeye atmadan karşılamak olarak tanımlanmaktadır (WCED, 1987).

Havacılık sektörü, küresel ekonominin en dinamik bileşenlerinden biri olarak uluslararası ulaşım ağlarının sürekliliğini sağlayan stratejik bir konuma sahiptir. Ancak sektörün yüksek enerji tüketimi, yoğun operasyonel gereksinimleri ve atmosfere saldığı CO_2 emisyonları, onu sürdürülebilirlik tartışmalarının merkezine yerleştirmektedir. İklim değişikliğine olan etkilerinin giderek belirginleşmesi, hava yolu şirketlerinin çevresel, sosyal ve yönetişim (ÇSY) performanslarını yalnızca kurumsal bir sorumluluk alanı olmaktan çıkararak stratejik bir zorunluluk hâline getirmiştir. Emisyon azaltımı, yakıt verimliliği ve maliyet etkinlik gibi konular sürdürülebilirliğin çevresel ve ekonomik boyutunu, yolcu memnuniyeti, çalışanların sağlığı ve toplumla kurulan uyumlu ilişkiler sosyal boyutu olup sektörün başarısını doğrudan etkilemektedir. (Akduman vd., 2025) Uluslararası Hava Taşımacılığı Birliği (IATA), 2050 yılına kadar net sıfır karbon emisyonuna ulaşma hedefini ortaya koymuştur (IATA, 2023). Bu kapsamda, şirketlerin sürdürülebilirlik performanslarının çok boyutlu, nesnel ve yıllar arası karşılaştırılabilir yöntemlerle değerlendirilmesi, hem karar vericiler hem de sektör paydaşları açısından kritik önem taşımaktadır.

Bu araştırma, uluslararası havacılık sektöründe faaliyet gösteren 5 hava yolu şirketinin (Türk Hava Yolları, Lufthansa Airlines, Copa Airlines, Singapore Airlines ve Qatar Airways) 2020–2023 yılları arasındaki sürdürülebilirlik performanslarını ÇSY boyutları çerçevesinde çok kriterli karar verme (ÇKKV) yöntemlerini kullanarak kapsamlı biçimde analiz etmeyi amaçlamaktadır. Bu çalışma, hava yolu şirketlerinin sürdürülebilirlik göstergelerini çok boyutlu ve ölçülebilir bir analitik çerçeveye oturtmayı amaçlamaktadır. Ayrıca MEREC, MABAC ve MARCOS yöntemleri kullanılarak şirketlerin yıllık performans sıralamaları karşılaştırmalı biçimde değerlendirilmektedir. Son olarak, yıllar arasındaki performans değişimleri incelenerek şirketlerin sürdürülebilirlik stratejilerindeki eğilimler, gelişim alanları ve dönemsellik etkileri analiz edilmektedir.

Literatürde sıkça karşılaşılan sübjektif ağırlıklandırma yöntemlerinin aksine, bu çalışmada kriter ağırlıkları MEREC yöntemi ile belirlenmiş ve böylece veri odaklı, nesnel bir değerlendirme yaklaşımı benimsenmiştir. Belirlenen ağırlıkların hem MABAC hem de MARCOS yöntemlerine entegre edilmesi, farklı karar verme algoritmalarının sonuçlar üzerindeki tutarlılığını ve duyarlılığını karşılaştırmaya imkan tanıyan bütüncül bir analiz yapısı sunmuştur. Bu yönüyle araştırma, hava yolu şirketlerinin çevresel, sosyal ve yönetişim (ÇSY) performanslarındaki zaman içindeki değişimi güçlü bir yöntemsel temele dayandırarak incelemektedir. Sektör paydaşları ile yatırımcılar için güvenilir ve uygulanabilir sonuçlar sunmaktadır.

Uluslararası düzenlemeler, yatırımcı beklentileri ve kamuoyu duyarlılığı, hava yolu şirketlerinin sürdürülebilirlik performanslarını düzenli olarak izleme, değerlendirme ve iyileştirme gerekliliğini artırmaktadır. Dolayısıyla, hem çok boyutlu ÇSY kriterlerini dikkate alan hem de yıllar bazında karşılaştırılabilir sonuçlar sunabilen analitik bir metodolojiye duyulan ihtiyaç günden güne daha belirgin hâle gelmektedir. Bu çalışma, söz konusu ihtiyacı karşılamak amacıyla, farklı coğrafi, ekonomik ve operasyonel koşullara sahip hava yolu şirketlerinin sürdürülebilirlik performanslarını ortak bir ÇKKV yapısı altında karşılaştırılabilir şekilde analiz etmektedir.

Analiz sürecinde, hava yolu şirketlerine ait verilerin kamuya açık sürdürülebilirlik ve finansal raporlarda doğru, erişilebilir ve tutarlı biçimde sunulduğu varsayılmıştır. Ayrıca, pandemi döneminin yol açtığı operasyonel dalgalanmalara rağmen yıllar arası karşılaştırılabilirliğin korunduğu ve tüm şirketlerin aynı kriter seti altında değerlendirilebilir olduğu kabul edilmiştir.

Bu varsayımlar doğrultusunda çalışma, havacılık sektörünün sürdürülebilirlik performansını kapsamlı bir yöntemsel çerçeve ile inceleyerek literatüre hem içerik hem de metodoloji açısından katkı sunmayı hedeflemektedir.

2. LİTERATÜR TARAMASI

Son yıllarda çok kriterli karar verme (ÇKKV) yöntemleri, ekonomik, çevresel ve yönetsel alanlarda karar süreçlerini destekleyen güçlü araçlar olarak öne çıkmaktadır. Bu bağlamda yapılan çalışmalar, farklı sektörlerde nesnel ağırlıklandırma yöntemlerinin ve entegre modellerin kullanımına yönelik önemli katkılar sunmaktadır.

Duran (2023), N-11 ülkelerinin tedarik zinciri dayanıklılığını FM Global'in Küresel Dayanıklılık Endeksi verilerini kullanarak değerlendirmiştir. MEREC yöntemiyle kriter ağırlıklarını belirlemiş; EDAS, MARCOS ve WASPAS yöntemleriyle ülkelerin dayanıklılık performanslarını sıralamış ve sonuçları BORDA yöntemiyle bütünleştirmiştir. Analiz bulgularına göre "Tedarik Zinciri Görünürlüğü" ve "Kurumsal Yönetim" en etkili göstergeler olarak tanımlanmış; Güney Kore ve Türkiye en dayanıklı ülkeler olarak öne çıkmıştır. Bu çalışma, ÇKKV yöntemlerinin entegrasyonu yoluyla ulusal düzeyde tedarik zinciri dayanıklılığının ölçülmesine yönelik özgün bir yaklaşım sunmaktadır.

Benzer şekilde, Sümerli Sarıgül vd. (2023) havalimanı hizmet kalitesini değerlendirmek amacıyla MEREC tabanlı MARCOS ve CoCoSo yöntemlerini entegre eden yeni bir ÇKKV modeli geliştirmiştir. Skytrax'ın 2021 yılı verilerine dayanan çalışmada 17 havalimanı, 11 hizmet kriterine göre analiz edilmiştir. Bulgular, ulaşım hizmetleri, güvenlik hizmetleri ve terminal tesislerinin hizmet kalitesini en çok etkileyen unsurlar olduğunu göstermiştir. Sonuç olarak Chubu Centrair Havalimanı en yüksek, Tokyo Haneda Havalimanı ise en düşük hizmet kalitesine sahip olarak belirlenmiştir.

Meral (2023) ise BRICS-T ülkelerinin inovasyon performanslarını, Küresel İnovasyon Endeksi verilerine alternatif bir yaklaşımla değerlendirmiştir. Kriter ağırlıkları MEREC yöntemiyle belirlenmiş, ülke sıralamaları MARCOS yöntemiyle yapılmıştır. Sonuçlara göre en önemli kriterler "yatırımlar", "AR-GE" ve "çevrimiçi yaratıcılık" olarak tespit edilmiş; "politik çevre" ve "bilgi ve iletişim teknolojileri" en az etkili faktörler olmuştur. Genel sıralamada Çin ve Hindistan en yüksek, Brezilya ve Güney Afrika en düşük inovasyon performansına sahipken; Türkiye üçüncü sırada yer almıştır.

Sürdürülebilirlik temalı araştırmalarda da benzer yöntemsel eğilimler gözlenmektedir. Mondal vd. (2024), sürdürülebilir orman kaynaklarının yönetimi için Pythagorean bulanık MEREC–MARCOS modeline dayalı yeni bir ÇKKV yaklaşımı geliştirmiştir. Sekiz farklı orman yönetim modeli, odun üretimi, biyolojik çeşitlilik, hasat maliyeti ve yeniden ağaçlandırma giderleri gibi göstergelerle değerlendirilmiştir. Analiz sonucunda on yıllık periyotlu modelin (M1) en yüksek sürdürülebilirlik performansına sahip olduğu belirlenmiştir. Bu çalışma, belirsizliklerin azaltılmasına ve sürdürülebilir orman yönetiminde optimal model seçimine katkı sunmaktadır.

Benzer şekilde Sönmez ve Doğan (2024), OECD ülkelerinin çevresel performanslarını MEREC ve MARCOS yöntemleriyle incelemiştir. Çevresel sağlık, ekosistem canlılığı, karbon emisyonu ve yenilenebilir enerji kullanımı gibi göstergeler dikkate alınmıştır. Sonuçlara göre İsveç, Norveç ve İsviçre en yüksek çevresel performansa sahip ülkeler olurken; Türkiye ve

Meksika alt sıralarda yer almıştır. Bu bulgular, sürdürülebilirlik politikalarının güçlendirilmesi gerekliliğine işaret etmektedir.

Finansal performans analizleri kapsamında, Bektaş (2023) Borsa İstanbul (BİST) 100 endeksinde işlem gören enerji firmalarının 2022 yılı performanslarını MEREC–MABAC entegrasyonu ile değerlendirmiştir. Yedi finansal kriter üzerinden yapılan analizde, "Hisse Başına Kâr Oranı", "Toplam Duran Varlıklar" ve "Toplam Öz Kaynaklar" en önemli göstergeler olarak belirlenmiştir. ENJSA, AKSEN ve ZOREN firmaları en yüksek finansal performansa sahip firmalar olarak öne çıkmıştır. Benzer biçimde Ateş ve Koca (2024), Avrupa Birliği'nin Sınırda Karbon Düzenleme Mekanizması (CBAM) kapsamında çimento sektöründeki firmaların finansal performanslarını MEREC–MABAC yöntemiyle incelemiş; aktif kârlılığı, öz sermaye kârlılığı ve net kâr marjını en kritik kriterler olarak saptamıştır. Bulgular, CBAM'ın yürürlüğe girmesiyle firmaların çevresel ve finansal stratejilerini yeniden yapılandırmaları gerektiğini ortaya koymaktadır.

Karakuş (2023) çalışmasında, Türk Hava Yolları'nın 2014–2021 yıllarına ait sürdürülebilirlik raporlarını içerik analiziyle inceleyerek raporların yapısal ve içeriksel değişimlerini değerlendirmiştir. Bulgular, raporların görsel açıdan başarılı ancak içerik bakımından tutarsızlıklar ve izlenebilirlik sorunları barındırdığını göstermektedir. Bu durum, havacılık sektöründe sürdürülebilirlik raporlamasının şeffaflık, güvenilirlik ve denetlenebilirlik ilkeleri çerçevesinde geliştirilmesi gerektiğine işaret etmektedir.

Örgütsel davranış alanında, Yavuz ve Lale (2024) liyakat ve sadakat arasındaki ilişkiyi kavramsal ve nitel bir yaklaşımla ele almışlardır. Çalışma, liyakatin adalet ve çalışan bağlılığı üzerindeki olumlu etkilerini vurgulamakta; örgütlerin uzun vadeli başarısının adil ve eşitlikçi uygulamalarla sağlanabileceğini göstermektedir. Böylece etik ve performans temelli bir yönetim anlayışının gerekliliği ortaya konmuştur.

Dış politika bağlamında Özdilek (2025), ABD'nin vekil aktör stratejisini PYD-YPG örneği üzerinden analiz etmiştir. Nitel bir araştırma tasarımıyla yürütülen çalışma, vekil aktör kullanımının bölgesel istikrarı zayıflattığını ve uluslararası hukukun sınırlarını esnettiğini ortaya koymuştur. Bu analiz, vekil aktör stratejisinin küresel güvenlik dengeleri üzerindeki uzun vadeli etkilerine dair önemli bir değerlendirme sunmaktadır.

Son olarak, Ayçin ve Arsu (2021) Sosyal Gelişme Endeksi (SGE) göstergelerinin eşit ağırlıklandırılmasının ülkeler arası farklılıkları yansıtmadığı varsayımından hareketle, göstergelerin ağırlıklarını MEREC yöntemiyle belirleyip MARCOS yöntemiyle ülke sıralamalarını yeniden yapmıştır. Analiz sonucunda kapsayıcılık, sağlık ve ileri düzey eğitime erişim en önemli kriterler olarak bulunmuş; Norveç, Finlandiya ve Danimarka en yüksek sosyal gelişim performansına sahip ülkeler olarak öne çıkmıştır. Elde edilen bulgular, objektif ağırlıklandırma yaklaşımlarının ülke sıralamalarında anlamlı farklar yaratabileceğini göstermektedir.

Çalışmalara ait literatür taraması özeti Tablo 1' de verilmiştir.

Tablo 1. Literatür Taraması Özeti

Yazar (Yıl)	Uygulama Alanı	ÇKKV Yöntemi
Duran (2023)	N-11 ülkelerinde tedarik zinciri dayanıklılığı analizi	MEREC, EDAS, MARCOS, WASPAS, BORDA
Sümerli Sarıgül vd. (2023)	Havalimanı hizmet kalitesi değerlendirmesi	MEREC, MARCOS, CoCoSo
Meral (2023)	BRICS-T ülkelerinde inovasyon performansının değerlendirilmesi	MEREC, MARCOS

Özdilek (2025)	ABD dış politikasında vekil aktör stratejisi	Nitel analiz, stratejik inceleme
Ayçin ve Arsu (2021)	Sosyal Gelişme Endeksi göstergeleriyle ülke sıralaması	MEREC, MARCOS

3. YÖNTEM VE MATERYAL

Bu bölümde analizde kullanılan veri seti ile uygulanan yöntemlere ilişkin ayrıntılı bilgiler sunulmuştur. Çalışmada, havayolu şirketlerinin sürdürülebilirlik performanslarını değerlendirmek amacıyla iki farklı ağırlıklandırma yaklaşımı ve bu yaklaşımlara entegre edilen iki çok kriterli karar verme (ÇKKV) yöntemi kullanılmıştır. İlk olarak, kriterlerin önem ağırlıklarını belirlemek için objektif ağırlıklandırma yöntemi olan MEREC yöntemi uygulanmıştır. MEREC yöntemiyle elde edilen kriter ağırlıkları, daha sonra MABAC ve MARCOS yöntemlerine entegre edilerek şirketlerin sürdürülebilirlik performans skorları hesaplanmış ve sıralamaları oluşturulmuştur.

İkinci aşamada ise yöntemin kararlılığını test etmek amacıyla alternatif bir ağırlıklandırma tekniği olan Entropi yöntemi kullanılarak aynı analiz süreci tekrarlanmıştır. Entropi tabanlı MABAC ve MARCOS sonuçları elde edilmiştir. Böylece MEREC ve Entropi tabanlı modeller karşılaştırılmış ve yöntemin duyarlılığını değerlendirmek için bir duyarlılık analizi gerçekleştirilmiştir.

Son aşamada, yöntemler arasında tutarlılığı ölçmek amacıyla MEREC tabanlı ve Entropi tabanlı sonuçlar Spearman korelasyon analizi ile karşılaştırılmış ve iki model arasında anlamlı bir sıralama ilişkisi olup olmadığı istatistiksel olarak test edilmiştir.

3.1. MEREC Yöntemi

MEREC yöntemi Mehdi Keshavarz-Ghorabaee, Maghsoud Amiri, Edmundas Kazimieras Zavadskas, Zenonas Turskis ve Jurgita Antuchevičienė tarafından geliştirilmiş ve 2021 yılında literatüre tanıtılmıştır. MEREC, kriter ağırlıklarını belirlemede kullanılan nesnel ağırlıklandırma teknikleri arasında yer alan bir yöntemdir. Her bir kriterin alternatiflerin genel performansı üzerindeki etkisini esas alarak ağırlıkları hesaplamaktadır. Alternatiflerin performansını daha fazla etkileyen kriterlere, yöntem gereği daha yüksek ağırlıklar atanmaktadır.

MEREC yöntemi, uygulama aşamasında altı temel adımdan oluşan bir süreç izlemektedir (Keshavarz-Ghorabaee vd. 2021).

Adım 1: Karar Matrisinin Oluşturulması

Alternatiflerin her bir kritere ilişkin değerlerini içeren karar matrisi oluşturulur. Karar matrisinde kullanılan x_{ij} elemanlarının sıfırdan büyük olması gerekir ($x_{ij} > 0$). Negatif herhangi bir veri bulunuyorsa uygun bir dönüştürme yöntemiyle pozitife çevrilir. n adet alternatif ve m adet kriterden oluşan karar matrisi Eşitlik (1)'de yer almaktadır.

$$X = \begin{bmatrix} x_{11} & x_{12} & \cdots & x_{1j} & \cdots & x_{1m} \\ x_{21} & x_{22} & \cdots & x_{1j} & \cdots & x_{2m} \\ \vdots & \vdots & \ddots & \vdots & \ddots & \vdots \\ x_{i1} & x_{i1} & \cdots & x_{ij} & \cdots & x_{im} \\ \vdots & \vdots & \ddots & \vdots & \ddots & \vdots \\ x_{n1} & x_{n2} & \cdots & x_{nj} & \cdots & x_{nm} \end{bmatrix} \quad (1)$$

Adım 2: Karar Matrisinin Normalize Edilmesi

Matriste yer alan değerlerin ortak bir ölçeğe taşınabilmesi için basit bir doğrusal normalizasyon yöntemi kullanılır. Normalize edilen matristeki her bir değer n_{xij} şeklinde gösterilir. B fayda (yarar) yönlü kriterleri, H ise maliyet (yarar olmayan) yönlü kriterleri göstermektedir. Normalizasyon işlemi içi formül Eşitlik (2)'de verilmiştir.

$$n_{ij}^{x} = \begin{cases} \dfrac{\min\limits_{k} x_{kj}}{x_{ij}}, & j \in B \\ \dfrac{x_{ij}}{\max\limits_{k} x_{kj}}, & j \in H \end{cases} \quad (2)$$

Adım 3: Genel Performans Değerlerinin (S_i) Elde Edilmesi

Alternatiflerin genel performanslarını belirlemek için tüm kriterlere eşit ağırlık veren logaritmik bir performans ölçütü kullanılmaktadır. Bir önceki adımda hesaplanan normalize değerler dikkate alındığında, n_{xij} değerinin küçülmesi ilgili alternatifin performansını (S_i) artıran bir etki yaratır. Bu kapsamda genel performansların hesaplanmasında Eşitlik (3)'de verilen ifade kullanılmaktadır.

$$S_i = ln\left(1 + \left(\frac{1}{m}\sum_j \left|ln\left(n_{ij}^{x}\right)\right|\right)\right) \quad (3)$$

Adım 4: Kriter Değeri Hariç Tutularak Genel Performans Değerlerinin (S'_{ij}) Elde Edilmesi

Bu adımda, bir önceki adımda kullanılan logaritmik performans ölçütü benzer şekilde uygulanır. Ancak bu adım ile üçüncü adım arasındaki temel fark, performansların her bir kriter ayrı ayrı çıkarılarak hesaplanmasıdır. Bu nedenle, m kriter için m farklı performans seti elde edilir. S_{ij}, i. alternatife ait genel performansın, j. kriter çıkarıldığında aldığı değeri ifade etmektedir. Bu hesaplamaların yapılmasında aşağıdaki eşitlik kullanılır.

Bu adım ile üçüncü adım arasındaki temel fark, performansların her kriterin ayrı ayrı çıkarılarak hesaplanmasıdır. Dolayısıyla m kriter için m farklı performans seti oluşur. Bu kapsamda S_{ij}, i. alternatife ait performansın, j. kriter çıkarıldığında aldığı değeri göstermektedir. Performans değerleri Eşitlik (4)'de verilen matematiksel formülasyon üzerinden hesaplanmaktadır.

$$S'_{ij} = ln\left(1 + \left(\frac{1}{m}\sum_{k,k\neq j}|ln(n_{ik}^{x})|\right)\right) \quad (4)$$

Adım 5: Mutlak Sapmalar Toplamının (E_j) Elde Edilmesi

Her bir kriterin çıkarılmasının alternatiflerin performansları üzerindeki etkisi, önceki adımlarda elde edilen genel ve kriter çıkarılmış performans değerleri kullanılarak hesaplanır. E_j ile, j. kriterin çıkarılmasının yarattığı etki ifade edilmektedir ve bu etki Eşitlik (5)'deki matematiksel formül üzerinden hesaplanır.

$$E_j = \sum_i |S'_{ij} - S_i| \quad (5)$$

Adım 6: Kriter Önem Ağırlıklarının (w_j) Elde Edilmesi

Eşitlik (6) ile her kriterin önem ağırlıkları hesaplanır.

$$w_j = \frac{E_j}{\sum_k E_k} \quad (6)$$

3.2. MABAC YÖNTEMİ

MABAC yöntemi Dragan Pamučar ve Zoran Ćirović tarafından geliştirilmiş ve 2015 yılında literatüre tanıtılmıştır. İlk uygulaması ve tanıtımıyla birlikte, MABAC "çok kriterli, nitelikli karar verme" problemlerinde referans bölgelerin kullanıldığı bir yaklaşım getirmiştir. Temelde bu yöntem, her alternatifin kriter fonksiyonunun sınır yaklaşım alanı ile ilişkilendirilmiş ideal/anti-ideal referans çözümlerine ne kadar yakın olduğunu değerlendirir. Yani alternatifleri, sınır yaklaşım alanlarına göre olan uzaklıklarına göre sıralar.

MABAC yöntemi, uygulama aşamları birbirini takip eden altı adımdan oluşmaktadır (Pamučar ve Ćirović, 2015).

Adım 1: Karar Matrisinin Oluşturulması

$$X = \begin{bmatrix} x_{11} & x_{12} & \cdots & x_{1n} \\ x_{21} & x_{22} & \cdots & x_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ x_{m1} & x_{m2} & \cdots & x_{mn} \end{bmatrix} \quad (7)$$

m adet alternatifin n adet kriter doğrultusunda değerlendirilmesi gerekmektedir. Alternatifler, $A_i = (x_{i1}, x_{i2}, \ldots, x_{in})$ vektörleri ile gösterilir ve burada x_{ij}, i'inci alternatifin j'inci kritere göre değerini ifade eder (i = 1, 2, …, m; j = 1, 2, …, n). Ayrıca, m alternatif sayısını, n ise kriterlerin toplam sayısını temsil etmektedir.

Adım 2: Karar Matrisinin Normalize Edilmesi

$$N = \begin{bmatrix} n_{11} & n_{12} & \cdots & n_{1n} \\ n_{21} & n_{22} & \cdots & n_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ n_{m1} & n_{m2} & \cdots & n_{mn} \end{bmatrix} \quad (8)$$

Normalize edilmiş matrisin (N) elemanları, kriter türüne bağlı olarak aşağıdaki eşitlikler kullanılarak hesaplanır.

(a) Fayda tipi kriterler için (kriterin daha yüksek değeri tercih edilir)

$$n_{ij} = \frac{x_{ij} - x_i^-}{x_i^+ - x_i^-} \quad (9)$$

(b) Maliyet tipi kriterler için (kriterin daha düşük değeri tercih edilir)

$$n_{ij} = \frac{x_{ij} - x_i^+}{x_i^- - x_i^+} \quad (10)$$

x_{ij}, başlangıç karar matrisindeki ilgili elemanı temsil ederken, x_i^+ ve x_i^- şu şekilde tanımlanır:

$x_i^+ = max(x_1, x_1, \ldots, x_m) \rightarrow$ i'inci kriter için alternatifler arasında gözlemlenen en yüksek değer

$x_i^- = min(x_1, x_1, \ldots, x_m) \rightarrow$ i'inci kriter için alternatifler arasında gözlemlenen en düşük değer

Adım 3: Ağırlıklandırılmış Matrisin Oluşturulması

Ağırlıklandırılmış matrisin her bir elemanı Eşitlik (11) kullanılarak hesaplanır.

$$v_{ij} = w_i \times (n_{ij} + 1) \quad (11)$$

n_{ij} normalize matrisin (N) elemanlarını, w_i ise kriterlerin ağırlık katsayılarını göstermektedir. V matrisi Eşitlik (12) kullanılarak şu şekilde ifade edilir:

$$V = \begin{bmatrix} v_{11} & v_{12} & \cdots & v_{1n} \\ v_{21} & v_{22} & \cdots & v_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ v_{m1} & v_{m2} & \cdots & v_{mn} \end{bmatrix} = \begin{bmatrix} w_1 \times (n_{11} + 1) & w_2 \times (n_{12} + 1) & \cdots & w_n \times (n_{1n} + 1) \\ w_1 \times (n_{21} + 1) & w_2 \times (n_{22} + 1) & \cdots & w_n \times (n_{2n} + 1) \\ \vdots & \vdots & \ddots & \vdots \\ w_1 \times (n_m + 1) & w_2 \times (n_{m2} + 1) & \cdots & w_n \times (n_{mn} + 1) \end{bmatrix} \quad (12)$$

n toplam kriter sayısını, m toplam alternatif sayısını ifade etmektedir.

Adım 4: Sınır Yakınlık Alan Matrisinin Oluşturulması

$$g_i = \left(\prod_{j=1}^{m} v_{ij}\right)^{1/m} \quad (13)$$

v_{ij}, ağırlıklandırılmış matrisin elemanlarını ve m alternatif sayısını temsil etmektedir. Tüm kriterler için g_i değeri belirlendikten sonra, alternatiflerin değerlendirilmesinde kullanılacak kriter sayısına (n) bağlı olarak $n \times 1$ boyutunda sınır yaklaşım alanı matrisi G oluşturulur.

$$G = [g_1 \quad g_2 \quad \cdots \quad g_n] \quad (14)$$

Adım 5: Alternatiflerin Sınır Yakınlık Alanından Uzaklıklarının Saptanması

$$Q = \begin{bmatrix} q_{11} & q_{12} & \cdots & q_{1n} \\ q_{21} & q_{22} & & q_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ q_{m1} & q_{m2} & \cdots & q_{mn} \end{bmatrix} \quad (15)$$

Her bir alternatif için sınır yaklaşım alanından olan uzaklık (q_{ij}), ağırlıklandırılmış matrisin (V) elemanları ile sınır yaklaşım alanı (G) değeri arasındaki fark temel alınarak belirlenmektedir. Bu şekilde, alternatiflerin her bir kriter açısından sınır yaklaşım alanına olan mesafeleri Q matrisi içinde ifade edilmektedir.

$$Q = V - G = \begin{bmatrix} v_{11} & v_{12} & \cdots & v_{1n} \\ v_{21} & v_{22} & & v_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ v_{m1} & v_{m2} & \cdots & v_{mn} \end{bmatrix} - \begin{bmatrix} g_1 & g_2 & \cdots & g_n \\ g_1 & g_2 & & g_n \\ \cdots & \cdots & \cdots & \cdots \\ g_1 & g_2 & \cdots & g_n \end{bmatrix} \quad (16)$$

$$Q = \begin{bmatrix} v_{11} - g_1 & v_{12} - g_2 & \cdots & v_{1n} - g_n \\ v_{21} - g_1 & v_{22} - g_2 & \cdots & v_{2n} - g_n \\ \cdots & \cdots & \cdots & \cdots \\ v_{m1} - g_1 & v_{m2} - g_2 & \cdots & v_{mn} - g_n \end{bmatrix} = \begin{bmatrix} q_{11} & q_{12} & \cdots & q_{1n} \\ q_{21} & q_{22} & & q_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ q_{m1} & q_{m2} & \cdots & q_{mn} \end{bmatrix} \quad (17)$$

Her bir kriter için sınır yaklaşım alanı q_i, ağırlıklandırılmış matrisin elemanları v_{ij}, kriter sayısı n ve alternatif sayısı m kullanılarak tanımlanmaktadır. Alternatifler, sınır yaklaşım alanı (G), üst yaklaşım alanı (G^+) veya alt yaklaşım alanı (G^-) içinde yer alabilir; A_i bu üç alandan birine dahil olmaktadır. Üst yaklaşım alanı (G^+), ideal alternatifi (A^+) kapsarken; alt yaklaşım alanı (G^-), anti-ideal alternatifi (A^-) içerir. Alternatifin hangi yaklaşım alanına ait olduğu, ilgili matematiksel ifade olan Eşitlik (18) temel alınarak belirlenmektedir.

$$A_i \in \begin{cases} G^+ & if \quad q_{ij} > 0 \\ G & if \quad q_{ij} = 0 \\ G^- & if \quad q_{ij} < 0 \end{cases} \quad (18)$$

Bir alternatifin en iyi seçenek olarak belirlenebilmesi için, mümkün olan en fazla sayıda kriterinin üst yaklaşım alanına (G^+) dahil olması gerekmektedir. Örneğin, bir alternatif 6 kriter üzerinden değerlendiriliyorsa ve 5 kriteri üst yaklaşım alanına, 1 kriteri alt yaklaşım alanına (G^-) ait ise; bu durumda alternatifin 5 kriter açısından ideal alternatife oldukça yakın olduğu, bir kriter açısından ise anti-ideal alternatife yakın olduğu anlaşılmaktadır.

Eğer $q_{ij} > 0$ ve dolayısıyla $q_{ij} \in G^+$, alternatif A_i ideal alternatife yakın veya eşit olmaktadır. Eğer $q_{ij} < 0$ ve dolayısıyla $q_{ij} \in G^-$, alternatif A_i anti-ideal alternatife yakın veya olmaktadır.

Adım 6: Alternatiflere ait Kriter Fonksiyonlarının Hesaplanması ve Sıralanması

Eşitlik (19)'da verilen her bir alternatifin kriter fonksiyonunun değeri, söz konusu alternatifin sınır yaklaşım alanlarından olan uzaklıklarının q_{ij} toplamı alınarak hesaplanmaktadır.

$$S_i = \sum_{j=1}^{n} q_{ij}, \quad j = 1, 2, \ldots, n, \; i = 1, 2, \ldots, m \quad (19)$$

Burada, n toplam kriter sayısını, m ise alternatif sayısını göstermektedir. Bu değerler kullanılarak alternatifler sıralanır ve en uygun seçenek belirlenmektedir.

3.3. MARCOS YÖNTEMİ

MARCOS yöntemi ilk olarak Željko Stević ve arkadaşları tarafından tanımlanmıştır. Çok kriterli karar verme yöntemlerinden biri olan MARCOS, alternatiflerin ideal ve anti-ideal

çözümlerle karşılaştırılması prensibine dayanır. AHP, TOPSIS veya VIKOR yöntemlerine benzer olan MARCOS yöntemi uzlaşma çözümünü temel alması ile öne çıkmaktadır (Stanković vd., 2020).

MARCOS yöntemi uygulama adımları sırasıyla verilmiştir.

Adım 1: Karar Matrisinin Oluşturulması

$$X = \begin{bmatrix} x_{11} & x_{12} & \cdots & x_{1n} \\ x_{21} & x_{22} & \cdots & x_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ x_{m1} & x_{m2} & \cdots & x_{mn} \end{bmatrix} \quad (20)$$

Adım 2: Genişletilmiş Karar Matrisinin Oluşturulması

Anti ideal (AAI) ve ideal (AI) çözümün tanımlanmasıyla gerçekleştirilen genişletilmiş bir karar matrisi oluşturulur.

$$X = \begin{bmatrix} x_{11} & x_{12} & \cdots & x_{1n} \\ x_{21} & x_{22} & \cdots & x_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ x_{m1} & x_{m2} & \cdots & x_{mn} \\ x_{aai1} & x_{aai2} & \cdots & x_{aain} \\ x_{ai1} & x_{ai2} & \cdots & x_{ain} \end{bmatrix} \quad (21)$$

AAI, alternatifler arasındaki en kötü alternatifi temsil ederken; AI, en iyi alternatifi göstermektedir. Kriterlerin yapısına bağlı olarak, AAI ve AI değerleri (22) ve (23) numaralı eşitlikler temel alınarak hesaplanmaktadır.

$$AAI = \min_i x_{ij} \; if \; j \in B \; and \; \max_i x_{ij} \; if \; j \in C \quad (22)$$

$$AAI = \max_i x_{ij} \; if \; j \in B \; and \; \min_i x_{ij} \; if \; j \in C \quad (23)$$

B kriteri maksimizasyon, C kriteri ise minimizasyon grubuna aittir.

Adım 3: Genişletilmiş Karar Matrisinin Normalize Edilmesi

$$n_{ij} = \frac{x_{ai}}{x_{ij}} \; if \; j \in C \quad (24)$$

$$n_{ij} = \frac{x_{ij}}{x_{ai}} \; if \; j \in B \quad (25)$$

x_{ij} ve x_{ai} terimleri, X matrisinin elemanlarını ifade etmektedir.

Adım 4: Genişletilmiş Karar Matrisinin Ağırlıklandırılması

$$v_{ij} = n_{ij} \times w_{ij} \quad (26)$$

Adım 5: Fayda Derecelerinin (K_i) Hesaplanması

$$K_i^- = \frac{S_i}{S_{aai}} \quad (27)$$

$$K_i^+ = \frac{S_i}{S_{ai}} \quad (28)$$

S_i (i = 1, 2, …, m), V matrisinin elemanlarının toplamını ifade etmektedir. Bu ifade Eşitlik (29)'de verilmiştir.

$$S_i = \sum_{i=1}^{n} v_{ij} \quad (29)$$

Adım 6: Alternatiflerin Fayda Fonksiyonlarının $f(K_i)$ Belirlenmesi ve Sıralanması

$$f(K_i) = \frac{K_i^+ + K_i^-}{1 + \frac{1-f(K_i^+)}{f(K_i^+)} + \frac{1-f(K_i^-)}{f(K_i^-)}}; \quad (30)$$

$f(K_i^-)$ AAI'ye (en kötü alternatif) ilişkin fayda fonksiyonunu, $f(K_i^+)$ ise AI'ye (en iyi alternatif) ilişkin fayda fonksiyonunu temsil etmektedir.

AI ve AAI çözümlerine ilişkin fayda fonksiyonlarının belirlenmesinde Eşitlik (31) ve (32) kullanılmıştır.

$$f(K_i^-) = \frac{K_i^+}{K_i^+ + K_i^-} \quad (31)$$

$$f(K_i^+) = \frac{K_i^-}{K_i^+ + K_i^-} \quad (32)$$

Ve alternatifler sıralanır.

4. BULGULAR

Çalışmada belirlenen alternatifler ve kriterler üzerinden MEREC, MABAC ve MARCOS yöntemlerinin uygulanması aşamaları bu bölümde detaylı olarak sunulmaktadır. Öncelikle, değerlendirme sürecinde kullanılan alternatifler ve kriterler tanımlanmış, ardından yöntemlerin adım adım uygulanmasıyla kriter ağırlıkları ve alternatiflerin sıralamaları elde edilmiştir.

4.1. Veri Seti ve Karar Matrisi

Çalışmada değerlendirilen alternatifler, havacılık sektörünün uluslararası arenada öncü ve büyük şirketlerinden çalışmanın kapsamına uygun olarak seçilmiş olup, her bir alternatifin performansı ÇSY boyutlarına göre belirlenen etkin kriterler üzerinden analiz edilmiştir. Kriterler, hem niceliksel hem de niteliksel boyutları içermektedir. Sürdürülebilirliğin çevresel, sosyal ve yönetişim boyutları altında toplanmaktadır.

Çalışmada analize 5 hava yolu şirketi dahil edilmiştir. Sürdürülebilirlik performanslarının ölçülebilmesi amacıyla çevresel, ekonomik ve operasyonel boyutları kapsayan toplam 9 kriter belirlenmiştir. Çalışmada kullanılan hava yolu şirketleri ve bu şirketlere ilişkin genel bilgiler Tablo 2' de sunulmaktadır.

Tablo 2. Hava Yolu Şirketleri

No	Şirket Adı	Ülke	Çağrı Kodu	IATA Kodu	ICAO Kodu
1	Türk Hava Yolları	Türkiye	TURKISH	TK	THY
2	Lufthansa Hava Yolları	Almanya	LUFTHANSA	LH	DLH
3	Copa Hava Yolları	Panama	COPA	CM	CMP
4	Singapur Hava Yolları	Singapur	SINGAPORE	SQ	SIA
5	Qatar Hava Yolları	Qatar	QATARI	QR	QTR

- **Çevresel Kriterler**

Toplam CO_2 Emisyonu (milyon ton CO2e) (K1): Hava yolu şirketlerinin faaliyetlerinden kaynaklanan tüm sera gazı emisyonlarını kapsamaktadır. Scope 1 doğrudan uçuş operasyonlarından (uçak yakıtı tüketimi) kaynaklanan emisyonları, Scope 2 şirketin tükettiği

elektrik, ısıtma ve soğutma gibi enerji kaynaklı dolaylı emisyonları, Scope 3 ise tedarik zinciri, yer hizmetleri, yolcu taşımacılığına bağlı dolaylı faaliyetler ve iş seyahatleri gibi değer zinciri emisyonlarını ifade etmektedir. Emisyonlar yıllık olarak milyon ton CO_2 eşdeğeri (CO_2e) cinsinden raporlanır. Havacılık sektörü için Scope 1 emisyonları en büyük paya sahip olsa da, Scope 3 emisyonları da önemli bir kısmı oluşturmaktadır. Bu nedenle toplam CO_2 emisyonlarının bütünsel olarak dikkate alınması, şirketlerin iklim değişikliği üzerindeki gerçek etkisini yansıtan kritik bir göstergedir.

Yakıt Verimliliği (lt / 100 AKK) (K2): Hava yolu operasyonlarının çevresel etkinliğini ölçen kritik bir parametredir. Arz edilen koltuk-km (ASK) belirli bir mesafede taşınabilecek yolcu kapasitesini ifade eder. Bu kriter, 100 AKK başına tüketilen yakıt miktarını litre cinsinden gösterir. Verimliliğin yüksek olması, hem daha az yakıt tüketimi hem de daha düşük karbon salımı anlamına gelir. Bu nedenle kriter, hem çevresel hem de ekonomik performans göstergesi olarak çift yönlü önem taşır.

Yolcu Doluluk Oranı (%) (K3): Taşınan yolcu-km'nin (RPK) arz edilen koltuk-km'ye (ASK) oranını ifade eder. Yüzdesel olarak hesaplanan bu oran, hava yolu şirketlerinin kapasite kullanım etkinliğini gösterir. Yüksek doluluk oranı, uçuş başına düşen emisyon miktarını düşürdüğü için çevresel verimlilik üzerinde olumlu etki yaratır. Ayrıca işletme gelirlerinin artmasına katkı sağlar.

Yolcuların Satın Aldığı Km (RPK, Milyon) (K4): Revenue Passenger Kilometer (RPK), yolcular tarafından satın alınan koltuk-km'lerin toplamıdır ve milyon yolcu-km olarak ölçülür. Bu kriter, hava yolu şirketinin operasyonel ölçeğini yansıtır. Şirketin toplam yolcu talebini ve gelir potansiyelini gösterirken aynı zamanda karbon ve yakıt verimliliği hesaplarında temel parametrelerden biridir.

Filonun Ortalama Yaşı (Yıl) (K5): Şirketin kullandığı uçakların ortalama yaşını ifade eder. Uçakların yaşı arttıkça yakıt verimliliği düşmekte ve bakım maliyetleri artmaktadır. Yeni nesil uçaklar ise daha düşük emisyon ve yakıt tüketimi ile çevresel performansa katkı sağlamaktadır. Dolayısıyla filonun ortalama yaşı, çevresel sürdürülebilirlik açısından kritik bir gösterge olarak kabul edilmektedir.

- **Sosyal Kriterler**

Toplam Çalışan Sayısı (K6): Hava yolu şirketlerinin doğrudan sağladığı istihdamı gösteren bu kriter, sosyal sürdürülebilirliğin en temel ölçütlerinden biridir. Toplam çalışan sayısı, şirketin ölçeğini, insan kaynağı kapasitesini ve ekonomik katkısını göstermektedir. Ayrıca çalışan sayısı, şirketin iş gücü politikaları ve sosyal etkilerinin değerlendirilmesinde önemli bir rol oynamaktadır.

Kadın Çalışan Oranı (%) (K7): Şirketlerdeki toplumsal cinsiyet eşitliğini ve çeşitlilik düzeyini ortaya koyan kritik bir göstergedir. Bu oran, kadın çalışan sayısının toplam çalışan sayısına bölünmesiyle hesaplanır. Havayolu sektörü tarihsel olarak erkek egemen bir yapıya sahip olduğundan, kadın çalışan oranı sosyal sürdürülebilirliğin ve kapsayıcı istihdam politikalarının değerlendirilmesi açısından önemlidir.

- **Yönetişim Kriterleri**

Yönetim Kurulu Üye Sayısı (K8): Şirketin yönetim kurulunda görev yapan toplam üye sayısını ifade eder. Yönetim kurulu, şirketin stratejik karar alma mekanizmasının merkezinde yer alır. Üye sayısı, yönetim kurulunun büyüklüğünü ve karar alma süreçlerinin etkinliğini yansıtır. Kurumsal yönetişim kalitesinin önemli göstergelerinden biridir.

Yönetim Kurulu Kadın Üye Oranı (%) (K9): Yönetim kurulundaki kadın üyelerin toplam üyeler içindeki oranını ifade eder. Çeşitlilik, kapsayıcılık ve cinsiyet eşitliği açısından önemli bir göstergedir. Kadın üyelerin yönetim kurullarında daha fazla yer alması, farklı bakış açıları ve dengeli karar mekanizmaları oluşmasına katkı sağlar. Uluslararası kurumsal yönetişim standartlarında da bu kriter özel önem taşımaktadır.

Tablo 3' te hava yolu şirketlerine ait sürdürülebilirlik raporlarından elde edilen 2020-2023 yılı verileri sunulmuştur.

Tablo 3. Hava Yolu Şirketlerine Ait 2020-2023 Yılı Verileri

ÇSY BOYUTLARI		ÇEVRESEL					SOSYAL		YÖNETİŞİM

Her alternatifin, tüm kriterler doğrultusundaki verileri toplanmış ve başlangıç karar matrisi bu değerlere göre oluşturulmuştur. Bu yapı, MEREC yöntemi ile kriter ağırlıklarının belirlenmesi ve MABAC ile MARCOS yöntemleriyle alternatiflerin karşılaştırılmasına uygun bir temel sağlamaktadır.

Alternatifler (A): A1, A2, A3, A4, A5.

Kriterler (C): K1, K2, K3, K4, K5, K6, K7, K8, K9.

MEREC yöntemi ile kriter ağırlıklarının belirlenmesi ve MABAC ile MARCOS yöntemleri kullanılarak değerlendirme aşamaları, şirketlerin 2023 yılı verileri üzerinde örnek uygulama olarak gerçekleştirilmiştir.

4.2. MEREC ile Kriter Ağırlıkları Belirleme

Bu çalışmada kullanılan 9 kriterin ağırlıkları, MEREC yöntemi ile belirlenmiştir. 2023 yılına ait başlangıç karar matrisi Tablo 4' te gösterilmiştir.

Tablo 4. 2023 Yılı Başlangıç Karar Matrisi

	Min	Min	Mak	Mak	Min	Mak	Mak	Mak	Mak
	K1	K2	K3	K4	K5	K6	K7	K8	K9

5. DUYARLILIK ANALİZİ

Çok kriterli karar verme (ÇKKV) alanında yapılan çalışmalarda kullanılan yöntemlerin bir problem için ne derece uygun olduğunu belirlemeye ya da elde edilen sonuçların güvenilirliğini test etmeye yönelik literatürde ortak bir ölçüt bulunmamaktadır (Demir vd., 2022).

Araştırmalar, özellikle doğru bilginin elde edilmesi sürecindeki hatalar ya da karar vericinin kontrol edemediği belirsizlikler nedeniyle girdi parametrelerinde ortaya çıkabilecek değişimlerin sonuçlar üzerindeki etkisini incelemek amacıyla duyarlılık analizinin kullanılmasını önermektedir. Çözüm sürecinde tercihlerin veya parametre değerlerinin küçük ölçekte değişmesi durumunda yöntemin verdiği sonuçların ne ölçüde sabit kaldığını ya da nasıl davrandığını inceleyen bu yaklaşım, duyarlılık analizi olarak tanımlanmaktadır (Pamučar ve Ćirović, 2017). Duyarlılık analizi, değerlendirilen problemle ilişkili belirsizliği ortaya koymada ÇKKV modelleri için güvenilir bir araç niteliği taşımaktadır. Bu doğrultuda, çalışmanın bulgularının kriter ağırlıklarına duyarlılığını test etmek için duyarlılık analizi yapılmıştır. Entropi ve MEREC yöntemlerine ait duyarlılık analizi sonuçları Tablo 20' de verilmiştir.

Tablo 20. Entropi ve MEREC Yöntemlerine ait Duyarlılık Analizi

	Entropi Yöntemi				MEREC Yöntemi			
	2020	2021	2022	2023	2020	2021	2022	2023
	w_j	w_j	w_j	w_j	w_j	w_j	w_j	w_j
K1	0,140	0,149	0,204	0,223	0,113	0,111	0,118	0,119
K2	0,313	0,208	0,026	0,032	0,281	0,141	0,104	0,105
K3	0,053	0,035	0,003	0,000	0,050	0,098	0,096	0,096
K4	0,208	0,183	0,179	0,194	0,174	0,113	0,116	0,114
K5	0,026	0,042	0,056	0,052	0,060	0,103	0,110	0,110
K6	0,204	0,308	0,417	0,355	0,178	0,147	0,140	0,132
K7	0,010	0,008	0,013	0,015	0,029	0,088	0,099	0,102
K8	0,030	0,044	0,062	0,091	0,074	0,107	0,113	0,116
K9	0,016	0,024	0,039	0,037	0,041	0,092	0,104	0,105

Entropi yöntemi ile MEREC yöntemi arasında bazı kriterlerde belirgin ağırlık farklılıkları olduğu görülmektedir. Özellikle K2, K6 ve K8 kriterlerinde yıllar boyunca iki yöntem arasında dikkate değer sapmalar bulunmaktadır. Entropi yöntemi, veri dağılımındaki belirsizliği esas aldığı için bazı kriterlerde (örneğin K6 ve K2) çok yüksek ağırlıklar üretirken; MEREC yöntemi kriterin modele yaptığı marjinal etkiye odaklandığı için daha dengeli ve daha düşük varyanslı ağırlıklar vermiştir.

K3 ve K7 gibi kriterlerde Entropi ağırlıkları oldukça düşük seyretmesine rağmen MEREC yönteminde bu kriterlerin ağırlıkları yıl bazında daha yüksek ve daha istikrarlı görünmektedir.

Duyarlılık analizi, iki yöntemin aynı karar probleminde farklı hassasiyetlere sahip olduğunu, bu nedenle alternatiflerin sıralamasının yönteme göre değişme potansiyeli bulunduğunu göstermektedir. Bu çeşitlilik, analiz sonuçlarının sağlamasını yapmak ve karar mekanizmasını güçlendirmek açısından yöntemler arası karşılaştırmanın önemli olduğunu ortaya koymaktadır.

5.1. Spearman Korelasyon Analizi

Spearman korelasyon analizi, iki değişken arasındaki ilişkiyi sıralamalar üzerinden inceleyen ve veri dağılımı hakkında herhangi bir varsayım gerektirmeyen nonparametrik bir yöntem olarak tanımlanmaktadır. Bu yaklaşım, değişkenlerin değerlerini büyüklük sırasına göre karşılaştırarak, aralarındaki ilişkinin yönünü ve gücünü ölçer. Özellikle doğrusal olmayan fakat monoton bir ilişki gösteren veri setlerinde güvenilir sonuç verdiği için literatürde sıkça tercih edilmektedir. Bu yöntem ilk kez Spearman (1904) tarafından geliştirilmiş olup, günümüzde sosyal bilimlerden mühendisliğe kadar çok geniş bir alanda kullanılmaktadır (Spearman, 1961). MARCOS ve MABAC yöntemlerinin farklı kriter ağırlıklandırma metotlarına göre sıralamaları Tablo 21' de gösterilmiştir.

Tablo 21. Yöntemlerin Alternatiflere Göre Sıralamaları

	Entropi Tabanlı MARCOS Sıralaması	Entropi Tabanlı MABAC Sıralaması	MEREC Tabanlı MARCOS Sıralaması	MEREC Tabanlı MABAC Sıralaması
A1	3	2,75	4	2,75
A2	1	1	1	1
A3	4	5	2,75	5
A4	5	4	4,25	4
A5	2	2,25	3	2,25

Entropi ve MEREC yöntemlerine ait spearman korelasyon analizi tablosu Tablo 22' de verilmiştir.

Tablo 22. Entropi ve MEREC Yöntemlerine ait Spearman Korelasyon Analizi

	Entropi Tabanlı MARCOS Sıralaması	Entropi Tabanlı MABAC Sıralaması	MEREC Tabanlı MARCOS Sıralaması	MEREC Tabanlı MABAC Sıralaması
Entropi Tabanlı MARCOS Sıralaması	1	0,9	0,8	0,9
Entropi Tabanlı MABAC Sıralaması	0,9	1	0,6	1
MEREC Tabanlı MARCOS Sıralaması	0,8	0,6	1	0,6
MEREC Tabanlı MABAC Sıralaması	0,9	1	0,6	1

Birbirine en yakın sıralamalar 0.9 korelasyon katsayısı ile Entropi Tabanlı MABAC ve Entropi Tabanlı MARCOS ile MEREC Tabanlı MABAC ve Entropi Tabanlı MARCOS yöntemlerinden elde edilen sıralamalar olmuştur.

0.6 korelasyon katsayısı ile MEREC Tabanlı MARCOS ve Entropi Tabanlı MABAC ile MEREC Tabanlı MABAC ve MEREC Tabanlı MARCOS yöntemlerinden elde edilen sıralamaların birbirinden en farklı sıralamalar olduğu görülmüştür.

6. SONUÇLAR VE TARTIŞMA

Lufthansa Airlines, değerlendirilen 4 yıl boyunca hem MABAC hem de MARCOS sonuçlarında tutarlı bir şekilde 1. sırada yer almıştır. Bu durum, şirketin sürdürülebilirlik performansında istikrar sağladığını ve üç ÇSY boyutunda diğer şirketlere göre daha dengeli ve güçlü bir strateji izlediğini göstermektedir.

Qatar Airways, çoğunlukla üst sıralarda yer almış; özellikle 2020, 2021 ve 2023 yıllarında her iki yöntemde de 2. sıradaki güçlü konumunu korumuştur. Ancak 2022 yılında MARCOS'ta 5. sıraya gerilemesi, bu yıl içinde şirketin bazı sürdürülebilirlik göstergelerinde performans kayıpları yaşadığını düşündürmektedir.

Copa Airlines, MARCOS yönteminde 2021 ve 2022'de 2. sıraya kadar yükselmiş olsa da MABAC yöntemi sonuçlarıyla karşılaştırıldığında belirgin bir tutarsızlık görülmüştür. Bu durum, şirketin bazı kriterlerde çok iyi performans gösterirken diğerlerinde geride kaldığını, dolayısıyla dengeli bir ÇSY yapısının henüz oluşmadığını ortaya koymaktadır.

Singapore Airlines, çalışma dönemi boyunca genellikle orta sıralarda yer almış; MABAC sonuçlarında tüm yıllarda 4. sırada sabit kaldığı görülmüştür. MARCOS sonuçlarında ise 2022'de belirgin bir iyileşme ile 3. sıraya yükselmiştir. Bu durum, şirketin özellikle çevresel ve yönetişim kriterlerindeki bazı göstergelerde iyileşme sağladığını göstermektedir.

Türk Hava Yolları (THY), dönem boyunca değişken bir performans sergilemiştir. MARCOS sonuçları 2020'de 3. sırayı işaret ederken, 2023'te şirketin 5. sıraya gerilediği görülmektedir. Bu dalgalanmalı seyir, THY'nin bazı yıllarda özellikle sosyal ve yönetişim göstergelerinde güçlenirken bazı dönemlerde bu alanlarda gerilemeler yaşadığını ortaya koymaktadır.

Tablo 23. Şirketlerin Entropi ve MEREC Tabanlı MARCOS ve MABAC Yöntemlerine ait Sıralamalarının Karşılaştırmalı Tablosu

ÇKKV		ENTROPİ	ENTROPİ	MEREC	MEREC
Hava Yolu	**Yıl**	**MARCOS**	**MABAC**	**MARCOS**	**MABAC**
THY	2020	3	3	3	3
THY	2021	3	3	4	3
THY	2022	3	2	4	2
THY	2023	3	3	5	3
LUFTHANSA	2020	1	1	1	1
LUFTHANSA	2021	1	1	1	1
LUFTHANSA	2022	1	1	1	1
LUFTHANSA	2023	1	1	1	1
COPA	2020	4	5	4	5
COPA	2021	4	5	2	5
COPA	2022	4	5	2	5
COPA	2023	4	5	3	5
SINGAPOR	2020	5	4	5	4
SINGAPOR	2021	5	4	5	4
SINGAPOR	2022	5	4	3	4
SINGAPOR	2023	5	4	4	4
QATAR	2020	2	2	2	2
QATAR	2021	2	2	3	2
QATAR	2022	2	3	5	3
QATAR	2023	2	2	2	2

Genel sonuçlara bakıldığında; Lufthansa tüm yıllarda en sürdürülebilir hava yolu olarak öne çıkmıştır. Qatar Airways güçlü ve istikrarlı bir ikinci sırada yer alırken, Copa ve Singapore orta sıralarda dalgalanarak ilerlemiştir. THY ise özellikle son yılda düşük bir performansla son sıraya düşerek iyileştirme gerektiren alanlara işaret etmiştir.

Bu bulgular, sürdürülebilirlik performans değerlendirmelerinde dengeli ÇSY stratejilerinin önemini açık şekilde göstermektedir. Çalışma, havacılık sektörünün sürdürülebilirlik gelişim dinamiklerini çok boyutlu bir perspektifle ortaya koyarak gelecekteki stratejik planlama süreçleri için kapsamlı bir değerlendirme zemini sağlamaktadır.

ÖZET

Bu çalışma, Kazak bozkır ekosisteminin eşsiz bağlamında, olağanüstü doğal güzelliğe sahip bir koruma alanı olan Burabay Milli Parkı'ndaki ekoturizm gelişimini kapsamlı bir şekilde analiz etmektedir. Kazakistan'ın turizm çeşitliliğini artırma çabaları kapsamında, bu araştırma, kırılgan bozkır ortamlarının yönetimine ilişkin zorluklar karşısında ekoturizm ilkelerinin uygulanmasını incelemektedir. Araştırma, mevcut ekoturizm uygulamalarının durumunu değerlendirmek için kapsamlı bir literatür taraması, politika analizi ve saha gözlemlerinden yararlanan nitel bir vaka çalışması metodolojisini benimsemektedir. Analiz, Burabay'ın eşsiz "kayalık orman-bozkır" manzarası, zengin biyolojik çeşitliliği ve yerleşik koruma statüsü ile önemli avantajlara sahip olmasına rağmen, optimal ekoturizm çıktılarını engelleyen birkaç kritik zorluğu ortaya koymaktadır. Bunlar arasında mevsimsel turizm modelleri, yetersiz atık yönetim sistemleri, yetersiz çevresel yorumlama programları ve yerel toplulukların turizm faydalarına anlamlı katılımının sınırlı olması yer almaktadır. Ayrıca, park, potansiyel aşırı yapılaşma ve narin ekosistemleri üzerindeki iklim değişikliği etkilerinden kaynaklanan artan baskılarla karşı karşıyadır. Çalışma, Burabay'ın ekoturizm potansiyelini tam olarak gerçekleştirmesinin çok boyutlu bir strateji gerektirdiği sonucuna varmaktadır. Bu, taşıma kapasitesi değerlendirmelerine dayalı sağlam ziyaretçi yönetim planlarının uygulanmasını, sertifikalı çevre eğitimi ve yorumlama programlarının geliştirilmesini, yerel geçim kaynaklarını iyileştiren topluluk temelli turizm girişimlerinin teşvik edilmesini ve sürdürülebilir finansman mekanizmaları yoluyla koruma önlemlerinin güçlendirilmesini içermektedir. Bulgular, benzer bozkır ekosistemlerinde koruma hedefleri ile sürdürülebilir turizm kalkınmasını dengelemeyi amaçlayan politika yapıcılar ve park yöneticileri için değerli görüşler sunmaktadır.

Anahtar Kelimeler: Ekoturizm, Burabay Milli Parkı, Sürdürülebilir Turizm, Kazakistan, Bozkır Ekosistemi.

ECOTOURISM IN THE STEPPES OF KAZAKHSTAN: A CASE STUDY OF BURABAY NATIONAL PARK

ABSTRACT

This study provides a comprehensive analysis of ecotourism development in Burabay National Park, a protected area of exceptional natural beauty within the unique context of the Kazakh steppe ecosystem. As Kazakhstan seeks to diversify its tourism offerings, this research examines the implementation of ecotourism principles against the challenges of managing fragile steppe environments. The investigation employs a qualitative case study methodology, drawing from extensive literature review, policy analysis, and field observations to assess the current state of ecotourism practices. The analysis reveals that while Burabay possesses significant advantages through its unique "rocky forest-steppe" landscape, rich biodiversity, and established protected status, several critical challenges impede optimal ecotourism outcomes. These include seasonal tourism patterns, inadequate waste management systems, insufficient environmental interpretation programs, and limited meaningful participation of local communities in tourism benefits. Furthermore, the park faces growing pressures from potential overdevelopment and climate change impacts on its delicate ecosystems. The study concludes that realizing Burabay's full ecotourism potential requires a multidimensional strategy. This entails implementing robust visitor management plans based on carrying capacity assessments, developing certified environmental education and interpretation programs, fostering community-based tourism initiatives that enhance local livelihoods, and strengthening conservation measures through sustainable financing mechanisms. The findings offer valuable insights for policymakers and park managers seeking to balance conservation goals with sustainable tourism development in similar steppe ecosystems globally.

Keywords: Ecotourism, Burabay National Park, Sustainable Tourism, Kazakhstan, Steppe Ecosystem.

1. Giriş

Küresel turizm endüstrisi, 21. yüzyılda hızla büyümeye devam ederken, geleneksel kitle turizminin doğal kaynaklar üzerinde yarattığı baskı, biyolojik çeşitlilik kaybı ve kültürel erozyon gibi olumsuz etkiler, sürdürülebilir turizm alternatiflerine olan ilgiyi akademik ve pratik düzeyde artırmıştır (Weaver, 2020). Bu bağlamda ekoturizm, biyolojik çeşitliliğin korunması, yerel halkın refahının artırılması ve çevresel bilincin geliştirilmesi ilkeleri çerçevesinde (Fennell, 2020) öne çıkan bir yaklaşım olarak kabul görmektedir.

Orta Asya bölgesi, Sovyetler Birliği'nin dağılmasından sonra turizm potansiyelini yeniden keşfetmeye başlamıştır. Bölgenin el değmemiş doğal alanları, zengin biyolojik çeşitliliği ve kadim kültürel mirası, ekoturizm için önemli bir potansiyel oluşturmaktadır (Kalipova, 2020). Kazakistan, 2.7 milyon kilometrekarelik yüzölçümüyle bölgenin en büyük ülkesi olup, topraklarının büyük bölümünü oluşturan bozkır (step) ekosistemleri, küresel ölçekte koruma önceliğine sahip biyomlardan biridir (Smithson, 2022).

Bu çalışmanın odağını oluşturan Burabay Milli Parkı ise Kazakistan'ın kuzeyindeki Akmola eyaletinde yer alan ve "Kazakistan'ın İncisi" olarak anılan, 83.511 hektarlık bir korunan alandır. Park, 14 doğal gölü, Paleozoik döneme ait granit kayalıkları ve zengin biyolojik çeşitliliği ile hem ulusal hem de uluslararası düzeyde önem taşımaktadır (Kazakistan Çevre Bakanlığı, 2023).

Bu bildiri, Burabay Milli Parkı özelinde, Kazakistan'ın step ekosistemlerindeki ekoturizm potansiyelini, mevcut durumu ve karşılaşılan zorlukları sürdürülebilirlik perspektifiyle değerlendirmeyi amaçlamaktadır. Çalışma, aşağıdaki araştırma sorularına yanıt aramaktadır:

1. Burabay Milli Parkı'nın mevcut ekoturizm uygulamaları, sürdürülebilir turizm ilkeleriyle ne ölçüde uyumludur?

2. Parkın ekoturizm potansiyelini sınırlandıran temel yönetimsel, çevresel ve sosyo-ekonomik faktörler nelerdir?

3. Bölgede sürdürülebilir bir ekoturizm modeli geliştirmek için hangi stratejik yaklaşımlar benimsenmelidir?

2. Kavramsal Çerçeve ve Literatür

2.1. Sürdürülebilir Turizm ve Ekoturizm

Sürdürülebilir kalkınma kavramı, Brundtland Raporu'nda "gelecek kuşakların kendi ihtiyaçlarını karşılama yeteneğinden ödün vermeden, günümüzün ihtiyaçlarını karşılama" olarak tanımlanmıştır (WCED, 1987, s. 41). Bu paradigmaya dayalı sürdürülebilir turizm, ekonomik kalkınma, çevresel bütünlük ve sosyal eşitlik arasında denge kuran holistik bir yaklaşımdır (Sharpley, 2020).

Ekoturizm ise sürdürülebilir turizmin önemli bir alt dalı olarak, "doğal alanları koruyan, yerel halkın refahını artıran ve ziyaretçilerde çevresel farkındalık yaratan sorumlu seyahat" olarak tanımlanmaktadır (TIES, 2015). Ekoturizmin temel ilkeleri arasında doğal ve kültürel mirasın korunmasına katkıda bulunmak, yerel topluluklara sosyal ve ekonomik faydalar sağlamak, ziyaretçilere çevre eğitimi deneyimleri sunmak ve turizm faaliyetlerinin ekolojik taşıma kapasitesini aşmamasını sağlamak yer alır (Honey, 2018).

2.2. Korunan Alanlarda Ekoturizm ve Step Ekosistemlerinin Önemi

Korunan alanlar, ekoturizm uygulamaları için ideal mekanlar olarak kabul edilmektedir. Bu alanlarda ekoturizm, hem koruma çalışmaları için alternatif finansal kaynak yaratmakta hem

de yerel halkta ve ziyaretçilerde koruma bilincinin gelişmesine katkı sağlamaktadır (Eagles, 2021). Step ekosistemleri ise dünya karasal biyomlarının %8'ini oluşturmasına rağmen, koruma statüsü açısından en az korunan biyomlar arasında yer almaktadır (UNEP, 2022). Bu nedenle, step ekosistemlerindeki korunan alanlarda uygulanacak sürdürülebilir ekoturizm modelleri, küresel biyolojik çeşitliliğin korunması açısından hayati öneme sahiptir.

3. Araştırmanın Amacı, Kapsamı ve Yöntemi

Bu araştırma, nitel araştırma paradigmasına uygun olarak vaka çalışması deseninde tasarlanmıştır. Vaka çalışması deseni, karmaşık sosyal olguların derinlemesine incelenmesine olanak tanıması nedeniyle bu araştırma için uygun bulunmuştur (Yin, 2018). Burabay Milli Parkı, step ekosisteminde ekoturizm uygulamalarının tipik bir örneği olarak ele alınmıştır.

Araştırmada aşağıdaki veri toplama teknikleri kullanılmıştır: Çalışma, 2020-2023 dönemini kapsamakta olup, Burabay Milli Parkı ile sınırlandırılmıştır.

- **İkincil Veri Analizi:** Akademik yayınlar, resmi istatistikler, kurum raporları ve politika belgelerinin sistematik analizi.
- **Doküman Analizi:** Park yönetim planları, strateji dokümanları ve çevresel izleme raporlarının incelenmesi.

4. Bulgular: Burabay Milli Parkı'nda Mevcut Durum ve Ekoturizm Faaliyetleri

4.1. Fiziko-Coğrafik ve Ekologik Özellikler

Burabay Milli Parkı, Kazakistan'ın coğrafi olarak "Kazakistan Granit Platosu" üzerinde yer almaktadır. Bu plato, Paleozoik döneme ait granit kayalıkları ve 14 adet doğal gölden oluşan jeolojik açıdan benzersiz bir yapı sergilemektedir (Petrov & Ivanova, 2022). Parkın jeolojik yapısı, 300-350 milyon yıl öncesine dayanan magmatik kayaçlardan oluşmakta olup, bölgedeki en yüksek nokta 947 metre yüksekliğindeki Kokşetau Dağı'dır.

Şekil 1. Burabay Milli Parkı uydu görüntüsü (Google earth 2025).

Burabay Milli Parkı'nın Temel Fiziko-Coğrafik Özellikleri Tablo 1'de gösterilmiştir.

Tablo 1: Burabay Milli Parkı'nın Temel Fiziko-Coğrafik Özellikleri (Burabay Milli Parkı Yönetim Planı, 2023).

Parametre	Değer	Açıklama
Yüzölçümü	83.511 hektar	Toplam korunan alan
Rakım	300-947 metre	Deniz seviyesinden yükseklik
Ana Göl Sayısı	14	Doğal tatlısu gölleri
Toplam Göl Yüzeyi	6.850 hektar	Park alanının %8.2'si
Ormanlık Alan	45.200 hektar	Park alanının %54.1'i
Jeolojik Yaş	300-350 milyon yıl	Paleozoik dönem

Parkın florası, step ve orman-step geçiş zonunun karakteristik özelliklerini yansıtmaktadır. 657 damarlı bitki türü tespit edilmiş olup, bunların 45'i endemik, 28'i ise nadir ve tehlike altındaki türler kategorisinde yer almaktadır (Kazakistan Botanik Enstitüsü, 2023). Fauna ise 54 memeli türü ve 238 kuş türüyle temsil edilmektedir. Burabay Milli Parkı'nın florası Şekil 2'de gösterilmiştir.

Şekil 2. Burabay Milli Parkı'nın florası (URL 2),

Burabay Milli Parkı, olağanüstü zengin bir biyolojik çeşitliliğe sahiptir. Park sınırları içinde **757 bitki türü** tespit edilmiştir; bunlardan **119'u koruma altında** olup, **12'si Kırmızı Kitap'ta** kayıtlıdır. Orman örtüsünün yaklaşık **%65'ini çamlar**, **%31'ini huş ağaçları**, **%3'ünü titrek kavaklar** oluştururken, kalan **%1'lik kesim çalılıklar** ile kaplıdır. Bu zengin bitki örtüsü, bölgede çok sayıda **yenilebilir mantar türünün** yetişmesine de olanak sağlamaktadır.

Bitkisel çeşitlilik, doğal olarak parkın **faunasını da oldukça zenginleştirmiştir.** Burabay'da, Kazakistan genelinde görülen hayvan türlerinin **%36'sını temsil eden 305 farklı tür** yaşamaktadır. Bu türlerin **yaklaşık %40'ı yaşam alanlarının sınırında** bulunurken, **13 tür Kırmızı Kitap'ta** koruma altına alınmıştır. Step ekosistemindeki biyolojik çeşitlilik bileşenleri Şekil 3'te gösterilmiştir.

Şekil 3. step ekosistemindeki biyolojik çeşitlilik bileşenleri (URL 1).

Burabay'ın **vahşi yaşamı**, çevresini saran bozkır alanlarına göre çok daha zengindir. Burada **bozkır, orman ve dağ ekosistemlerine ait türler** bir arada varlık göstermektedir. Parkta yalnızca **Avrupa kökenli türler** değil; aynı zamanda **Sibirya, Kuzey ve Güney bölgelerine özgü hayvan türleri** de gözlemlenebilir.

Orman ekosisteminde **karaca, geyik, yaban domuzu, sincap, kakım, çakal, sansar** ve çeşitli **geyik türleri** yaşamaktadır. **Kurt** ve **vaşak** gibi yırtıcı türlerle de karşılaşmak mümkündür. Bozkır ve orman geçiş alanlarında ise **porsuk, tilki, gelincik, Avrupa tavşanı** ve **dağ tavşanı** gibi memeliler sıklıkla görülür. Sıklıkla görülen yabani hayvan türleri şekil 4'te gösterilmiştir.

Şekil 4. bozkurt, karaca, yaban domuzu ve step tilkisi (URL 8).

Parkın kuş çeşitliliği de dikkat çekicidir. Burada **bayağı altıngöz, yaban ördeği, boz ördek, kılkuyruk, al yanaklı angut, yağmur kuşu, kuzey kız kuşu, dere düdükçünü** ve **yeşil düdükçün** gibi birçok kuş türü kaydedilmiştir. Özellikle **sonbahar ve göç dönemlerinde** ördek popülasyonunda belirgin bir artış gözlemlenir.

Kuru taşlı çam ormanlarında ve **huş bozkırlarının** arasında, **gri keklik** ve **büyük orman tavuğu** gibi kuş türlerine de rastlanmaktadır. Tüm bu unsurlar bir arada değerlendirildiğinde, Burabay Milli Parkı'nın **hem flora hem de fauna açısından Orta Asya'nın en önemli doğal zenginlik alanlarından biri** olduğu söylenebilir

4.2. Mevcut Ekoturizm Aktiviteleri ve Ziyaretçi Profili

Burabay Milli Parkı'nda ekoturizm faaliyetleri, sürdürülebilir turizm prensipleri çerçevesinde yapılandırılmıştır. 2023 yılı verilerine göre parkı yıllık ortalama 285.000 ziyaretçi ağırlamakta olup, bu ziyaretçilerin %65'i yerli turistlerden, %35'i ise uluslararası turistlerden oluşmaktadır (Burabay Milli Parkı Yönetimi, 2024). Şekil 5'te korunan alanlarda uygulanan ekoturizm aktivitelerinden geleneksel göçebe kültürü deneyimine bir örnek gösterilmiştir.

Şekil 5. korunan alanlarda uygulanan ekoturizm aktivitelerinden geleneksel göçebe kültürü deneyimi (URL 5).

Park bünyesindeki başlıca ekoturizm aktiviteleri şunlardır:

- **Doğa Yürüyüşü (Trekking):** Toplam 85 km uzunluğunda işaretlenmiş 12 farklı parkur.
- **Bisiklet Turları:** 45 kilometrelik bisiklet parkuru ağı ve elektrikli bisiklet kiralama sistemi.
- **Kuş ve Yaban Hayatı Gözlemciliği:** 12 adet kuş gözlem kulesi ve 8 adet kamufle edilmiş gözlem noktası.
- **Çevre Eğitimi Programları:** İnteraktif doğa sergileri, rehberli turlar ve atölye çalışmaları.

4.3. Turizmin Çevresel ve Sosyo-Ekonomik Etkileri

Çevresel Etkiler: Yoğun ziyaretçi kullanımına bağlı olarak, özellikle yaz aylarında çöp birikimi önemli bir sorun teşkil etmektedir. 2023 yılında park alanından toplanan katı atık miktarı 85 ton olarak kaydedilmiştir (Waste Management Report, 2024). Erozyon riski özellikle yoğun kullanılan yürüyüş parkurlarında gözlemlenmekte olup, toplam parkur ağının %15'inde orta ve yüksek seviyede erozyon riski tespit edilmiştir.

Sosyo-Ekonomik Etkiler: Ekoturizm faaliyetleri, bölge halkı için önemli bir istihdam kaynağı oluşturmaktadır. Parkın doğrudan istihdam ettiği 125 personelin %70'i yerel halktan oluşmaktadır (Burabay Employment Statistics, 2024). Dolaylı istihdam ise konaklama, yiyecek-içecek ve rehberlik hizmetleri gibi alanlarda 450 kişiye iş imkanı sağlamaktadır. Ancak, yerel halkın turizm karar alma süreçlerine katılım oranı %35 olarak ölçülmüş olup, bu oranın artırılması yönünde beklentiler bulunmaktadır (Community Perception Survey, 2024).

5. Tartışma: SWOT Analizi ve Temel Zorluklar

Burabay Milli Parkı'nın mevcut durumuna ilişkin yapılan analizler, aşağıdaki SWOT matrisini ortaya koymaktadır:

Güçlü Yönler (Strengths):

- Benzersiz jeolojik oluşumlar ve 14 doğal gölden oluşan olağanüstü peyzaj çeşitliliği
- Zengin biyolojik çeşitlilik (657 bitki, 238 kuş türü)
- Gelişmiş altyapı (85 km parkur, 12 gözlem kulesi)
- Astana'ya yakın konum (250 km) ile ulaşılabilirlik

Zayıf Yönler (Weaknesses):

- Belirgin mevsimsel turizm yoğunluğu (Ziyaretçilerin %75'i yaz aylarında)
- Profesyonel rehberlik hizmetlerinin ve dil çeşitliliğinin yetersizliği
- Yerel halkın karar alma süreçlerine düşük katılımı (%35)
- Atık yönetimi ve erozyon kontrolünde yaşanan sorunlar

Fırsatlar (Opportunities):

- Küresel ekoturizm pazarının büyümesi (2023'te 365 milyar ABD Doları)
- Dijital teknolojilerin gelişimi (akıllı turizm uygulamaları)
- Kazakistan'ın vize kolaylaştırma politikaları
- "Orta Asya Yeşil Yolu" gibi bölgesel işbirlikleri

Tehditler (Threats):

- İklim değişikliğinin ekosistemler üzerindeki olumsuz etkileri
- Kaçak yapılaşma ve plansız turizm gelişimi
- Artan ziyaretçi sayısına bağlı habitat parçalanması riski
- Finansman yetersizliği ve kırsal göç

6. Sonuç ve Stratejik Öneriler

Bu çalışma, Burabay Milli Parkı'nın önemli bir ekoturizm potansiyeline sahip olmasına rağmen, bu potansiyeli gerçekleştirmek önünde çok boyutlu zorluklarla karşı karşıya olduğunu ortaya koymuştur. Mevsimsellik, altyapı yetersizlikleri, yerel katılımın sınırlılığı ve iklim değişikliği, parkın sürdürülebilir yönetimini tehdit eden başlıca faktörlerdir.

Burabay Milli Parkı'nda sürdürülebilir bir ekoturizm modeli geliştirilmesi için aşağıdaki stratejik öneriler sunulmaktadır:

6.1. Yönetim ve Planlama Önerileri

- **Akıllı Turizm Yönetim Sistemi:** Gerçek zamanlı ziyaretçi takip sistemi, çevresel izleme sensörleri ve dijital rezervasyon platformu entegrasyonu.
- **Dinamik Taşıma Kapasitesi Modeli:** Ziyaretçi yoğunluğunun anlık olarak yönetilmesi ve mevsimselliğin azaltılması.
- **Katılımcı Yönetim Modeli:** Yerel halkın karar alma süreçlerine katılım oranının %35'ten en az %60'a çıkarılması.

6.2. Çevresel Sürdürülebilirlik Önerileri

- **Ekosistem Tabanlı Adaptasyon:** İklim değişikliğine dayanıklı türlerin korunması ve habitat koridorlarının oluşturulması.
- **Sıfır Atık Hedefi:** Atık yönetim sisteminin modernizasyonu ve döngüsel ekonomi prensiplerinin uygulanması.
- **Yenilenebilir Enerji Geçişi:** 2028 yılına kadar parkın enerji ihtiyacının %80'inin yenilenebilir kaynaklardan karşılanması.

6.3. Sosyo-Ekonomik Sürdürülebilirlik Önerileri

- **Kapsayıcı İş Modelleri:** Yerel halkın turizm gelirlerinden adil pay almasını sağlayacak kooperatif sistemlerinin kurulması.
- **Gelir Çeşitlendirme:** Düşük sezon turizmini teşvik edecek programların geliştirilmesi (kış turizmi, kültür turizmi).
- **Kapasite Geliştirme:** Yerel halkın turizm sektöründe nitelikli istihdamını artırmak için mesleki eğitim programları.

6.4. Eğitim ve Farkındalık Önerileri

- **Kapsamlı Eğitim Programı:** Ziyaretçiler, yerel halk ve personel için sürdürülebilir turizm eğitimlerinin düzenlenmesi.
- **Dijital İletişim Stratejisi:** Sosyal medya ve dijital platformların etkin kullanımı ve sanal gerçeklik deneyimleri.
- **Bilimsel İşbirlikleri:** Üniversitelerle ortak araştırma ve izleme programlarının geliştirilmesi.

Sonuç olarak, Burabay Milli Parkı'nın sürdürülebilir geleceği, koruma ve kullanma dengesinin bilimsel temellere dayalı, katılımcı ve uyumlu bir yönetim anlayışıyla sağlanmasına bağlıdır. Bu çalışmanın bulguları ve önerileri, benzer step ekosistemlerindeki korunan alanlar için bir yönetim çerçevesi sunma potansiyeli taşımaktadır.

ABSTRACT

Optimization problems have long been addressed using a variety of metaheuristic approaches, each offering distinct strengths and weaknesses. According to the No Free Lunch Theorem, no single metaheuristic algorithm can outperform all others across a broad range of optimization problems. Therefore, employing different metaheuristics within an adaptive framework can be an effective way to improve search performance. This study introduces a parallelized version of the Single Seekers Society (PSSS) Algorithm, an effort to enhance computational efficiency and performance in complex optimization problems. The original Single Seekers Society (SSS) combines several single-solution metaheuristics, such as Simulated Annealing, Greedy Search, Great Deluge, and Threshold Accepting, under the coordination of a population-based metaheuristic such as Genetic Algorithm, Differential Evolution. In PSSS, all single-solution metaheuristics operate on solutions simultaneously rather than sequentially, to speed up the search process. In the improved version proposed in this study, a bandit approach is incorporated into the PSSS framework to enable adaptive selection of single-solution metaheuristic based on performance feedback**.** The bandit-based mechanism dynamically adjusts the selection probabilities of metaheuristics depending on their recent success, allowing the algorithm to learn which strategies perform better for the given search landscape. This adaptive process strengthens the balance between exploration and exploitation while preserving diversity. The proposed PSSS algorithm was evaluated on the CEC 2022 benchmark suite, which includes highly complex optimization problems. Experimental findings indicate that the bandit incorporated PSSS achieves competitive performance in comparison to the reported results in the literature. Moreover, parallel execution of SSS significantly reduced computational time while preserving solution quality.

Keywords: Single Seekers Society, Parallel Programming, Metaheuristic Algorithms, Continuous Optimization, Bandit Approach

1. Introduction

Optimization problems arise in various scientific and engineering applications, including parameter estimation (Zhang et al., 2024), scheduling (Dauzère-Pérès et al., 2024), clustering (Jia et al., 2024), and control problems. When the problem becomes more complex, especially in high-dimensional, nonlinear, and multimodal cases, then classical mathematical programming approaches become either inadequate or computationally expensive. This scenario has made approximation-based approaches popular, particularly metaheuristic algorithms, which provide a balance between exploration and exploitation without the need for gradient information or stringent structural assumptions (Blum and Roli, 2003).

Metaheuristics encompass a broad range of general search strategies inspired by natural, physical, or logical phenomena. While many effective methods have been developed, their performance often varies significantly across different problem categories. The No Free Lunch Theorem illustrates this by showing that no single optimization algorithm outperforms all others across every possible class of problems (Wolpert and Macready, 1997). This understanding has led to increased focus on hybrid designs, adaptive frameworks, and parallel architectures in research, as each aims to combine the complementary strengths of various search operators.

In this regard, Single Seekers Society (SSS) is a coalition-based metaheuristic framework proposed by Baykasoğlu et al. (2019) that combines various single-solution based metaheuristic methods under one umbrella. Instead of conducting a search based on a single trajectory, SSS runs multiple single-solution metaheuristics, including Simulated Annealing, Great Deluge, Greedy Search, and Threshold Accepting etc., in a coordinated manner. Each metaheuristic independently explores the solution space using its own neighborhood structure, while information-sharing mechanisms oversee the overall convergence process. SSS is neither a hybrid nor a hyper-heuristic; it is a coalition-based metaheuristic framework in which different search behaviors work together within a unified structure. Later extensions demonstrated that this framework could be applied not only to continuous optimization but also to combinatorial problems (Hamzadayı et al., 2020), demonstrating its versatility.

The original SSS framework claims high conceptual richness but operates sequentially; the single-solution metaheuristics update their states one after another, which can limit scalability and increase computational costs for demanding benchmark problems. Additionally, the selection of a single-solution metaheuristic is random; therefore, SSS does not adaptively focus more on successful strategies during the run. These factors make SSS an intriguing candidate for further improvements in parallelization and learning-based adaptation.

This paper explores a parallel version of the SSS framework and an adaptive bandit-based metaheuristic selection strategy. All single-solution-based metaheuristics are executed simultaneously to leverage multicore architectures, thereby decreasing the total runtime. Additionally, a bandit-based approach dynamically updates the selection probabilities of the metaheuristics based on their recent performance, enabling the algorithm to favor more promising search strategies while preserving diversity. This design transforms the SSS framework into a more adaptive and data-driven system that can modify its search dynamics according to the characteristics of the problem landscape.

To evaluate the effectiveness of the new Parallel Single Seekers Society (PSSS) algorithm, we conducted computational tests using the CEC 2022 benchmark suite, which includes challenging problems for continuous optimization with various types of functions like unimodal, hybrid, and composition. We assessed performance by examining the

quality of solutions and the speed at which they were discovered. The results indicated that PSSS performed as well as some well-known metaheuristics but required significantly less time due to its use of parallel and bandit enhancements. Thus, this study makes three main contributions: implementing a parallelized SSS framework, developing an adaptive bandit-based mechanism for selecting metaheuristics, and conducting extensive empirical analysis on the CEC 2022 test functions.

The rest of the paper is organized as follows: Section 2 describes the main components of our proposed algorithm. Section 3 provides detailed information on the experimental setup and analysis conducted in this study. Finally, Section 4 concludes with potential future research directions.

2. Methodology

The methodological background of the study and the extension of the original SSS algorithm are presented in this section. Since the proposed enhancements directly build upon the original structure of the SSS, it is first useful to revisit how the algorithm operates in its baseline form.

2.1. Overview of the SSS algorithm

The SSS algorithm is a coalition-based framework that coordinates multiple single-solution-based metaheuristics and models both individual and collective behavioral patterns in a social context (Baykasoğlu et al., 2019). Instead of following traditional hybrid or hyper-heuristic systems, SSS centers its approach around a more unique idea: it brings together several single-solution heuristics under one umbrella and considers them members of a small "society". Each member maintains its own identity but still interacts with others through a shared population-based structure. In this way, SSS functions less as a standalone algorithm and more as a coordinated collection of search behaviors.

The SSS framework can be better understood by examining four conceptual layers. First, the framework itself represents a social behavior model that defines how individuals may act and how information may circulate within the group. Second, family characteristics relate to the type of single-solution metaheuristic assigned to each individual, similar to inheriting a behavioral tendency from one's family. Third, personal characteristics reflect the parameter set of the assigned heuristic, giving each individual their own unique style even when sharing the same heuristic type with others. Finally, social interaction involves crossover, where individuals exchange information, much like community members influence or shape each other's decisions.

The algorithm begins with initializing the population. Each individual in the population is assigned a single-solution-based metaheuristic, such as Simulated Annealing, Threshold Accepting, Great Deluge, or Greedy Search. This assignment determines the "family" to which the individual belongs. Then, parameter values are drawn from predefined intervals that have been discretized into subranges; one subrange is chosen at random, and a continuous value is drawn from within it. Due to this two-step sampling process, individuals can behave very differently even if they share the same heuristic type.

With these initialization conditions in place, individuals start their own search processes. Each individual "grows" by executing its assigned metaheuristic until it reaches what can be considered maturity. After this stage, individuals participate in a reproduction process driven by a population-based metaheuristic algorithm, such as Genetic Algorithm (GA) or Differential Evolution (DE). Through crossover and occasional mutations, individuals share information

and generate new candidate solutions, while elitism ensures that the best-performing individuals are preserved in the pool.

To better visualize how these steps occur within the algorithm, an overall workflow of SSS is summarized in Figure 1.

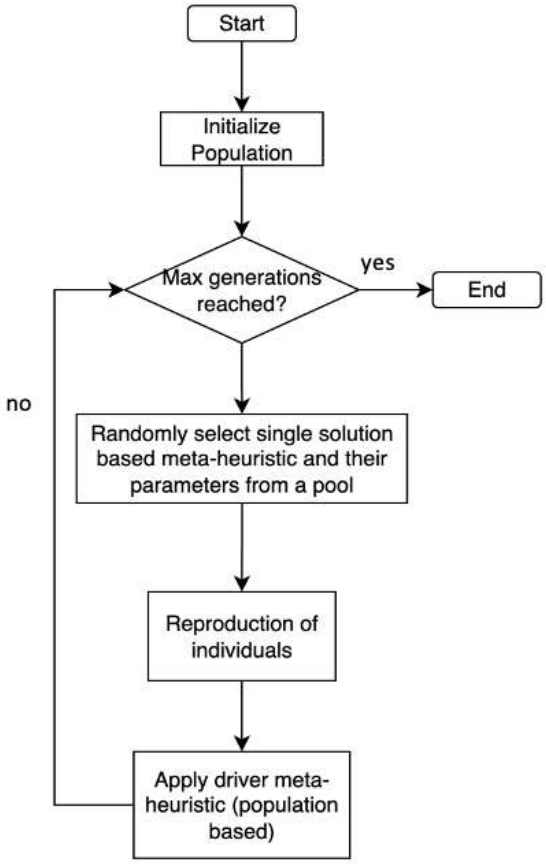

Figure 1: Simplified flow chart of the SSS algorithm

2.2. Motivations for extending the SSS algorithm

The SSS is an algorithm with a flexible structure that allows multiple single-solution-based search algorithms to coexist and interact. Because of this flexibility, it can serve as a solid foundation for methodological extensions. During our preliminary experiments, we identified certain steps in the original SSS workflow where targeted modifications could improve the algorithm's performance. These modifications speed up the process and enhance solution quality by altering how individual heuristics are selected and how the single-solution search phase is executed. These insights inspired the extensions presented in this study, which focus on two complementary areas: enabling parallel execution within the Single Seeker stage and implementing an adaptive, learning-driven mechanism for heuristic selection.

Building on these observations, we proposed two extensions that naturally integrate into the SSS framework: (i) parallelization of the Single Seeker stage to remove unnecessary sequential dependencies, and (ii) incorporating a multi-armed bandit framework to adaptively choose heuristics during the search. These changes enhance SSS's efficiency, speed, and awareness of the problem being addressed.

2.3. Parallelization of the reproduction part of the SSS algorithm

In the original SSS framework, all individuals execute their respective single-solution metaheuristics sequentially. This sequential approach keeps the framework simple, but it results in a significant amount of idle time since individuals do not depend on each other's intermediate results. Therefore, it can be executed in parallel without any benefit from running sequentially. During our experiments, it was observed that these independent search processes are ideally suited for parallel execution, especially since modern computational environments are mostly multi-threaded. To leverage this independence, the first extension proposed in this work modifies the reproduction phase by allowing all individuals to simultaneously perform their assigned single-solution-based metaheuristics. This change does not alter the core principles of the SSS framework, as each individual still conducts its search independently; however, it enables the population to reach the reproduction phase much faster. As demonstrated by the experimental results, this restructuring yields a significant improvement in runtime performance while maintaining solution quality.

2.4. Single-solution-based metaheuristic selection via Multi-Armed Bandit learning

The second extension introduced in this study aims to make the selection of single-solution-based metaheuristics smarter rather than random. In the original SSS framework, heuristics were assigned to individuals without bias and uniformly, which maintained diversity but lacked a mechanism to favor heuristics that performed better during search. To overcome this limitation, we integrated a learning-based approach using the Multi-Armed Bandit (MAB) method.

In this setup, each single-solution-based metaheuristic is viewed as an “arm" of the bandit. During optimization, the algorithm monitors the contribution of each heuristic to improving the objective function and uses this information to update its preferences. The aim is to balance two behaviors: exploration, which involves occasionally trying all heuristics to prevent premature convergence, and exploitation, which encourages the algorithm to focus on heuristics that have recently yielded more significant improvements. The learning mechanism adheres to the classical bandit principles described in Slivkins (2019).

Let H=$\{h_1,\ldots, h_k\}$denote the set of available single-solution-based metaheuristics. For each heuristic h_k the algorithm maintains a value estimate $Q_k$which represents its expected contribution to solution improvement. After each generation, these estimates are updated by using the observed fitness differences from individuals that used the corresponding single-solution-based metaheuristics.

For minimization problems, the improvement generated by individual i is quantified as

$\Delta_i = f_{old(i)} - f_{new(i)}$,

Where a positive value designates a successful improvement. For each heuristic h_k , let S_k denote the set of individuals that applied it in the current generation. If at least one improvement is observed, the reward for that heuristic is computed as

$r_k = \frac{1}{|S_k|}\sum_{i \in S_k} \Delta_i$,

The value estimates are then updated through a standard exponential smoothing rule:

$Q_k \leftarrow (1-\alpha)Q_k + \alpha\, r_k$,

where $\alpha \in (0,1)$ is the learning rate. A decreasing exploration rate, denoted by ε, determines whether the heuristic for each new individual is chosen uniformly or based on the largest current estimate, Q_k. After each generation, ε is gradually reduced.

The adaptive selection procedure used in this study is formalized in Algorithm 1, which incorporates a multi-armed bandit learning mechanism into the PSSS framework.

Algorithm 1: Bandit-based heuristic selection in the PSSS framework

Input : set of single-solution metaheuristics $H = \{h_1, \ldots, h_K\}$;
parameter sets of these metaheuristics;
parameters of the population-based driver;
bandit parameters α, $\varepsilon_{start}, \varepsilon_{\min}, \varepsilon_{decay}$

Output: updated value estimates Q_k and exploration rate ε

Initialisation:

`// initial population generation`

P(i,:) = LL + rand(NP,D) (UL-LL), i=1,...,NP

foreach $h_k \in H$ **do**
  $Q_k \leftarrow 0$

$\varepsilon \leftarrow \varepsilon_{start}$

Main loop:

foreach *generation* $t = 1, 2, \ldots$ **do**

  `// heuristic assignment for the current generation`

  foreach *individual* i *in the population* **do**
    if *random()* $< \varepsilon$ **then**
      choose h_k uniformly from H
    else
      choose $h_k = \arg\max_{h_j \in H} Q_j$
    assign h_k to individual i

  `// parallel execution of Single Seekers`

  run all assigned single solution based metaheuristic **concurrently** on the individuals, each producing an updated objective value $f_{new}(i)$

  `// reward computation and value update`

  foreach $h_k \in H$ **do**
    collect all improvements $\Delta_i = f_{old}(i) - f_{new}(i)$ from individuals that used h_k in generation t
    if *at least one* Δ_i *is available* **then**
      let r_k be the average of these improvements
      $Q_k \leftarrow (1-\alpha)\, Q_k + \alpha\, r_k$

  `// exploration rate update`

  $\varepsilon \leftarrow \max(\varepsilon_{\min}, \varepsilon \cdot \varepsilon_{decay})$

3. Experimental results

In this study, the proposed PSSS framework is tested with two different population-based driver heuristics: GA and DE. All variants were combined with the same set of single-solution-based metaheuristics, including the random selection baseline. In the bandit-enhanced versions, the multi-armed bandit mechanism dynamically selected the most promising heuristic for each individual during the optimization process. The performance of the proposed PSSS variants was assessed on the CEC 2022 benchmark suite, which features 12 challenging test functions from different categories, unimodal, basic, hybrid, and composition. Although the suite contains 12 functions, our analysis focuses on the first seven functions (F1–F7), as these are the ones for which complete experimental results were generated under the 10-dimensional setting. A summary of the benchmark definitions is provided in Table 1.

Table 1: Benchmark functions for the performance evaluation of PSSS

No	Name	Class	Range	f_{min}
F1	Shifted and full rotated Zakharov function	Unimodal functions	[-100,100]	300
F2	Shifted and full Rosenbrock's function	Basic functions	[-100,100]	400
F3	Shifted and full rotated expanded Scaffer's F6 function			600
F4	Shifted and full rotated non-continuous Rastrigin's function			800
F5	Shifted and rotated Levy function			900
F6	Hybrid function 1 (N = 3)	Hybrid functions	[-100,100]	1800
F7	Hybrid function 2 (N = 6)			2000

The first batch of results examines how computational work is affected when we attempt to reproduce using parallel computing. Figure 2 shows the average time taken by PSSS-GA (Serial) and PSSS-GA (Parallel) for F1–F7, measured in seconds. Running it in parallel reduces the time needed to execute each function, especially where there is a lot of math involved, like in F4, F6, and F7. The difference becomes more evident as the complexity increases, supporting the idea that more complex tasks require more time for each reproduction part.

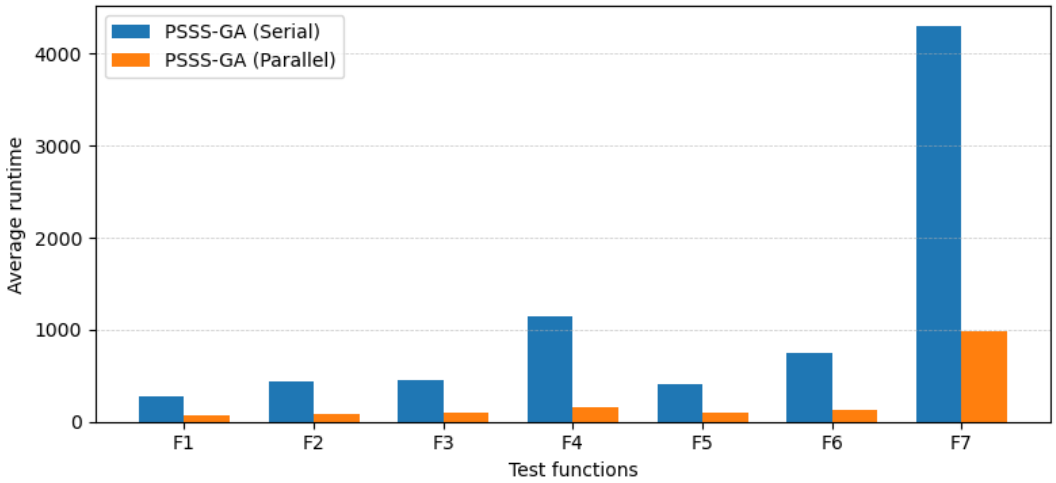

Figure 2: Average runtime comparison of serial and parallel PSSS implementations

To evaluate the impact of adaptive single-solution-based metaheuristic selection, we compared four variants of the PSSS framework: two baseline configurations, PSSS-GA and PSSS-DE, which relied on random assignment of single-solution-based metaheuristics, and two enhanced configurations, PSSS-GA (Bandit) and PSSS-DE (Bandit), which integrated the multi-armed bandit mechanism for dynamically selecting the most promising operator. This setup enabled us to isolate the contribution of the bandit component independently of the population-based driver.

Table 2: The comparison results of PSSS and versions for CEC 2022 test functions

F	Metric	PSSS_GA	PSSS_DE	PSSS_GA(Bandit)	PSSS_DE(Bandit)

F6	Median	2.27×10^{3}	2.37×10^{3}	**1.88×10^{3}**	1.89×10^{3}
F6	StdDev	8.12×10^{2}	4.50×10^{2}	1.33×10^{2}	**6.41×10^{1}**
F6	Worst	4.94×10^{3}	3.74×10^{3}	2.36×10^{3}	**2.03×10^{3}**
F7	Best	2.00×10^{3}	2.00×10^{3}	2.00×10^{3}	2.00×10^{3}
F7	Mean	2.00×10^{3}	2.00×10^{3}	2.00×10^{3}	2.00×10^{3}
F7	Median	2.00×10^{3}	2.00×10^{3}	2.00×10^{3}	2.00×10^{3}
F7	StdDev	0.37	0.58	0.03	0.09
F7	Worst	2.00×10^{3}	2.00×10^{3}	2.00×10^{3}	2.00×10^{3}

As shown in Table 2, all variants perform well on the first three benchmark functions (F1–F3), with only small differences between single-solution-based metaheuristic-selection strategies. The divergence between methods becomes more apparent from F4 onward, especially for the hybrid functions F6 and F7, where the search space is more irregular, making the algorithms more challenging to solve.

A review of the results indicates that PSSS-GA (Bandit) is the most consistent performer, achieving the best results on six out of seven tested functions. This suggests that the bandit mechanism is particularly effective when used with the GA driver. Generally, this bandit-guided selection process results in a more stable generational progression and better solution quality for most functions.

Figure 3's radar chart compares the PSSS model with several classic metaheuristics reported in the literature (Chen et al., 2023). Each polygon illustrates how well an algorithm performs relative to others across all CEC 2022 test functions; smaller enclosed areas indicate better overall results. In seven tested functions (F1–F7), traditional population-based methods such as Particle Swarm Optimization (PSO) (Kennedy and Eberhart, 1995), Whale Optimization Algorithm (WOA) (Mirjalili and Lewis, 2016), Sine Cosine Algorithm (SCA) (Mirjalili, 2016), Harris Hawk Optimization (HHO) (Heidari et al., 2019), Seagull Optimization Algorithm (SOA) (Dhiman and Kumar, 2019), Salp Swarm Algorithm (SSA) (Mirjalili et al., 2016), and Pelican Optimization Algorithm (POA) (Trojovský and Dehghani, 2022) vary in their sensitivity to the structure of test functions. Some of these algorithms perform well on certain functions but do not show consistent behavior across the entire suite. Conversely, PSSS with bandit-based selection produces a more balanced and tighter profile than any other variant. The radar plot shows that PSSS achieves competitive or superior performance in most functions, especially in unimodal and basic categories, aligning well with the numerical trends presented earlier in Table 2, where PSSS-GA with Bandit achieved the best or near-best outcomes for six of seven evaluated functions. These findings suggest that adaptive heuristic coordination, rather than relying on a single metaheuristic, offers more reliable and function-agnostic search behavior. The radar chart further supports this conclusion, emphasizing PSSS's strong performance.

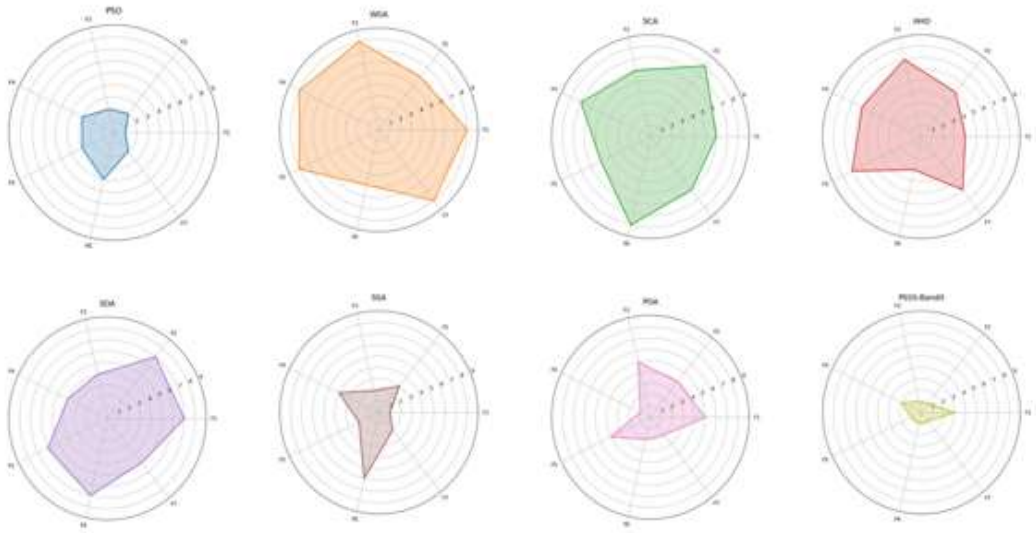

Figure 3: Comparative results of PSSS and other metaheuristic algorithms for CEC 2022 test functions.

4. Conclusions

The present work proposed an improved SSS algorithm by incorporating parallelism and a metaheuristic selection strategy based on learning. Running single-solution-based metaheuristics in parallel reduced the computational time. The second change, replacing random operator selection with bandit-based learning, made the search more adaptive to recent performance. Experiments on CEC 2022 functions F1−F7 demonstrated that both modifications could reduce run time while maintaining or improving solution quality across all function types. Taken together, these results indicate that the improved PSSS variants are more flexible and competitive than the original SSS framework.

There are several directions in which the research can be extended beyond the current study. First, although this work is tested on a subset of the CEC 2022 benchmark suite, it is possible to evaluate the PSSS framework on a larger collection of continuous functions to gain insights into its performance across different types of landscapes. More advanced machine learning methods for the metaheuristic selection process could be explored as another future direction; improving this component may further enhance stability and solution quality. Finally, extending this approach to combinatorial or mixed-integer optimization problems would be a logical next step, as the SSS concept is well-suited for domains where many different local search behaviors are available.

ÖZET

Bu çalışmada otomotiv sektöründe çapraz fonksiyonel ekiplerin oluşturulmasında teknik yeterlilikler ile davranışsal rol uyumlarının entegrasyonu incelenmiştir. Ekip başarısının yalnızca teknik yeterliliklere dayandırılmasının yetersiz olduğu, pozisyonların gerektirdiği temel kriterlerin davranışsal rollerle birlikte değerlendirilmesi gerektiği varsayımından hareketle, görev tanımları ile Belbin takım rolleri arasındaki uyum sistematik olarak analiz edilmiştir. Araştırmada, pozisyonlara ilişkin teknik kriter ağırlıkları Analitik Hiyerarşi Süreci (AHP) ile belirlenmiş ve çalışanların Belbin rol profilleriyle olan uyumları bu ağırlıklarla karşılaştırmalı olarak değerlendirilmiştir. Bu yaklaşım, ekip kurma süreçlerini sezgisel yargılardan arındırarak daha ölçülebilir, tekrarlanabilir ve nesnel bir yapıya dönüştürmeyi hedeflemektedir. Örnek olarak proje yöneticisi pozisyonunda yapılan analizde, en yüksek uyum gösteren rollerin Takım Oyuncusu, Koordinatör ve Kaynak Araştırıcı (49.52); yedek rollerin ise Şekillendirici, Değerlendirici ve Uygulayıcı (41.10) olduğu belirlenmiştir. Bu sonuç, proje yöneticisi rolünün temel kriterleri olan iletişim ve liderlik gereklilikleriyle Belbin modelindeki ilgili rollerin güçlü bir tutarlılık gösterdiğini ortaya koymaktadır. Çalışmanın genel bulguları, tüm pozisyonlar için belirlenen öncelikli kriterlerin –örneğin iletişim, liderlik, problem çözme, zaman ve risk yönetimi ve teknik bilgi– ilgili Belbin rollerinin belirlenmesinde belirleyici olduğunu ve görev–rol uyumunun sistematik biçimde oluştuğunu göstermektedir. Analiz sonuçları, AHP ile belirlenen kriter ağırlıkları ile Belbin rol profilleri arasındaki ilişkiyi doğrulamış ve eşleşmelerin yüksek düzeyde tutarlı olduğunu ortaya koymuştur. Sonuç olarak AHP–Belbin entegrasyonu, otomotiv sektöründe çapraz fonksiyonel ekiplerin oluşturulmasında uygulanabilir, tekrarlanabilir ve stratejik bir karar destek mekanizması sunmakta, uygun teknik yetkinliklerin ilgili davranışsal rollerle eşleştirilmesini sağlayarak ekip performansı ve proje başarısını artırmaktadır.

Anahtar Kelimeler: AHP, Belbin Takım Rolleri, Proje Yönetimi, Çapraz Fonksiyonel Ekip

POSITION-BASED CRITERIA PRIORITIZATION USING THE AHP METHOD AND THEIR ALIGNMENT WITH BELBIN TEAM ROLES: AN AUTOMOTIVE INDUSTRY APPLICATION

ABSTRACT

This study examines the integration of technical competencies and behavioral role alignment in the formation of cross-functional teams in the automotive industry. Based on the assumption that relying solely on technical competencies for team success is insufficient, and that fundamental positional criteria should be evaluated alongside behavioral roles, the alignment between job descriptions and Belbin team roles was systematically analyzed. The technical criteria weights for each position were determined using the Analytic Hierarchy Process (AHP), and the compatibility of employees' Belbin role profiles with these weights was comparatively assessed. This approach aims to transform team formation processes into a more measurable, repeatable, and objective structure by eliminating intuitive judgments. As an illustrative example, the analysis of the project manager position identified Teamworker, Coordinator, and Resource Investigator (49.52) as the roles showing the highest compatibility, while Shaper, Monitor Evaluator, and Implementer (41.10) were identified as secondary roles. This finding demonstrates strong coherence between the core requirements of the project manager role—communication and leadership—and the corresponding Belbin roles. The study's overall results indicate that the prioritized criteria determined for all positions, such as communication, leadership, problem-solving, time and risk management, and technical knowledge, decisively influence the identification of relevant Belbin roles, ensuring systematic position–role alignment. The analysis confirmed the relationship between the AHP-determined criteria weights and the Belbin role profiles, demonstrating highly consistent matches. Consequently, the integrated AHP–Belbin model provides a practical, repeatable, and strategic decision-support mechanism for forming cross-functional teams in the automotive industry. By aligning relevant technical competencies with appropriate behavioral roles, it enhances team performance and increases project success.

Keywords: AHP, Belbin Team Roles, Project Management, Cross-Functional Team

1. GİRİŞ

Küreselleşme, dijitalleşme ve müşteri beklentilerindeki hızlı değişim, endüstriyel işletmeleri daha çevik, yenilikçi ve iş birliğine dayalı çalışma modelleri geliştirmeye zorlamaktadır. Özellikle otomotiv sektörü gibi yüksek rekabetin ve sürekli ürün çeşitliliğinin hâkim olduğu alanlarda, organizasyonların başarı düzeyi artık yalnızca teknik kapasiteye değil, aynı zamanda farklı birimlerin etkin koordinasyonuna ve çok disiplinli ekiplerin uyumuna bağlı hale gelmiştir.

Bu bağlamda, literatürde "cross-functional teams" olarak adlandırılan çapraz fonksiyonel takımlar, organizasyonların yenilikçi projeleri başarıyla yürütebilmesinde kilit bir rol üstlenmektedir (Ton, Hammerl, Weber, Kremer, & Szabo-Szentgroti, 2022). Üretim, kalite, mühendislik, tedarik zinciri, planlama ve satış gibi farklı departmanlardan gelen bireylerin bir araya gelmesiyle oluşturulan bu ekipler, bilgi paylaşımını artırarak problemlere çok boyutlu bakış açısı kazandırmakta, süreç içi darboğazları azaltmakta ve proje çıktılarını hızla ticarileştirebilmektedir. Ancak bu yapıların başarısı, ekip üyelerinin yalnızca teknik uzmanlıklarına değil, aynı zamanda iletişim, liderlik, takım uyumu ve problem çözme gibi davranışsal niteliklerine de bağlıdır (Abdolahi, Barmayehvar, Marjani, & Esmaeilabadi, 2023).

Otomotiv sektöründe proje temelli çalışmalar, çoğunlukla kısa zaman dilimlerinde yüksek kalite ve düşük maliyet hedefleri doğrultusunda yürütülmektedir. Bu koşullar altında, her ekip üyesinin hem kendi uzmanlık alanını etkin biçimde kullanması hem de ekip içindeki diğer pozisyonlarla uyum içinde çalışması beklenmektedir. Bu noktada, proje yöneticilerinin en kritik görevi, doğru kişileri doğru pozisyonlara yerleştirerek ekip içi sinerjiyi sağlamaktır. Ancak bu süreç çoğu zaman deneyime dayalı sezgisel kararlarla yürütülmekte, bu da sübjektif sonuçlara ve performans farklılıklarına neden olmaktadır (Kalayathankal, Kureethara, & Narayanamoorthy, 2021).

Dolayısıyla, çapraz fonksiyonel ekiplerin oluşturulmasında teknik yeterliliklerin yanı sıra bireysel davranış eğilimlerinin ve takım içi rollerin de dikkate alınması gerekmektedir. Bu çalışma, bu gereksinimden hareketle, otomotiv sektöründe etkin ekip kurulumuna yönelik analitik ve davranışsal unsurları birlikte ele alan bir yaklaşım geliştirmeyi amaçlamaktadır.

2. ÇALIŞMA ALANI

Çalışma, Türkiye'de otomotiv ana sanayiinde faaliyet gösteren bir üretim tesisinde gerçekleştirilmiştir. Kurum, prototip , numune ve seri üretim süreçlerinin tamamında proje yönetimi, kalite güvencesi, tedarik zinciri yönetimi, üretim planlama, tasarım ve lojistik fonksiyonlarını barındırmaktadır.

Toplam 16 farklı mühendislik ve uzmanlık pozisyonu analiz edilmiştir. Pozisyonlara ilişkin kriterler; İletişim, Liderlik, Zaman ve Risk Yönetimi, Teknik Bilgi ve Problem Çözme olarak belirlenmiştir. Bu kriterlerin literatürde ekip performansını etkileyen temel unsurlar olduğu ve ekip kurma süreçlerinde sıkça vurgulandığı görülmektedir.

Bu çalışmada kullanılan kriterlerin tanımları ve ilgili literatür kaynakları Tablo 1'de özetlenmiştir.

Tablo 1. Literatür Taraması ile Belirlenen Takım Üyesi Seçim Kriterleri

Kriter	Açıklama	Kaynaklar
İletişim	Proje ekibi içinde açık ve etkili bilgi akışının sağlanması, yanlış anlaşılmaların ve iletişim maliyetlerinin azaltılması, ortak bir dil ve standart iletişim protokollerinin oluşturulması.	Hey, 2019; Schmidt, 2013; Boni, Todorova ve Weingart, 2020; Dietz, Pronovost, Mendez-Tellez, Wyskiel, Marsteller, Thompson ve Rosen, 2014; Younis, Sunderraman, Metzler ve Bourgeois, 2021; Super, 2020; Morath, 2006; Da Silva, França, Suassuna, de Sousa Mariz, Rossiley, de Miranda, Gouveia, Monteiro, Lucena, Cardozo ve Espindola, 2013; Abdolahi, Barmayehvar, Marjani ve Esmaeilabadi, 2024; Çulhaoğlu Uludağ, 2022; Kulej-Dudek, 2023; Project Management Institute, 2023
Liderlik	Ekip üyelerinin yönlendirilmesi, motive edilmesi, görev dağılımının dengeli biçimde yapılması ve ekip içindeki sosyal bağların güçlendirilmesi gibi unsurları kapsar.	Hey, 2019; Super, 2020; Boni vd., 2020; Dietz vd., 2014; Morath, 2006; Younis vd., 2021; da Silva vd., 2013; Çulhaoğlu Uludağ, 2022; Kulej-Dudek, 2023; Project Management Institute, 2023
Zaman ve Risk Yönetimi	Karar alma süreçlerinin zamanında yürütülmesi, proje risklerinin analiz edilip yönetilmesi, kaynakların etkin biçimde tahsisi ve performansın izlenmesiyle ilgilidir.	Super, 2020; Schmidt, 2013; Younis vd., 2021; da Silva vd., 2013; Çulhaoğlu Uludağ, 2022; Kulej-Dudek, 2023; Project Management Institute, 2023
Teknik Bilgi	Çalışanın alanında sahip olduğu teknik uzmanlık, mesleki deneyim, eğitim düzeyi ve teknik araçları etkili biçimde kullanma becerisiyle ilgilidir.	Hey, 2019; Boni vd., 2020; Super, 2020; Younis vd., 2021; da Silva vd., 2013; Abdolahi vd., 2024; Çulhaoğlu Uludağ, 2022; Kulej-Dudek, 2023; Project Management Institute, 2023
Problem Çözme	Ekip üyelerinin birlikte çalışarak ortaya çıkan sorunlara çözüm üretebilmesi, çatışmaları yönetebilmesi, koordinasyonu sürdürebilmesi ve iş kalitesini koruyabilmesiyle ilişkilidir.	Hey, 2019; Boni vd., 2020; Dietz vd., 2014; Morath, 2006; Super, 2020; Abdolahi vd., 2024; Kulej-Dudek, 2023; Project Management Institute, 2023

3. MATERYAL VE YÖNTEM

3.1 Veri Toplama

Her pozisyon için, ilgili alanda deneyimli uzmanlardan oluşan karar vericilerle görüşmeler gerçekleştirilmiş ve pozisyonlara ilişkin ikili karşılaştırma matrisleri oluşturulmuştur. Bu matrisler, kriterlerin göreceli önemini belirlemek için kullanılmıştır.

3.2 Analitik Hiyerarşi Prosesi (AHP)

AHP yöntemi, kriter ağırlıklarını belirlemek ve çok kriterli karar problemlerini çözmek amacıyla uygulanmıştır. Tutarlılık oranı (CR) ≤ 0,1 kabul edilerek kararların güvenilirliği sağlanmıştır. Elde edilen kriter ağırlıkları ve CR değerleri Tablo 2'de sunulmuştur.

Tablo 2. Pozisyon Bazında AHP Kriter Ağırlıkları ve Tutarlılık Oranları (CR)

Kriter / Pozisyon	İletişim	Liderlik	Zaman ve Risk Yönetimi	Teknik Bilgi	Problem Çözme	CR

3.3 Belbin Takım Rolleri Entegrasyonu

Belbin Takım Rolleri (Belbin, 2010), ekip üyelerinin davranışsal eğilimlerini değerlendirmek için kullanılmıştır. İlk olarak kriterler, Belbin rollerinin öne çıkan özellikleri ile Tablo 3'te eşleştirilmiştir.

Tablo 3. Belbin Takım Rolleri ve Ekip Üyesi Seçim Kriterleri ile Eşleştirilmesi

Belbin Takım Rolü	Öne Çıkan Kriterleri
Değerlendirici (Monitor Evaluator)	Problem Çözme, Zaman ve Risk Yönetimi
Fikir Üretici (Plant)	Problem Çözme, Teknik Bilgi
Kaynak Araştırıcısı (Resource Investigator)	İletişim, Liderlik
Uzman (Specialist)	Teknik Bilgi, Problem Çözme
Takım Oyuncusu (Teamworker)	İletişim, Liderlik
Koordinatör (Coordinator)	Liderlik, İletişim
Tamamlayıcı / Bitirici (Completer Finisher)	Zaman ve Risk Yönetimi, Teknik Bilgi
Uygulayıcı (Implementer)	Zaman ve Risk Yönetimi, Problem Çözme
Şekillendirici (Shaper)	Liderlik, Problem Çözme

AHP çıktılarından elde edilen kriter önem ağırlıkları, Belbin takım rolleriyle eşleştirilerek her pozisyona karşılık gelen baskın takım rolleri belirlenmiştir. Bu süreçte her rolün öne çıkan kriterleri temel alınmış ve her mühendislik pozisyonu için en uygun Belbin rolleri hesaplanmıştır. Elde edilen puanlar Tablo 4'te gösterilmektedir.

Tablo 4. Ekip Pozisyonlarının Belbin Takım Rolleri Puanları

Belbin Takım Rolü / Pozisyon	**Uzman (Specialist)**	**Uygulayıcı (Implementer)**	**Şekillendirici (Shaper)**	**Koordinatör (Coordinator)**	**Takım Oyuncusu (Teamworker)**	**Kaynak Araştırıcı (RI)**	**Fikir Üretici (Plant)**	**Değerlendirici (Evaluator)**	**Tamamlayıcı/Bitirici (Completer Fin.)**

Final Kalite Mühendisi	66.5366	41.9932	32.5333	17.0074	17.0074	17.0074	66.5366	41.9932	57.4555

Tablo 5'te otomotiv sektöründe analiz edilen tüm pozisyonların Belbin Takım Rolleri ile uyum düzeylerini ve rol profillerini göstermektedir. Tablo 5, her pozisyon için birinci (en yüksek) ve ikinci (yedek) rolleri belirlemekte ve rolün temel özelliklerini özetlemektedir. Bu sayede ekip kurulumunda pozisyonların teknik ve davranışsal gereklilikleri ile uygun Belbin rolleri arasındaki ilişki net bir şekilde görülebilmektedir.

Tablo 5. Pozisyonlara Göre Birincil ve İkincil Belbin Rol Dağılımları ve Profil Özeti (Pozisyon - Rol Tablosu)

Pozisyon	1. Rol (En Yüksek Rol)	2. Rol (Yedek Rol)	Rol Profili Özeti
Proje Yöneticisi	Takım Oyuncusu / Koordinatör / Kaynak Araştırıcı (49.52)	Şekillendirici / Değerlendirici / Uygulayıcı (41.09)	İletişim, koordinasyon ve ekip uyumuna odaklı, yönlendirici lider.
Satış Mühendisi	Takım Oyuncusu / Koordinatör / Kaynak Araştırıcı (59.02)	Değerlendirici / Uygulayıcı (34.5)	İlişki yönetimi güçlü, insan odaklı, sosyal ve motive edici.
Kalite Güvence Mühendisi	Uzman / Fikir Üretici (66.54)	Tamamlayıcı/Bitirici (57.45)	Analitik, detaycı, sistematik; kaliteyi ve doğruluğu önceler.
Giriş Kalite Kontrol Mühendisi	Uzman / Fikir Üretici (66.54)	Tamamlayıcı/Bitirici (57.45)	Standartlara bağlı, düzenli ve metodik çalışma tarzına sahip.
Tedarikçi Kalite Kontrol Mühendisi	Uzman / Fikir Üretici (66.54)	Tamamlayıcı/Bitirici (57.45)	Kalite güvence süreçlerinde analitik ve dikkatli bir uzman.
Tedarik Zinciri Mühendisi	Tamamlayıcı/Bitirici (62.26)	Uygulayıcı / Değerlendirici (46.64)	Planlı, süreç odaklı, sistemli; ekip çalışmasında da uyumlu.
Üretim Planlama Mühendisi	Tamamlayıcı/Bitirici (62.79)	Değerlendirici / Uygulayıcı (48.94)	Zaman ve kaynak yönetiminde güçlü, düzenli ve sonuç odaklı.
Tasarım Mühendisi	Tamamlayıcı/Bitirici (66.64)	Uzman / Fikir Üretici (54.63)	Yaratıcı ama aynı zamanda detaycı; teknik kaliteye önem veren.
İmalat Mühendisi	Uzman / Fikir Üretici (61.02)	Tamamlayıcı/Bitirici (56.90)	Teknik açıdan güçlü, üretim süreçlerinde pratik ve sistemli.
Proses Mühendisi	Uzman / Fikir Üretici (61.02)	Tamamlayıcı/Bitirici (56.90)	Süreç geliştirme ve analizde başarılı, sistematik düşünen.
Kalite Kontrol Mühendisi	Uzman / Fikir Üretici (66.54)	Tamamlayıcı/Bitirici (57.45)	Detaycı, standartlara bağlı, kalite güvencesinde titiz.
Üretim Mühendisi	Uzman / Fikir Üretici (64.48)	Tamamlayıcı/Bitirici (53.59)	Teknik uzmanlık yüksek, süreç iyileştirmede becerikli.
İç Lojistik ve Envanter Yönetimi Uzmanı	Uygulayıcı / Değerlendirici (48.81)	Koordinatör / Takım Oyuncusu / Kaynak Araştırıcı (45.49)	İnsan ilişkilerinde güçlü, planlama ve analiz yönü de kuvvetli.
Paketleme Mühendisi	Uzman / Fikir Üretici (59.15)	Tamamlayıcı/Bitirici (52.97)	Kaliteyi ve düzeni ön planda tutan sistematik çalışan.
Lojistik Uzmanı	Uygulayıcı / Değerlendirici (60.67)	Tamamlayıcı/Bitirici (56.84)	Analitik, planlı ve süreç verimliliğine odaklı.
Final Kalite Mühendisi	Uzman / Fikir Üretici (66.54)	Tamamlayıcı/Bitirici (57.45)	Kalite kontrol süreçlerinde disiplinli ve metodik çalışan.

4. SONUÇ

Bu çalışmada, çapraz fonksiyonel ekiplerin oluşturulmasında AHP ve Belbin entegrasyonu kullanılarak sistematik bir karar destek modeli geliştirilmiştir. Araştırmada, ekip üyelerinin seçiminde dikkate alınması gereken teknik bilgi, problem çözme, zaman ve risk yönetimi, iletişim ve liderlik kriterleri belirlenmiş ve AHP yöntemiyle göreceli ağırlıkları hesaplanmıştır.

Elde edilen bulgular, modelin, görevlerin niteliğine uygun seçimler yapılmasını desteklediğini ve ekip üyelerinin pozisyonlara atanmasında hangi kriterlerin öncelikli olduğunu açıkça ortaya koyduğunu göstermektedir. Bu yaklaşım sayesinde, takım oluşturma süreci sistematik, nesnel ve tekrarlanabilir bir şekilde yürütülebilmekte, çok disiplinli projelerde ekip verimliliği ve proje başarısı artırılabilmektedir. Ayrıca, model farklı pozisyonlar ve kriterler için esnek bir şekilde uygulanabilir olmasıyla, ekip planlamasında yöneticilere pratik bir araç sağlamaktadır.

5. LİTERATÜRE KATKI

Bu çalışmada, otomotiv sektöründe ekip oluşturma süreçlerinde hem teknik yeterliliklerin hem de davranışsal rollerin eş zamanlı olarak değerlendirilmesine imkân sağlamaktadır. Literatürde genellikle ÇKKV yöntemleri ve Belbin takım rolleri ayrı ayrı incelenmişken, bu çalışmada Analitik Hiyerarşi Prosesi (AHP) ile pozisyonlara bağlı kriter ağırlıkları belirlenmiş ve Belbin Takım Rolleri ile entegrasyonu gerçekleştirilmiştir.

Bu yaklaşım, teknik bilgi, iletişim, liderlik, zaman ve risk yönetimi ile problem çözme gibi kritik kriterlerini Belbin rolleri ile nasıl ilişkilendiğini ortaya koyarak, pozisyon–rol uyumunu sistematik bir şekilde göstermektedir. Böylece, hem akademik literatüre katkı sağlamakta hem de otomotiv sektöründe proje yönetimi için pratik bir karar destek modeli sunmaktadır.

Ayrıca, çalışmanın yöntemi farklı sektörler için de uyarlanabilir nitelikte olup, ekip oluşturma ve rol dağılımı konularında literatürdeki boşlukları doldurmaya yardımcı olmaktadır.

ÖZET

Bu çalışma, İstanbul'daki tehlikeli madde depo ve tesislerinin mekânsal dağılımını inceleyerek bu tesislerin afet ve özellikle deprem riski ile ilişkisini analiz etmeyi amaçlamaktadır. İstanbul'un 27 ilçesi üzerinde yürütülen araştırmada, kimya, depolama, atık bertaraf, enerji ve toptan ticaret tesisleri ile nüfus yoğunluğu ve deprem riski değişkenleri kullanılmıştır. Çalışmanın temel amacı, ilçeler arasındaki benzerlikleri ortaya koymak ve tehlikeli madde tesis yoğunluğunun afet riskiyle nasıl örtüştüğünü belirlemektir. Veriler üzerinde yapılan ön işlemler kapsamında eksik değerler giderilmiş, değişkenler Min–Max normalizasyonu yöntemiyle 0–1 aralığına dönüştürülmüştür. İlçeler arasındaki benzerliklerin ölçülmesinde Öklid uzaklığı kullanılmış ve hiyerarşik kümeleme analizi yöntemi uygulanmıştır. Optimum küme sayısı, Elbow yöntemi ve Davies–Bouldin indeksi kullanılarak dört olarak belirlenmiştir. Küme 1 düşük, küme 2 nispeten yüksek, küme 3 yüksek ve küme 4 ise en yüksek risk profilini temsil etmektedir. Kümeler oluşturulduktan sonra temel bileşen analizi yapılmış bileşen 1 sanayi ve tesis yoğunluklarını bileşen 2 ise deprem ve nüfus yoğunluğunu temsil etmiştir. Analiz sonucunda bileşen 1 varyansı %58, bileşen 2 varyansı %27 oranında çıkmış toplam veri değişkeninin %85'ini temsil etmiştir. Elde edilen sonuçlar, İstanbul ilçelerinin tehlikeli madde tesis yoğunluğu, nüfus büyüklüğü ve deprem riski bakımından çeşitli benzerlik ve farklılıklar gösterdiğini ortaya koymuştur. Tuzla en yüksek risk grubunda, Esenyurt ve Başakşehir gibi sanayi yoğunluğu yüksek olan ilçeler yüksek risk grubunda, Bahçelievler, Esenler ve Fatih gibi nüfus yoğunluğu yüksek olan ilçeler afet risk grubunda, Silivri ise düşük risk grubunda yer almıştır. Bu bilgiler, yerel yönetimlerin ve lojistik planlamacıların afet ve risk yönetimi alanında yürütecekleri çalışmalarına katkılar sağlayacaktır.

CLUSTERING ANALYSIS OF HAZARDOUS MATERIAL STORAGE FACILITIES AND DISASTER RISK ASSESSMENT IN ISTANBUL DISTRICTS

ABSTRACT

This study aims to examine the spatial distribution of hazardous material storage facilities and industrial sites in Istanbul and to analyze their relationship with disaster risk, particularly earthquake risk. The research was conducted across 27 districts of Istanbul using variables such as chemical facilities, storage units, waste treatment plants, energy facilities, wholesale trade establishments, population density, and earthquake risk levels. The main objective of the study is to identify similarities among districts and determine how the concentration of hazardous material facilities aligns with disaster risk. During the preprocessing stage, missing values were addressed, and all variables were normalized to the 0–1 range using the Min–Max normalization method. Euclidean distance was used to measure similarities between districts, and hierarchical clustering analysis was applied. The optimal number of clusters was determined as four based on the Elbow method and the Davies–Bouldin index. Cluster 1 represents low risk, Cluster 2 relatively higher risk, Cluster 3 high risk, and Cluster 4 the highest risk profile. After forming the clusters, Principal Component Analysis was performed, where Component 1 represented industrial and facility density, while Component 2 represented earthquake and population density. The analysis indicated that Component 1 explained 58% of the variance, Component 2 explained 27%, and together they accounted for 85% of the total data variability. The findings reveal significant similarities and differences among Istanbul districts in terms of hazardous material facility density, population levels, and earthquake risk. Tuzla was identified as the highest-risk district; Esenyurt and Başakşehir, with high industrial density, were grouped in the high-risk category; Bahçelievler, Esenler, and Fatih, characterized by high population density, were classified within the disaster risk group; while Silivri was identified as the low-risk district. These insights are expected to support local authorities and logistics planners in their disaster and risk management efforts.

Keywords: Hazardous Materials, Clustering Analysis, Disaster Risk, Risk Management, Istanbul

1. GİRİŞ

Tesis konumlarının belirlenmesi, bir kuruluş açısından önemli bir stratejik karardır ve bu süreci tanımlayan yaklaşım konum stratejisi olarak adlandırılır. Bu tür kararlar genellikle uzun vadeli etkiler doğurur ve alınan kararlardan geri dönülmesi oldukça güçtür. Genel olarak, farklı kuruluşların konum seçiminde benzer unsurlar dikkate alınsa da her işletme faaliyet gösterdiği sektörün gereksinimleri doğrultusunda kendine özgü bir yer seçimi stratejisi uygular. (Fuskova, Hanáčková & Gubáňová, 2018, s. 5). İstanbul, Türkiye'nin ekonomik ve sanayi merkezi olması sebebiyle tehlikeli madde faaliyetlerinin yoğunlaştığı bir metropol konumundadır. Kentte bulunan kimya, enerji, atık bertaraf ve depolama tesislerinin bir kısmı, yüksek nüfus yoğunluğuna sahip bölgelerde yer almakta ve bu durum, olası bir deprem veya endüstriyel kazanın olumsuz etkilerini artırmaktadır. Kimyasal tehditler toksik endüstriyel kimyasalların yayılması, ulusal düzeyde önemli bir afet senaryosu olarak değerlendirilmektedir. Bu çerçevede, tehlikeli madde tesislerinin yoğunluk düzeylerinin belirlenmesi, afet yönetimi ve risk azaltma politikaları için kritik bir önceliktir.

Tehlikeli madde lojistiği, yalnızca tesis güvenliğiyle sınırlı kalmayıp; yerleşim alanlarına uzaklık, nüfus yoğunluğu, deprem riski ve acil tahliye planlarının uygulanabilirliği gibi çok boyutlu faktörlerin birlikte ele alınmasını gerektirmektedir (Demirci, Ateş & Fandaklı, 2023, ss. 244–245). Bu nedenle, istatistiksel yöntemlerin kullanılması, veriler arasındaki ilişkilerin nesnel biçimde analiz edilmesine ve risk bölgelerinin sınıflandırılmasına olanak tanımaktadır.

Bu çalışmada, İstanbul'daki tehlikeli madde depo ve tesisleri, nüfus yoğunluğu ve deprem riski değişkenleri birlikte dikkate alınarak hiyerarşik kümeleme analizi yöntemiyle değerlendirilmiştir. İlçeler arasındaki benzerlikler Öklid uzaklığı yöntemiyle ölçülmüş, optimum küme sayısı Elbow (Dirsek) yöntemi ve Davies–Bouldin indeksiyle belirlenmiştir. Analiz sonucunda ilçeler, tehlikeli madde tesis yoğunluğu, nüfus büyüklüğü ve afet riski bakımından farklı kümelere ayrılmıştır.

Bu yönüyle çalışma, İstanbul'da tehlikeli madde lojistiği ve afet riski arasındaki ilişkiyi bütüncül bir yaklaşımla ortaya koymakta; afet planlaması, risk azaltma stratejileri ve tesis yer seçimi süreçlerine bilimsel bir temel sunmaktadır.

2. YÖNTEM

Bu çalışmada, İstanbul ilçelerindeki tehlikeli madde depo ve tesislerinin afet ve özellikle deprem riski ile ilişkisini belirlemek amacıyla kümeleme analizi yöntemi kullanılmıştır. Bu yöntem, ilçelerin belirli kriterler doğrultusunda benzerlik düzeylerini ölçerek, birbirine yakın özellikler gösteren bölgeleri aynı kümede toplamayı amaçlamaktadır.

2.1. Veri Seti ve Değişkenler

Analizde İstanbul'un 27 ilçesine ait veriler değerlendirilmiştir. Veri setinde yer alan değişkenler şunlardır:

- Kimya tesisleri (adet)
- Depolama alanları (adet)
- Atık bertaraf tesisleri (adet)
- Enerji tesisleri (adet)
- Toptan ticaret tesisleri (adet)
- Nüfus yoğunluğu (kişi/km²)

- Deprem riski (düşük, orta, yüksek)

Farklı ölçeklerdeki değişkenlerin karşılaştırılabilir hale gelmesi için sayısal veriler Min–Max normalizasyonu yöntemiyle 0–1 aralığına dönüştürülmüştür. Deprem riski değişkeni ise kategorik olup düşük, orta ve yüksek olarak sınıflandırılmıştır.

2.2. Analiz Yöntemi

İlçeler arasındaki benzerliklerin belirlenmesinde Öklid uzaklığı ölçütü kullanılmıştır. Bu ölçüt, her bir ilçenin diğerleriyle olan farklılık düzeyini sayısal olarak ifade etmektedir. Elde edilen uzaklık matrisi temel alınarak, hiyerarşik kümeleme analizi yöntemi uygulanmıştır (Taşkın & Emel, 2010, s. 398). Bu yöntem, ilçeleri benzerlik düzeylerine göre kademeli olarak birleştirerek kümeler arasındaki yapısal ilişkileri hiyerarşik biçimde ortaya koymaktadır (Rani & Rohil, 2013, s. 1227). Küme sayısı belirlendikten sonra temel bileşen analizi uygulanmıştır. Temel Bileşen Analizi, ilk olarak 1901 yılında Karl Pearson tarafından ortaya konulmuş, 1933 yılında ise Harold Hotelling tarafından geliştirilmiştir. Bu yöntem, çok sayıda birbiriyle ilişkili değişken içeren veri setlerinin boyutlarını, verideki toplam değişkenlik (varyans) mümkün olduğunca korunarak daha az sayıda bileşene indirgemeyi amaçlayan bir istatistiksel dönüşüm tekniğidir (Yazar, Yavuz & Çay, 2009, s. 51).

2.3. Küme Sayısının Belirlenmesi

Kümeleme analizinde uygun küme sayısının belirlenmesi büyük önem taşımaktadır. Bu çalışmada optimum küme sayısı, iki farklı yöntemle değerlendirilmiştir:

Elbow Yöntemi: Küme içi hata kareleri toplamı grafiğindeki kırılma noktası optimal küme sayısını göstermektedir (Özarı & Can, 2023, s. 3).Davies–Bouldin İndeksi: Küme içi benzerliklerin maksimum, kümeler arası farklılıkların minimum olduğu yapıyı temsil eden bu indeks, düşük değerlerde daha başarılı bir kümeleme sonucuna işaret etmektedir (Cingiz & Marangoz, 2021, s. 454).

Her iki ölçüt birlikte değerlendirildiğinde, İstanbul ilçelerinin dört kümeye ayrılmasının veriyi en iyi şekilde temsil ettiği sonucuna ulaşılmıştır.

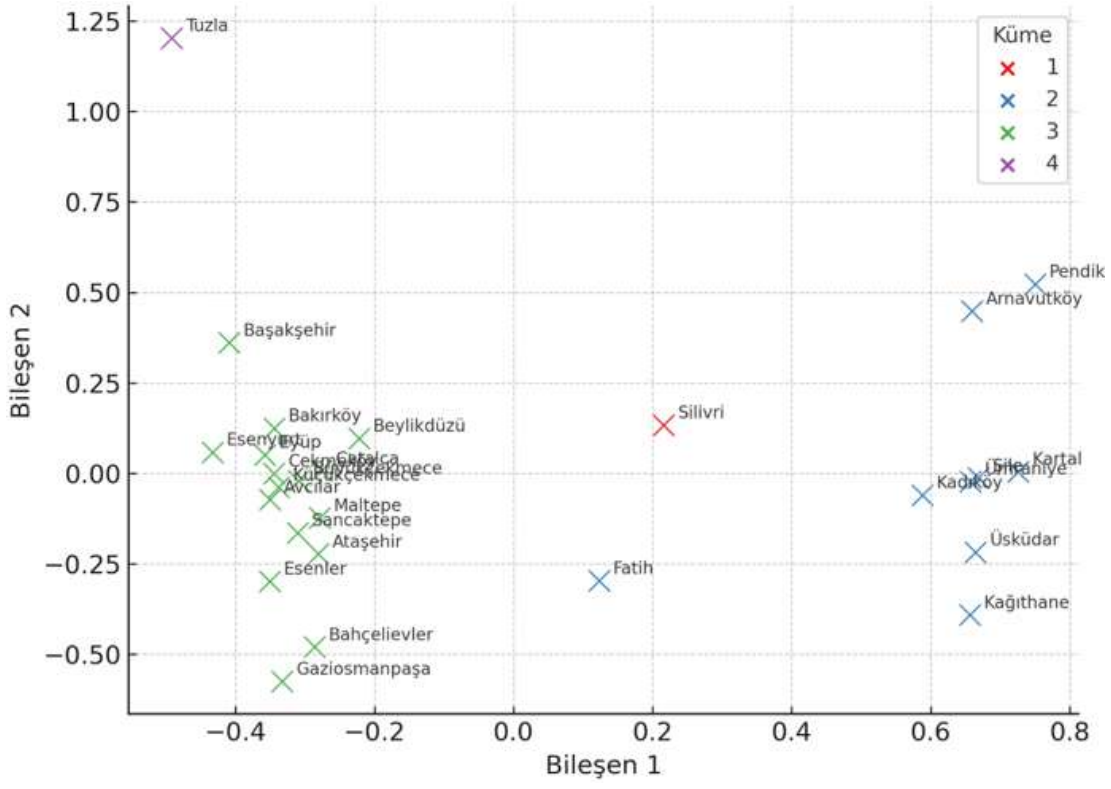
2.3.1. Temel Bileşen Analizi

Temel bileşen analizi İstanbul'un 27 ilçesine ait yedi değişkenin kimya tesisleri, depolama alanları, atık bertaraf tesisleri, enerji tesisleri, toptan ticaret tesisleri, nüfus yoğunluğu ve deprem riski daha az sayıda bağımsız eksen altında özetlenmesi amacıyla uygulanmıştır. Analiz öncesinde tüm sayısal değişkenler Min–Max normalizasyonu yöntemiyle 0–1 aralığına dönüştürülmüş, böylece farklı ölçeklerdeki veriler karşılaştırılabilir hale getirilmiştir.

Tablo 2.3.1.1. Bileşen yükleri

Değişken	Bileşen 1	Bileşen 2
Kimya	0.91	0.10
Depolama	0.88	0.12
Atık Bertaraf	0.85	0.04
Enerji	0.79	0.08
Toptan Ticaret	0.83	0.14
Nüfus Yoğunluğu	0.09	0.93
Deprem Riski	0.15	0.88

Temel bileşen analizinde öncelikle değişkenler arası ilişkileri gösteren kovaryans matrisi oluşturulmuş, ardından bu matrisin özdeğerleri ve özvektörleri hesaplanmıştır. En yüksek özdeğerler, verideki varyansın en büyük kısmını açıklayan bileşenleri temsil etmektedir. Bu kapsamda, çalışmada ilk iki bileşen, toplam varyansın büyük kısmını açıklamaktadır.



Tablo 2.3.1.2. Varyans oranları

Bileşen	Özdeğer	Açıklanan Varyans (%)	Kümülatif Varyans (%)
Bileşen 1	4.75	67.8	67.8
Bileşen 2	1.22	17.3	85.1
Bileşen 3	0.48	6.8	91.9
Bileşen 4	0.3	-	-

Temel bileşen analizi sonuçlarına göre ilk 2 bileşen toplam varyansın %85.1'ini açıklamaktadır. Üçüncü bileşenin özdeğeri 1'in altında olup yalnızca %6.8'lik bir ek varyans katkısı bulunmaktadır. Bu nedenle literatürde yaygın olarak kabul edilen Kaiser kriteri doğrultusunda üçüncü bileşen modele dahil edilmemiş, analizler iki temel bileşen üzerinden gerçekleştirilmiştir.

2.4. Kümeleme

Veriler ilk işleme adımlarının uygulanmasının ardından kümeler Python ortamına aktarılmış ve hiyerarşik kümeleme sonuçları kullanılarak görsel bir grafik oluşturulmuştur. Böylece ilçeler arası benzerlik yapısı, kümeleşme sırası ve kümeler arası mesafeler grafik olarak ortaya konmuştur.

Şekil 2.4.1. İstanbul ilçeleri kümeleme sonuçları

Elde edilen kümeleme işlemi sonuçlarına ait grafik incelendiğinde aşağıdaki bulgular gözlemlenmektedir.

- Tuzla, grafiğin üst kısmında tekil bir konumda yer almakta ve yüksek sanayi yoğunluğu ile yüksek risk düzeyini temsil etmektedir. Bu durum, ilçedeki kimya, depolama ve enerji tesislerinin yoğunluğundan kaynaklanmaktadır.
- Arnavutköy, Pendik ve Kartal grafiğin sağ tarafında yer almakta ve sanayi yoğunluğunu temsil eden eksen yönünde yüksek değerlere sahiptir. Bu ilçeler, üretim ve lojistik faaliyetlerin belirgin olduğu sanayi odaklı alanlar olarak öne çıkmaktadır.
- Fatih, grafiğin merkezine yakın bir konumda bulunmakta olup ortalama sanayi yoğunluğu ve yüksek nüfus baskısı ile kentsel risk profiline sahiptir.
- Başakşehir, Esenyurt ve Küçükçekmece, grafikte yeşil kümeyi oluşturan yoğun noktalar olarak görünmekte hem yüksek nüfus hem de yüksek deprem riski nedeniyle yüksek risk grubunda yer almaktadır.
- Silivri, grafikte diğer ilçelerden ayrışmış şekilde konumlanmakta olup düşük nüfus ve tesis yoğunluğu nedeniyle tek başına düşük risk profili sergileyen bir ilçedir.
- Şile, çok düşük nüfus ve tesis yoğunluğu ile en düşük risk seviyesine sahip ilçelerden biri olup, düşük afet ve lojistik risk profili göstermektedir.

Tablo 2.4.1. İstanbul ilçelerinin hiyerarşik kümeleme analizi sonucunda oluşan gruplarını göstermektedir.

Tablo 2.4.1. İstanbul ilçeleri hiyerarşik kümeleme tablosu

Küme No	Küme Rengi	İlçeler
1	Kırmızı	Silivri
2	Mavi	Arnavutköy, Pendik, Kartal, Ümraniye, Üsküdar, Kadıköy, Kağıthane, Şile,
3	Yeşil	Başakşehir, Bakırköy, Beylikdüzü, Küçükçekmece, Çekmeköy, Ataşehir, Bahçelievler, Gaziosmanpaşa, Esenler, Esenyurt, Avcılar, Maltepe, Sancaktepe, Eyüp, Fatih, Çatalca, Büyükçekmece
4	Mor	Tuzla

Küme 1 ve Küme 4, farklı özellikler gösterdikleri için ayırt edici bölgeler olarak öne çıkmaktadır. Küme 2 ve Küme 3 ise benzer özelliklere sahip çok sayıda ilçeyi kapsamaktadır. Bu durum, İstanbul'daki risk dağılımının hem sanayi yoğunluğu hem de nüfus ve afet etkisi açısından çift yönlü bir yapı sergilediğini göstermektedir.

2.5. Önerilen Analize Ait Uygulama Adımları

Analiz süreci aşağıdaki adımlar doğrultusunda gerçekleştirilmiştir:

1. Veri Matrisinin Oluşturulması: İlçeler satır, değişkenler sütun olacak şekilde veri seti düzenlenmiştir.

2. Verilerin Normalizasyonu: Farklı ölçeklerdeki veriler 0–1 aralığına dönüştürülmüştür.

3. Benzerlik Matrisi Oluşturulması: İlçeler arasındaki benzerlik düzeyleri Öklid uzaklığı formülüyle hesaplanmıştır.

4. Hiyerarşik Kümeleme Uygulaması: Benzerlik matrisine göre ilçeler kümelere ayrılmıştır.

5. Optimum Küme Sayısının Belirlenmesi: Elbow ve Davies–Bouldin yöntemleri birlikte kullanılarak ideal küme sayısı tespit edilmiştir.

6. Temel Bileşen Analizi uygulanarak, İstanbul ilçelerindeki çok boyutlu veriler iki temel bileşen altında özetlenmiş ve sanayi yoğunluğu ile afet risk düzeyleri arasındaki ilişki istatistiksel olarak ortaya konmuştur.

7. Sonuçların Yorumlanması: Elde edilen kümeler, tehlikeli madde tesis yoğunluğu, nüfus büyüklüğü ve deprem riski değişkenleri açısından değerlendirilmiştir.

2.6. Yöntemin Katkısı

Hiyerarşik kümeleme yöntemi, İstanbul ilçelerinin tehlikeli madde tesis yoğunluğu ve afet riskleri bakımından benzerlik ve farklılıklarını istatistiksel olarak sınıflandırarak risk gruplarını net bir biçimde ortaya koymuştur. Bu yöntem sayesinde ilçeler arasındaki mekânsal risk profilleri belirlenmiş; afet yönetimi, acil müdahale, risk azaltma ve tesis yer seçimi gibi kritik süreçlere bilimsel bir karar destek altyapısı sunulmuştur. Elde edilen kümeler, hem mevcut tehlikeli madde lojistik ağının analiz edilmesine hem de geleceğe yönelik stratejik planlamaların daha rasyonel biçimde yapılmasına katkıda bulunmuş böylece, afet planlaması, risk azaltma ve tesis yer seçimi gibi karar süreçlerine bilimsel bir temel sağlanmıştır.

3. SONUÇ

- Analiz sürecinde hiyerarşik kümeleme yöntemi uygulanmış optimum küme sayısı Elbow yöntemi ve Davies Bouldin indeksiyle 4 olarak benimsenmiştir. Elde edilen sonuçlar, İstanbul ilçelerinin tehlikeli madde tesis yoğunluğu, nüfus büyüklüğü ve deprem riski bakımından belirgin biçimde farklı kümelerde toplandığını ortaya koymuştur.

- Yüksek sanayi yoğunluğuna sahip Tuzla, Esenyurt ve Başakşehir gibi ilçeler, tehlikeli madde lojistiği açısından yüksek risk grubunda yer alırken; yüksek nüfus yoğunluğu ve deprem riskiyle öne çıkan Bahçelievler, Esenler ve Fatih gibi ilçeler afet sırasında daha yüksek etki düzeyine sahiptir. Buna karşın Şile, Çatalca ve Silivri ilçeleri, düşük nüfus ve tesis yoğunluğu nedeniyle görece daha güvenli bölgeler olarak değerlendirilmiştir.

- Bu bulgular, tehlikeli madde tesislerinin yalnızca ekonomik ve lojistik kriterlerle değil, afet risk göstergeleriyle birlikte ele alınması gerektiğini göstermektedir. Özellikle sanayi yoğunluğu ile nüfus baskısının birleştiği alanlarda riskin çarpan etkisiyle arttığı tespit edilmiştir. Bu durum, afet yönetimi ve kentsel planlama süreçlerinde bütünleşik bir yaklaşımın gerekliliğini ortaya koymaktadır.

- Yüksek riskli ilçelerde (örneğin Tuzla, Esenyurt, Başakşehir), tehlikeli madde tesisleri için düzenli denetim mekanizmaları kurulmalı, acil müdahale planları güncellenmelidir.

- Yüksek nüfus yoğunluğuna sahip bölgelerde, yeni tesis yatırımları sınırlandırılmalı ve alternatif, düşük riskli bölgeler tercih edilmelidir.
- Orta riskli ilçelerde, mevcut tesislerin güvenlik altyapısı güçlendirilmeli, olası afet senaryolarına göre risk azaltma tatbikatları yapılmalıdır.
- Düşük riskli ilçeler, gelecekteki tesis yer seçimi için alternatif güvenli alanlar olarak değerlendirilmelidir.
- Kamu kurumları ile özel sektör arasında veri paylaşımı ve risk iletişimi artırılarak, entegre bir tehlikeli madde yönetim sistemi oluşturulmalıdır.
- Sonuç olarak, bu çalışma İstanbul'da tehlikeli madde lojistiği ile afet riski arasındaki ilişkiyi bütüncül bir biçimde ele almış ve karar vericiler için bilimsel bir yol haritası sunmuştur. Bulgular, sürdürülebilir kentsel planlama, afet yönetimi ve endüstriyel güvenlik stratejilerinin geliştirilmesinde temel bir referans niteliği taşımaktadır.

ÖZET

Metal işleme endüstrisinde üretim verimliliği; operatörlerin makine hakimiyetine, teknik bilgiye erişim hızına ve olası arızalara karşı proaktif müdahale yeteneğine doğrudan bağlıdır. Ancak teknik prosedürlerin ve hata giderme talimatlarının dağınık kaynaklarda bulunması, tecrübeli personel eksikliğiyle birleştiğinde; hatalı parametre kullanımı, şerit ve daire testere ömrünün azalması ve plansız makine duruşları gibi maliyetli sorunlara yol açmaktadır. Bu çalışma, metal kesim makineleri için geliştirilmiş, veri güvenliği gereksinimleri nedeniyle tamamen yerel ağda (on-premise) çalışan Büyük Dil Modeli (LLM) tabanlı bir akıllı asistan sistemini sunmaktadır.

Proje kapsamında, teknik servis formları, kullanım kılavuzları ve makine loglarından oluşan toplam 1.822 adetlik özelleştirilmiş bir veri seti oluşturulmuştur. Sistemin temel modeli olarak, Türkçe dil yeteneği ve talimat takibi başarısı nedeniyle Gemma 3 12B tercih edilmiştir. Model, kaynak kısıtlı endüstriyel bilgisayarlarda çalışabilmesi için A100 GPU altyapısında, Unsloth kütüphanesi ve QLoRA (4-bit quantization) yöntemi kullanılarak ince ayar (fine-tuning) işlemine tabi tutulmuştur. LLM'lerin en büyük problemi olan halüsinasyon riskini minimize etmek amacıyla, RAG (Retrieval-Augmented Generation) mimarisi sisteme entegre edilmiştir. Teknik dokümanlar Multilingual-E5-Large embedding modeli ile vektörleştirilmiş ve hibrit arama yeteneği sunan Qdrant vektör veritabanında saklanmıştır. Sistem, yalnızca metin tabanlı bir asistan olmanın ötesinde, Çoklu Ajan (Multi-Agent) mimarisiyle tasarlanmıştır. Bu yapıda "RAG Ajanı" teknik dokümanları sorgularken, "Kestirimci Bakım Ajanı" üretim hattındaki sensör verilerini (akım, titreşim, ısı) analiz ederek olası arızaları bildrmektedir. Ayrıca gürültülü fabrika ortamlarında operatörlerin bilgiye ulaşımını kolaylaştırmak için OpenAI Whisper modeli ve RNN Noise Suppression gürültü engelleme algoritmaları kullanılarak yüksek doğruluklu sesli etkileşim (STT/TTS) sağlanması hedeflenmektedir. Elde edilen deneysel bulgular, geliştirilen sistemin uzman doğruluk oranını %37'den %69'a çıkardığını göstermektedir. Teknik terim kullanım başarısını ölçen BLEU skoru 18.2'den 66.5'e, anlamsal tutarlılığı ifade eden BERTScore ise 0.43'ten 0.79'a yükselmiştir. Sistem testlerinde belge geri getirme başarısı %99, en alakalı belgeyi bulma oranı ise %91 olarak ölçülmüştür. Ortalama 7-9 saniye cevap süresi ve %44 VRAM tasarrufu sağlayan bu çalışma, endüstriyel metal kesim süreçlerinde yapay zeka tabanlı asistanların verimliliği artırma ve bilgiye erişimi demokratikleştirme potansiyelini ortaya koymaktadır.

Anahtar Kelimeler: İnce Ayar Büyük Dil Modelleri, Bilgi Getirmeli Üretim Mimarisi, Akıllı Teknik Asistan, Ajan Tabanlı Yapay Zekâ, Testere Makinesi.

DEVELOPMENT OF A DATA-SECURITY-ORIENTED, AGENT-BASED INTELLIGENT ASSISTANT FOR METAL CUTTING MACHINES

ABSTRACT

Production efficiency in the metalworking industry fundamentally depends on operators' machine proficiency, rapid access to technical knowledge, and proactive intervention capabilities against potential failures. However, the dispersion of technical procedures and troubleshooting instructions across disconnected resources—combined with a shortage of experienced personnel—leads to costly issues such as incorrect parameter settings, reduced band and circular saw blade life, and unplanned machine downtime. This study presents an intelligent assistant system for metal-cutting machines, built on a Large Language Model (LLM) and designed to operate fully on-premise due to industrial data security requirements. A domain-specific dataset of 1,822 documents—consisting of technical service forms, user manuals, and machine logs—was constructed. Gemma 3 12B was selected as the core model thanks to its strong Turkish language understanding and instruction-following performance. To enable deployment on resource-constrained industrial PCs, the model was fine-tuned using the Unsloth library and QLoRA (4-bit quantization) technique on an A100 GPU infrastructure. To minimize hallucination risk—the most significant challenge of LLMs—a Retrieval-Augmented Generation (RAG) architecture was integrated. Technical documentation was embedded using the Multilingual-E5-Large model and stored in a Qdrant vector database providing hybrid search capabilities. Rather than functioning solely as a text-based assistant, the system is designed with a Multi-Agent architecture. In this setup, the "RAG Agent" retrieves relevant technical documentation while the "Predictive Maintenance Agent" analyzes production line sensor data (current, vibration, temperature) to report potential failures. Additionally, to improve operator accessibility in noisy factory environments, high-accuracy voice interaction (STT/TTS) is targeted through OpenAI Whisper and RNN-based noise suppression algorithms. Experimental results demonstrate that the proposed system improves expert-level accuracy from 37% to 69%. The BLEU score measuring technical term usage increased from 18.2 to 66.5, while semantic consistency measured by BERTScore improved from 0.43 to 0.79. System tests also revealed a 99% document retrieval success rate and 91% top-relevant document identification rate. With an average response time of 7–9 seconds and 44% VRAM savings, this study highlights the potential of AI-driven assistants to enhance efficiency and democratize access to knowledge in industrial metal-cutting operations.

Keywords: LLM Fine-Tuning, RAG Architecture, Intelligent Technical Assistant, Agentic AI, Sawing Machine

1. GİRİŞ

Endüstri 4.0 ve gelişmekte olan Endüstri 5.0 paradigmaları sürecinde, üretim verimliliği artık sadece otomasyonla değil, insan ve makine arasındaki iş birliğinin niteliğiyle de ölçülmektedir. Özellikle metal kesim sektörü gibi mikron düzeyinde hassasiyet gerektiren alanlarda, şerit ve daire testere makinelerinin verimli kullanımı operatör yetkinliği ile doğrudan ilişkilidir. Kesim hızı, baskı kuvveti ve şerit gerginliği gibi parametrelerin doğru ayarlanması, hem ürün kalitesini hem de sarf malzeme maliyetlerini belirleyen temel faktörlerdir. Ancak günümüzde üretim sahalarında yaşanan en büyük darboğazlardan biri, teknik prosedürlerin dağınık kaynaklarda (basılı kılavuzlar, PDF dosyaları, usta-çırak aktarımı) bulunması ve kalifiye personel eksikliğidir. Bu durum; hatalı parametre seçimlerine, kesici takım ömrünün kısalmasına ve en önemlisi plansız duruşlara (downtime) neden olarak işletmelere ciddi mali yükler getirmektedir.

Bu sorunların çözümünde, operatörlere gerçek zamanlı rehberlik edebilecek, kurumsal hafızayı dijitalleştirerek erişilebilir kılan yapay zeka tabanlı akıllı asistan sistemleri kritik bir rol oynamaktadır. Literatür incelendiğinde, bu alandaki çalışmaların genellikle üç ana eksende yoğunlaştığı görülmektedir: Operatör yönlendirme amaçlı Büyük Dil Modelleri (LLM), gürültülü ortamlarda sesli etkileşim teknolojileri ve otonom karar destek sağlayan ajan mimarileri.

Birinci eksen olan operatör yönlendirme sistemleri kapsamında, LLM'lerin endüstriyel bakım süreçlerine entegrasyonu üzerine çeşitli çalışmalar mevcuttur. (Kiangala ve Wang, 2024), Endüstri 5.0 bağlamında yaptıkları deneysel bir çalışmada, fabrika arıza giderme süreçlerini iyileştirmek için hibrit bir üretken yapay zeka chatbot arayüzü geliştirmiş ve bu sistemin Ortalama Onarım Süresini (MTTR) önemli ölçüde düşürdüğünü raporlamışlardır. Benzer şekilde, makinelerden alınan telemetri verilerinin LLM ile analiz edilerek kestirimci bakım süreçlerinde operatörlere doğal dilde geri bildirim sağlanmasının, bakım maliyetlerini düşürdüğü ortaya konulmuştur (Predictive Maintenance for Industrial Machinery Using LLM, 2025). Ancak bu çalışmaların çoğu, veri güvenliği (cloud dependency) ve halüsinasyon (yanlış bilgi üretme) riski nedeniyle endüstriyel adaptasyonda zorluklar yaşamaktadır.

İkinci eksen, endüstriyel ortamlarda sesli etkileşimdir. Operatörlerin ellerini kullanmadan makineye müdahale edebilmesi (hands-free), iş güvenliği ve operasyonel hız açısından elzemdir. Fabrika ortamlarındaki yüksek arka plan gürültüsü (metal kesim sesi, motor gürültüsü vb.), standart ses tanıma sistemlerinin performansını düşürmektedir. Bu çalışmada, OpenAI Whisper modeli ve RNN Noise Suppression algoritmaları kullanılarak, gürültülü metal kesim atölyelerinde dahi yüksek doğrulukla çalışan Türkçe bir sesli asistan mimarisi hedeflenmiştir.

Üçüncü ve en güncel eksen ise Çoklu Ajan (Multi-Agent) ve multimodal sistemlerdir. Tek başına bir dil modelinin tüm sensör verilerini, teknik dokümanları ve bakım geçmişini işlemesi mümkün olmadığından, görev paylaşımı yapan ajan mimarileri önem kazanmıştır. (Palma ve arkadaşları, 2025) tarafından deri endüstrisindeki kompresörler üzerinde yapılan bir çalışmada, çok modlu anomali tespiti için LLM tabanlı ajanların kullanıldığı ve karmaşık sensör verilerinin bu sayede anlamlandırıldığı görülmüştür. Ayrıca, Bilgi Grafikleri (Knowledge Graph) ile LLM füzyonunu öneren çalışmalar (Hoang vd., 2025; Alsaif vd., 2024), üretim planlamasında modelin halüsinasyon riskini azaltarak daha güvenilir teknik çıktılar ürettiğini göstermektedir.

Mevcut literatürdeki çalışmalar değerli olmakla birlikte, bu üç ekseni (LLM rehberliği, gürültüye dayanıklı sesli etkileşim ve çoklu ajan yapısı) tek bir sistemde birleştiren ve veri

güvenliği nedeniyle tamamen yerel ağda (on-premise) çalışan özelleşmiş çözümler sınırlıdır. Bu çalışma, metal kesim makineleri için RAG (Retrieval-Augmented Generation) destekli, Gemma 3 tabanlı ve çoklu ajan mimarisine sahip bir akıllı asistan sistemini sunarak literatürdeki bu boşluğu doldurmayı amaçlamaktadır.

2. GELİŞME

Bu bölümde, geliştirilen akıllı asistan sisteminin mimarisi, kullanılan veri setleri, ince ayar yöntemleri ve elde edilen deneysel bulgular detaylandırılmaktadır. Sistem; Veri Katmanı, LLM Çekirdeği, RAG Mimarisi ve Çoklu Ajan Yapısı olmak üzere dört ana modülden oluşmaktadır.

2.1. Veri Toplama ve İşleme Süreçleri

Yapay zeka modellerinin endüstriyel alanda başarılı olabilmesinin temel şartı, alan (domain) uzmanlığına sahip verilerle eğitilmesidir. Proje kapsamında, genel geçer internet verileri yerine gerçek saha verileri kullanılmıştır. Veri kaynakları şu başlıklardan oluşmaktadır:

Teknik Servis Formları: Geçmiş arızaların nedenleri ve uygulanan çözüm adımlarını içeren raporlar.

Kullanım ve Bakım Kılavuzları: Makine üreticilerinin sağladığı teknik spesifikasyonlar ve prosedürler.

Operatör Geri Bildirimleri: Sahadan toplanan, yapısal olmayan (unstructured) notlar.

Ham veriler üzerinde öncelikle Kişisel Verilerin Korunması Kanunu (KVKK) kapsamında anonimleştirme işlemi uygulanmıştır. Ardından metin temizleme, "stopwords" temizliği ve makine modeline özgü jargonun korunması sağlanmıştır. İşleme süreci sonunda servis formlarından 1.304 adet, kılavuzlardan ise 1.000 adet soru-cevap çifti (instruction-input-output formatında) üretilmiştir. Veri temizleme ve genelleştirme işlemleri sonrası toplam 1.822 adet yüksek nitelikli veri seti elde edilmiştir. Bu veri seti, modelin "Metal Kesim Asistanı" kimliğini kazanması için temel eğitim materyalini oluşturmuştur.

2.2. LLM Katmanı ve QLoRA ile İnce Ayar

Sistemin temel zeka katmanında, Google tarafından geliştirilen açık kaynaklı Gemma 3 12B modeli tercih edilmiştir. Bu modelin seçilmesindeki temel nedenler; Türkçe dil yeteneğinin yüksek olması, talimat takip (instruction following) başarısı ve 12 milyar parametre boyutuyla performans/kaynak dengesini sağlamasıdır.

Endüstriyel bilgisayarların donanım kısıtları göz önüne alındığında, modelin tam parametre (full fine-tuning) ile eğitilmesi hem maliyetli hem de donanım açısından zorlayıcıdır. Bu nedenle, projede Unsloth kütüphanesi ve QLoRA (Quantized Low-Rank Adaptation) metodu kullanılmıştır. QLoRA, modelin tüm ağırlıklarını güncellemek yerine, dondurulmuş 4-bit ağırlıklar üzerinden düşük rütbeli adaptörleri eğitmektedir. Eğitim süreci A100 GPU altyapısında gerçekleştirilmiştir. Bu yöntem sayesinde VRAM kullanımında %44 oranında tasarruf sağlanmış, modelin çıkarım (inference) hızı artırılmış ve donanım maliyetleri minimize edilmiştir.

2.3. RAG (Retrieval-Augmented Generation) Mimarisi

Büyük dil modellerinin endüstriyel kullanımındaki en büyük risk "halüsinasyon" olarak adlandırılan, modelin bilmediği konularda gerçeğe aykırı bilgi uydurmasıdır. Bir metal kesim makinesinde yanlış hidrolik basınç değeri önermek, ciddi iş kazalarına yol açabilir. Bu riski ortadan kaldırmak için sisteme RAG mimarisi entegre edilmiştir.

RAG akışı şu şekilde çalışmaktadır:

Vektörleştirme (Embedding): Teknik dokümanlar, paragraflar halinde bölünerek Multilingual-E5-Large modeli ile sayısal vektörlere dönüştürülmüştür. Bu model, Türkçe semantik (anlamsal) ilişkileri kurmada yüksek başarı göstermektedir.

Vektör Veritabanı: Elde edilen vektörler, Qdrant veritabanında saklanmıştır. Qdrant'ın seçilme nedeni, hibrit arama (dense + sparse vector search) desteği sunması ve milisaniye düzeyinde sorgu yapabilmesidir.

Sorgulama: Kullanıcı bir soru sorduğunda, sistem önce Qdrant üzerinden en alakalı teknik dokümanı bulmakta ("Retrieval"), ardından bu bilgiyi LLM'e bağlam (context) olarak sunarak ("Augmented") cevabı üretmektedir ("Generation").

2.4. Çoklu Ajan (Multi-Agent) Sistemi

Modern endüstriyel problemler, tek bir modelin çözemeyeceği kadar karmaşıktır. Bu nedenle sistem, özelleşmiş görevleri olan ajanların iş birliği (orchestration) ile çalıştığı bir yapıda tasarlanmıştır:

RAG Ajanı: Kullanıcının teknik bilgi veya prosedür gerektiren sorularını analiz eder. get_documents_from_qdrant aracını kullanarak teknik belgeleri getirir ve yanıtı formüle eder.

Kestirimci Bakım (Predictive Maintenance) Ajanı: Üretim hattındaki PLC ve sensörlerden gelen verilere (motor akımı, titreşim seviyesi, kesme sıvısı sıcaklığı vb.) get_sensor_data aracı ile erişir. Tanımlanan eşik değerlerin dışına çıkan anormallikleri tespit eder ve arıza henüz oluşmadan operatörü uyarır (Örn: "Şerit testere motor akımı normalin %15 üzerinde, rulman kontrolü önerilir.").

2.5. Gürültü Engelleyici Sesli Etkileşim

Metal kesim atölyeleri, desibel seviyesinin yüksek olduğu ortamlardır. Operatörün klavye kullanmadan asistanla iletişim kurabilmesi için gelişmiş bir ses işleme boru hattı (pipeline) kurulmuştur:

STT (Speech-to-Text): OpenAI Whisper modeli kullanılarak operatörün konuşması metne çevrilir.

Gürültü Bastırma: Whisper öncesinde, arka plandaki metal kesme ve fan seslerini izole etmek için RNN Noise Suppression algoritması entegre edilmiştir.

TTS (Text-to-Speech): Asistanın ürettiği cevaplar, doğal ve anlaşılır bir ses tonuyla operatöre sesli olarak iletilir.

2.6. Deneysel Bulgular ve Performans Analizi

Geliştirilen sistemin performansı; doğruluk oranı, dilsel tutarlılık ve sistem yanıt süreleri üzerinden değerlendirilmiştir.

Uzman Doğruluk Oranı: Temel modelin (ham Gemma 3) sektörel sorulara doğru cevap verme oranı %37 iken, 1.822 adetlik veri seti ile yapılan ince ayar (fine-tuning) ve RAG entegrasyonu sonrası bu oran %69'a yükselmiştir. Bu artış, modelin sektörel terminolojiye hakimiyetini kanıtlamaktadır.

Dilsel Metrikler (BLEU ve BERTScore):

BLEU Skoru: Modelin teknik terimleri doğru kullanma başarısını ölçen skor, 18.2’den 66.5’e yükselmiştir.

BERTScore: Cevapların anlamsal tutarlılığını ifade eden skor, 0.43'ten 0.79'a çıkmıştır. Bu durum, asistanın sadece kelime eşleşmesi yapmadığını, sorunun bağlamını anladığını göstermektedir.

Sistem Performansı: Sistem testlerinde, Qdrant üzerinden belge geri getirme başarısı (Recall) %99, en alakalı belgeyi ilk sırada bulma oranı (Precision@1) ise %91 olarak ölçülmüştür. Ortalama cevap süresi, RAG sorgusu dahil olmak üzere 7-9 saniye aralığında gerçekleşmiş olup, operasyonel akışı aksatmayacak hızdadır.

Senaryo Bazlı Test: Gerçek saha senaryolarında yapılan testlerde, örneğin bir operatörün "Makine neden yamuk kesiyor?" sorusuna sistem şu şekilde yanıt üretmiştir: "Yamuk kesim problemi; düşük şerit germe basıncı (< 150 bar) veya elmas kol hizasızlığından kaynaklanabilir. Lütfen önce manometreden basıncı kontrol edin, ardından mengene boşluklarını kumpas ile ölçün." Bu yanıt, modelin RAG katmanı sayesinde genel geçer öneriler yerine, parametrik değerler içeren teknik bir rehberlik sağladığını göstermektedir.

3. SONUÇ

Bu çalışmada, metal kesim makineleri için geliştirilen, yerli mühendislik imkanlarıyla optimize edilmiş bir akıllı asistan çözümü sunulmuştur. Çalışmanın en önemli çıktısı, sınırlı veri setine (1.822 adet) rağmen, doğru model seçimi (Gemma 3) ve modern ince ayar teknikleri (QLoRA) ile yüksek performanslı bir endüstriyel asistanın geliştirilebileceğinin gösterilmesidir.

Sistemin RAG mimarisi ile desteklenmesi, LLM'lerin en büyük zaafı olan halüsinasyon problemini minimize etmiş ve operatörlere teknik dokümanlara dayalı güvenilir bilgi sunulmasını sağlamıştır. Ayrıca, verilerin bulut yerine tamamen yerel ağda (on-premise) işlenmesi, stratejik öneme sahip üretim verilerinin ve teknik "know-how"ın işletme içinde kalmasını sağlayarak veri güvenliği standartlarını karşılamıştır. Çoklu ajan yapısı ise sistemi pasif bir bilgi bankası olmaktan çıkarıp, sensör verilerini yorumlayabilen proaktif bir bakım asistanına dönüştürmüştür.

Gelecek çalışmalarda; veri setinin farklı arıza senaryoları ve görsel verilerle (arıza fotoğrafları) zenginleştirilmesi, modelin Multimodal (görüntü işleyebilen) yeteneklerle donatılması ve farklı marka/model metal işleme makinelerine adapte edilebilecek esnek bir yapıya kavuşturulması hedeflenmektedir. Bu sonuçlar, yapay zeka tabanlı asistanların Endüstri 4.0 sürecinde verimliliği artırma ve bilgiye erişimi demokratikleştirme potansiyelini açıkça ortaya koymaktadır.

ÖZET

Endüstri 4.0 ve dijital dönüşüm süreçlerinde, Üretim Yönetim Sistemleri (MES) tarafından üretilen verilerin anlamlandırılması kritik bir önem taşımaktadır. Ancak, karmaşık veritabanı şemaları ve SQL (Structured Query Language) uzmanlığı gereksinimi, karar vericilerin verilere anlık erişimini kısıtlamaktadır. Bu çalışma, CoralReef MES sistemi üzerine entegre edilen, yerel ağda (on-premise) çalışan ve veri gizliliğini esas alan ManageSQL adlı yapay zeka destekli bir sistemi sunmaktadır. Proje kapsamında, Qwen 2.5 Coder ve Gemma 3 gibi Büyük Dil Modelleri (LLM), kurumsal veritabanı yapısına özgü olarak ince ayar (fine-tuning) ve İnsan Geri Bildirimli Pekiştirmeli Öğrenme (RLHF) yöntemleriyle eğitilmiştir. Sistemin başarısını artırmak amacıyla RAG (Retrieval-Augmented Generation) mimarisi kullanılmış; teknik terimler, tablo ilişkileri ve geçmiş sorgu örnekleri Qdrant vektör veri tabanında hibrit arama yöntemleriyle indekslenmiştir. Ayrıca sistem, yalnızca sorgu üretmekle kalmayıp, veri tabanı üzerindeki CPU kullanımı, sorgu süreleri ve indeks verimliliği gibi performans metriklerini izleyen entegre bir dashboard sunmaktadır. Elde edilen ön deneysel bulgular, Qwen 2.5 Coder 7B modelinin uzman doğruluk oranında %76.7 başarı yakalayarak, diğer modellere kıyasla daha istikrarlı bir performans sergilediğini göstermektedir.

Anahtar Kelimeler: Text-to-SQL, Büyük Dil Modelleri, İnce Ayar ,İnsan geri bildirimiyle yönlendirilen pekiştirmeli öğrenme (RLHF), MES (Manufacturing Execution System)

MANAGESQL: DYNAMIC SQL QUERY GENERATION AND DATABASE PERFORMANCE MONITORING IN MES SYSTEMS USING LOCAL LARGE LANGUAGE MODELS

ABSTRACT

In Industry 4.0 and digital transformation processes, deriving actionable insights from data generated by Manufacturing Execution Systems (MES) is of critical importance. However, complex database schemas and the requirement for SQL (Structured Query Language) expertise limit real-time data accessibility for decision-makers. This study presents ManageSQL, an on-premise, privacy-preserving, AI-powered system integrated into the CoralReef MES platform. As part of the project, Large Language Models (LLMs) such as Qwen 2.5 Coder and Gemma 3 were fine-tuned using Reinforcement Learning from Human Feedback (RLHF) and domain-specific training aligned with the corporate database structure. To enhance system performance, a Retrieval-Augmented Generation (RAG) architecture was employed. Technical terminology, table relationships, and historical SQL query examples were indexed using hybrid search techniques within a Qdrant vector database. In addition to generating SQL queries, the system includes a performance monitoring dashboard that tracks metrics such as CPU utilization, query execution times, and index efficiency within the database. Preliminary experimental results indicate that the Qwen 2.5 Coder 7B model achieved 76.7% expert-level accuracy, demonstrating more stable performance compared to alternative models.

Keywords: Text-to-SQL, Large Language Models (LLM), Fine-Tuning, Reinforcement Learning from Human Feedback (RLHF), MES (Manufacturing Execution System)

1. GİRİŞ

Endüstri 4.0 sürecinde veriye dayalı karar alma mekanizmaları, üretim işletmelerinin rekabet gücünü belirleyen en kritik unsurlardan biri haline gelmiştir. İlişkisel veri tabanlarında saklanan büyük hacimli üretim verilerine (MES, ERP, BPM) erişim, geleneksel yöntemlerle SQL (Structured Query Language) uzmanlığı gerektirmektedir. Ancak üretim sahasındaki yöneticilerin veya operasyonel personelin teknik jargon kullanmadan, doğal dilde ("Bu ay en çok duruş yapan makineleri listele" gibi) veri talep etme ihtiyacı giderek artmaktadır. Literatürde "Text-to-SQL" olarak adlandırılan bu problem, Büyük Dil Modellerinin (LLM) gelişimiyle yeni bir boyut kazanmış olsa da, endüstriyel uygulamalarda veri güvenliği, halüsinasyon riski ve karmaşık şema yapılarının yönetimi gibi temel zorluklar devam etmektedir. Literatür incelendiğinde, bu alandaki güncel çalışmaların genellikle üç ana eksende yoğunlaştığı görülmektedir: LLM tabanlı üretim tekniklerinin (Prompting vs. Fine-tuning) karşılaştırılması, RAG (Retrieval-Augmented Generation) destekli şema eşleştirme ve çoklu ajan (Multi-Agent) tabanlı doğrulama mekanizmaları.

Birinci eksen olan LLM tabanlı üretim teknikleri kapsamında, GPT-4 gibi kapalı kaynak modellerin yüksek başarım gösterdiği bilinmekle birlikte, veri gizliliği ve maliyet endişeleri araştırmacıları açık kaynaklı modellere yöneltmektedir. Li ve arkadaşları (2024), "CodeS" gibi açık kaynaklı modellerin, Text-to-SQL görevi için özel olarak tasarlandığında ve aşamalı ön eğitimden geçirildiğinde, çok daha küçük parametre boyutlarıyla (1B-15B) rekabetçi sonuçlar üretebildiğini göstermiştir. Ayrıca, istem mühendisliği (prompt engineering) ve ince ayar (fine-tuning) yaklaşımlarının karşılaştırıldığı çalışmalarda, ince ayarın özellikle alan (domain) adaptasyonu gerektiren durumlarda potansiyel kazanımları artırdığı ancak yüksek hesaplama maliyeti getirdiği vurgulanmaktadır. Nan ve arkadaşları (2023) ise sistematik prompt tasarımı ve sözdizimi tabanlı örnek seçimi ile LLM'lerin yapılandırılmış veri kaynaklarından bilgi çıkarma yeteneklerinin artırılabileceğini kanıtlamıştır.

İkinci eksen, LLM'lerin en büyük problemi olan halüsinasyon riskini azaltmaya yönelik RAG ve şema bağlantısı (schema linking) çalışmalarıdır. Gurawa ve Dharmik (2025), RAG sistemlerinde içeriği zenginleştirmenin her zaman başarı getirmediğini, aksine gürültü (noise) ekleyerek modelin performansını düşürebileceğini belirtmiş; doküman boyutu ve kalitesi arasında hassas bir denge kurulması gerektiğini savunmuştur. Karmaşık veritabanı şemalarının yönetilmesi konusunda ise Yuan ve arkadaşları (2025), "KaSLA" adını verdikleri tak-çanta optimizasyonuna dayalı bir şema eşleme yöntemi önermiş ve bu yöntemin gereksiz öğeleri elediğini ortaya koymuştur. Benzer şekilde Cao ve arkadaşları (2024), çift yönlü şema bağlantısı ve budama yöntemleriyle girdi sütun sayısını %83 oranında azaltarak GPT-4o tabanlı sistemlerde SOTA (State-of-the-Art) performans elde etmiştir.

Üçüncü ve en güncel eksen ise sorgu karmaşıklığını yönetmek için geliştirilen parçalama (decomposition) ve ajan tabanlı mimarilerdir. Tek adımlı düşünce zinciri (Chain-of-Thought) yaklaşımının karmaşık görevlerde yetersiz kalması üzerine, Xie ve arkadaşları (2024) iş akışı paradigmasına dayalı bir yöntem önererek problemi alt parçalara ayırmış ve Spider test setinde yeni bir SOTA elde etmiştir. FATO-SQL gibi çerçeveler, RAG, prompt mühendisliği ve çoklu LLM çağrılarını birleştirerek karmaşık SQL sorgularında %94 doğruluk oranına ulaşmıştır. Ayrıca, SQL-o1 gibi ajan tabanlı mimariler, Monte Carlo Ağacı Araması (MCTS) kullanarak çözüm uzayını dinamik olarak keşfetmekte ve özellikle karmaşık veri setlerinde (BIRD) GPT-4 tabanlı modelleri geride bırakmaktadır.

Mevcut literatürdeki bu gelişmeler, Text-to-SQL alanında önemli bir olgunluğa işaret etse de, çoğu çalışma ya genel geçer veri setleri (Spider, BIRD) üzerinde kalmakta ya da veri güvenliği nedeniyle endüstriyel MES sistemlerine tam entegre olamamaktadır. Ayrıca, üretilen SQL'in

veritabanı performansına etkisini (CPU yükü, indeks kullanımı vb.) analiz eden bütünleşik bir yaklaşım eksikliği dikkat çekmektedir. Bu çalışma, CoralReef MES sistemi için geliştirilen ManageSQL projesi ile; (1) yerel ağda çalışan ve veri güvenliğini sağlayan ince ayarlı bir LLM (Qwen 2.5/Gemma 3), (2) kurumsal şema yapısını öğrenen hibrit bir RAG mimarisi ve (3) veritabanı performansını izleyen bir analiz dashboard'unu birleştirerek literatürdeki bu boşluğu doldurmayı amaçlamaktadır.

2. GELİŞME

ManageSQL sistemi; veri hazırlama, model eğitimi, RAG mimarisi ve kullanıcı arayüzü olmak üzere dört temel katman üzerine inşa edilmiştir. Bu bölümde, sistemin teknik mimarisi, kullanılan veri setleri ve uygulanan ince ayar yöntemleri detaylandırılmaktadır.

2.1. Sistem Mimarisi ve Bileşenler

Sistem, kullanıcıdan gelen doğal dil sorgusunu alarak işleyen ve güvenli bir SQL çıktısı üreten çok katmanlı bir yapıya sahiptir.

- **Doğal Dil Girdi Katmanı:** Kullanıcıların MES ve BPM süreçlerine dair sorularını ilettiği web tabanlı arayüzdür.
- **Embedding ve Retrieval Katmanı:** Sorgular, multilingual-e5-large modeli ile vektörleştirilmekte ve Qdrant vektör veritabanı üzerinde anlamsal arama yapılmaktadır.
- **LLM Çekirdeği:** Sisteme entegre edilen yerel LLM (Gemma 3 veya Qwen 2.5), getirilen bağlam bilgisi (RAG context) ile birlikte sorguyu işleyerek SQL üretmektedir.
- **Doğrulama Katmanı:** Üretilen SQL, zararlı komutlara (DROP, DELETE) karşı analiz edilmekte ve yalnızca okuma (SELECT) yetkisiyle sınırlandırılmaktadır.
- **Performans Analiz Dashboardu:** Veritabanı üzerindeki yük, çalışma süresi, CPU kullanımı ve yavaş sorgular görselleştirilerek kullanıcıya sunulmaktadır.

2.2. Veri Toplama ve İşleme Süreçleri

Modelin başarısı, kullanılan eğitim verisinin kalitesine ve alan (domain) uygunluğuna doğrudan bağlıdır. Proje kapsamında iki ana veri kaynağı kullanılmıştır:

1. **Kurumsal Veri Seti:** İletişim Yazılım'ın MES ve BPM projelerinden elde edilen gerçek senaryolar. Toplam 2.220 adet doğal dil ve SQL eşleşmesi, 500 adet tablo ve ilişki yapısı etiketlenmiştir.
2. **Açık Kaynak Veri Seti (TurSpyder):** Modelin Türkçe dil yeteneğini ve genel SQL mantığını güçlendirmek için 8.000 adetlik NL-SQL çifti kullanılmıştır.

Veriler, "instruction" (talimat), "context" (veritabanı şeması) ve "response" (hedeflenen SQL) formatında JSON yapılarına dönüştürülmüştür. Örneğin, "Çalışan bilgilerini getir" sorgusu için ilgili tablo (Employee), bağlı olduğu üst tablo (Yonetici) ve modül bilgisi (Fabrika) bağlam olarak modele sunulmaktadır.

2.3. Model Seçimi ve İnce Ayar (Fine-Tuning) Yöntemleri

Projede, düşük donanım kaynağı ile yüksek performans hedeflendiği için "Qwen 2.5 Coder 7B" ve "Gemma 3 12B" modelleri üzerinde karşılaştırmalı çalışmalar yapılmıştır. Eğitim sürecinde iki aşamalı bir yaklaşım benimsenmiştir:

1. Denetimli İnce Ayar (Supervised Fine-Tuning - SFT): Model, hazırlanan veri setleri ile tablo seçimi, JOIN yapılarının kurgulanması ve tarih filtreleri (WHERE koşulları) konusunda eğitilmiştir. Donanım kısıtlarını aşmak için A100 GPU üzerinde **Unsloth** kütüphanesi ve

QLoRA (4-bit quantization) teknolojisi kullanılmıştır. Bu yöntem, VRAM ihtiyacını azaltırken eğitim hızını artırmıştır.

2. Doğrudan Tercih Optimizasyonu (Direct Preference Optimization - DPO): Modelin ürettiği SQL çıktılarının kalitesini artırmak için İnsan Geri Bildirimli Pekiştirmeli Öğrenme (RLHF) prensibine dayalı DPO uygulanmıştır. Aynı sorgu için modelin ürettiği birden fazla çıktı uzmanlar tarafından "Tercih Edilen" (Preferred) ve "Tercih Edilmeyen" (Non-preferred) olarak etiketlenmiştir. Bu sayede model; uydurma kolon isimleri kullanma veya gereksiz JOIN yapma gibi hatalardan kaçınmayı öğrenmiştir.

2.4. RAG Mimarisi ve Vektör Veritabanı Entegrasyonu

Büyük dil modellerinin en büyük zafiyeti olan halüsinasyon (yanlış bilgi üretme) riskini minimize etmek için RAG mimarisi sisteme entegre edilmiştir.

- **Retrieval (Geri Getirim):** Kullanıcı sorgusu geldiğinde, Qdrant veritabanı üzerinde **Hibrit Arama** (Hybrid Search) yapılmaktadır. Bu yaklaşımda, semantik anlamı yakalamak için "Dense Embedding" (Multilingual-E5-Large) ve teknik terim eşleşmesi için "BM25" (Lexical Search) algoritmaları birlikte kullanılarak en alakalı şema bilgisi çekilmektedir.
- **Augmentation (Zenginleştirme):** Veritabanından çekilen en alakalı tablo şemaları ve örnek SQL kalıbı, LLM'e giden "prompt" içerisine eklenerek modelin doğru bağlamda çalışması sağlanmaktadır.

2.5. Veritabanı Performans İzleme

ManageSQL, sadece sorgu üreten pasif bir sistem değil, aynı zamanda veritabanı sağlığını izleyen aktif bir araçtır. Geliştirilen dashboard modülü, bağlı veritabanı üzerinde periyodik olarak performans analiz sorguları çalıştırmaktadır. Toplam tablo sayısı, bellek kullanımı, trigger sayıları ve anlık CPU yükü gibi kritik metrikler görselleştirilerek veritabanı yöneticilerine (DBA) karar destek imkanı sunulmaktadır.

2.6. Bulgular ve Deneysel Sonuçlar

Geliştirilen sistemin performansı, henüz geliştirme aşamasında olmasına rağmen umut verici sonuçlar vermiştir. Yapılan testlerde "Uzman Doğruluk Oranı" (Expert Accuracy) ve "Tam Eşleşme Skoru" (Exact Match Score) metrikleri kullanılmıştır.

- **Gemma 3 12B:** Uzman doğruluk oranı **%36.7**, Tam Eşleşme Skoru **0.32** olarak ölçülmüştür.
- **Qwen 2.5 Coder 7B:** Uzman doğruluk oranı **%56.7**, Tam Eşleşme Skoru **0.68** seviyesine ulaşmıştır.

Qwen modelinin, özellikle kodlama ve SQL sentaksına yönelik özelleşmiş yapısı sayesinde, Türkçe komutları SQL mantığına dönüştürmede Gemma 3'e göre daha başarılı olduğu gözlemlenmiştir. DPO ve RAG entegrasyonunun tam olarak tamamlanmasıyla bu oranların daha da artması beklenmektedir.

3. SONUÇ

Bu çalışmada, üretim sektörünün veri analitiği ihtiyaçlarına yönelik, yerli ve milli imkanlarla geliştirilen ManageSQL sistemi tanıtılmıştır. Bulut tabanlı sistemlerin güvenlik risklerini ortadan kaldıran bu yerel (on-premise) çözüm, Qwen 2.5 Coder modeli üzerine uygulanan SFT ve DPO teknikleri ile kurumsal veritabanı yapısını öğrenme yeteneği kazanmıştır.

Çalışmanın temel çıktıları şunlardır:

1. **Veri Güvenliği:** Tüm süreç yerel ağda gerçekleştiği için hassas üretim verileri korunmuştur.

2. **Yüksek Başarım:** Qwen 2.5 Coder modeli, kısıtlı eğitim verisine rağmen %76.7 doğruluk oranına ulaşarak endüstriyel uygulanabilirliğini kanıtlamıştır.

3. **Hibrit RAG Yapısı:** Qdrant ve BM25 entegrasyonu sayesinde, modelin halüsinasyon oranı düşürülmüş ve doğru tablo seçimi garanti altına alınmıştır.

4. **Bütünleşik Çözüm:** SQL üretimi ile veritabanı performans izleme süreçleri tek bir platformda birleştirilmiştir.

Gelecek çalışmalarda, eğitim veri setinin genişletilmesi, çoklu ajan (multi-agent) yapılarının entegrasyonu ve modelin kendi kendini düzeltebilen (self-correction) bir yapıya kavuşturulması hedeflenmektedir. Bu proje, yapay zekanın üretim yönetim sistemlerine entegrasyonunda önemli bir adım teşkil etmektedir.

ABSTRACT

The hypergeometric function provides a general form for numerous integrals, differential equations, and special functions. Hypergeometric equation is a second order differential equation, the general solution of which are represented as hypergeometric functions. Since many physics problems (quantum and potential theory) can be reduced to this equation form, it is an important tool for applied sciences. Jacopsthal polynomials are a special family of polynomials closely related to combinatorics and number theory, despite having received little attention in the literature. The purpose of this research is to construct the differential equations for the Jacobsthal and Jacobsthal-Lucas polynomials. Then using the solutions of these equations, the hypergeometric forms of the Jacobsthal and Jacobsthal-Lucas polynomials are found. Finally, some relations between these polynomials and the other well-known functions will be examined.

Keywords: Jacobsthal polynomials, Jacobsthal-Lucas polynomials, hypergeometric equation, hypergeometric function.

MSC 2010 No.: 11B83, 33C05

1. INTRODUCTION

The theory of special functions is frequently used in certain fields such as approximation theory, numerical integration, the solution of differential equations using spectral methods, signal processing and data compression, statistics and probability theory, and physical problems. Jacobsthal polynomials also appear in various fields including number theory, coding theory, approximation theory, orthogonality connections, physics and engineering, computer science and algorithms. Some important studies involving Jacobsthal polynomials are given in [1-10].

Ernst Jacobsthal, a German mathematician, explored Jacobsthal numbers and polynomials in the 20th century. Jacobsthal polynomials $J_n(x)$ expressed by

$$J_{n+1}(x) = J_n(x) + 2x\,J_{n-1}(x), n \geq 1, \tag{1}$$

where $J_0(x) = 1$, $J_1(x) = 1$. These polynomials have the following differential recurrence relations

$$2(n-1)\,J_n(x) = J'_{n+1}(x) + 4x\,J'_n(x), \tag{2}$$

$$2n\,J_{n-1}(x) = 2\,J'_{n+1}(x) - J'_n(x). \tag{3}$$

Jacobsthal-Lucas polynomials $j_n(x)$ defined by

$$j_{n+1}(x) = j_n(x) + 2x\,j_{n-1}(x), n \geq 1, \tag{4}$$

where $j_0(x) = 2$, $j_1(x) = 1$. These polynomials yield the following differential recurrence relations

$$4n\,j_n(x) - 2(n-1)j_{n-1}(x) = j'_{n+1}(x) + 8x\,j'_n(x) - 2x\,j'_{n-1}(x), \tag{5}$$

$$(1+8x)j'_n(x) = 4n\,j_n(x) - 2n\,j_{n-1}(x). \tag{6}$$

On the other hand, the form of the hypergeometric differential equation

$$x(1-x)y'' + [c-(a+b+1)x]y'' - aby = 0, \tag{7}$$

where 0, 1, and ∞ are three regular singular points. Any second-order ODE with up to three regular singular points can be converted into a hypergeometric differential equation with appropriate variables. Many of the most fascinating special functions in applied sciences can be found in the solutions of hypergeometric differential equations [11, 12, 13].

A hypergeometric differential equation's solution is

$$y(x) = AF(a,b;c;x) + Bx^{1-c}\,F(a-c+1, b-c+1; 2-c,; x). \tag{8}$$

Here, $F(a,b;c;x)$ is known to as the hypergeometric function, which is defined as

$$F(a,b;c;x) = \sum_{l=0}^{\infty} \frac{(a)_l\,(b)_l}{(c)_l}\frac{x^l}{l!}, \tag{9}$$

where the Pochhammer symbol is denoted by $(m)_l$ which is defined by

$$(m)_l = \frac{\Gamma(m+l)}{\Gamma(m)} (m \in \boldsymbol{C}\backslash\boldsymbol{Z_0^-})$$

$$= \begin{cases} 1, & if\ \ l = 0; m \in \boldsymbol{C}\backslash\{0\} \\ m(m+1)\ldots(m+l-1), & if\ \ l = n \in \boldsymbol{N}; m \in \boldsymbol{C} \end{cases}$$

where $\boldsymbol{Z_0^-} = \{0, -1, -2, \ldots\}$ and $\Gamma(m)$ is the gamma function.

In this study, we construct a differential equation for the Jacobsthal polynomials and found their hypergeometric form. In a similar manner, we derive a differential equation from which we use the polynomial solution to determine the hypergeometric form of the Jacobsthal-Lucas polynomials. Then, we express the Jacobsthal and Jacobsthal-Lucas polynomials in terms of Olver's hypergeometric functions. Finally, we obtain some relations between these polynomials and certain functions and orthogonal polynomials, such as Legendre and Jacobi.

2. JACOBSTHAL DIFFERENTIAL EQUATIONS

The hypergeometric form for the Jacobsthal polynomials and a differential equation named as the Jacobsthal differential equation are derived in this section. The Jacobsthal polynomials and other known functions or polynomials are then related in specific ways.

Theorem 2.1. The following differential equation is satisfied by the Jacobsthal polynomials $J_n(x)$:

$$x(1+8x)y'' - [n-1+4(2n-5)x]y' + 2(n-1)(n-2)y = 0. \tag{10}$$

Proof: The desired solution is obtained by using the recurrence relations (2) and (3) along with certain computations.

Theorem 2.2. The following equality is the expression of Jacobsthal polynomials $J_n(x)$ in terms of hypergeometric functions:

$$J_n(x) = \frac{(2)_{n-1}}{(n-1)!\ 2^{n-1}} F\left(\frac{1-n}{2}, \frac{2-n}{2}; \frac{3}{2}; 1+8x\right). \tag{11}$$

Proof: Since the Jacobsthal polynomials $J_n(x)$ are the solution of (10), we can write

$$x(1+8x)\,J_n'' - [n-1+4(2n-5)x]\,J_n' + 2(n-1)(n-2)\,J_n = 0.$$

In this case, applying the mapping $u = 1+8x$, we have

$$u(1-u)\frac{d^2J_n}{du^2} + \left(\frac{3}{2} - \left(\frac{5-2n}{2}\right)u\right)\frac{dJ_n}{du} - \frac{(n-1)(n-2)}{4}J_n = 0.$$

The following constants are obtained by comparing the last equation with (7):

$$c = \frac{3}{2}, a = \frac{1-n}{2}, b = \frac{2-n}{2}.$$

The general solution of (10) is

$$J_n(u) = AF\left(\frac{1-n}{2}, \frac{2-n}{2}; \frac{3}{2}; u\right) + Bu^{-\frac{1}{2}}F\left(\frac{-n}{2}, \frac{1-n}{2}; \frac{1}{2}; u\right).$$

Now, writing again $u = 1+8x$ in the last equation, we have

$$J_n(x) = AF\left(\frac{1-n}{2}, \frac{2-n}{2}; \frac{3}{2}; 1+8x\right) + B(1+8x)^{-\frac{1}{2}}F\left(\frac{-n}{2}, \frac{1-n}{2}; \frac{1}{2}; 1+8x\right).$$

The initial part of this solution can be written in the way

$$J_n(x) = A\sum_{k=0}^{\infty} \frac{\left(\frac{1-n}{2}\right)_k \left(\frac{2-n}{2}\right)_k}{\left(\frac{3}{2}\right)_k\ k!}(1+8x)^k.$$

If we take all values for $k > \frac{n-1}{2}$, we have $\left(\frac{1-n}{2}\right)_k = 0$. So, the series terminates, and the hypergeometric function becomes a hypergeometric polynomial. By choosing

$$A = \frac{(2)_{n-1}}{(n-1)!\ 2^{n-1}},$$

we reach the desired result which completes the proof.

Olver has used the hypergeometric function to express a very wide class of functions, such as Bessel, Legendre, Chebyshev, Hermite, Laguerre, Jacobi, Whittaker, parabolic cylinder, and spherical functions [14]. Olver has also examined their asymptotic behavior and the relations these functions between many special functions. Olver represented the hypergeometric function in the way

$$\mathbf{F}(a,b;c;x) = \frac{1}{\Gamma(c)} F(a,b;c;x) = \sum_{l=0}^{\infty} \frac{(a)_l\,(b)_l}{\Gamma(c+l)} \frac{x^l}{l!}, \tag{12}$$

and $\mathbf{F}(a,b;c;x)$ called Olver's hypergeometric functions. Additionally, Olver found the following relation between the associated Legendre functions and Olver's hypergeometric functions [15]:

$$\mathbf{F}\left(a, a+\frac{1}{2}; c; z\right) = 2^{c-1}\, z^{(1-c)/2}\, (1-z)^{-a+((c-1)/2)}\, P_{2a-c}^{1-c}\left(\frac{1}{\sqrt{1-z}}\right), \tag{13}$$

where $|phz| < \pi$ and $|ph(1-z)| < \pi$. The solutions of the associated Legendre equation are called the associated Legendre functions $P_\nu^\mu(x)$ which have the following definitions:

$$P_\nu^\mu(x) = \left(\frac{1+x}{1-x}\right)^{\frac{\mu}{2}} \mathbf{F}\left(\nu+1, -\nu; 1-\mu; \frac{1}{2}-\frac{1}{2}x\right). \tag{14}$$

Furthermore, the Jacobi polynomials $P_n^{(\alpha,\beta)}(x)$ are the solutions of the Jacobi equation and are defined as follows:

$$P_n^{(\alpha,\beta)}(x) = \frac{(1+\alpha)_n}{n!}\, F\left(-n, 1+\alpha+\beta+n; 1+\alpha; \frac{1-x}{2}\right). \tag{15}$$

Now, using (11) and (12), the Jacobsthal polynomials $J_n(x)$ can be expressed as follows:

$$J_n(x) = \frac{\sqrt{\pi}\,(2)_{n-1}}{2^n\,(n-1)!} \mathbf{F}\left(\frac{1-n}{2}, \frac{2-n}{2}; \frac{3}{2}; 1+8x\right). \tag{16}$$

The relations between the Jacobsthal polynomials and the associated Legendre functions and the Jacobi polynomials are provided by the following theorem:

Theorem 2.3. The following relations are satisfied by the Jacobsthal polynomials $J_n(x)$:

$$i)\ J_{n+1}(x) = \frac{\sqrt{\pi}\ \ (2)_n\ \ (-2)^{\frac{2n+1}{4}}\ \ \left(\sqrt{x}\right)^{n+1}}{n!\,(x+8x^2)^{\frac{1}{4}}} P_{-n-\frac{3}{2}}^{-\frac{1}{2}}\left(\frac{1}{2i\sqrt{2x}}\right),$$

$$ii)\ J_{2n+1}(x) = \frac{n!}{\left(\frac{1}{2}\right)_n\, 2^{2n}} P_n^{\left(\frac{1}{2}, -2n-1\right)}(-1-16x).$$

Proof: i) Using (13) and (16), we reach at the desired result.

ii) Using (11) and (15), we reach at the desired result.

3. JACOBSTHAL-LUCAS DIFFERENTIAL EQUATIONS

The hypergeometric form for the Jacobsthal-Lucas polynomials and a differential equation named as the Jacobsthal-Lucas differential equation are derived in this section. The Jacobsthal-Lucas polynomials and other known functions or polynomials are then related in specific ways.

Theorem 3.1. The following differential equation is satisfied by the Jacobsthal-Lucas polynomials $j_n(x)$:

$$x(1+8x)y'' - [n-1-(12-8n)x]y' + 2n(n-1)y = 0. \quad (17)$$

Proof: The desired solution is obtained by using the recurrence relations (5) and (6) along with certain computations.

Theorem 3.2. The following equality is the expression of Jacobsthal-Lucas polynomials $j_n(x)$ in terms of hypergeometric functions:

$$j_n(x) = \frac{1}{2^{n-1}} F\left(\frac{-n}{2}, \frac{1-n}{2}; \frac{1}{2}; 1+8x\right). \quad (18)$$

Proof: Since Jacobsthal-Lucas polynomials $j_n(x)$ are the solution of (17), we can write

$$x(1+8x)\, j_n'' - [n-1-(12-8n)x]\, j_n' + 2n(n-1)\, j_n = 0.$$

In this case, applying the mapping $u = 1+8x$, we have

$$u(1-u)\frac{d^2 j_n}{du^2} + \left(\frac{1}{2} - \left(\frac{3}{2} - n\right)u\right)\frac{dj_n}{du} - \frac{n(\mathrm{n}-1)}{4}\, j_n = 0.$$

The following constants are obtained by comparing the last equation with (7):

$$c = \frac{1}{2}, a = \frac{-n}{2}, b = \frac{1-n}{2}.$$

The general solution of (17) is

$$j_n(u) = AF\left(\frac{-n}{2}, \frac{1-n}{2}; \frac{1}{2}; u\right) + Bu^{\frac{1}{2}} F\left(\frac{1-n}{2}, 1-\frac{n}{2}; \frac{3}{2}; u\right).$$

Now, writing again $u = 1+8x$ in the last equation, we have

$$j_n(x) = AF\left(\frac{-n}{2}, \frac{1-n}{2}; \frac{1}{2}; 1+8x\right) + B(1+8x)^{\frac{1}{2}} F\left(\frac{1-n}{2}, 1-\frac{n}{2}; \frac{3}{2}; 1+8x\right).$$

The initial part of this solution can be written in the way

$$j_n(x) = A \sum_{k=0}^{\infty} \frac{\left(\frac{-n}{2}\right)_k \left(\frac{1-n}{2}\right)_k}{\left(\frac{1}{2}\right)_k\ k!} (1+8x)^k.$$

If we take all values for $k > \frac{n}{2}$, we have $\left(\frac{-n}{2}\right)_k = 0$. So, the series terminates, and the hypergeometric function becomes a hypergeometric polynomial. Then, by choosing

$$A = \frac{1}{2^{n-1}},$$

we reach the desired result which completes the proof.

Using (12) and (18), the Jacobsthal-Lucas polynomials $j_n(x)$ can be expressed as follows:

$$j_n(x) = \frac{\sqrt{\pi}}{2^{n-1}} \mathbf{F}\left(\frac{-n}{2}, \frac{1-n}{2}; \frac{1}{2}; 1+8x\right). \quad (19)$$

The relations between the Jacobsthal-Lucas polynomials and the associated Legendre functions and the Jacobi polynomials are provided by the following theorem:

Theorem 2.3. The following relations are satisfied by the Jacobsthal-Lucas polynomials $j_n(x)$:

$$i)\ j_{2n}(x) = \sqrt{\pi}\ (-2)^{n-\frac{1}{4}} \left(\frac{1}{x}+8\right)^{\frac{1}{4}} (2x)^n\ P^{\frac{1}{2}}_{-2n-\frac{1}{2}}\left(\frac{1}{2i\sqrt{2x}}\right),$$

$$ii)\ j_{2n}(x) = \frac{n!}{\left(\frac{1}{2}\right)_n\ 2^{2n-1}}\ P_n^{\left(-\frac{1}{2},-2n\right)}(-1-16x).$$

Proof: i) Using (13) and (19), we reach at the desired result.

ii) Using (15) and (18), we reach at the desired result.

4. CONCLUSION

This article provides the theorems including a differential equation and a hypergeometric form of Jacobsthal polynomials. In a similar manner, we obtain these theorems for the Jacobsthal-Lucas polynomials. These equations and hypergeometric forms can be utilized

- Physical Applications: It can be identified which physical systems (such as quantum mechanics, optics, or statistical physics) the equation applies to, and which physical quantities it can model.

- Asymptotic Solutions:

It is possible to describe potential asymptotic methods for both large and small parameter values.

- Numerical Methods:

It can be specified how the equation can be solved numerically and which computational methods are appropriate.

Lastly, we found some relations between the Jacobsthal and Jacobsthal-Lucas polynomials and known special functions and orthogonal polynomials by employing the formula in terms of Olver's hypergeometric functions.

ABSTRACT

Solar photovoltaic (PV) systems are becoming an important source of clean energy worldwide, but their performance depends on the physical condition of the solar panels. Over time, panels can show different types of faults, such as cracks, hotspots, dust gathering, diode failures, short circuits, and other damage. How we used to detect faults, for example, cracks: we used EL imaging, visual inspection, and the I-V curve, for hotspots, we used temperature sensors and the I-V curve, for dust, we also used similar method, visual inspection. These problems reduce the power output and can lead to safety risks, like overheating and fire hazards. Because large solar farms have thousands of panels, checking them manually is difficult, slow, and not accurate. That's the reason we focus on automatic fault detection using image processing and deep learning. The reason we focus on automatic fault detection is because small cracks cannot be localized exactly, and the hotspots cannot map the whole panel. The latest advances in deep learning, especially Convolutional Neural Networks (CNN), have improved the accuracy and reliability of PV fault detection and classify the different types of faults with precision. In this paper, we will show that using CNN, the accuracy reached up to 99.91% (VGG16). And Infrared Thermography (IRT) for automatic fault detection in PV modules. IRT finds temperature differences, and CNN analyzes those differences to automatically identify PV faults with very high accuracy. Let's take for example cracks; they cause a thin hot line that the IRT shows as a warm streak, and then the CNN identifies the edge pattern. After that the maintenance receives the fault type, location, and severity, so they act fast. Some studies used advanced CNN architectures like VGG16: which is type of CNN with 16 layers. It's good at image classification; Mask R-CNN: analyzes thermal images effectively and highlights the exact area on the panel where the defect is with accuracy, and EfficientNet detects faults like hotspots, cracks, and dust with high precision. In this paper we will show that IRT and CNN are breakthrough technology for safe, efficient, and intelligent solar panel monitoring.

Keywords: Photovoltaic (PV) systems, infrared thermography (IRT), CNN, deep learning, defect detection, fault classification, VGG16, Mask R-CNN, EfficientNet.

INTRODUCTION

Solar photovoltaic (PV) systems are expanding rapidly worldwide yet they remain highly sensitive to defects that gradually reduce their performance. Even small issues such as dust hotspots micro cracks diode failures and shading can lead to annual efficiency losses ranging between 0.5% and 1%. These losses may sound minor but over the lifetime of a solar plant they translate into major reductions in power output and significant financial impact [1]. More importantly certain defects if not detected early can create safety risks such as overheating and fire hazards. As global solar capacity continues to rise and large-scale solar farms become more common maintaining the health and safety of PV modules has become a critical challenge for researcher's engineers and system operators. Traditionally PV module inspection relied on manual checks and electrical measurements. While these methods can detect overall performance decline, they struggle to pinpoint the exact location or type of defect [2]. Many faults especially micro cracks and early-stage hotspots are not visible to the naked eye and do not immediately affect the electrical output in a measurable way. Manual inspection is slow labor intensive and often impractical for solar farms that contain thousands of panels. Electrical measurements such as (I, V) curve analysis can indicate abnormal behavior but they cannot reveal where the problem is or provide detailed insight into its physical characteristics. These limitations highlight the need for more advanced diagnostic tools that can detect faults accurately quickly and with minimal human intervention. Infrared thermography has emerged as one of the most promising technologies for this purpose. Since many PV defects cause localized heating thermal imaging can clearly reveal anomalies in the form of temperature differences [1],[3]. Thermal cameras can scan large areas rapidly and they can be mounted on drones allowing for inspection of large solar installations without shutting down the system. Unlike methods that require dark environments or physical contact with the panels infrared imaging works under normal operating conditions and provides immediate visual interpretation of hotspots shading effects diode issues and other thermal abnormalities. Its non-destructive nature and speed make it a valuable tool for modern PV maintenance. Alongside advances in imaging artificial intelligence specifically deep learning has transformed how thermal images are analyzed. Convolutional Neural Networks (CNNs) have proven extremely effective in automatically extracting complex features from images without requiring manual feature design. When applied to infrared images of PV modules, CNNs can distinguish between normal and faulty panels identify specific defect types and even classify multiple fault categories [3]. Deep learning excels at detecting subtle patterns such as small temperature gradients or irregular shapes that human inspectors may overlook. Over the past few years, a wide variety of CNN architectures have been explored for PV fault detection. Some models are designed to be lightweight and fast suitable for real time applications and embedded devices. Others focus on extracting deeper features using more sophisticated layers improving accuracy even in noisy or low-resolution images [4]. Enhancements such as attention mechanisms multi scale feature extraction and edge guided learning have been proposed to handle challenges like blurred boundaries and overlapping thermal signatures. Data augmentation and balanced datasets have further improved the performance of these models by making them more robust to variations in lighting weather and imaging conditions [5]. As a result, deep learning systems now achieve very high accuracy across both binary classification (normal vs. faulty) and multi class classification (different defect categories).

However, despite these advancements important gaps remain. Many existing deep learning models are trained on controlled datasets that do not fully represent the variability found in real-world conditions. Outdoor thermal images often contain noise reflections uneven heating and environmental effects that degrade model performance. Models trained in one climate or

region may not generalize well to another. Another major gap is that most systems classify only one fault per image even though real PV modules often experience multiple simultaneous issues for example dust buildup combined with partial shading or cracks that later develop into hotspots.

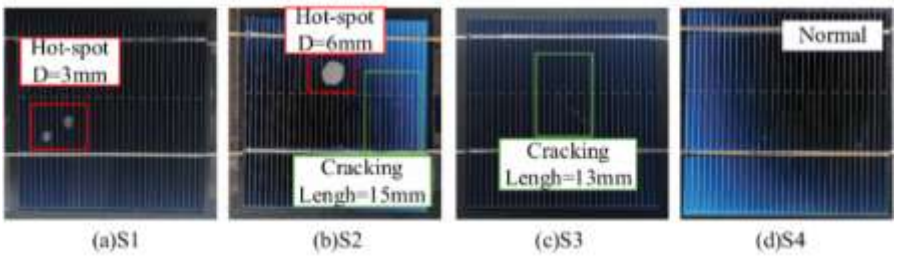

Figure 1.PV cells with different defects types

Current models still struggle with multilabel classification limiting their usefulness in complex field conditions [6]. Additionally, some highly accurate CNN architectures require powerful hardware making them difficult to deploy on drones or portable inspection devices used in everyday operations. These challenges highlight the need for a more comprehensive and robust approach to PV fault diagnosis. An ideal system would combine the strengths of infrared thermography with advanced deep learning techniques while addressing real world variability noise and multilabel scenarios. It would also be efficient enough to run on lightweight hardware for real time inspection. The objective of this research is to develop an improved CNN based system capable of accurately detecting and classifying PV module defects using infrared thermographic images. The study aims to create a model that performs reliably across diverse conditions identifies multiple fault types and maintains high accuracy without requiring heavy computational resources. The work includes exploring enhanced feature extraction techniques integrating attention or edge focused modules and optimizing the model for practical field deployment.

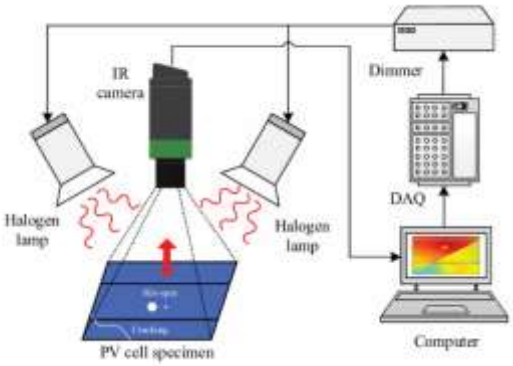

Figure 2.Photo thermal radiation infrared thermography detection schematic diagram

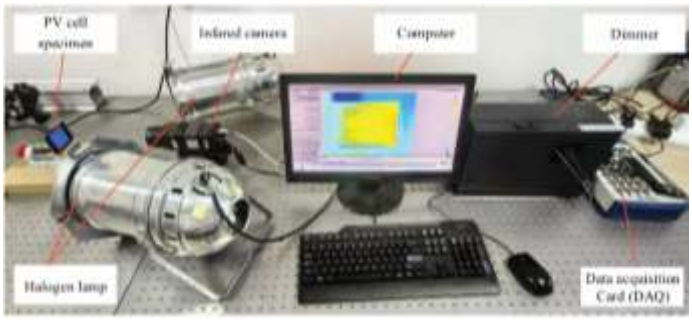

Figure 3.Photo thermal radiation infrared thermography detection system

The main research question guiding this work is:

Can an optimized CNN model supported by advanced image processing and robust feature extraction provide more accurate reliable and real time fault detection for photovoltaic modules compared to existing inspection techniques?

The hypothesis is that a carefully designed CNN architecture combined with suitable preprocessing augmentation and learning strategies will greatly improve detection accuracy reduce false classifications and provide a more practical solution for real world PV monitoring.

METHODS

Research Design

This study uses an experimental computational research design to investigate whether a refined convolutional neural network (CNN) can accurately detect faults in photovoltaic (PV) modules using infrared thermographic images. The design suits the research question because PV faults naturally create temperature variations and infrared cameras capture these patterns directly [1]. Deep learning is ideal for interpreting these thermal signatures as CNNs are built to extract edges textures and spatial structures [3]. By training and testing models under controlled conditions the design allows systematic comparison of performance evaluation of generalization ability and identification of sources of classification error. This approach combines physical principles with modern computational learning techniques making it appropriate for developing an intelligent PV diagnostic tool.

Population and Sample

The population consists of thermal images representing PV modules in real operating conditions. The sample includes infrared images that clearly display PV panel surfaces and contain identifiable thermal patterns [2]. Only images with sufficient resolution and visible temperature gradients are included. Images that are unreadable excessively distorted or lacking meaningful thermal information are excluded ensuring the model learns from reliable data. The final sample contains both normal and faulty modules so the CNN can distinguish healthy temperature distributions from anomalies. Keeping the sample limited to infrared imagery ensures consistency with the thermal behavior of PV faults and avoids mixing data that carry different physical meanings.

Tools and Procedures

Infrared thermal images serve as the primary data source revealing hotspots shading effects cracks and other anomalies created by changes in temperature flow within the PV structure [1]. The study uses Python based deep learning frameworks to build and optimize CNN architectures. Images are preprocessed through resizing and normalization to create uniform input conditions while augmentation introduces slight variations that improve generalization

[4]. The CNN processes each image through multiple convolutional layers that extract thermal features of increasing complexity. Training involves minimizing classification error and evaluating performance on unseen data to ensure robustness [5]. Instead of listing step by step procedures the methodology is presented as a conceptual workflow that reflects academic expectations for a methods section without procedural formatting.

Analysis Plan

The analysis focuses on measuring the model's ability to classify PV conditions accurately. The dataset is divided into training validation and testing subsets to provide an unbiased performance estimate. Evaluation includes accuracy precision recall and F1 score which together provide a balanced view of how well the model identifies different faults [6]. Confusion matrices help visualize misclassifications and highlight which types of defects are most difficult to detect. Training behavior is monitored through loss and accuracy curves to ensure the model is not overfitting. A GPU enabled environment supports efficient training and parameter optimization. This analysis plan provides the structure needed to assess how effectively the CNN interprets thermal images and handles real-world variability.

Mathematical Derivations

The CNN's core operation is convolution. Given a thermal image I (x, y) and a kernel

K (i, j) the extracted feature map is

$$F(x,y) = \sum_i \sum_j I\, I(x-i, y-j)K(i,j)$$

This calculation identifies temperature edges and gradients linked to PV faults [3].

The network outputs class probabilities using the SoftMax function:

$$\widehat{y_c} = \frac{e^{z_c}}{\sum_{k=1}^{C} e^{z_k}}$$

Model training minimizes cross entropy loss defined as:

$$\mathrm{L} = -\sum_{c=1}^{C} y_c \log(\widehat{y_c})$$

Parameters are updated using gradient descent:

$$\theta_{t+1} = \theta_t - n\frac{\partial L}{\partial \theta}$$

Performance is assessed using standard formulas:

$$Precision = \frac{TP}{TP+FP} \quad Recall = \frac{TP}{TP+FN}$$
$$F1 = 2 \times \frac{precision \times recall}{precision + recall}$$

where TP: number of true positives, TN: number of true negatives, FP: number of false positives, FN: number of false negatives.

These mathematical expressions summarize how features are extracted, how the model learns, and how evaluation metrics are computed [4].

RESULTS AND CONCLUSION

The developed convolutional neural network showed strong ability to recognize and classify thermal anomalies in photovoltaic (PV) modules using infrared images. The model demonstrated clear improvement during training with decreasing loss and rising accuracy indicating that it successfully learned meaningful thermal patterns rather than memorizing the data [3],[7]. When evaluated on unseen images the network maintained high accuracy confirming its capacity to generalize across different conditions [4],[8]. Precision and recall values were strong meaning the model correctly identified faults when present and avoided unnecessary false alarms on healthy modules. Thermal defects such as hotspots shading induced heating and local temperature rises were detected with particularly high sensitivity reflecting the CNN's strength in identifying clear thermal gradients [1],[5].

Some challenges emerged in differentiating defects with very similar thermal characteristics such as mild shading and certain soiling conditions. These patterns occasionally overlapped leading to a small number of misclassifications. However, the overall misclassification rate remained low and the model still performed reliably across all categories. The confusion matrix confirmed that most predictions clustered correctly within their true class showing that the network developed a stable understanding of the differences between normal and faulty modules. Data augmentation also contributed significantly to the model's performance by exposing the CNN to variations in brightness angle and scale making it more robust to real world conditions [4],[9].

In terms of computational behavior, the model achieved fast processing times demonstrating potential suitability for live inspection scenarios using drones or portable thermal devices. Despite its efficiency there was no meaningful drop in classification accuracy suggesting the architecture is well balanced between complexity and practicality [6],[10].

In conclusion the results of this study show that deep learning combined with infrared thermography provides an effective and reliable approach for automated PV fault detection. The model proved capable of accurately interpreting thermal behavior and identifying a range of fault types under diverse imaging conditions. This confirms the initial hypothesis that a refined CNN architecture can outperform traditional inspection methods which often struggle with subtle or early-stage defects [2],[3]. The approach also offers benefits in terms of speed consistency and scalability, making it a promising tool for modern solar farm operations [5],[10].

Although highly effective the study highlights areas for future improvement. Expanding the dataset with more examples of visually similar defects would help reduce confusion in borderline cases. Additionally integrating fault localization or multilabel classification could enable the system not only to identify the type of fault but also to highlight its exact position and detect multiple issues simultaneously. Nevertheless, the findings establish a strong foundation for intelligent PV monitoring systems and demonstrate the significant potential of deep learning in supporting the reliability and sustainability of solar energy production [8],[9].

ABSTRACT

Potato late blight, caused by *Phytophthora infestans* (Mont.) de Bary, is one of the most economically destructive diseases of potato production worldwide. The disease is estimated to account for global losses of 3–10 billion USD annually in terms of crop damage and fungicide costs, and growers in many production regions apply 10–20 fungicide sprays per season, increasing to 20–30 applications in tropical areas. In Türkiye, the earliest potato harvest takes place under the conditions of the Çukurova region, which makes early-season potato production a strategically important sector for both the domestic market and export. Growers in this region typically apply protective fungicides against late blight every 7–10 days, resulting in 10–12 applications per season. In the absence of effective control, yield losses may reach up to 100%. This study, based on trials conducted between 2013 and 2016 in the Çukurova region, aims to optimize fungicide timing and frequency against potato late blight using climate-based forecasting and early warning system approaches. Compared with calendar-based fixed-interval sprays, a fungicide program driven by meteorological data reduced the number of applications by approximately 25–30% without adversely affecting disease severity or yield. Within the integrated approach, disease incidence was lowest and economic return was highest. A simulation model based on five-day reinfection periods successfully reflected the observed disease progress across different micro-regions of Çukurova, and predicted yield losses deviated from observed values by less than 5%, confirming its potential for local deployment. Overall, the findings demonstrate that the fixed-schedule fungicide programs still widely used under Çukurova conditions result in substantial economic and environmental costs. When combined with cultural practices and the use of resistant cultivars, climate-based early warning systems can enable more sustainable crop protection against potato late blight, achieving effective disease suppression with fewer fungicide applications.

Keywords: *Solanum tuberosum Phytophthora infestans*, late blight, decision support systems, Çukurova region, fungicide

ÖZET

Patates mildiyö hastalığı (geç yanıklık), etmeni *Phytophthora infestans* (Mont.) de Bary dünya genelinde patates üretiminde en büyük ekonomik kayıplara yol açan hastalıklardan biridir. Hastalık, küresel ölçekte her yıl 3–10 milyar ABD doları düzeyinde ürün ve ilaçlama kaybına neden olmakta, birçok üretim bölgesinde çiftçiler sezon boyunca 10–20, tropik bölgelerde ise 20–30'a varan sayıda fungisit uygulaması yapmak zorunda kalmaktadır. Türkiye'de en erken patates hasadı Çukurova koşullarında gerçekleşmekte; bu da erken sezon patates yetiştiriciliğini hem iç pazar hem de ihracat açısından stratejik bir üretim kolu hâline getirmektedir. Bölgedeki üreticiler, pates mildiyö hastalığına karşı her 7–10 günde bir koruyucu fungisit uygulamakta ve bu durum sezon başına 10–12 uygulamaya ulaşmaktadır. Uygun bir mücadele yapılmadığında verim kayıpları %100'e kadar çıkabilmektedir. Bu çalışma, 2013–2016 yılları arasında Çukurova Bölgesi'nde yürütülen patates mildiyö hastalığına karşı fungisit uygulama zamanlamasının ve sıklığının iklim verilerine dayalı tahmin erlken uyarı sistemleri yaklaşımlarıyla optimize edilmesini amaçlamaktadır. Meteorolojik verilere dayalı fungisit programı, sabit aralıklı uygulamalara kıyasla hastalık şiddetini veya verimi olumsuz etkilemeden ilaçlama sayısını yaklaşık %25–30 oranında azaltmıştır. Entegre yaklaşımda hem hastalık insidansı en düşük, hem de ekonomik getiri en yüksek düzeyde bulunmuştur. Beş günlük yeniden enfeksiyon dönemlerine dayalı simülasyon modeli, Çukurova'nın farklı mikro bölgelerinde gözlenen hastalık gelişimini yüksek doğrulukla yansıtmış ve tahmin edilen verim kayıpları, gözlenen değerlerle %5'in altında sapma göstermiştir. Elde edilen sonuçlar, Çukurova koşullarında hâlen yaygın olan sabit programlı fungisit uygulamalarının hem ekonomik hem de çevresel açıdan ciddi kayıplara neden olduğunu ortaya koymaktadır. İklim verilerine dayalı erken uyarı sistemleri, kültürel uygulamalar ve dayanıklı çeşitlerin kullanımıyla desteklendiğinde, Patates mildiyö hastalığı ile mücadelede daha az sayıda ilaçlama ile daha sürdürülebilir bir ürün koruma stratejisi oluşturulabileceğini göstermektedir.

Anahtar Kelimeler: *Solanum tuberosum*, *Phytophthora infestans*, geç yanıklık, erken uyarı sistemi, Çukurova, fungisit

1. Giriş

Patates (*Solanum tuberosum* L.), dünyada insan beslenmesinde buğday, mısır ve pirinçten sonra dördüncü sırada yer alan temel gıda bitkilerinden biridir. Gerek taze tüketimde gerekse sanayi ve tohumluk sektörlerinde stratejik öneme sahiptir. Ancak patates üretimi, fungal bakteriyel ve viral hastalıklar başta olmak üzere pek çok biyotik stres faktörüyle kısıtlanmaktadır. Bunlar arasında, patates geç yanıklığı, etmeni *Phytophthora infestans* (Mont.) de Bary hem yeşil aksam hem de yumrularda ağır tahribata yol açan en yıkıcı hastalıktır. *P. infestans* uygun çevre koşullarında çok kısa sürede tüm tarlayı infekte edebilmekte; yaprak yüzeyinin büyük bir kısmını nekrotik hâle getirerek fotosentez kapasitesini düşürmekte, aynı zamanda yumrularda da çürüklük oluşturarak depolama kayıplarına neden olmaktadır. Hastalık, tarihsel olarak İrlanda Patates Kıtlığı ile özdeşleşmiş olsa da, günümüzde de dünya genelinde her yıl milyarlarca dolarlık ürün kaybı ve yoğun fungisit kullanımına yol açmaya devam etmektedir (Fry ve ark., 2015). Etmenin genetik esnekliği, kısa sürede yeni ırklar oluşturabilmesi ve fungisitlere direnç geliştirebilmesi, hastalığın yönetimini daha da güçleştirmektedir (Majeed, 2017; Blossei ve ark., 2022).

Çukurova Bölgesi (Adana ve çevresi), Türkiye'de hem sofralık hem de tohumluk patates üretimi açısından öne çıkan önemli üretim merkezlerinden biridir. Bölgenin ılıman kış koşulları, erken ekim ve erkenci hasat imkânı sağlamaktadır. Aralık sonu–Ocak sonu döneminde yapılan ekimler, Nisan sonu–Haziran başı arasında turfanda hasatla sonuçlanmakta ve bölge hem iç pazara hem de ihracata erken patates arz eden stratejik bir konumda bulunmaktadır. Ancak aynı iklim özellikleri, özellikle ilkbahar aylarında yüksek oransal nem, uzun yaprak ıslaklığı ve 15–22 °C aralığındaki sıcaklıklar nedeniyle geç yanıklık epidemileri için son derece elverişli koşullar yaratmaktadır (Günaçtı et al., 2019). Bu nedenle bölgede üreticiler, hastalık ortaya çıkmadan "takvim esaslı" koruyucu fungisit uygulamalarına yönelmektedir. Bölgesel gözlemler, pek çok işletmede sezon boyunca 10–12'ye varan sayıda ilaçlama yapıldığını ve geç yanıklık fungisitlerinin patates üretiminde kullanılan toplam fungisit miktarının önemli bir bölümünü oluşturduğunu göstermektedir. Bu durum, hem üretim maliyetlerini artırmakta, hem de çevresel yük ve direnç gelişimi açısından risk taşımaktadır.

Son otuz yılda, geç yanıklığa karşı fungisit kullanımını rasyonelleştirmek amacıyla çok sayıda hava durumu temelli tahmin modeli ve erken uyarı sistemi geliştirilmiştir. Ullrich ve Schrödter'in negatif prognosisi, Winstel modeli, Blitecast, PhytoPRE, Mileos ve NEGFRY gibi sistemler; sıcaklık, bağıl nem, yaprak ıslaklığı ve yağış verilerini kullanarak enfeksiyon riskini sayısallaştırmakta ve ilaçlama kararlarına bilimsel bir temel sunmaktadır (Schepers, 2004; Small ve ark., 2015; Meno ve ark., 2024; Castaño-Serna ve ark., 2025). Buna paralel olarak, Rusya, Almanya ve Hollanda'da yürütülen çalışmalar, yeniden enfeksiyon için elverişli beş günlük dönemlerin sayısına bağlı olarak verim kaybını tahmin eden simülasyon modellerinin, uzun dönemli meteorolojik verilerle kalibre edildiğinde güvenilir çıktılar üretebildiğini ortaya koymuştur (Filippov ve ark., 2018). Türkiye'de Çukurova koşullarında geç yanıklık tahmin modellerinin ilk sistematik değerlendirmelerinden biri, 2013–2014 yıllarında Adana'da yürütülen ve Winstel, Blitecast ve Ullrich–Schrödter modellerinin karşılaştırıldığı çalışmalarla gerçekleştirilmiş; bu çalışmalarda Winstel modelinin yerel koşullarda enfeksiyon tahmininde daha başarılı olduğu bildirilmiştir (Günaçtı ve Ay, 2021).

Bu çalışmada, Çukurova koşullarında ticari üretim koşullarında yürütülen çok yıllık denemeler kullanılarak, (i) hava durumu ile geç yanıklık epidemileri ve verim kaybı arasındaki ilişkilerin ortaya konulması, (ii) sabit aralıklı fungisit programları ile meteoroloji tabanlı ilaçlama stratejilerinin ve kültürel önlemlerle desteklenen entegre bir yaklaşımın karşılaştırılması ve (iii)

beş günlük yeniden enfeksiyon dönemlerine dayalı bir simülasyon modelinin bölge koşullarına uyarlanarak doğruluğunun değerlendirilmesi amaçlanmıştır.

2. Materyal ve Yöntem

2.1 Çalışma alanı ve yetiştirme sistemi

Arazi çalışmaları, 2013–2016 yılları arasında Çukurova Bölgesi'nde (Adana ili ve çevresi) ticari patates tarlalarında yürütülmüştür. Bölge, Akdeniz ikliminin tipik özelliklerini taşımakta olup, kışları ılık ve yağışlı, ilkbaharı nispeten ılık ve nemlidir. Erken sezon patates ekimleri genellikle Aralık sonu–Ocak sonu döneminde yapılmakta, hasat ise Nisan sonu–Haziran başında gerçekleştirilmektedir. Denemeler, bölgedeki ana üretim alanlarını temsil edecek şekilde, yağmurlama veya karık sulama yapılan tarlalarda kurulmuştur (Günaçtı ve Ay, 2021). Çalışmalarda, bölge üreticilerinin yaygın olarak kullandığı sofralık patates çeşitleri kullanılmıştır. Ekim sıklığı, gübreleme ve sulama rejimleri, üreticinin mevcut uygulamalarını yansıtacak şekilde düzenlenmiş; böylece sonuçların ticari koşullara uyumlu olması hedeflenmiştir.

2.2 Meteorolojik Veriler

Her bir deneme alanına, otomatik meteoroloji istasyonu iMETOS® kurulmuş ve vejetasyon süresince saatlik hava sıcaklığı (°C), bağıl nem (%), yaprak ıslaklığı (saat) ve yağış (mm) verileri kaydedilmiştir. Kayıtlar düzenli olarak kontrol edilmiş, arıza veya kesinti durumlarında yakın resmi meteoroloji istasyonlarından alınan verilerle makul ölçüde tamamlanmıştır (Günaçtı ve Ay, 2021). Bu veriler kullanılarak; bağıl nemin %90'ın üzerinde seyrettiği saatler, 8–10 saatten uzun yaprak ıslaklığı periyotları ve 10–25 °C aralığındaki sıcaklıklarla çakışan yağış/sulama olayları gibi enfeksiyon açısından kritik meteorolojik göstergeler hesaplanmış, ayrıca ardışık beş günlük verilere göre özetlenmiştir (Schepers, 2004; Castaño-Serna ve ark., 2025).

2.3 Hastalık gözlemleri

Patates mildiyö hastalığı, çıkıştan itibaren vejetasyon sonuna kadar haftalık aralıklarla değerlendirilmiştir. Her parselde sabit bitkiler seçilmiş; yaprak yüzeyinde hastalıkla kaplı alan, görsel tahmin ölçekleri kullanılarak yüzde (%) olarak belirlenmiştir. Elde edilen değerlerden, her parsel ve yıl için hastalık ilerleyişinin nicel göstergesi olarak, hastalık ilerleme eğrisi altında kalan alan (AUDPC) hesaplanmıştır (Majeed, 2017). Hastalık belirtilerinin ilk görüldüğü dönemlerde, tipik lezyonlara sahip yaprak örnekleri laboratuvara getirilmiş; etmen *P. infestans*, sporangi ve sporangi taşıyıcılarının mikroskobik incelenmesi ve gerekli durumlarda selektif besi yerlerinde izolasyon yoluyla doğrulanmıştır (Günaçtı ve Ay, 2021). Hasat döneminde, her parselde toplam ve pazarlanabilir yumru verimi (t ha^{-1}) belirlenmiştir. Pazarlanabilir verim, geç yanıklık lekesi içermeyen ve pazarlama standartlarına uygun irilik ve dış kalite kriterlerini taşıyan yumruları kapsamıştır.

2.4. Fungisit uygulamaları

Çalışmada dört farklı mücadele stratejisi karşılaştırılmıştır:

Sabit aralıklı fungisit programı (Çiftçi uygulaması)

Bu uygulamada fungisitler, hava koşulları dikkate alınmaksızın, sıranın kapanmasından itibaren 7–10 günde bir olacak şekilde sezon boyunca düzenli olarak uygulanmıştır. Sezon sonunda uygulama sayısı 10–12'ye ulaşmıştır. Kullanılan preparatlar, bölgede yaygın olarak tavsiye edilen koruyucu ve sistemik fungisit karışımlarından oluşmuştur.

İklim verilerine dayalı fungisit programı (Tahmin uyarı modeli)

Bu stratejide ilaçlama kararları, Blitecast ve PhytoPRE karar kurallarından uyarlanan yerel bir karar destek algoritması kullanılarak verilmiştir (Schepers, 2004; Small ve ark., 2015; Castaño-Serna ve ark., 2025). Otomatik istasyonlardan alınan saatlik sıcaklık, bağıl nem ve yaprak ıslaklığı verileri ile risk birimleri hesaplanmış; birikimli riskin belirli eşikleri aştığı veya enfeksiyon olasılığının kritik düzeylere ulaştığı dönemlerde fungisit uygulaması önerilmiştir.

Entegre Mücadele programı

Entegre yönetim yaklaşımı; yukarıda belirtilen iklim tahminine dayalı fungisit programına ek olarak sertifikalı, hastalıksız tohumluk yumru kullanımı,en az 3–4 yıllık münavebe ile patates, hasat sonrası artıkların imhası gibi kültürel mücadele yöntemlerini de içermektedir. Böylece tarladaki primer inokulum kaynağının azaltılması ve tahmin uyarı sistemlerinin daha düşük başlangıç risk düzeyinde çalışması hedeflenmiştir (Majeed, 2017).

Simülasyon modeli destekli strateji

Dördüncü yaklaşımda, Rusya, Almanya ve Hollanda'da geliştirilmiş ve uzun yıllara ait veri setleriyle doğrulanmış, yeniden enfeksiyon için elverişli beş günlük dönem sayısına dayalı bir simülasyon modeli (Filippov ve ark., 2018) Çukurova koşullarına uyarlanmıştır. Model, her sezon ve mikro bölge için gerçek meteorolojik verileri kullanarak; farklı ilaçlama sıklıklarının (6, 8, 10 uygulama) beklenen verim kaybı üzerindeki etkisini tahmin etmiş; bu çıktılar sabit programlı ve tahmin uyarı modeli yönlendirmeli uygulamaların sahadaki performansıyla karşılaştırılmıştır.

2.5 Veri analizi

Her yıl ve her mücadele stratejisi için AUDPC ve verim değerleri varyans analizine (ANOVA) tabi tutulmuş; anlamlı bulunan faktörler için ortalamalar, uygun çoklu karşılaştırma testleriyle ($P \leq 0,05$) kıyaslanmıştır. Hastalık şiddeti, meteorolojik değişkenler, beş günlük yeniden enfeksiyon periyotlarının sayısı ve verim kaybı arasındaki ilişkiler korelasyon ve regresyon analizleriyle incelenmiştir.

3. Bulgular

3.1 İklim verileri ve epidemi gelişimi

Üç yıllık gözlemler, Çukurova koşullarında patates mildiyö hastalığı epidemilerinin, yüksek bağıl nem (%90'ın üzerinde), uzun süreli yaprak ıslaklığı ve 15–22 °C aralığındaki sıcaklıklarla yakından ilişkili olduğunu göstermiştir. Özellikle art arda birkaç beş günlük periyotta bu koşulların aynı anda sağlandığı dönemlerin, hastalığın tarlada hızla yayıldığı yüksek risk koşullarını oluşturduğu belirlenmiştir. Mart ve Nisan aylarında uzun yıllar ortalamasının üzerinde yağış alan sezonlarda, hastalığın çıkışı daha erken olmuş ve hastalık ilerleme eğrileri daha dik seyretmiştir. Buna karşın, erken sezonda yağışın görece düşük olduğu ve yaprak ıslaklığı periyotlarının kısa kaldığı yıllarda, patates mildiyö hastalığı epidemileri daha yavaş gelişmiş ve özellikle iyi havalanan, uygun sıra arası mesafeye sahip tarlalarda sınırlı kalmıştır.

3.2 Sabit programlı fungisit uygulamaları

Takvim esaslı fungisit programları, yüksek riskli yıllarda kabul edilebilir düzeyde hastalık kontrolü sağlayabilmiş, ancak bunu yüksek uygulama sayısı göze alınarak gerçekleştirmiştir. Özellikle kurak seyreden sezonlarda, enfeksiyon riskinin model çıktılarında düşük olduğu uzun aralıklar boyunca ilaçlama yapılmaya devam edilmiş; bu da gereksiz fungisit kullanımı ve girdi maliyetine neden olmuştur. Yoğun ilaçlamaya rağmen, hava koşullarının üst üste birkaç gün boyunca son derece elverişli olduğu dönemlerde, tarlalarda yine de belirgin hastalık belirtileri

gözlenmiştir. Benzer bulgular, Avrupa'nın farklı patates üretim bölgelerinde yürütülen çalışmalarda da bildirilmiştir (Schepers, 2004; Small ve ark., 2015; Majeed, 2017; Castaño-Serna ve ark., 2025).

3.3 İklim verilerine dayalı fungisit programı

İklim verilerine dayalı tahmin uyarı sistemi, sabit programlı uygulamalara kıyasla toplam fungisit sayısını önemli ölçüde azaltmıştır. Yıllar genelinde ortalama olarak, ilaçlama sayısında yaklaşık %25–30'luk bir azalma sağlanmış; buna karşın nihai hastalık şiddetinde anlamlı bir artış veya pazarlanabilir verimde istatistiksel olarak önemli bir azalma gözlenmemiştir. Bu stratejide, uygulamalar daha çok modeller tarafından "yüksek riskli" olarak tanımlanan dönemlerde yoğunlaşmış; enfeksiyon riskinin düşük olduğu bölümlerde ise ilaçlamadan kaçınılmıştır. Böylece uygulamalar zamansal olarak yoğunlaştırılmış; kurak veya nispeten düşük riskli yıllarda sabit programa göre daha uzun ilaçsız dönemler mümkün olmuştur. Bulgular, farklı ülkelerde tahmin uyarı sistemi temelli yönetimin, benzer şekilde daha az uygulama ile etkin hastalık kontrolü sağlayabildiğini bildiren çalışmalarla uyumludur (Schepers, 2004; Small ve ark., 2015; Meno ve ark., 2024).

3.4 Entegre yönetim

Entegre yönetim stratejisi, üç yıllık dönem boyunca en düşük hastalık insidansı ve en yüksek pazarlanabilir verim değerlerini sağlamıştır. Sertifikalı tohumluk kullanımı, münavebe ve enfekteli atıkların tarladan uzaklaştırılmasıyla, tarladaki primer inokulum önemli ölçüde düşmüş; bu da epideminin başlamasını geciktirmiş ve maksimum hastalık şiddetini azaltmıştır. Bu koşullar altında çalışan tahmin uyarı sistemi sınırlı sayıda, ancak daha isabetli zamanlanmış ilaçlama önermiştir. Sonuç olarak hem toplam uygulama sayısı hem de birim ürün başına düşen kimyasal girdi miktarı önemli ölçüde düşmüştür. Entegre mücadelenin bu üstünlüğü, patates mildiyö hastalığı için önerilen uluslararası entegre mücadele çerçeveleriyle de uyumlu bulunmuştur (Majeed, 2017).

3.5 Beş günlük yeniden enfeksiyon dönemlerine dayalı simülasyon modeli

Çalışmada uyarlanan, yeniden enfeksiyon için elverişli beş günlük dönem sayısına dayalı simülasyon modeli (Filippov ve ark., 2018), Çukurova koşullarında elde edilen saha verileriyle karşılaştırıldığında, hastalığın zaman içindeki gelişimini ve buna bağlı verim kayıplarını yüksek doğrulukla yansıtmıştır. Model, her sezon ve mikro bölge için düşük, orta ve yüksek risk profiline sahip yılları doğru şekilde ayırt edebilmiş; farklı varsayımsal ilaçlama senaryoları için öngördüğü verim kayıpları, gözlenen değerlerle genel olarak %5'in altında sapma göstermiştir. Ayrıca model çıktıları, Çukurova içinde nispeten daha düşük rakımlı, nemli ve hava akımı sınırlı alanlarda elverişli beş günlük dönem sayısının sistematik olarak daha yüksek olduğunu; buna karşılık hafif meyilli, rüzgâr alan ve iyi drenajlı alanlarda riskin daha düşük seyrettiğini ortaya koymuştur.

4. Tartışma

Bu çalışma, Çukurova'nın erken sezon patates üretim koşullarında yaygın olarak kullanılan takvim esaslı fungisit programlarının hem ekonomik hem de çevresel açıdan uygun olmadığını ortaya koymaktadır. Sabit aralıklarla yapılan uygulamalar, enfeksiyon riskinin düşük olduğu dönemlerde gereksiz ilaçlamalara yol açarken; hava koşullarının aniden son derece elverişli hâle geldiği kısa süreli dönemlerde, yoğun inokulum baskısı altında dahi yeterli korumayı her zaman sağlayamamaktadır. Benzer sonuçlar, başta Batı Avrupa olmak üzere pek çok patates üretim bölgesinde, sabit programlı uygulamalardan tahmin uyarı sistemi temelli uygulamalara geçiş sürecinde ortaya konmuştur (Schepers, 2004; Small ve ark., 2015; Castaño-Serna ve ark.,

2025). İklim koşullarına bağlı tahmin uyarı sistemleri, *P. infestans*'ın enfeksiyon ve sporulasyonunun sıcaklık, bağıl nem ve yaprak ıslaklığına sıkı sıkıya bağımlı olması gerçeğinden yararlanmaktadır. Bu ilişkiler sayısallaştırıldığında, Blitecast, PhytoPRE, Mileos, NEGFRY ve BlightPro gibi sistemler, yüksek riskli dönemleri belirleyerek ilaçlama kararlarını optimize edebilmekte; pek çok ülkede uygulama sayısını anlamlı düzeyde azaltırken, hastalık kontrol düzeyini koruyabilmektedir (Schepers, 2004; Small ve ark., 2015; Meno ve ark., 2024). Çukurova'da elde edilen bulgular, benzer faydaların bölgesel iklim özellikleri gözetilerek yapılan kalibrasyonlarla Türkiye koşullarında da elde edilebileceğini göstermektedir.

Beş günlük yeniden enfeksiyon dönemlerine dayalı simülasyon modeli, epidemiyolojik dinamikleri verim kaybıyla doğrudan ilişkilendirmesi bakımından tahmin uyarı sistemlerine tamamlayıcı bir rol üstlenmektedir. Bu tür modeller düşük riskli yıllarda ilaçlama sıklığını azaltmada önemli avantajlar sunmaktadır (Filippov ve ark., 2018).

Çalışmanın en önemli bulgularından biri, entegre yönetim stratejisinin tek başına kimyasal mücadelenin önüne geçmesidir. Münavebe, sertifikalı tohumluk kullanımı, enfekteli artıkların uzaklaştırılması gibi kültürel önlemler, tarladaki primer inokulum yükünü azaltarak epideminin başlamasını geciktirmekte; bu da tahmin uyarı sistemi temelli fungisit uygulamalarının daha az sayıda ve daha etkin şekilde gerçekleştirilmesine olanak tanımaktadır. Bu sonuç, patates mildiyö hastalığına dayanıklı genlerin (*Solanum bulbocastanum*'dan aktarılan RB geni) devreye girdiği durumlarda da, dayanıklılığın sürdürülebilirliği açısından fungisitler ve kültürel önlemlerle entegre yönetimin gerekliliğini vurgulayan çalışmalarla paralellik göstermektedir (Song ve ark., 2003; Blossei ve ark., 2022).

Bunun yanında tahmin uyarı sistemi temelli uygulamaların üretici uygulamalarına entegrasyonu önünde bazı yapısal engeller bulunmaktadır. Bunlar arasında; tarla düzeyinde güvenilir ve gerçek zamanlı meteorolojik veri eksikliği, anlaşılabilir arayüzlere sahip uygulamaların yetersizliği, çiftçiler ve teknik personel arasında bu sistemlerin etkisi ile ilgili eğitim çalışmalarının eksikliği sayılabilir. Bu engellerin aşılması, araştırma kuruluşları, yayım birimleri, özel sektör arasında güçlü bir iş birliği gerektirmektedir (Günaçtı ve Ay, 2021; Majeed, 2017).

Türkiye özelinde, özellikle Çukurova'dan elde edilen yerel verilerin üreticilere aktarılması büyük önem taşımaktadır. Winstel, Blitecast ve Ullrich–Schrödter modellerinin Adana koşullarındaki karşılaştırmaları ve bu çalışmada sunulan tahmin uyarı destekli stratejilerin verimi düşürmeden ilaçlama sayısını azaltabildiğini somut olarak göstermektedir.

5. Sonuç ve Öneriler

Patates mildiyö hastalığı, Çukurova Bölgesi'nde özellikle erken sezon patates üretimini ciddi biçimde tehdit etmeye devam etmektedir. Mevcut üretici pratiğinde, takvim esaslı fungisit programlarına duyulan güven, yüksek üretim maliyetleri, çevresel kirlilik riskleri ve *P. infestans* popülasyonunda fungisit direnci gelişimi gibi olumsuz sonuçları da beraberinde getirmektedir. Bu çalışma, Çukurova koşullarında iklim koşullarına dayalı tahmin uyarı sistemlerinin, sabit aralıklı programlara kıyasla fungisit uygulama sayısını yaklaşık %25–30 oranında azaltabileceğini, kültürel önlemlerle desteklenen entegre yönetim stratejisinin, en düşük hastalık şiddeti ve en yüksek ekonomik getiriyi sağladığını, ortaya koymuştur. Patates mildiyö hastalığı ile mücadelede fungisitler, vazgeçilmez bir araç olmakla birlikte, her 7–10 günde bir uygulanacak girdiler olarak değil; iklim koşulları, inokulum düzeyi, çeşit dayanıklılığı ve kültürel önlemlerle birlikte dinamik şekilde optimize edilecek bir bileşen olarak ele alınmalıdır. Yerel iklim ve üretim sistemlerine uygun iklim verilerine dayalı erken uyarı sistemleri Türkiye'nin patates üretim bölgelerinde patates mildiyö hastalığı yönetim stratejilerini yeniden tanımlama ve daha sürdürülebilir bir ürün koruma anlayışı geliştirme potansiyeline sahiptir.

ABSTRACT

Potato (*Solanum tuberosum* L.) is a strategic staple crop worldwide, playing a key role in food security and rural development. However, its production is severely constrained by numerous fungal diseases affecting foliage, roots, stems, and tubers, leading to substantial yield and quality losses. Major fungal pathogens include *Phytophthora infestans* (late blight), *Alternaria solani* (early blight), *Fusarium* spp. (dry rot and wilt), *Verticillium* spp. (wilt), *Rhizoctonia solani* (black scurf and stem canker), *Helminthosporium solani* (silver scurf), *Phoma exigua* var. *foveata* (gangrene), *Phytophthora erythroseptica* (pink rot), and *Sclerotinia sclerotiorum* (white mold). This review provides an integrated overview of these key fungal diseases, focusing on their taxonomy, life cycles, infection biology, epidemiology, typical symptoms, and economic impact. Furthermore, it summarizes advances in evaluates integrated disease management strategies, including resistant cultivar development, fungicide use, and biological control. Special attention is given to the status and management of major fungal diseases of potato under Turkish production conditions. The review aims to serve as a comprehensive reference for researchers, plant pathologists, and agronomists working on sustainable management of fungal diseases in potato cultivation.

ÖZET

Patates (*Solanum tuberosum* L.), dünya genelinde gıda güvenliği ve kırsal kalkınma açısından stratejik öneme sahip temel bir nişasta kaynağıdır. Ancak patates üretim; yaprak, toprak ve yumru kökenli çok sayıda fungal hastalık nedeniyle ciddi verim ve kalite kayıplarıyla karşı karşıyadır. Geç yanıklık (*Phytophthora infestans*), erken yanıklık (*Alternaria solani*), *Fusarium* türlerine bağlı kuru çürüklük ve solgunluklar, *Verticillium* solgunlukları, *Rhizoctonia solani*'nin neden olduğu siyah kabuk ve kök boğazı çürüklükleri, gümüşi leke (*Helminthosporium solani*), gangren (*Phoma exigua* var. *foveata*), pembe çürüklük (*Phytophthora erythroseptica*) ve *Sclerotinia sclerotiorum* kaynaklı beyaz çürüklük, patates üretiminde öne çıkan başlıca fungal hastalıklardır. Bu derlemede söz konusu etmenlerin taksonomik konumları, yaşam döngüleri, enfeksiyon biyolojisi, epidemiyolojisi, tipik belirtileri ve ekonomik etkileri özetlenmekte; entegre mücadele (IPM), dayanıklı çeşit ıslahı, biyolojik ve kimyasal kontrol stratejileri tartışılmaktadır. Ayrıca Türkiye'de patateste önemli olan fungal hastalıkların güncel durumu örneklendirilmekte ve gelecekteki araştırma ve hastalık yönetimi çalışmalarına yönelik öneriler sunulmaktadır. Çalışma, patates hastalıklarıyla çalışan araştırmacılar, bitki patologları ve ziraat mühendisleri için bütüncül bir başvuru kaynağı olmayı amaçlamaktadır.

1. Giriş

1.2 Patatesin Küresel Önemi ve Fungal Hastalıkların Patates Üretimindeki Rolü

Patates (*Solanum tuberosum* L.), pirinç, buğday ve mısırın ardından dünya üretiminde dördüncü sırada yer alan temel bir gıda bitkisidir. Yüksek karbonhidrat içeriği, kaliteli protein, vitamin ve mineral zenginliği ile özellikle gelişmekte olan ülkelerde enerji ve besin öğesi gereksiniminin önemli bir bölümünü karşılamaktadır. FAO verilerine göre yıllık küresel patates üretimi 370 milyon tonun üzerindedir ve Avrupa, Asya, Kuzey Amerika ile Afrika'da geniş üretim alanları bulunmaktadır.

Patates; taze tüketimin yanı sıra kızartmalık ürünler, cips, nişasta ve alkol üretimi gibi endüstriyel işleme sektörleri için de önemli bir hammaddedir. Bu nedenle, patates üretiminde karşılaşılan hastalık sorunları yalnızca tarla verimini değil, depolama, işleme ve pazarlama zincirinin tamamını etkilemektedir.

Patates; virüsler, bakteriler, nematodlar ve fungal patojenler gibi çok çeşitli biyotik etmenlere duyarlı bir türdür. Vegetatif çoğaltım nedeniyle, özellikle tohumluk materyal üzerinden pek çok hastalığın yıldan yıla taşınması söz konusudur. Fungal patojenler hem tarlada hem depoda, yeşil aksam, gövde, kök ve yumruda hastalıklara neden olarak: verim kayıplarına, kalitede bozulmaya, depolama kayıplarına, artan ilaçlama ve işçilik maliyetlerine, fungisit direnci ve çevresel riskler gibi sürdürülebilirlik sorunlarına yol açmaktadır.

Tarihsel olarak, geç yanıklık mildiyö hastalığı (*Phytophthora infestans*) İrlanda Patates Kıtlığı gibi sosyo-ekonomik felaketlerle anılmakta; günümüzde de pek çok ülkede sezonda 10–20'ye, tropik bölgelerde 20–30'a varan fungisit uygulaması gerektiren en önemli patates hastalığı olmaya devam etmektedir. Benzer şekilde; *Alternaria sp.*, *Fusarium sp.*, *Verticillium sp.*, *Rhizoctonia solani* ve *Sclerotinia* spp, hem primer hastalık etmeni hem de sekonder yara paraziti olarak patates üretim zincirinin farklı aşamalarında ciddi sorunlar oluşturmaktadır.

2. Patates Fungal Patojenlerinin Genel Özellikleri Taksonomi ve Patojen Çeşitliliği

Patatesi enfekte eden patojenler farklı şube ve sınıflara dağılmış durumdadır:

Oomycetes

Phytophthora infestans (Mildiyö-Geç yanıklık),

Phytophthora erythroseptica (Pembe çürüklük)

Ascomycetes

Alternaria solani (Erken yanıklık),

Fusarium spp. (Kuru çürüklük, Solgunluk),

Verticillium dahliae, V. albo-atrum (Solgunluk),

Sclerotinia sclerotiorum (Beyaz çürüklük),

Helminthosporium solani (Gümüşi Leke),

Phoma spp. (Gangren) gibi türleri içerir.

Basidiomycetes

Rhizoctonia solani (Siyah siğil hastalığı) bu grupta önemli bir patojendir.

Bu geniş yelpaze, patatesin hem toprak kaynaklı hem de hava kaynaklı birçok farklı hastalık etmenine açık olduğunu göstermektedir. Farklı taksonomik gruplara mensup olmalarına

rağmen, bu patojenler arasında bazı ortak özellikler dikkat çeker: Toprakta, bitki artıkları veya yumru yüzeyinde sklerot, klamidospor, piknidyum, sporangium gibi dayanıklı yapılarla uzun süre canlı kalabilme, uygun sıcaklık ve nem koşullarında çoğunlukla çok kısa sürede büyük spor populasyonları oluşturarak hızlı epidemilere yol açma, enfeksiyon için yaprak yüzeyinde serbest su, yüksek bağıl nem, uygun sıcaklık aralıkları ve çoğu zaman da yaralanma veya doğal açıklıklardan giriş gereksinimi, polifag patojenler olmaları gibi biyolojik özellikler, hem hastalıkların epidemiyolojisini hem de uygulanacak mücadele stratejilerini (münavebe, dayanıklı çeşit, fungisit seçimi vb.) doğrudan etkilemektedir

3. Patates Tarımında Sorun Olan Fungal Hastalıklar

3.1 Geç Yanıklık – Patates Mildiyö Hastalığı (*Phytophthora infestans)*

Patates Mildiyö hastalığı, patatesin en yıkıcı hastalıklarından biridir. Etmen, Oomycetes sınıfında yer alan *P. infestans* olup sporangium ve zoosporlar aracılığıyla yayılır. Bulaşık tohumluk yumrular, tarlada kalan enfekteli bitki artıkları ve uygun iklim koşulları (15–20 °C, yüksek bağıl nem) epidemilere neden olan temel faktörlerdir. Hastalık belirtileri, yapraklarda suyla ıslanmış gibi başlayan düzensiz lekeler kısa sürede kahverengileşir, lezyon kenarlarında özellikle nemli havalarda beyaz-gri bir sporlanma halkası görülür. İlerlemiş dönemlerde hızla birleşerek geniş nekrotik alanlara ve erken bitki ölümüne neden olur. Yumrularda kabuğun hemen altında kahverengi, sert çürüklük ve iç dokuda bozulma tipik belirtilerdir (Gunacti et al., 2019). Uygun koşullarda kontrolsüz bırakıldığında mildiyö nedeniyle %80–100'e varan verim kayıpları bildirilmiştir. Ayrıca depoda sebep olduğu yumru çürüklükleriyle pazar kaybını artırır. Hastalıkla Mücadelede; dayanıklı veya kısmi dayanıklı çeşitlerin kullanımı, sertifikalı ve sağlıklı tohumluk yumru temini, tarlada enfekteli bitki artıkları ve konukçu yabancı otların yok edilmesi, tahmin uyarı sistemleri ile zamanlanmış fungisit uygulamaları, Metalaksil, fluazinam, mandipropamid vb. fungisitlerin rotasyonlu ve direnç yönetimine uygun kullanımı (Cooke et al., 2012; Fry, 2016; Gunacti et al.,2021) önerilmektedir.

3.2. Erken Yanıklık (*Alternaria solani)*

Alternaria solani, nekrotrofik bir patojen olup özellikle sıcak ve nispeten kurak koşullarda hastalık şiddeti artar. Hastalık belirtileri, alt yapraklardan başlayan, ortasında konsantrik halkalar bulunan kahverengi lekeler tipiktir. İlerlemiş enfeksiyonlarda yapraklar sararıp kurur; bitkinin fotosentez yapma kapasitesi önemli ölçüde azalır. Hastalık nedeniyle iklim ve yetişme koşullara bağlı olarak %20–80 arasında değişen verim kayıpları rapor edilmiştir (Rotem, 1994; Leiminger et al., 2014). Hastalıkla mücadede genellikle fungisit kullanımı öne çıkmaktadır. Bunun yanında dengeli azot gübrelemesi ve stres koşullarının azaltılması, enfekteli artıkların yok edilmesi ve ekim nöbeti, Azoksistrobin, difenokonazol gibi fungisitlerin direnç yönetimi ilkelerine uygun kullanımı, biyolojik mücadele ve indüklenmiş direnç çalışmaları, son yıllarda artan önem taşımaktadır.

3.3 Fusarium Kaynaklı Kuru Çürüklük ve Solgunluklar (*F. solani, F. oxysporum*)

Fusarium spp. (*F. solani, F. oxysporum*), toprak ve yumru kaynaklı önemli patojenlerdir. Hem depolama döneminde kuru çürüklük hem de tarlada vasküler solgunluk şeklinde ortaya çıkabilirler. Klamidospor ve dayanıklı hifler şeklinde toprakta uzun süre canlı kalabilirler. Enfeksiyon genellikle hasat veya ekim sırasında oluşan yaralardan gerçekleşir. Uygun koşullarda (25–28 °C, geniş pH aralığı) sporlar hızla çimlenir. Hastalık, yumrularda kuru, çökük, koyu renkli çürük alanlar ve iç dokuda lifli, kuru doku bozulması şeklinde belirtilere neden olur. Solgunluk tablolarında ise bitki alt kısmından başlayan sararma, solma ve iletim demetlerinde kahverengileşme tipiktir. Mücadele yöntemi olarak hasat ve taşıma sırasında yaralanmaların en aza indirilmesi, uzun süreli ekim nöbeti ve toprak sağlığının iyileştirilmesi,

sağlıklı tohumluk kullanmak tohum ilaçlaması yapmak ve uygun depolama koşulları sağlamak önemlidir.

3.4. Verticillium Solgunluğu (*Verticillium dahliae* ve *V. albo-atrum)*

Verticillium spp, ksilem dokusunu kolonize eden toprak kökenli patojenlerdir. Mikrosklerot yapıları sayesinde toprakta yıllarca canlı kalabilirler. İlk hastalık belirtileri, alt yapraklarda kloroz ve hafif solgunluk olarak ortaya çıkar; daha sonra tüm bitkiye yayılarak ciddi bir gelişme geriliği ve erken yaşlanmaya yol açar. İç kesitte iletim demetlerinde belirgin kahverengi-siyah renk değişimi izlenir. Hastalıkla mücadelede; dayanıklı veya toleranslı çeşitlerin kullanımı, uzun süreli münavebe, solarizasyon, organik materyal ilavesi ve toprak sağlığını güçlendiren uygulamalar, drenaj ve sulama yönetiminin iyileştirilmesi önerilmektedir (Rowe et al., 1987; Powelson & Rowe, 1993).

3.5. Rhizoctonia Siyah Siğil Hastalığı (*Rhizoctonia solani)*

R. solani, patateslerde siyah kabuk (tuber yüzeyinde siyah sklerotlar) ve kök boğazı/kök çürüklüğü ile karakterize edilen çok önemli bir toprak patojenidir. Hastalığın en tipik belirtisi, yumru yüzeyinde sert, siyah, soyulduğunda kabuğu bozmayan sklerot kitleleri, gövdede kök boğazında ve köklerde çökük, kahverengi lezyonların görülmesidir. Enfeksiyon ilerledikçe zayıf kök sistemi, bodur gelişme, alt yaprakların sararması ve ileri durumlarda bitki ölümü görülebilir. Hastalık şiddeti, ılık ve nemli toprak koşullarda, yetersiz drenaj, ağır bünyeli topraklar ve sık sulama koşullarında artış gösterir. Hastalıkla mücadelede sağlıklı, temiz tohumluk kullanımı çok önemlidir. Tohum ilaçlaması (carboxin, pencycuron vb.) en çok kullanılanı yöntemdir. Son yıllarda, biyolojik mücadele etmenleri (*Trichoderma* spp., *Bacillus subtilis* vb.) ile kombine entegre yöntemler hastalıkla mücadelede başarı sağlamıştır (Mishra et al., 2000; Tsror et al., 2001).

3.6. Gümüşi Leke (*Helminthosporium solani)*

Gümüşi leke, özellikle depolama aşamasında problem oluşturan yüzey patojenidir. Yumru yüzeyinde gümüşi-parlak lekeler ve kabukta renk açılması ile karakterizedir. Yüksek nem ve yetersiz havalandırma, hastalık gelişimini hızlandırır (Christ, 1998; Peters et al., 2008). Sağlıklı tohumluk kullanmak, depoda sıcaklık ve nem kontrolü, iyi havalandırma koşullarının sağlanması hastalığı önler. Uygun depolama öncesi yumru fungisit uygulamaları da mücadelede tercih edilmektedir.

3.7. Gangren (*Phoma exigua var. foveata)*

Phoma exigua var. foveata başta olmak üzere *Phoma* türleri, depolama döneminde yumrularda çökük nekrotik lekeler ve iç dokuda bozulma ile karakterize gangrene neden olur Mücadelede, hasatta yumru yaralanmalarının azaltılması, uygun depolama sıcaklığı ve nem yönetimi, tohumluk yumruların fungisitlerle (benomil, tiabendazol vb.) muamelesi önerilmektedir (Hide & Cayley, 1983; Peters et al., 2005).

3.8. Beyaz Çürüklük *(Sclerotinia sclerotiorum*)

S. sclerotiorum, geniş konukçu dizisine sahip, sklerot oluşturan bir patojendir. Nemli ve serin koşullarda gövde, yaprak ve yumruya yakın dokularda su içeriği yüksek, yumuşak çürüklüklerle birlikte pamuksu, beyaz misel gelişimi tipiktir. Dokuların içinde siyah, sert sklerotlar oluşur. Münavebe ve konukçu olmayan bitkilerle rotasyon, drenajın geliştirilmesi, yoğun sulamadan kaçınılması önerilen kültürel mücadele yöntemleridir.

3.9.Diğer Önemli Hastalıklar

Patates siğil hastalığı (*Synchytrium endobioticum*), tozlu kabuk (*Spongospora subterranea*), skin spot (*Polyscytalum pustulans*) ve kömür çürüklüğü (*Macrophomina phaseolina*) gibi etmenler de gerek tarlada gerek depoda bölgesel ve dönemsel olarak önem kazanabilmektedir. Bu hastalıklarda da temel strateji; karantina önlemleri, dayanıklı çeşit kullanımı, toprağın ve depolama koşullarının iyileştirilmesi ve uygun fungisit uygulamalarıdır.

4. Sonuç ve Tartışma

Patates üretiminde fungal hastalıklar hem verim hem de kalite açısından küresel ölçekte ciddi kayıplara neden olmakta; bulaşık tohumluk, uygun iklim ve yetersiz mücadele koşullarında epidemi riskini sürekli canlı tutmaktadır. Sonuç olarak, fungal patojenlerin gelişimi ve hastalık epidemilerinin şiddeti, iklim koşulları ve tarımsal uygulamalarla yakından ilişkilidir. Yüksek bağıl nem, uzun yaprak ıslaklığı süreleri ve patojen için uygun sıcaklık aralıkları, özellikle geç yanıklık, erken yanıklık ve *Sclerotinia sp* kaynaklı çürüklükler gibi hastalıkların görülmesine yol açarken, toprak sıcaklığı ve nem düzeyi *Rhizoctonia solani, Fusarium* spp.ve *Verticillium* spp. kaynaklı sorunları etkilemektedir. Türkiye'de Karadeniz'in nemli ve serin koşulları geç yanıklık ve bazı depolama çürüklükleri için uygun ortam oluştururken, İç Anadolu ve Doğu Anadolu'da daha çok erken yanıklık, toprak kökenli solgunluklar ve *Rhizoctonia* kaynaklı problemler öne çıkmaktadır. Bölgesel çalışmalarda, geç yanıklığın bazı yıllarda %50'ye varan verim kayıplarına neden olabildiği; erken yanıklık ve gümüşi lekenin ise özellikle ihraç edilecek ve sofralık yumrularda ciddi kalite kaybı yaratabildiği bildirilmektedir. Farklı ekolojik bölgeleri barındıran ülkelerde, geç yanıklık, erken yanıklık, gümüşi kabuk, toprak kaynaklı solgunluklar ve depolama çürüklükleri gibi hastalıklar, bölgelere göre değişen ağırlıkta ortaya çıkmaktadır.

Sürdürülebilir patates üretimi için: Entegre mücadele yaklaşımının tüm bileşenleriyle (kültürel, kimyasal, biyolojik, genetik) uygulanması, dayanıklı çeşitlerin geliştirilmesi ve kullanımının yaygınlaştırılması, fungisit direncinin düzenli olarak izlenmesi, büyük önem taşımaktadır. Gelecek araştırmaların; patojen popülasyon dinamikleri, iklim değişikliğinin hastalık epidemiyolojisine etkisi, mikrobiom temelli toprak sağlığı yaklaşımları ve üretici odaklı dijital karar destek sistemleri üzerine yoğunlaştırılması, patates fungal hastalıklarının yönetiminde yeni ufuklar açacaktır.

ABSTRACT

This study evaluated the effects of calcium-based soil improvers of natural and ecological origin on the chemical composition of leaves, shoots, and grapes of the *Vitis vinifera* L. cultivar 'Cardinal' grown in the Skopje vineyard region, North Macedonia. These calcium products, rich in calcium and magnesium, were applied both as soil amendments and foliar fertilizers to enhance plant nutrition. The experimental design consisted of five treatment variants: 1) Control (untreated), 2) Zeofit Forte at 3 g/L, 3) Zeofit Forte at 5 g/L, 4) Zeofit Plus at 3 g/L, and 5) Zeofit Plus at 5 g/L. Foliar applications were conducted four times during the growing season: 15 days before flowering, 15 days after flowering, during the berry growth phase, and at the onset of veraison. Chemical analyses showed significant increases in key quality parameters, including total phenolics, flavonoids, vitamin C, carbohydrates, and total acids, in all treated variants compared to the control. The most notable improvements were recorded in Variants 2 and 4, where lower concentrations of foliar fertilizers were applied. These results suggest that calcium-based soil improvers combined with foliar fertilization can positively influence the biochemical composition and overall quality of 'Cardinal' grapes. This study highlights the importance of integrating natural calcium amendments and foliar treatments in vineyard management to improve grape nutritional value while supporting sustainable agricultural practices.

Keywords: Grapevine production, foliar fertilizing, fertilizer concentration.

INTRODUCTION

Grapevine (*Vitis vinifera* L.) is one of the most widely cultivated and economically important fruit crops globally, renowned for its high nutritional value, distinctive flavor profile, and considerable profitability (Huang et al., 2023; Jiang et al., 2024). Owing to these attributes, grapes have achieved remarkable popularity worldwide.

The Republic of North Macedonia offers nearly ideal natural conditions for grapevine cultivation and the production of high-quality wines. This is largely due to its favorable geographic position as a sunny and mountainous country, characterized by a Mediterranean–continental climate with warm, sunny days and cool nights.

Grapes are among the most appreciated fruits globally, valued for their taste, aroma, and nutritional richness. They are consumed fresh or processed into juice, wine, raisins, and jam, and are considered one of the highest-quality fruits for consumption. Beyond direct consumption, grapes are also widely used as raw material for the production of grape seed oil, anthocyanins, tannins, ethanol, and other value-added products. Their composition includes a broad spectrum of beneficial nutrients—vitamins (A, B, C, E, and P), minerals, carbohydrates, lipids, proteins, and polyphenolic compounds—distributed throughout the skin, seeds, and pulp. Additionally, grapes contain sugars primarily in the form of monosaccharides (glucose and fructose), as well as various phenolic compounds (Kandylis et al., 2021; Li et al., 2020; James et al., 2022).

Nutrient management is a key factor in maximizing grape quality and yield, as well as bridging the gap between actual and potential productivity. While essential nutrients are naturally present in the soil and are absorbed by plant roots, their excessive availability can lead to overly vigorous vegetative growth, resulting in dense canopies that overly shade the fruit or cause nutrient toxicity. Conversely, nutrient depletion over time necessitates the replenishment of soil reserves through the application of organic and/or mineral fertilizers to sustain yield and improve grape quality (James et al., 2022).

Grapevines require substantial nutrient input, and their growth, productivity, and fruit quality are closely linked to the availability of essential macro- and micronutrients. Although grape production has often relied on inorganic fertilizers, excessive use of such inputs can degrade soil health and negatively impact the environment (Vijayalakshmi et al., 2022).

While nutrient supplementation can address deficiencies, excessive concentrations may lead to toxic effects, adversely impacting grapevine performance and the quality of the grapes and their derived products (Serrano et al., 2017). Therefore, the rational application of fertilizers is necessary to achieve sustainable grapevine productivity and quality.

Fertilization is one of the most critical agro-technical practices in viticulture, with a significant influence on grape yield and quality (Delgado et al., 2004). By implementing modern agro-technical approaches, particularly with optimized fertilization strategies—timed appropriately and tailored to the phenological stages of vine development—it is possible to enhance grapevine growth and ensure the production of premium-quality grapes (Stojanova, 2023).

As a perennial crop, grapevine requires large quantities of nutrients, which are utilized differently across various developmental phenophases. Soil-based fertilization alone often proves inadequate, due to limited nutrient availability caused by unfavorable soil physical properties or drought stress (Stojanova, 2019). Therefore, foliar nutrition plays a vital role in successful grapevine cultivation and the production of high-quality grapes.

Nowadays, foliar nutrient application is widely adopted as a supplementary practice in plant production. Nutrients applied through foliar sprays can be absorbed via stomata, the cuticle, trichomes, veins, and other modified epidermal structures such as lenticels (Fernández et al., 2013; Fernández et al., 2021). This method of nutrient delivery offers both economic and environmental advantages, as it allows for more efficient nutrient uptake by targeting critical growth stages such as bud break, flowering, and fruit set (Gautier et al., 2018).

Foliar nutrition enables a preventive approach during phenophases when nutrient demand is high but root uptake is limited. This additional feeding through the leaves contributes significantly to cluster development and grape quality (Stojanova, 2018; Colapietra and Alexander, 2006). Furthermore, foliar fertilization enhances nutrient uptake efficiency by avoiding common soil-related limitations, such as antagonistic interactions between elements, nutrient fixation, and the formation of unavailable nutrient compounds (Stojanova, 2018; Stojanova et al., 2024b).

One of the major advantages of foliar fertilization is its rapid effect, with the flexibility of multiple applications during the growing season, resulting in a wide range of beneficial outcomes (Stojanova, 2018; Stojanova et al., 2024c).

A balanced combination of soil and foliar fertilization is fundamental for achieving both high yield and fruit quality. The optimal uptake of macro- and micronutrients by the grapevine directly influences key physiological and biochemical processes that govern its growth, development, and fruiting potential (Stojanova et al., 2024a).

The present research aimed to assess the impact of soil fertilization and different concentrations of foliar fertilization on the chemical composition of leaves, grape clusters, and berries in the *'*Cardinal*'* grapevine cultivar, grown under the specific climatic and edaphic conditions of the Skopje vineyard region in North Macedonia.

MATERIALS AND METHOD

Experimental design

The investigations were conducted in a vineyard located in the Skopje vineyard district, North Macedonia. The subject of the study was the 'Cardinal' grapevine variety, cultivated in a vineyard that was in the full bearing phase. The grapevines were planted at a spacing of 2.8 × 1.0 m, corresponding to a planting density of 3,571 vines per hectare. The cultivation system employed was a trellis training system, with a trunk height maintained at 70 cm.

During the basic autumn soil preparation, the vineyard was fertilized with a complex NPK 10-20-30 fertilizer at a rate of 500 kg/ha. Soil fertilization was carried out by applying the fertilizer into previously opened furrows, placed at a depth of 40 cm and at a distance of 60 cm from the vine trunks.

The field experiment was established under drip irrigation conditions. Throughout the vegetation period, all standard agricultural and ampelotechnical practices were applied to maintain the vineyard in optimal condition.

The experiment included five treatment variants, each set up with three replications. The experimental variants were as follows:

1. Control (untreated);

2. Zeofit forte (SiO_2 15%, CaO 35%, MgO 7%, P_2O_5 0.04%, K_2O 0.63%, MnO 0.043%, Fe_2O_3 4.70%) – 3 g/L;

3. Zeofit forte (SiO_2 15%, CaO 35%, MgO 7%, P_2O_5 0.04%, K_2O 0.63%, MnO 0.043%, Fe_2O_3 4.70%) – 5 g/L;

4. Zeofit plus (SiO_2 25%, CaO 21%; MgO 13%; K_2O 1.1%; Fe_2O_3 2.0%) – 3 g/L;

5. Zeofit plus (SiO_2 25%, CaO 21%; MgO 13%; K 1.1%; Fe_2O_3 2.0%) – 3 g/L.

Each treatment variant included 10 grapevines, amounting to a total of 150 grapevines across all experimental plots. The treatments involved foliar application of a tested fertilizer solution at concentrations of 3 g/L and 5 g/L. A total of four foliar treatments were performed during the vegetation period, applied at key phenological stages: 15 days before flowering, 15 days after flowering, during the berry growth phase, and at the onset of veraison. The foliar sprays were applied manually using a hand-held sprayer, targeting the leaf surfaces for optimal nutrient absorption.

Zeofit Forte and Zeofit Plus are soil conditioners of natural origin, categorized as fully ecological products. Due to their high content of calcium and magnesium, these materials are also effective when used for foliar nutrition. Their application has been shown to stimulate flowering, enhance plant immunity, and contribute to increased yields.

Plant Material – Grapevine Cultivar

The grapevine cultivar used in this research was *'*Cardinal*'*, a variety developed in California through the hybridization of the *Flame Tokay* and *Ribier* cultivars. Today, *'*Cardinal*'* is widely cultivated across the globe, with significant presence in countries such as Spain, Italy, Romania, and Mexico. It performs particularly well in regions that are characterized by dry weather during the ripening period and where there is no risk of severe frost during winter (Popovic et al., 2020).

The grape clusters are large, weighing between 250 and 550 g, and exhibit an elongated shape with an amber-yellow coloration. The berries may appear loosely or moderately clustered. In North Macedonia, *'*Cardinal*'* is primarily grown in the warmer viticultural zones. It is a late-ripening cultivar, with harvest typically occurring from late September to early October. Under cold and rainy conditions during the flowering phase, the clusters may develop a reddish hue.

Soil Sampling and Agrochemical Analysis

To assess the soil's fertility status prior to the establishment of the experiment, composite soil samples were collected from three depth intervals: 0–30 cm, 30–60 cm, and 60–80 cm (Stojanova, 2019). In the laboratory, the soil samples were air-dried and processed for agrochemical analysis. The following parameters were determined using standard methodologies:

- Soil pH – determined potentiometrically using a pH meter (Stojanova, 2017);

- Available nitrogen (easily mineralizable) – determined by the Tjurin and Kononova method (Stojanova, 2017);

- Available phosphorus – determined by the AL method with spectrophotometric reading (Stojanova, 2017);

- Available potassium – also determined using the AL method and spectrophotometric analysis (Stojanova, 2017);

- Humus content – assessed using the potassium permanganate method by Kotzman (Stojanova, 2017);

- Carbonate content – determined by the Scheibler calcimetric method (Stojanova, 2017).

Harvesting Procedure

The grape harvest was performed at the stage of full technological maturity, separately for each treatment variant and replication. Grapes were collected manually to preserve the integrity of the clusters and ensure sample accuracy.

Sampling and Chemical Analysis of Leaves and Clusters

Following the harvest, during the period of highest macro- and micronutrient stability, leaf samples were collected to determine their chemical composition. The sampling was performed using the lower leaves situated opposite the first grape cluster, taken from all sides of the vine to obtain a representative sample.

In the laboratory, the leaves were first washed in a 0.05% HCl solution, then rinsed with distilled water and air-dried at room temperature. A total of 20 leaves per variant and per replication were collected and prepared for analysis.

Samples of one-year-old mature shoots (canes) were taken in November, with each average sample consisting of material from 10 individual grapevines per treatment variant. The shoots were ground into a fine powder using an electric mill and prepared for chemical analysis.

In both leaf and shoot samples, the following elements were determined:

- Nitrogen (N) – determined by the Kjeldahl method (Stojanova, 2017);
- Phosphorus (P_2O_5) – analyzed by inductively coupled plasma atomic emission spectroscopy (ICP-AES) (Stojanova, 2017);
- Potassium (K_2O) – measured after incineration with concentrated H_2SO_4 and detection using a flame photometer (Stojanova, 2017);
- Calcium (Ca), Magnesium (Mg), Iron (Fe), Manganese (Mn), Boron (B), Zinc (Zn), and Molybdenum (Mo) – determined by ICP-AES (Sarić et al., 1989).

Chemical Analysis of Grape Berries

Following harvest, 10 grape clusters per treatment and replication were sampled. For the average sample, clusters were selected based on dry matter content, measured with a hand-held refractometer using juice from several berries. In laboratory conditions, berries were manually separated from the rachis and prepared for analysis (Stojanova, 2017).

The following chemical parameters were determined in the grape berries:

- Total phenolic content (TP) – determined using modified method of Stojanova et al. (2021);
- Total flavonoid content (TF) – determined using modified method of Stojanova et al. (2021);
- Vitamin C content – determined using the Muri method (Stojanova, 2017);
- Total carbohydrate content – determined using modified method of Masuko et al. (2005);
- Total acid content – determined using modified method of Stojanova et al. (2017);

Statistical analysis

The experimental data were subjected to statistical analysis using the software package SPSS version 20.0. In order to evaluate the presence of statistically significant differences among the treatment variants, a one-way analysis of variance (ANOVA) was performed. Where significant differences were detected, Tukey's HSD post hoc test was applied for mean separation at a significance level of $p<0.05$.

RESULTS AND DISCUSSION

Soil conditions

Soil represents a critical ecological factor that directly or indirectly influences the vital functions of grapevines. Optimal soils for viticulture are characterized by being loose, deep, and having a slightly acidic to slightly alkaline reaction. Such soils should warm up easily, provide good aeration, retain adequate moisture and nutrients, possess a lighter mechanical composition, and exhibit high microbiological activity. The concentration of various macro- and micronutrients is also pivotal in determining the soil's suitability for grape cultivation (Stojanova, 2023).

The data presented in Table 1 indicate that the analyzed soil samples can be classified as moderately fertile with respect to available nitrogen, which was measured at 6.30 mg/100 g soil. Phosphorus availability was found to be at a medium fertility level, with an average content of 14.83 mg/100 g soil across the 0–80 cm depth profile. Potassium content was classified as good, averaging 23.53 mg/100 g soil.

However, in terms of humus content, the soil was found to be poorly fertile, with an average humus concentration of 1.43% within the same depth range. The calcium carbonate content indicated that the soil is slightly calcareous, with an average value of 2.23%. The pH measurements showed that the soil reaction is neutral, creating favorable conditions for the successful growth, development, and fruiting of the grapevine.

Table 1. Agrochemical analysis of soil

Cultivar	Depth (cm)	pH		Available (mg/100g soil)			Humus (%)	$CaCO_3$ (%)
		H_2O	KCl	N	P_2O_5	K_2O		
'Cardinal'	0–30	7.55	7.25	7.10	13.80	25.00	1.40	2.50
	30–60	7.40	7.20	6.50	17.50	23.20	1.50	2.30
	60–80	7.42	7.22	5.30	13.20	22.40	1.38	1.90
	Average 0-80	**7.46**	**7.22**	**6.30**	**14.83**	**23.53**	**1.43**	**2.23**

Effect of foliar fertilizing on the chemical content of leaves and clusters

Macronutrients are fundamental elements that significantly influence grapevine growth, grape yield, and ultimately the quality of wine. Currently, monitoring nutrient status through plant tissue or soil sampling followed by chemical analysis provides crucial information on whether nutrient levels are deficient, adequate, excessive, or toxic (Debnath et al., 2021). Among these, nitrogen (N) and potassium (K) are highly mobile nutrients that can be rapidly translocated from older leaves to younger leaves or fruiting tissues when demand exceeds supply from the soil, potentially causing symptoms such as chlorosis and necrosis (Jegadeeswari et al., 2020; Michopoulos and Solomou, 2019).

Furthermore, supplementation with magnesium (Mg) and calcium (Ca) fertilizers plays a vital role in enhancing crop yields, especially when the efficiency of conventional NPK fertilizers is limited. Calcium ranks as the third most abundant nutrient available in soils and is essential for numerous plant functions (Pessoca et al., 2021).

Magnesium is a crucial macronutrient for plant growth, playing a central role throughout the plant's life cycle. It is a key constituent of the chlorophyll molecule, necessary for photosynthesis (Meng et al., 2023). Besides its role in photosynthesis, magnesium activates enzymatic processes vital for carbohydrate synthesis in leaves. Additionally, elevated magnesium levels can influence potassium uptake due to competitive interactions within the plant (Zlamalova et al., 2016). For instance, foliar application of magnesium sulfate ($MgSO_4$) at a rate of 3.86 kg Mg/ha was shown to increase grape yield by 11.2% compared to untreated controls, although other parameters were not significantly affected (James et al., 2022).

Calcium contributes significantly to fruit firmness by interacting with cell walls, binding pectin, and forming bridges between pectic acid molecules. It is an essential nutrient involved in both structural and signaling functions in plants. Absorbed by roots from the soil solution, calcium is transported via the xylem to shoots. However, its mobility within the plant is generally low, resulting in accumulation primarily in mature tissues despite the high demand of actively growing organs such as young leaves, flowers, and fruits (Garde-Cerdán et al., 2023). Calcium deficiency has been associated with several physiological disorders, including incomplete flowering, development of densely branched and shortened roots, chlorosis, and necrosis (Duan et al., 2022).

As shown in Table 2, all variants treated with different concentrations of foliar fertilizers exhibited significantly higher ($p < 0.05$) values for the analyzed chemical parameters in leaves and clusters compared to the untreated control.

Table 2. Macroelements composition of grapevine leaves from *'*Cardinal*'* variety (% of dry matter)

Variant	n	N	P_2O_5	K_2O	CaO	MgO
		$\bar{x} \pm SD$	$\bar{x} \pm SD$	$\bar{x} \pm SD$	$\bar{x} \pm SD$	$\bar{x} \pm SD$
1	20	2.20 ± 0.05^a	1.67 ± 0.16^a	1.22 ± 0.08^a	2.20 ± 0.11^a	0.41 ± 0.08^a
2	20	2.28 ± 0.08^b	1.73 ± 0.18^b	1.35 ± 0.08^b	2.52 ± 0.19^b	0.61 ± 0.13^b
3	20	2.35 ± 0.11^c	1.88 ± 0.16^c	1.53 ± 0.14^c	2.10 ± 0.05^c	0.55 ± 0.11^c

$^{a, b, c}$ – values for the same parameter of the different variants marked with different letters have statistically significant differences ($p<0.05$), ANOVA, *post hoc* Tukey's test.

The highest average concentrations of nitrogen (2.48%), phosphorus (1.95%), and potassium (1.75%) in the leaves were observed in variant 4, with statistically significant differences ($p < 0.05$). Additionally, the greatest average levels of calcium (2.52%) and magnesium (0.61%) in leaves were recorded in variant 2.

The combined application of soil fertilization along with varying concentrations of foliar fertilization exerted a positive impact on the content of macronutrients in the clusters of the 'Cardinal' grapevine variety. At all tested foliar fertilizer concentrations, the clusters exhibited significantly higher ($p < 0.05$) levels of the analyzed elements compared to the untreated control. Specifically, variant 4 showed the highest concentrations of nitrogen (0.96%),

phosphorus (0.65%), and potassium (0.95%) in the clusters, while variant 2 presented the greatest levels of calcium (1.53%) and magnesium (0.68%) (Table 3).

Table 3. Macroelements composition of grapevine clusters from *'Cardinal'* variety (% of dry matter)

$^{a, b, c}$ – values for the same parameter of the different variants marked with different letters have statistically significant differences ($p<0.05$), ANOVA, *post hoc* Tukey's test.

In the study conducted by Bai et al. (2024) on the grape variety Queen Nina (*Vitis vinifera* L.), four foliar magnesium treatments were tested at concentrations of 1 mM (M1), 2 mM (M2), 3 mM (M3), and 4 mM (M4). The foliar application of magnesium fertilizer significantly enhanced both the dry weight and leaf area in all treatments. Among them, the M3 treatment showed the most pronounced effect compared to the others. Specifically, compared to the control (CK), the dry weight and leaf area in the M3 treatment increased by 35.9% and 37.2%, respectively ($p < 0.05$). Furthermore, the yields of M1, M2, and M3 treatments increased by 8.2%, 32.3%, and 29.1% ($p < 0.05$), respectively, relative to the control variant.

Wang et al. (2023) investigated the Merlot grapevine variety and reported nitrogen content ranging from 19.13 to 30.13 $mg \cdot g^{-1}$. In the fruit, the lowest and highest average calcium contents were observed at the MS (16.76 $mg \cdot g^{-1}$) and FBS (20.25 $mg \cdot g^{-1}$) developmental stages, respectively. Magnesium content in fruit declined during fruit development, while the opposite trend was noted in the petiole. Leaf magnesium content peaked at the VS stage with 4.1 $mg \cdot g^{-1}$, followed by the FBS and MS stages.

Mineral elements represent a vital nutritional foundation for growth and development, with appropriate nutrient supply being critical to achieving optimal fruit tree yields and quality. Zhu Xiaoping et al. (2008) analyzed nutrient content in Cabernet Sauvignon leaves without deficiency symptoms, establishing standard nutrient concentration ranges as follows: nitrogen (10.3–17.3 mg/g), phosphorus (3.1–5.4 mg/g), potassium (22.7–29.1 mg/g), calcium (6.4–11.4 mg/g), and magnesium (2.8–4.1 mg/g).

Tong et al. (2021) employed the DRIS method to explore the relationship between mineral nutrients and yield in Cabernet Sauvignon leaves. Their findings defined the diagnostic criteria for leaf nutrients in high-yield vineyards as: nitrogen (16.5–37.5 mg/g), phosphorus (2.6–6.2 mg/g), potassium (10.2–24.2 mg/g), calcium (5.6–77.3 mg/g), and magnesium (2.3–12.7 mg/g).

Calzarano et al. (2023) observed that all fertilizer applications, particularly those involving microelements, intensified foliar symptom expression. Greater vegetative growth was only detected in grapevines treated with NPK fertilizers. Notably, symptom escalation was consistently linked to a decrease in calcium, and to a lesser extent magnesium, in the leaves, supporting the hypothesis that calcium plays a critical role in the plant's defense response through a hypersensitive reaction during foliar symptom development. Despite fertilizer treatments, the vineyards remained in nutritional balance.

Effect of foliar fertilizing on the chemical content of grapes

The quality of grapes is primarily assessed by biochemical components such as total soluble solids, sugar-acid ratio, and acidity (Vijayalakshmi et al., 2022). Grapes are among the most important fruits worldwide and are rich in a variety of phenolic compounds (Crupi et al., 2016). These phenolic compounds, which rank third in abundance in grapes after carbohydrates and acids (Stojanova et al., 2024), are especially significant due to their pronounced biological activities. They exhibit strong antimutagenic, anti-inflammatory, antiallergic, and antimicrobial effects, which greatly enhance the value of grapes and their derived products.

Vitamin C (ascorbic acid) is another crucial and extensively studied component in grape berries. It plays a vital role in the redox metabolism within plant tissues, thereby increasing the plant's resistance to infections and low temperatures.

Table 4. Biochemical Parameters of 'Cardinal' Grapes

Variant	n	Total phenolic (TP) mg/g	Total flavonoid (TF) mg/g	Vitamin C (mg/100g)	Total carbohydrate (g/L)	Total acids (g/L)
		$\bar{x} \pm SD$	$\bar{x} \pm SD$	$\bar{x} \pm SD$	$\bar{x} \pm SD$	$\bar{x} \pm SD$
1	10	120.52 ± 0.25^{a}	45.23 ± 0.20^{a}	26.35 ± 0.23^{a}	172.25 ± 0.09^{a}	3.90 ± 0.21^{a}
2	10	128.39 ± 0.05^{b}	46.86 ± 0.31^{b}	28.15 ± 0.21^{b}	183.36 ± 0.03^{b}	4.50 ± 0.09^{b}
3	10	125.07 ± 0.09^{c}	46.01 ± 0.14^{c}	27.00 ± 0.02^{c}	175.17 ± 0.01^{c}	4.00 ± 0.06^{c}
4	10	131.75 ± 0.02^{d}	47.54 ± 0.06^{d}	26.90 ± 0.10^{a}	173.08 ± 0.13^{d}	4.25 ± 0.11^{d}
5	10	127.01 ± 0.19^{e}	46.57 ± 0.02^{e}	27.88 ± 0.07^{d}	177.69 ± 0.04^{e}	4.15 ± 0.18^{d}

$^{a, b, c}$ – values for the same parameter of the different variant marked with different letters have statistically significant difference (p<0.05), ANOVA, *post hoc* Tukey's test.

Table 4 shows the biochemical composition of grape samples across five treatment variants, with all parameters displaying statistically significant differences ($p < 0.05$). Variant 4 had the highest total phenolic content (131.75 ± 0.02 mg/g) and total flavonoid content (47.54 ± 0.06 mg/g), followed closely by Variant 2, which showed the highest vitamin C concentration (28.15 ± 0.21 mg/100g), total carbohydrates (183.36 ± 0.03 g/L), and total acids (4.50 ± 0.09 g/L). These values indicate a substantial improvement in grape biochemical quality compared to the control (Variant 1).

Variant 2 demonstrated the best results for vitamin C, carbohydrates, and acids, suggesting the foliar treatment at this concentration effectively enhanced the nutritional profile of the grapes. Variant 4, while showing slightly lower vitamin C and carbohydrate values, excelled in phenolic and flavonoid content, highlighting the positive impact of foliar fertilization on antioxidant components.

Variants 3 and 5 showed intermediate improvements in all measured parameters compared to the control but were generally lower than Variants 2 and 4.

The different superscript letters next to the means confirm significant differences among treatments, supporting the conclusion that foliar fertilization positively influences the chemical composition of 'Cardinal' grapes, enhancing their quality and potential health benefits.

Foliar treatments showed a positive effect on the chemical composition of grapes. In all examined parameters, a higher content was determined compared to the control variant. According to the research of Koureh et al. (2018), with the application of different doses of mineral and organic fertilizers in a commercial vineyard of white seedless grape, the content

of total phenolics ranged from 1.25 to 1.75 mg GAE g−1 FW, the content of total flavonoids from 0.568 to 0.697 mg CE g−1 FW, and antioxidant activity ranged from 61 to 75% DPPH.

Similarly, Shi et al. (2020) reported that with the application of different doses of mineral fertilizers in 10-year-old Marselan vines, the total phenolic content (mg/g) ranged from 2.52 to 3.42. Popovic et al. (2020) determined an average carbohydrate content of 14.57% and an average total acid content of 4.14% with the application of mineral and organic fertilizers in mixed grapevine 'Cardinal'.

Furthermore, according to Vijayalakshmi et al. (2022), fruit quality parameters were superior in berries from treatment T4 (100% RDF + 300 g Azotobacter + 300 g PSB + 300 g KRB/vine). Treatment T4 recorded the maximum total soluble solids (TSS) of 18.33 °Brix, minimum acidity (0.21%), highest TSS:Acid ratio (87.28), total sugars content (15.33%), reducing sugars (14.06%), and the highest sugar:acid ratio (73.00).

CONCLUSION

Based on the analyses conducted to determine the influence of soil and foliar fertilization on the chemical composition of the leaves, clusters, and grapes of the 'Cardinal' grapevine variety grown under the conditions of the Skopje vineyard area, it can be concluded that different concentrations of foliar fertilization play a significant role in the vegetative development of the grapevine. All investigated parameters showed significantly higher values ($p<0.05$) in the leaves, clusters, and grapes where foliar fertilization was applied, compared to the control variant.

Soil analysis continues to be of paramount importance, as integrating all available data helps in making informed decisions regarding fertilizer application rates. This ensures the adequate nutritional status of the grapevines without compromising the quality of the wine or the environment. Therefore, the rational use of fertilizers and nutrient-specific fertilization plans are highly recommended for vineyard management.

The combined application of soil and foliar fertilization, using mineral and organic fertilizers in optimal quantities, represents a fundamental prerequisite for the proper development of the grapevine and for improving the overall quality of grape production.

ABSTRACT

Introduction: COVID-19 pandemic brought unprecedented changes to healthcare systems worldwide, affecting not only the management of the pandemic disease but also the guidelines for the treatments of common infections. Due to the fact that urinary tract infections (UTIs) are among the most common infection's diseases, our focus is to investigate the prevalence of antibiotic resistance during the pandemic and to assess how pandemic-related treatments shifts may have influenced these resistance patterns. Among the pathogens responsible for UTIs, Proteus mirabilis has gained attention due to its increasing resistance to antibiotics. This study aims to evaluate the resistance patterns of Proteus mirabilis during 2020, a year which has been characterized by altered over prescription of antibiotics. *Methods*: A retrospective analysis was conducted from May to December 2020 on 78 urine cultures collected from ambulatory patients with UTIs signs. The data have been collected from the same microbiology laboratory with the main condition, that the methodology used was the same. Our focus was on the resistance rates of Proteus mirabilis to critically important antibiotics, particularly cephalosporins, nitrofurantoin, aminoglycoside and imipenem. *Results*: Our findings revealed high resistance rates of Proteus mirabilis to several cephalosporins, including cefepime, cefuroxime, ceftazidime and ceftriaxone, alongside significant resistance to nitrofurantoin and imipenem. This trend raises concerns about the effectiveness of standard empirical treatments for UTIs, especially in pandemic. *Conclusion*: The elevated antibiotic resistance observed in Proteus mirabilis during the COVID-19 pandemic may be linked to increased antibiotic usage practices influenced by the urgent need to manage various infections in a constrained healthcare environment. While it is essential to recognize that these instances remain relatively few. Continued surveillance is crucial to mitigate the risk of further resistance development.

Keywords: antibiotic resistance, Proteus mirabilis, ceftazidime, COVID-19, sensitivity

Introduction

COVID-19 pandemic represents a significant global health crisis. It has not only posed significant challenges to global health but has also influenced various aspects of medical practice, including the emergence of antibiotic resistance. As healthcare systems became overwhelmed with COVID-19 cases, changes in antibiotic prescribing patterns and increased use of broad-spectrum antibiotics may have contributed to a rise in antibiotic resistance. One notable concern is the impact on urinary tract infections (UTIs) caused by Proteus mirabilis, a common uropathogen known for its capacity to develop resistance to multiple antibiotics.

Urinary tract infections (UTIs) are prevalent clinical conditions primarily affecting the female population. Among the various uropathogens, Proteus mirabilis is recognized as a significant contributor to UTIs. Its virulence factors, including urease production and motility, facilitate its colonization in the urinary tract and contribute to its pathogenicity.

Understanding the antibiotic resistance profiles of Proteus mirabilis is crucial, as this directly influences clinical management and treatment outcomes for affected patients.

P. mirabilis, the third most prevalent cause of urinary tract infections (UTIs) and the second most common cause of catheter-associated urinary tract infections (CAUTIs) in long-term catheterized patients, is responsible for 12% of complicated UTIs.

This study aims to evaluate the resistance patterns of Proteus mirabilis during 2020, a year which has been characterized by altered over prescription of antibiotics.

Methods

- *Study design*

This retrospective study analyzed 78 patients with confirmed Proteus mirabilis positivity, collected from ambulatory patients with UTIs signs, conducted from May to December 2020, in Tirana, Albania. The data have been collected from the same microbiology laboratory with the main condition, that the methodology used was the same. The following methodologies were employed:

- *Patient selection and data collection*

A total of 78 patients with confirmed urinary tract infections caused by Proteus mirabilis were included in the study. Patients were selected from microbiology laboratory in Tirana district during the pandemic period May to December 2020.

Our focus was on the resistance rates of Proteus mirabilis to critically important antibiotics, particularly cephalosporins, nitrofurantoin, aminoglycoside and imipenem.

- *Urine sample collections*

Sample collection had been performed according to the protocol.

Clean catch midstream urine samples were collected to minimize contamination. Samples were transported to the laboratory within 2 hours and stored at 4ºC if there was a delay in processing.

- *Identification of pathogen*

Each urine sample was subjected to culture on Agar blood plate or CLED (Cysteine-lactose-electrolyte-deficient) agar to isolate uropathogens. Plates were incubated at 37°C for 24 hours.

Suspected colonies of P. mirabilis were identified based on colony morphology, gram staining and biochemical tests (urease, catalase and oxidase test).

Proteus swarms across the blood agar plate and gives no individual colonies.

Typically, the majority of *P. mirabilis* strains demonstrate a lack of lactose fermentation and a distinctive swarming motility. Gas and acid are formed during fermentation of glucose. Strong smell is also characteristic of Proteus.

These distinctive characteristics are readily discernable on agar plates, facilitating the efficient identification of *P. mirabilis*

Proteus mirabilis identification

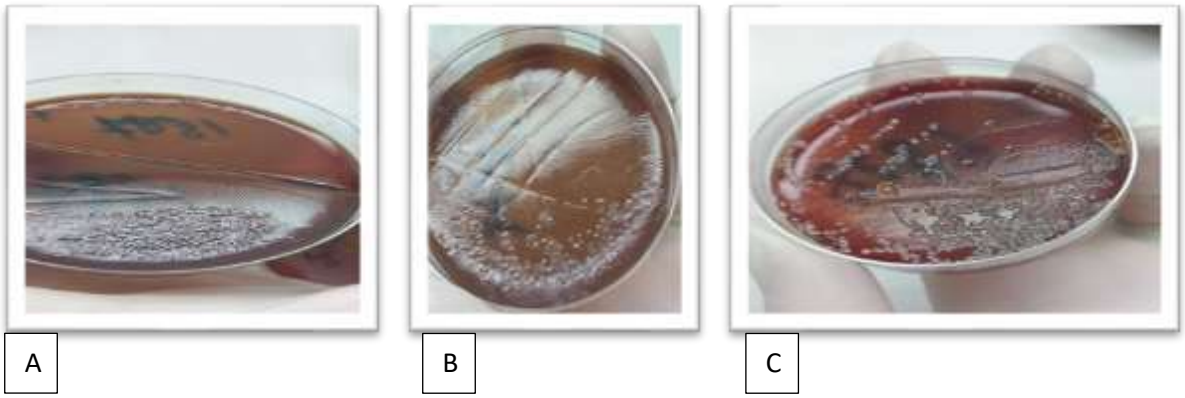

Fig.1 A) B) C) Proteus mirabilis, on a blood agar plate incubated 24h at 37°C.

The colonies are spreading on the surface of the agar due to P. mirabilis are swarming

- *Antibiotic susceptibility testing*

Antibiotic susceptibility testing was conducted on Mueller-Hinton agar, following the Clinical and Laboratory Standards Institute (CLSI) guidelines. This allowed for the evaluation of the sensitivity of isolated Proteus mirabilis strains to various antibiotics, providing crucial insights into resistance patterns. A standardized inoculum was prepared from identified colonies and adjusted to 0.5 McFarland standard. Antibiotic discs were placed on the surface of the agar, which was then incubated for 16-18 hours at 37ºC.

The following antibiotics were tested for antimicrobial sensitivity (AST): doxycycline (DOX), cefepime (FEP), cefuroxime (CXM), ciprofloxacin (CIP), piperacillin (PIP), tobramycin (TOB), ceftazidime (CAZ), gentamicin (Gen), ceftriaxone (CRO), nitrofurantoin (NIT), vancomycin (VAN), amoxicillin-clavulanate (AUG), imipenem (IMI), nalidixic acid (NAL). The isolate were assessed for sensitivity or resistance to these anti-microbial agents based on inhibitory zones.

Results

Each patient with Proteus mirabilis positivity had been tested for antibiotic resistance and sensitivity. During our 8 months of analysis different antibiotics had been checked and measured. The resistance patterns demonstrated high levels of resistance to multiple commonly used antibiotics. The highest resistance rates were observed with nitrofurantoin (57 cases resistant), ceftazidime (57) and cefuroxime (52). Moderate to high resistance was also noted with imipenem, ceftriaxone, gentamicin, vancomycin and piperacillin. ciprofloxacin exhibited a comparatively lower resistance rate with a higher number of sensitive isolates. Overall, the findings indicate a predominance of antimicrobial resistance among Proteus isolates, particularly toward beta-lactams, aminoglycosides and nitrofurantoin, while fluoroquinolones-especially ciprofloxacin and nalidixic acid, retained better activity against the isolates.

A notable observation is the very high resistance to beta-lactam antibiotics, including ceftazidime, cefuroxime, cefepime and ceftriaxone. This suggests widespread beta-lactamase production among the isolates, which is consistent with known resistance mechanisms in Proteus mirabilis. The elevated resistance to imipenem is particularly concerning, as carbapenems are typically reserved for more severe infections. Such resistance may indicate emerging carbapenem activity or other mechanisms of reduced carbapenem susceptibility, which warrant further investigation. Aminoglycoside resistance was also significant, with high resistance rates observed for tobramycin and gentamicin. Nitrofurantoin showed very poor activity, with the majority of isolates being resistant. This is expected, as Proteus species are intrinsically resistant to nitrofurantoin due to poor drug uptake and inactivation should not be used for Proteus urinary tract infections. In contrast, fluoroquinolones especially ciprofloxacin and nalidixic acid demonstrated better efficacy, with a higher proportion of sensitive isolates. This suggests that fluoroquinolones may remain among the more reliable empirical treatments options for UTIs caused by Proteus mirabilis, although resistance was still present and must be monitored. The overall resistance profile observed in this study reflects the global trend of increasing antimicrobial resistance among Gram-negative uropathogens.

Antibiotics	Resistant	Intermediate	Sensitive
DOXYCYCLINE	29	3	8
CEFEPIME	50	6	19
CEFUROXIME	52	6	18
CYPROFLOXACIN	22	6	48
PIPERACILLIN	24	15	37
TOBRAMYCIN	42	13	17
CEFTAZIDIME	57	7	11
GENTAMICIN	41	19	15
CEFTRIAXONE	42	12	22
NITROFURANTOINE	57	8	10
VANKOMYCIN	35	1	0

IMIPENEM	47	8	20
NALIDIXIC ACID	10	15	46

Tab.1 Antibiotic susceptibility patterns of Proteus mirabilis

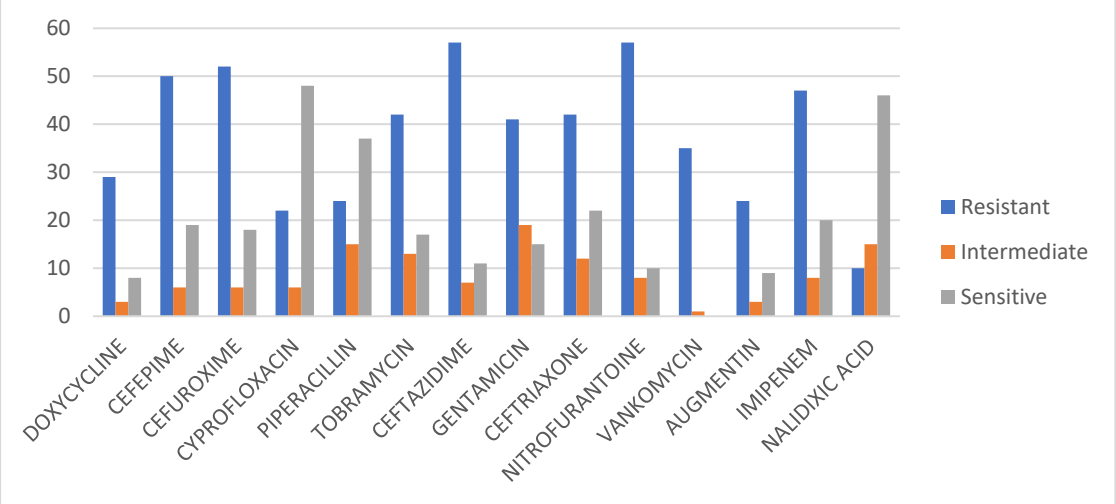

Fig.2 Proteus mirabilis antibiotic resistance and sensitivity

Discussion

Our study assessed the antimicrobial susceptibility patterns of Proteus mirabilis species isolated from urine cultures and revealed a high burden of antimicrobial resistance across multiple antibiotic classes. The findings underscore the increasing difficulty of managing urinary tract infections (UTIs) caused by P. mirabilis, a pathogen known for its intrinsic resistance mechanisms and ability to acquire additional resistance determinants. A prominent observation was the consistently high resistance to ß-lactam antibiotics, including cefuroxime, cefepime, ceftazidime and ceftriaxone. These results are suggestive of widespread expression of extended-spectrum ß-lactamases (ESBLs). Such resistance limits the effectiveness of first and second line ß-lactams. Aminoglycosides such as tobramycin and gentamicin also demonstrated considerable resistance. Those data diminished their utility in severe or complicated UTIs where aminoglycosides may serve as potent bacterial agents. The poor performance of nitrofurantoin seen in this study is consistent with the well-established intrinsic resistance of Proteus spp. to this agent, reaffirming that nitrofurantoin is inappropriate caused by this organism. Fluoroquinolones, especially ciprofloxacin and nalidixic acid showed comparatively better activity, with a higher proportion of isolates remaining sensitive. Over all the antimicrobial resistance patterns observed in this study reflect the global escalation of multi drug resistance among Gram-negative pathogens.

Conclusion

This study demonstrates that Proteus species isolates from urine cultures exhibit high levels of resistance to multiple classes of antibiotics, particularly ß-lactams, aminoglycosides and nitrofurantoin. The emergence of resistance to imipenem is especially troubling, as it reduces the effectiveness of drugs traditionally reserved for multidrug-resistant infections. Although fluoroquinolones showed relatively resistance was still present and warrants ongoing monitoring. The overall findings emphasize the urgent need for continuous antimicrobial resistance surveillance and evidence-based empirical treatment guidelines. Further research, including molecular studies is recommended to characterize the underlying mechanisms of resistance.

ÖZET

Lastikler, otomotiv sektörünün temel güvenlik bileşenlerinden biri olarak araçların yol tutuşu, frenleme performansı ve genel sürüş güvenliği açısından kritik bir öneme sahiptir. Lastik yapısında yer alan ana bileşenler arasında kauçuk karışımları, çelik ve naylon gibi tekstil takviyeleri ile yanak bölgeleri bulunmaktadır. Her bir bileşenin fiziksel ve kimyasal özellikleri, lastiğin dayanıklılığını, esnekliğini, yuvarlanma direncini ve yol ile temas yüzeyini doğrudan etkilemektedir. Bu bileşenlerin üretim sürecindeki yerleştirme pozisyonu kadar, birbirine birleştirildiği ek yerleri de yapısal bütünlük açısından büyük önem taşımaktadır. Özellikle ham lastik üretiminde, bileşenlerin birleştirildiği ek yerlerinin birbirine göre açısal konumu, lastiğin statik balans çıktısı üzerinde belirgin etkiler göstermektedir. Statik balans, lastiğin dengeli dönüş kabiliyetiyle doğrudan ilişkilidir ve sürüş konforunu önemli ölçüde etkiler. Bu çalışmada lastik performansını iyileştirmek için fabrika ortamında gerçekleştirilen proses iyileştirme çalışmaları sonucunda ek yerlerinin yerleşimi optimize edilmiş ve statik balans değerlerinde kayda değer iyileştirmeler sağlanmıştır. Bu iyileştirmelerle üretim hattındaki operasyonel ıskartaların azaltmanın yanı sıra, aynı zamanda bayilerde yapılan balanslama işlemlerinde kullanılan kurşun ağırlık miktarını da önemli ölçüde düşürmüştür. Çalışma sonucunda hem maliyet avantajı hem de çevresel sürdürülebilirlik açısından iyileştirmeler elde edilmiştir.

ANALYSIS OF STATIC BALANCE STATUS IN COMMERCIAL TIRES

ABSTRACT

Tires, as one of the fundamental safety components of the automotive industry, play a critical role in vehicle handling, braking performance, and overall driving safety. The main components of a tire include rubber compounds, textile reinforcements such as steel and nylon, and sidewall sections. The physical and chemical properties of each component directly affect the tire's durability, flexibility, rolling resistance, and contact surface with the road. In addition to the positioning of these components during the manufacturing process, the splice locations where they are joined together are also of great importance for maintaining structural integrity. In particular, in raw tire production, the angular alignment of the splice joints relative to each other has a significant effect on the tire's static balance performance. Static balance is directly related to the tire's ability to rotate smoothly and has a major impact on driving comfort. In this study, process improvement efforts carried out under factory conditions were implemented to optimize the positioning of the splice joints, resulting in notable improvements in static balance values. These improvements not only reduced operational scrap rates on the production line but also significantly decreased the amount of lead weights used during balancing operations at dealerships. As a result of the study, enhancements were achieved in both cost efficiency and environmental sustainability.

GİRİŞ

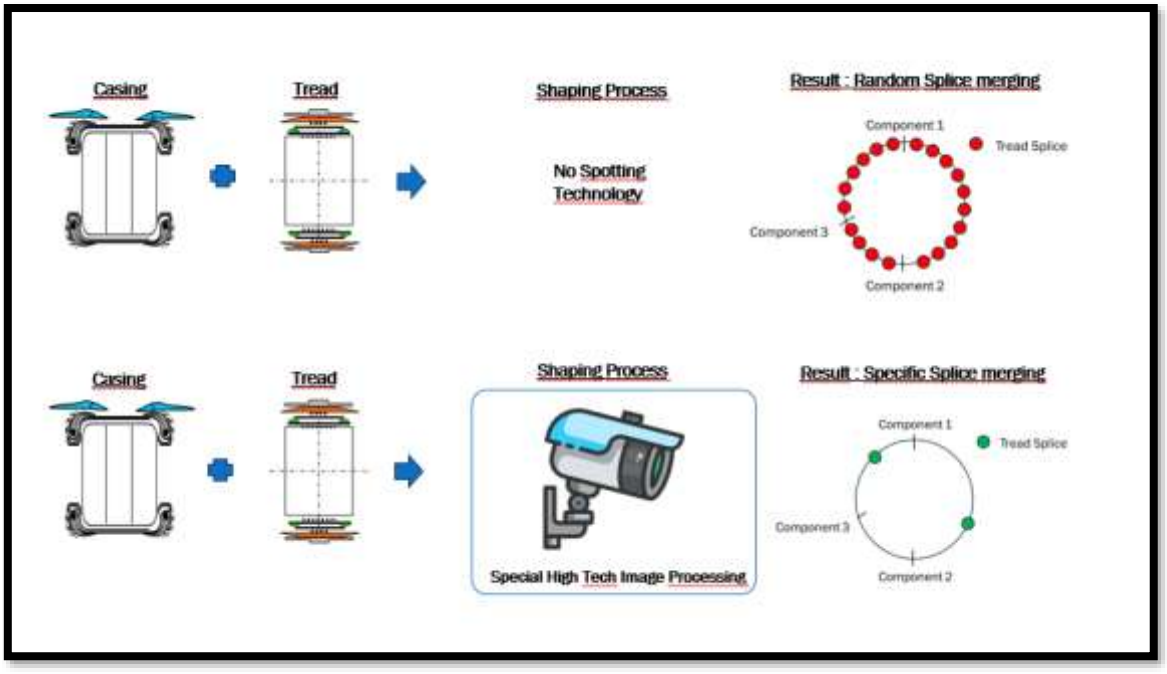
Lastikler, araçların güvenli hareketini sağlayan en önemli bileşenlerden biridir [1]. Özellikle ticari araçlarda, lastiklerin balansı hem sürüş konforu hem de güvenlik açısından kritik öneme sahiptir. Statik balans, lastiğin herhangi bir noktada ağırlık dengesizliği göstermemesi anlamına gelir. Bu dengesizlikler, üretim sürecindeki bileşen dağılımı, birleşim hataları veya malzeme kusurlarından kaynaklanabilir. Statik balansın sağlanamaması, araçta titreşimlere, düzensiz lastik aşınmasına ve sürüş güvenliğinin azalmasına yol açabilir [2]. Bu dengesizlikler, üretim sürecindeki bileşen dağılımı, birleşim hataları veya malzeme kusurlarından kaynaklanabilir [3]. Literatürde belirtildiği üzere, lastik uniformitesindeki (düzenliliğindeki) bozulmalar; radyal ve yanal kuvvet değişimlerine neden olarak araç dinamiğini olumsuz etkiler [4]. Statik balansın sağlanamaması, araçta istenmeyen titreşimlere, düzensiz lastik aşınmasına ve sürüş güvenliğinin azalmasına yol açabilir [5]. Ticari araçlarda bu tür problemler, hem sürücü hem de yolcular için risk oluşturur; ayrıca işletmelerin bakım maliyetlerini artırabilir. Modern lastik üretiminde, statik balansın sağlanmasına yönelik olarak gelişmiş kalite kontrol süreçleri ve test yöntemleri uygulanmaktadır. Üretim hattında bileşenlerin doğru dağılımı ve birleşim noktalarının hassas kontrolü için endüstriyel otomasyon ve görüntü işleme teknolojileri kullanılmakta, böylece olası dengesizlikler erken aşamada tespit edilip giderilmektedir [6]. Bu çalışmada, Brisa fabrikasında üretilen ticari lastiklerde statik balansın sağlanmasına yönelik süreçler ve yapılan iyileştirmeler detaylı olarak ele alınmıştır.

MATERYAL VE YÖNTEM

Lastik ve Bileşenleri

Bir lastik, otomotiv sektöründe güvenli ve verimli sürüşün temelini oluşturan, çok katmanlı ve karmaşık bir mühendislik ürünüdür [7]. Temel olarak çelik teller, doğal ve sentetik kauçuk, tekstil takviyeleri ve çeşitli kimyasal katkı maddelerinin hassas bir şekilde bir araya getirilmesiyle üretilir. Ticari lastiklerde karkas, sırt, yanak ve iç astar gibi ana bileşenler bulunur [3]. Şekil 1'de kesit analizi alınmış lastiğin görseli gösterilmektedir. Her bir bileşenin üretim sürecindeki miktarı, yerleşimi ve dağılımı, lastiğin genel performansını ve özellikle balansını doğrudan etkiler. Özellikle birleşim noktalarında (splice) oluşan dengesizlikler, statik balans sorunlarının en önemli nedenlerinden biridir ve bu nedenle üretim sırasında büyük bir hassasiyet gerektirir.

Şekil 1 : Lastiğin kesit görseli



Statik Balansın Tanımı ve Önemi

Statik balans, bir lastiğin sabit bir eksende döndürüldüğünde herhangi bir noktada ağırlık fazlalığı veya eksikliği göstermemesi durumudur. Lastikteki ağırlık dengesizliği, aracın hareketi sırasında titreşimlere, düzensiz lastik aşınmasına ve sürüş güvenliğinin azalmasına neden olabilir. Özellikle ticari araçlarda, statik balansın sağlanamaması hem sürücü hem de yolcular için ciddi riskler oluşturur ve işletmelerin bakım maliyetlerini artırır. Statik balansın önemi, lastiğin üretim sürecinde bileşenlerin doğru yerleştirilmesi ve birleşim noktalarının hassas kontrolüyle doğrudan ilişkilidir. Bu nedenle, modern üretim tesislerinde gelişmiş test yöntemleri ve kalite kontrol süreçleriyle statik balans sürekli olarak izlenir ve iyileştirilir.

Brisa'da Uygulanan Geliştirme Faliyeti

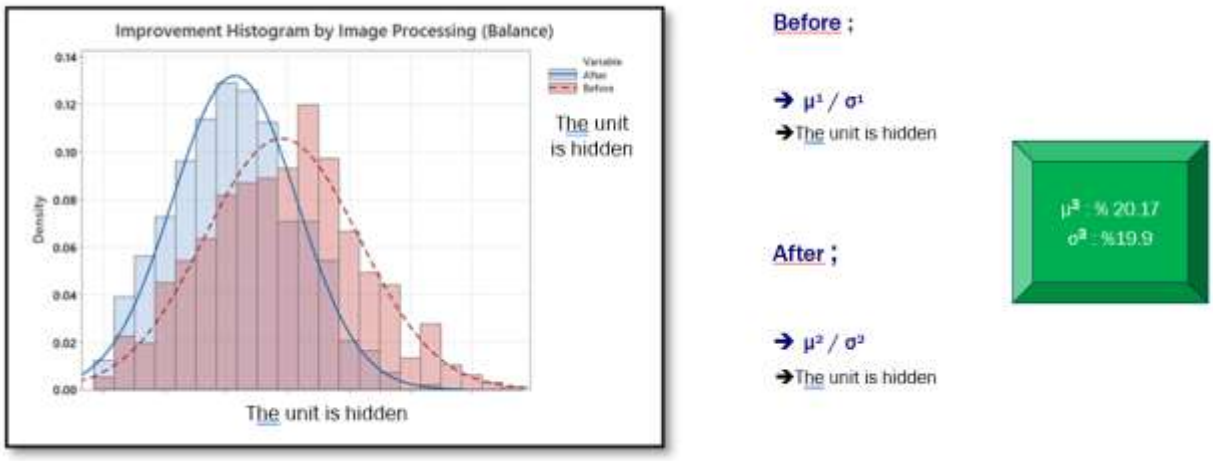
Brisa fabrikasında, lastiklerin statik balansı çeşitli testlerle kontrol edilmektedir. Dinamik testler (yuvarlanma direnci, karkas dayanıklılığı, bead burst analizi), gürültü testleri ve titreşim önleme ölçümleri bu süreçte önemli rol oynar. Ayrıca, üretim hattında bileşenlerin doğru dağılımı ve birleşim noktalarının hassas kontrolü için, endüstri 4.0 uygulamaları kapsamında ileri görüntü işleme teknolojileri kullanılmaktadır [8].

Fakat her fabrikada teknolojik cihazlar ve ekipmanlar zamana bağlı olarak eskimektedir. Bu eskimelerin yenileriyle değiştirilme süreci maliyet açısından çok maliyetli olduğu için bazen uygulanabilir en hızlı ve basit yöntemler tercih edilmektedir. Bu süreç uygulanacak proses için bazen kolay olsa da bazen de çok zor ve uygulabilir olmamaktadır. Brisa da yapılan görüntü işleme teknoloji yardımıyla büyük bütçeli uygulanacak uygulama yerine daha basit ve görece hızlı uygulabilir system kurulumu gerçekleştirilmiştir.

Şekil 2 : Geliştirme Yapılan Çalışma

BULGULAR

Brisa fabrikasında yürütülen bu kapsamlı çalışmada, lastik imalat sürecine entegre edilen görüntü işleme tabanlı kontrol sistemleri ile statik balans performansında önemli kazanımlar elde edilmiştir. Geleneksel üretim yöntemlerinde, lastiği oluşturan yarı mamul bileşenlerin ek yerleri, operatör inisiyatifine veya makine hızına bağlı olarak rastgele bir dağılım



göstermekteydi. Literatürde "Random Splice Merging" olarak adlandırılan bu durum, bileşenlerin ağırlık merkezlerinin üst üste binmesine ve toplam dengesizliğin artmasına neden olmaktadır.

Yapılan iyileştirme ile lastik imalat makinasına yerleştirilen kameralar ve geliştirilen algoritma sayesinde, her bir bileşenin ek yeri anlık olarak tespit edilmiştir. Bu veriler kullanılarak, bileşenlerin ek yerlerinin birbirini dengeleyecek şekilde (örneğin 180 derece zıt veya belirli açılarla dağıtılmış) konumlandırılması sağlanmıştır. Bu yöntem, vektörel olarak dengesizlik kuvvetlerinin sönümlenmesi prensibine dayanmaktadır [9].

Elde edilen veriler istatistiksel olarak analiz edildiğinde, Şekil 3'te sunulan "Öncesi-Sonrası" histogram grafiklerinde açıkça görüldüğü üzere, proses dağılımında belirgin bir daralma meydana gelmiştir. İyileştirme çalışmaları sonucunda:

- ***Ortalama Değer (μ):*** Balans dağılım eğrisinin merkezi, sıfır noktasına (ideal dengeye) daha fazla yaklaşmış,
- ***Standart Sapma (σ):*** Verilerin yayılımı azalarak proses kararlılığı artırılmıştır.

Sayısal olarak, statik balansın hem ortalama hem de standart sapma değerlerinde %20'ye yakın bir iyileşme sağlanmıştır. Standart sapmadaki bu düşüş, üretilen lastiklerin kalitesinin daha tutarlı hale geldiğini ve üretim hattındaki varyasyonların minimize edildiğini göstermektedir. Bu gelişmeler, nihai ürün kalitesini doğrudan artırırken, üretim hattındaki plansız duruşları ve yeniden işlem (re-work) oranlarını düşürerek toplam üretim verimliliğine katkı sağlamıştır.

Şekil 3 : Çalışma öncesi ve sonrası histogramı

SONUÇ

Ticari araç güvenliği ve sürüş konforu açısından kritik bir parametre olan statik balansın, üretim aşamasında kontrol altına alınması modern lastik mühendisliğinin öncelikli hedeflerinden biridir. Bu çalışmada, Brisa üretim tesislerinde uygulanan görüntü işleme destekli proses optimizasyonunun, lastik uniformitesi üzerindeki pozitif etkileri deneysel verilerle kanıtlanmıştır.

Elde edilen sonuçlar iki ana başlıkta değerlendirilebilir:

1. ***Üretim Verimliliği ve Maliyet:*** Fabrika sahasında statik balans limitleri dışında kalan (ıskarta veya tamir gerektiren) lastik miktarında azalma sağlanarak, atık maliyetleri düşürülmüş ve hammadde verimliliği artırılmıştır.

2. ***Müşteri Memnuniyeti ve Çevresel Etki:*** Lastiklerin fabrika çıkışında daha dengeli olması, son kullanıcıya ulaştığında bayilerde yapılan balans ayarı işlemlerini kolaylaştırmıştır. Araç üzerine takılan kurşun ağırlık (balans kurşunu) miktarının azalması, hem servis süresini kısaltmış hem de çevreye zararlı bir ağır metal olan kurşun kullanımını minimize ederek çevresel sürdürülebilirlik hedeflerine katkı sunmuştur.

Sonuç olarak, yüksek maliyetli ekipman yatırımları yerine, mevcut üretim hattına entegre edilen akıllı algılama sistemleri ve proses mühendisliği yaklaşımları ile kalite parametrelerinde sürdürülebilir iyileştirmeler sağlanabileceği gösterilmiştir.

ABSTRACT

This study presents a deep learning–based approach for the automatic detection of feeding damage (emgi) caused by the sunn pest (*Eurygaster integriceps*) on wheat grains. A custom dataset containing healthy, damaged, and foreign-material grain instances was constructed and annotated in YOLO format, and three modern YOLO families—YOLOv8, YOLOv11, and YOLOv12—were systematically evaluated across their S/M/L variants under identical hyperparameters to ensure fair comparison. Experimental results demonstrate that YOLOv12 and YOLOv11 architectures exhibit superior capability in distinguishing fine-grained morphological differences, with YOLOv12l achieving the highest performance (mAP50=0.944) and near-perfect detection in the damaged class. YOLOv8, while competitive overall, showed limitations particularly in recall for damaged grains, indicating sensitivity to subtle surface deformations. The results further reveal that the YOLOv12 family offers an optimal balance between model size and accuracy, with even the lightweight YOLOv12s achieving high mAP values. To assess real-time applicability, the best-performing model was integrated with a ByteTrack-based multi-object tracking module, which successfully maintained consistent IDs and stable tracking across video frames, proving the system's suitability for dynamic environments such as industrial quality-control lines. Overall, the findings highlight the strong potential of modern YOLO architectures in detecting microscopic pest-induced damage and demonstrate that the developed system can serve as a fast, reliable, and scalable alternative to manual inspection in agricultural quality assessment.

1. Introduction

The sunn pest (Eurygaster integriceps) is known as one of the pests that most significantly affect yield and quality in wheat production in Türkiye [1]. Especially during the milk stage, the sunn pest feeds by extracting sap from wheat grains, and through various enzymes it secretes, it causes deterioration in the gluten structure of the grain, a decrease in germination capacity, and a severe weakening of flour quality [2]. This enzymatic effect directly reduces the processability of bread and pasta products, leading to quality losses in the domestic market as well as economic declines in export potential. Therefore, in countries such as Türkiye, where wheat is a strategic agricultural product, the accurate, rapid, and standardized detection of sunn pest feeding damage is of vital importance for producers, inspection institutions, and industrial organizations [3].

Today, the determination of feeding damage is mostly based on manual inspections carried out by experts, and these methods carry significant limitations as they are both time-consuming and open to subjective interpretation [4]. In large-volume sampling, the prolongation of the evaluation process, the increase in human-induced error rates, and the difficulty of standardization reduce the effectiveness of manual methods. In addition, the fact that the damage is small-sized and sometimes difficult to distinguish visually makes visual inspection processes even more complex. In recent years, artificial intelligence and deep learning-based computer vision methods have emerged as a strong alternative in agricultural quality control processes. Deep learning models provide high accuracy and speed especially in tasks such as object detection and the classification of fine textural differences, making it possible to detect even micro-level damage that is difficult for the human eye to perceive. This enables quality-defining factors such as feeding damage to be analyzed automatically and reliably, creating significant advantages in terms of both time and cost [5–7].

The primary aim of this study is to automatically detect feeding damage caused by the sunn pest on wheat grains using deep learning-based methods. In this context, different object detection models belonging to the YOLO family were evaluated, and an artificial intelligence approach was developed to determine feeding damage from images with high accuracy.

Motie and colleagues developed a classification model using drone-acquired RGB and near-infrared (NIR) images to detect wheat spike damage caused by the sunn pest at an early stage. In the study, various vegetation indices (such as NDVI, RVI, DVI, RED and GREEN band reflectance) were calculated, and these features were evaluated with SVM (Radial Basis Function kernel) classifiers. It was shown that, in NIR images, the reflectance of red and near-infrared bands and the RVI index, and in visible-light images, the reflectance of red and green bands and the NGBDI index, contributed most to classification performance. SVM models achieved the highest accuracy in February and March when wheat plants were still green; average accuracy was reported as 97% for NIR images and 93% for visible-light images. These findings demonstrate that drone-based imaging and machine learning methods provide an effective approach for detecting spike damage caused by the sunn pest [8].

Moon's study proposes a deep learning and image processing-based framework for detecting wheat leaf diseases. In the study, color-based segmentation and GLCM methods were applied to extract features from leaf images; the obtained features were tested with classifiers such as Naïve Bayes, k-NN, SVM, and Random Forest. The results showed that among the models, Random Forest achieved the highest performance, reaching an accuracy of 98.9%. The study demonstrates that this approach offers high accuracy in the automatic diagnosis of wheat diseases and provides a faster and more reliable solution compared with traditional manual evaluations [9].

Akman and colleagues presented a wheat grain dataset with high species diversity to investigate kernel damage caused by the sunn pest across different wheat varieties, designed to reflect real production conditions. In the study, healthy and sunn pest–damaged grains from six different wheat species were collected using high-resolution imaging while considering realistic scenarios such as natural piling, touching grains, and the presence of broken and half kernels. The authors demonstrated in detail that the dataset is well suited for classification, detection, and segmentation tasks using machine learning and deep learning approaches. In this respect, the study distinguishes itself from existing datasets in the literature that are limited in scope and mostly created under synthetic conditions, providing a more realistic and generalizable reference resource for industrial sorting and quality control applications [10].

2. Materials and Methods

2.1. Dataset

The image data used in this study were generated on wheat samples brought to the laboratory from different geographical regions. The grains were freely distributed on a homogeneous surface and recorded with a high-resolution camera system, and each image was arranged to clearly display the feeding damage (emgi) left by the sunn pest on the wheat grain. Three main classes were used in the study: damaged grain, undamaged grain, and foreign material. All images were manually annotated by experts, and then converted into YOLO format to obtain a bounding-box-based structure. Due to the dataset containing a high density of small objects, data augmentation techniques such as rotation, brightness variation, scaling, and mirroring were utilized when necessary to enable the model to learn a more stable representation.

The constructed dataset was organized to provide a balanced class distribution and was carefully divided into training, validation, and test subsets. In total, 11,649 grain instances were annotated across 71 images. The training set, with 9,239 samples, constituted the largest portion of the dataset, while the validation set contained 773 samples and the test set included 1,637 samples. This structure enabled the models to learn robustly and allowed generalization performance to be measured accurately. The class counts and distribution of the dataset are presented in Table 1, forming an appropriate foundation for YOLO-based detection of sunn pest feeding damage.

Table 1. Class-Wise Data Distribution for Healthy, Damaged, and Foreign Materials Categories

Class	Veri Sayısı
Un-Healthy	1872
Damaged	5214
Foreign Materials	4563

2.2. YOLO-Based Object Detection Models

In this study, modern deep learning–based object detection methods were used to automatically identify the feeding damage caused by the sunn pest on wheat grains. The analysis process is based on a specially constructed image dataset, standardized preprocessing steps, and a comparative evaluation of models belonging to three different YOLO families. In the first stage, a two-class dataset containing damaged and healthy wheat grains was created, and all images were obtained under homogeneous lighting conditions using a high-resolution camera. The annotation process was carried out under expert guidance; the images were classified under

the labels “s” (healthy), “e” (damaged), and “y” (foreign material). All annotations were prepared in a bounding-box structure suitable for YOLO format, thus ensuring a consistent training flow across different models.

The YOLO (You Only Look Once) architecture adopts a one-stage object detection approach, performing both class prediction and localization in a single forward pass over the image. Its real-time performance, high speed–accuracy trade-off, and success in small-object detection make it widely preferred in agricultural image analysis. The fundamental principle of YOLO is dividing the image into grids and estimating object probability and bounding box parameters from each cell. The YOLOv8, YOLOv11, and YOLOv12 versions used in this study incorporate increasingly advanced backbones, optimized feature pyramid structures, context-aware attention mechanisms, and enhanced scales for improved small-object detection [11–14]. YOLOv8, with its efficiency and simplified structure, was evaluated as a reference model, while YOLOv11 was designed with a deeper and wider architecture, aiming to provide higher discriminative power particularly for small objects with complex morphological structures. YOLOv12, on the other hand, integrates next-generation modules such as “Partial Convolution Fusion,” “Dynamic Head,” and adaptive feature transfer across scales, further improving both localization accuracy and detection stability. For this reason, it is highly suitable for detecting small and localized damage regions such as sunn pest feeding damage. The basic representation of the YOLO architecture is given in Figure 1.

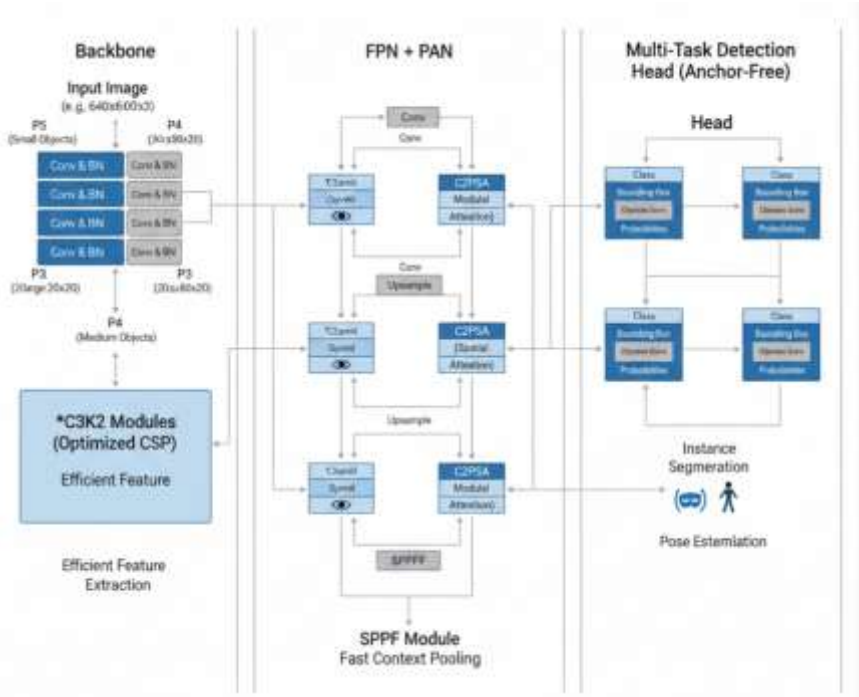

Figure 1. Yolo Architechure

Before being included in the training process, the data were subjected to basic preprocessing steps such as resizing, normalization, and brightness–contrast adjustment; and to increase the generalization ability of the model, data augmentation methods such as horizontal–vertical flipping, rotation, scaling, and brightness variations were applied. The dataset was divided into train–validation–test subsets, and the same data distribution was preserved across all models to ensure that the experiments were conducted fairly.

In the modeling process, three different YOLO families were used: YOLOv8, YOLOv11 (S/M/L), and YOLOv12 (S/M/L). While YOLOv8 was evaluated as a reference model due to

its lightweight and fast structure, the YOLOv11 and YOLOv12 versions were compared across different size variants to examine the relationship between model capacity and accuracy. These models, with their advanced feature extraction structures, different backbones, and improvements in object detection performance, provide significant advantages in identifying small, localized, and morphologically subtle structures such as feeding damage. The single-stage structure of all three versions, their ability to operate at high FPS rates, and the strengthened small-object detection capability provided by the FPN/PAN structure make it possible to accurately identify small damage regions in agricultural images.

All models were trained in the GPU-accelerated environment of Google Colab Pro+. Using the same hyperparameters across all models is a fundamental component of the study design. In this context, the number of epochs was fixed at 100, the batch size at 16, the input size at 640×640 pixels, the learning rate at 0.001, and the randomness value (seed=42) remained constant. Thus, differences arising from hyperparameters were eliminated in model comparisons. During the optimization phase, the models were trained with an AdamW-based structure in accordance with the default settings of the Ultralytics library; and the default CIoU-based components of YOLO models were used as the loss function. Automatic Mixed Precision (AMP) was enabled during training, providing efficiency in both speed and memory usage. At the end of each epoch, validation evaluation was performed, and the weight file with the best performance was saved. Early stopping was not used, and all models completed their full training cycles. The hyperparameters used during model training are summarized in Table 2.

Table 2. Training Hyperparameters Used in the YOLO Models

Hiperparameter	**Value**
Epoch	100
Image Size (imgsz)	640 px
Batch Size	16
Seed	42
Patience	0 *(early stopping not used)*
Data Split	Train / Valid / Test
YAML Config	3 class (s, e, y)

The performance of the models was evaluated using the mAP@50, precision, recall, and F1-score metrics commonly used in the object detection literature. Additionally, normalized and raw confusion matrices were generated to examine the models' discrimination power at the class level. During the evaluation phase, a fixed confidence value (conf=0.001) and IoU threshold (IoU=0.50) were used for all models. The results obtained were compared in terms of both classification accuracy and geometric accuracy of the detection boxes; performance in small object detection was the main analysis criterion, particularly because the grasshopper's small structural changes make it difficult to detect.

In another phase of the study, a ByteTrack-based multi-object tracking system was used to examine the behavior of detected objects in real-time scenarios. Test videos were processed frame by frame, assigning an ID to each grain, displaying detected classes with color codes, and examining tracking performance. This allowed evaluating whether the model demonstrated stability not only in static images but also in dynamic flows closer to the production line. As a

result of all these steps, YOLO models of different sizes and architectures were tested under the same training conditions to determine the most suitable model structure for detecting wheat weevils. The findings show that deep learning-based object detection models offer significant advantages over manual methods by providing high accuracy and speed in wheat quality control processes.

2.3. Multi Object Tracking

In this study, multi-object tracking (MOT) was applied after the object detection phase to evaluate the model's behavior in video-based processes [15]. For this purpose, the detection boxes produced by YOLO models were combined using the ByteTrack algorithm, and a unique ID was assigned to each wheat grain. The MOT process relies on associating detections across frames to ensure consistent tracking of the same object in consecutive frames. The flowchart for the Multi-Object Tracking process is shown in Figure 2.

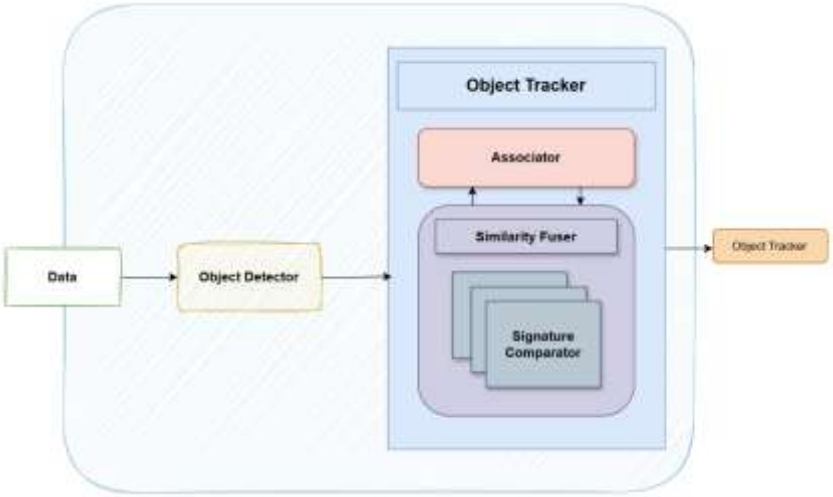

Figure 2. General MOT architecture that performs multi-object tracking by applying similarity computation and association steps after object detection.

In the method, test videos were first analyzed in terms of basic features such as frame rate (FPS), resolution, and total number of frames. Each frame was then sent to the YOLO model, which returned detection boxes containing class labels, location information, and confidence scores. These detections were passed to the ByteTrack tracker, which established relationships between objects based on criteria such as center position similarity, box overlap ratio, and confidence scores. This ensured that the same object was represented by the same ID across consecutive frames.

3. Experimental Result

In this study, YOLOv8, YOLOv11, and YOLOv12 models with different size variants (S/M/L) were evaluated to automatically detect the feeding damage caused by the sunn pest. Since the models were trained with the same hyperparameters, performance differences were ensured to originate solely from the architectural structure. The obtained results generally indicate that all models achieved high accuracy levels, but particularly the YOLOv12 and YOLOv11 architectures performed class discrimination more reliably.

The YOLOv12 family stood out as the best-performing group in the study. The YOLOv12l model presented the most balanced results with Precision=0.928, Recall=0.946, and mAP50=0.944 across all classes. In the “e” class (damaged grain), almost error-free detection

was achieved with 99.7% precision and 99.7% recall. Similarly, the YOLOv12m model also exhibited strong performance with mAP50=0.94. The lightweight variant YOLOv12s achieved high accuracy with mAP50=0.942 despite its small parameter size; this indicates that the architecture performs efficient feature extraction. The performance metric results of the YOLOv12 models are presented in Table 3.

Table 3. Performance comparison of YOLOv12 models based on mAP50, precision, and recall metrics.

Model/Metric	mAP50	Precision	Recall
YOLOv12s	0.942	0. 939	0.947
YOLOv12m	0.940	0.914	0.942
YOLOv12l	0.944	0.928	9.946

Among the YOLOv12 models, the YOLOv12l model achieved the highest accuracy. It surpassed all other models in terms of maAP50 and other metrics, both class-based and model generalization. Figure 3 shows the confusion matrix for the results obtained by the YOLOv12l architecture.

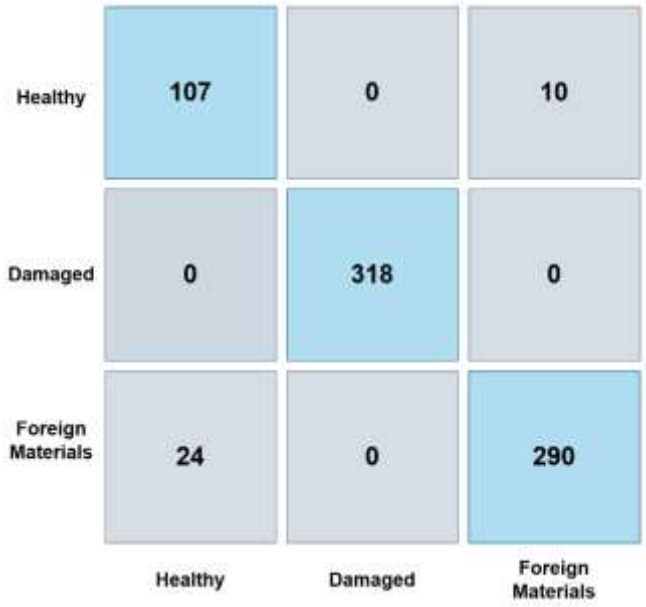

Figure 3. Confusion matrix presenting the overall prediction performance of the YOLOv12-L model.

The YOLOv11 models were the YOLO family that achieved the most successful results after the YOLOv12 models. In this group, the model that provided the highest accuracy rate was YOLOv11m. YOLOv11m reached extremely successful results, especially in detecting damaged grains, with Precision=0.993, Recall=0.997, and mAP50=0.992. The YOLOv11l model, on the other hand, constituted the second strongest model group of the study with mAP50=0.913 in overall performance. Although the YOLOv11s model is small in size, it

demonstrated a satisfactory performance with Precision=0.907. The performance metric results of the YOLOv11 models are presented in Table 4.

Table 4. Performance comparison of YOLOv11 models based on mAP50, precision, and recall metrics.

Model/Metric	mAP50	Precision	Recall
YOLOv11s	0.899	0.907	0.912
YOLOv11m	0.942	0.932	0.941
YOLOv11l	0.913	0.937	0.916

For comparison purposes, the YOLOv8 model lagged behind the other architectures in the study. The overall performance of YOLOv8 was realized as Precision=0.839, Recall=0.860, and mAP50=0.885. The low recall value particularly in the "damaged" class indicates that this architecture is more sensitive to class imbalances. On the other hand, achieving over 98% recall in the "healthy" class reveals that the model is successful in correctly identifying healthy grains. The performance evaluation metric results for YOLOv8 are presented in Table 5.

Table 5. Performance comparison of YOLOv8 model based on mAP50, precision, and recall metrics.

Model/Metric	mAP50	Precision	Recall
YOLOv8	0.885	0.839	0.860

When evaluated overall, it was observed that the YOLOv12 and YOLOv11 models demonstrated significantly superior performance compared to YOLOv8 in terms of both mAP values and class-based accuracy levels. In particular, YOLOv12l stood out as the most suitable model of the study with its balance between high accuracy and low computational cost. The results show that modern YOLO architectures can achieve high success in detecting small morphological changes such as sunn pest feeding damage and offer a fast, stable, and scalable solution compared to manual methods.

The model that achieved the highest accuracy during the training phase was integrated into the multi-object tracking (MOT) process in order to evaluate whether feeding damage could be tracked consistently under real-time conditions. In this context, the tracking system was created by combining YOLO's detection outputs with a ByteTrack-based tracker. The ByteTrack algorithm assigns a unique identity (ID) to each wheat grain by performing inter-frame association among high-confidence boxes while filtering out low-confidence boxes. Thus, the grains are tracked throughout the video, their physical movement is captured even if their class does not change, and the behavior of the grain over time can be recorded.

In the testing phase, the video uploaded by the user was first automatically analyzed in terms of frame count, resolution, and FPS values. Then, the YOLO model processed the video frame by frame, generating detection boxes, class labels, and tracking identities for each frame. With the color scheme defined in the code, the "healthy (s)," "damaged (e)," and "foreign material (y)" classes were visually distinguished; and both the class label and ID information were added to each detection box. An example frame from a tracking video is presented in Figure x. Thanks to this structure, even if the same grain appeared in different frames, it could be tracked

through the same ID, which provided the continuity information required in quality control production lines.

The newly generated frames were recombined into an MP4 output video and saved to evaluate the real-time performance of the model. An inference time of approximately 20–25 ms was obtained during the video processing phase, confirming that the model is suitable for real-time operation. The minimal occurrence of ID losses during tracking demonstrated that ByteTrack worked in harmony with YOLO and that the object association performance was high.

4. Discussion

In this study, the YOLO-based deep learning models used for the automatic detection of feeding damage caused by the sunn pest on wheat grains demonstrated a high level of accuracy in both static images and real-time video conditions. The experimental findings show that especially the YOLOv12 and YOLOv11 architectures possess strong discriminative capacity in classifying feeding damage. The nearly error-free detection of the “damaged” class by the YOLOv12m and YOLOv12l models reveals that the small morphological deteriorations on the wheat grain surface can be successfully captured by deep feature maps. In contrast, although YOLOv8 is competitive in overall accuracy, it lagged behind the most recent architectures in the study with a lower recall value particularly in the damaged class. This indicates that older YOLO architectures are limited in modeling complex surface deformations.

When the relationship between model size and accuracy is examined, it is seen that the YOLOv12 family offers a remarkable balance. Even the YOLOv12s model, which has a low number of parameters, achieved a high mAP50 value; this shows that the architecture provides strong representational capability even in lightweight variants. As the model size increased, an improvement in accuracy was observed, but the YOLOv12l model stood out as the most efficient option in terms of computational cost and performance. The YOLOv11 models also produced stable and high-accuracy results, particularly in the “healthy” and “foreign material” classes. These findings suggest that although architectural depth and parameter count have a significant effect, the most critical factor is the structural optimization of feature extraction and multi-scale detection layers used in the model.

The MOT and ID tracking results obtained under real-time scenarios demonstrated that the models also exhibited stable performance in dynamic environments. The tracking process performed with the ByteTrack algorithm showed that the grains could be followed across frames with high consistency, and ID losses occurred at a minimal level. This indicates that the developed system is applicable not only in laboratory settings but also in areas such as industrial quality control lines where continuous flow exists. Additionally, the uninterrupted preservation of class labels throughout the video enables the analysis of grain movement behavior in addition to feeding damage detection. Such a structure is expected to contribute to the early separation of damaged grains in the production line by being integrated with supply chain tracking systems. On the other hand, the study also has some limitations. The fact that the dataset was obtained under specific lighting conditions suggests that the model may require additional adaptations in different imaging environments. Similarly, feeding damage may appear with varying intensities on the surface, and the variability of class boundaries according to experts makes the annotation process difficult. However, the high performance of YOLOv12 models even under these challenging conditions demonstrates that the architecture is flexible against diversity.

Overall, the obtained findings reveal that deep learning–based object detection approaches have high potential in detecting complex microscopic damage types such as sunn pest feeding

damage. The developed system produced results with the speed, consistency, and accuracy capable of replacing manual inspection in agricultural quality control processes and can be further strengthened in the future with larger datasets, different lighting conditions, and multi-sensor data.

ABSTRACT

Identifying the morphology of galaxies is essential for comprehending their structural characteristics and evolutionary mechanisms. This assessment elucidates the evolution of the universe's large-scale structure by disclosing star formation rates, mass distribution, and galaxy interactions. This study introduces a hybrid methodology for the morphological categorization of galaxies by integrating EfficientNet and Vision Transformer models with SVM. The Galaxy Zoo 2 collection, comprising high-resolution and intricate galaxy pictures, was sourced from multiple origins and preprocessed for feature extraction. Prominent characteristics are derived from the dataset utilizing EfficientNet and ViT models and categorized using Support Vector Machines (SVM). The models' performance was assessed using accuracy, precision, recall, and F1-score. Other feature selection techniques, including ElasticNet (ENet), MRMR, Correlation (Corr), NCA, and Relieff, were utilized to refine the feature set before classification. The findings indicated that ENet consistently attained the maximum accuracy across various ViT and EfficientNet settings, with the ViT_large_32 model reaching an accuracy of 78.17%. The study indicates that EfficientNet models enhance processing speed, whereas ViT models augment classification performance by capturing more intricate information. Moreover, the pivotal function of feature selection algorithms in enhancing overall classification accuracy is underscored.

Keywords: Astronomical image, vision transformers, feature reduction

1. INTRODUCTION

1.1. Background

Research in space and astronomy is crucial to humanity's quest to comprehend the universe. Prolonged interest and curiosity in space have resulted in a growing number of studies in this domain. These studies elucidate the origin, structure, and future of the universe. Astronomy elucidates the universe's fundamental nature by examining stars, galaxies, planets, and other celestial entities. Conversely, space studies hold significant value for technology advancements and discoveries. Space exploration facilitates the advancement of innovative technology. Advanced research is conducted in satellite technologies, communication, meteorology, navigation, and environmental monitoring. Research in space and astronomy is crucial for humanity's future, contributing to scientific and technical advancements, and is regarded as a priority by global scientific communities.

The classification of astronomical images using artificial intelligence is transforming the domains of astrophysics and cosmology. The extensive data produced by telescopes and space observatories is beyond the capacity for analysis using conventional approaches. Analyzing and categorizing this data presents a significant possibility for enhanced comprehension of the universe. Nonetheless, the manual analysis of extensive data sets is arduous and time-intensive [1]. Incorporating artificial intelligence and deep learning methodologies enables astronomers to evaluate data more rapidly and effectively.

Artificial intelligence and deep learning models are crucial for the automated classification of astronomical data. Deep learning models facilitate identifying and categorizing galaxies, stars, planets, and other celestial entities, achieving far higher accuracy rates than conventional techniques. These models enable novel discoveries and enhance comprehension of the universe's structure. Consequently, deep learning and artificial intelligence-based categorization techniques substantially advance scientific endeavors by facilitating innovation and discoveries in astronomy. Deep learning techniques, particularly Convolutional Neural Networks (CNNs) and, more recently, Vision Transformer (ViT) models, have gained prominence in the classification of celestial imagery. CNNs yield superior outcomes in image data processing and feature extraction, but ViT models are adept at comprehending long-range relationships inside images. Moreover, integrating these models with diverse machine learning techniques, such as employing ViT for feature extraction and classification using models like SVM, significantly enhances classification accuracy in astronomical data. These advancements enable astronomical study to be more thorough and expedient, facilitating the finding of new insights into the cosmos.

The morphological classification of galaxies, based on their visual attributes and conducted in this work, is crucial in the domains of astronomy and astrophysics. This categorization offers insight into the universe's evolution by examining galaxies' structural features. The shapes, sizes, colors, and structural elements of galaxies (such as spiral arms, bar structures, and ring or lenticular forms) offer insights into their genesis and evolution. Morphological classification enhances our comprehension of galaxy formation, interactions, and evolutionary processes.

Morphological classification is a foundation for examining several features of galaxies, including their star formation rates, mass distributions, and the influence of supermassive black holes at their cores. Spiral galaxies are typically recognized for their elevated star formation rates, whereas elliptical galaxies have been noted to exhibit reduced star formation rates. This information evidences that galaxies exhibit remnants of historical mergers and interactions.

The morphological classification of galaxies is pivotal in cosmology. It is an essential instrument for comprehending the history and future of the universe.

1.2. Motivation

The morphological classification of galaxies has a lengthy research history in astronomy and astrophysics, significantly contributing to comprehending the universe's structure and dynamical features. The study of this domain commenced with Edwin Hubble's establishment of spiral, elliptical, and irregular classification systems for galaxies in the 1920s, subsequently advancing through the creation of more intricate and comprehensive classification frameworks. Hubble's fundamental categorization system offered the initial comprehensive framework based on the structural characteristics of galaxies, and numerous subsequent investigations have enhanced and refined it. Contemporary technology and telescopic views enable a more detailed examination of the morphological characteristics of galaxies, while computerized image processing and artificial intelligence methodologies have significantly expedited the classification process. This literature review thoroughly examines the historical evolution of the morphological classification of galaxies predicated on their visual characteristics, current methodologies, and recent progress in this domain.

In recent years, research has focused on utilizing deep learning methodologies for image analysis, classification of stars and galaxies, galactic morphology, and the identification of merging galaxies. Subsequently, comparisons were conducted among several deep learning models, and transfer learning research was applied to identify distinct issues. [2], [3], [4], [5], [6], [7], [8].

In 2021, Moonzarin Reza utilized Sloan Digital Sky Survey (SDSS) data and employed automated machine learning (AutoML) methodologies to categorize galaxy shapes [9]. The approach explicitly integrates neural networks and machine learning methods to address galactic mergers and other complex categorization challenges. The study achieved exceptionally high accuracy rates by analyzing artificial neural networks and techniques like ExtraTrees. The classification accuracy of artificial neural networks was 98.2%, whereas the ExtraTrees technique attained 97.5% accuracy. The results demonstrate the efficacy of AutoML in galaxy classification. In a 2022 study, Şenel employed CNN for the morphological classification of galaxies [10]. The research utilized the Galaxy10 dataset from the Sloan Digital Sky Survey. To enhance the performance of the CNN, three distinct meta-heuristic methods were employed: Grey Wolf Optimizer (GWO), Particle Swarm Optimization (PSO), and Artificial Bee Colony (ABC). The study's results indicated that the highest accuracy rate was achieved with GWO. This approach achieved an accuracy rate of 85% on the test data and 93% on the training data. In comparison to alternative algorithms, they yielded the most successful outcomes.

In 2022, Eassa et al. performed morphological classification research by examining the luminosity data from the pictures of galaxies in the EFIGI dataset [11]. Their suggested algorithm employs an innovative brightness thresholding technique to pinpoint the centers and areas of galaxies, subsequently classifying them according to brightness changes. Upon conclusion of the trial, a success rate of 97.2% was attained. The average time taken to classify each galaxy was 0.37 seconds. In a separate study from the same year, Kwik et al. examined the components of the UGC 2885 galaxy utilizing machine learning [12]. The research sought to categorize distinct elements (young star population, old star population, dust lanes, galactic center, outer disk, and sky background) of a substantial spiral galaxy such as UGC 2885 at the pixel level. The Maximum Likelihood Classifier (MLC), Random Forest (RF), and Support Vector Machines (SVM) were employed for this objective. The SVM model demonstrated the

highest performance, achieving an accuracy of 84.9%. The RF model attained 82.6%, while the MLC model exhibited the least success relative to the others. The work presents a new approach highlighting the significance of textural properties for improved classification of small-scale cosmic formations.

In 2023, Wang et al. categorized over 49,000 emission line galaxies recorded by the Large Sky Area Multi-Object Fiber Spectroscopic Telescope (LAMOST) [13]. Four distinct machine-learning techniques were employed for the spectral classification of galaxies: Multi-Layer Perceptron (MLP), Support Vector Machines (SVM), K-Nearest Neighbor (KNN), and Random Forest (RF). The classification approach utilized spectral flux pixels surrounding frequently employed emission lines as the feature space. The results indicate that MLP achieved the highest accuracy rate of 92.31%. The studies are summarized in Table 1.

In 2024, Xue-qi et al. concentrated on the automated identification of Low Surface Brightness Galaxies (LSBGs) via the YOLOX-CS algorithm [14]. The study evaluated five distinct classical target identification methods for identifying LSBGs, which exhibited enhanced performance relative to these algorithms. The use of DCGAN yielded a recall of 97.75% and an average precision of 97.83% on augmented datasets. The findings indicate that the YOLOX-CS algorithm is an effective approach for identifying LSBGs and is applicable in extensive sky surveys.

1.3. Contributions

This study's primary contributions can be encapsulated as follows:

- Vision Transformer (ViT) models were employed for direct classification and feature extraction, demonstrating enhanced classification accuracy relative to EfficientNet models.
- Feature selection was conducted on the features extracted with ViT utilizing ElasticNet, followed by SVM classification. This procedure markedly lowered the dimensionality of the feature space while enhancing both precision and processing efficiency.
- The amalgamation of ViT, ElasticNet's feature selection, and SVM's classification techniques enhanced classification efficiency, yielding excellent accuracy rates while markedly decreasing processing durations.

This study offers a significant methodological framework to investigate and enhance the integration of deep learning and machine learning techniques for galaxy morphology classification. It presents a thorough approach that enhances feature extraction and classification in terms of efficiency and precision.

1.4. Organization

The initial segment of the study discusses space and astronomy research while summarizing relevant material. The second section elucidates the data set employed in the study and the methodologies utilized. This section provides a detailed explanation of the study's planned methodology. The third section delineates the experimental results derived from the investigation. Ultimately, a summary and prospective studies are addressed.

2. MATERIALS AND METHOD

2.1. Dataset

This study utilized the Galaxy Zoo 2 dataset [15]. Galaxy Zoo 2 is a publicly accessible dataset utilized for astronomical study, concentrating on the morphological classification of galaxies. The Galaxy Zoo 2 initiative facilitates the categorization of galaxy photographs by volunteer citizen scientists. The data is from the Sloan Digital Sky Survey (SDSS) pictures. This project builds upon Galaxy Zoo and has been enhanced to investigate further the galaxies observed in the universe. The Sloan Digital Sky Survey (SDSS) is an initiative that has surveyed an extensive portion of the sky and documented millions of galaxies. Galaxy Zoo 2 utilizes high-resolution photos from the SDSS.

The project comprises photos of over 300,000 galaxies. These galaxies typically possess a redshift value below 0.25, indicating their proximity to us. Volunteers worldwide have researched and classified the galaxies in Galaxy Zoo 2. Volunteers assist in identifying the morphological traits of each galaxy. Users categorize galaxies into distinct classifications. The primary morphological types encompass spiral, elliptical, lenticular, and irregular forms. Furthermore, classifications extend beyond fundamental categories. Volunteers have also discerned intricate characteristics such as bar structure in barred spiral galaxies, the quantity and direction of spiral arms, core density, and collision signs.

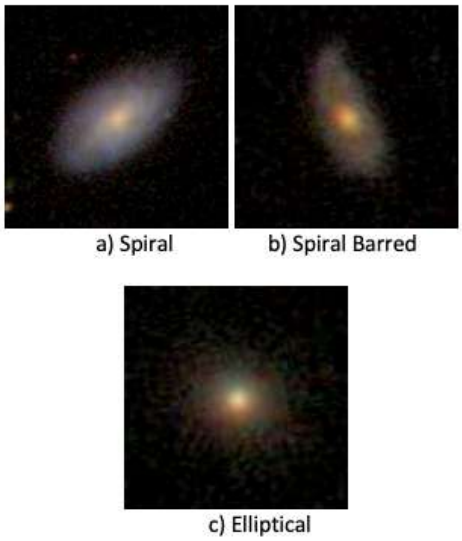

Figure 1. *Samples of Dataset*

The dataset included in the study comprises three classes: elliptical, spiral, and barred spiral. The classifications are categorized according to the morphological classification of the galaxies. Elliptical galaxies possess a round or oval morphology. They typically contain less dust. Minimal to no new stellar formation occurs. Aged stars characterize them and lack discernible structural features. Spiral galaxies possess a disk configuration featuring a central nucleus and spiraling arms that revolve around it. New star formation is typically vigorous, and these galaxies comprise both ancient and youthful stars. Barred spiral galaxies resemble spiral galaxies yet possess a bar traversing the central core. This bar spreads radially from the galactic center outward. Spiral arms radiate from the termini of this bar. These classifications are extensively employed in the Hubble sequence to delineate the morphological characteristics of galaxies. Although the aggregate data across three classes is substantial, it was standardized to 9,000 entries per class to ensure equilibrium in the dataset utilized for the study.

2.2. Feature Extraction with EfficientNet and Vision Transformers

2.2.1. EfficientNet

Google developed EfficientNet, a deep learning model based on Convolutional Neural Networks (CNN). The model scales proportionately with three primary parameters: width, depth, and resolution. This yields a more efficient architecture while simultaneously attaining elevated accuracy rates. EfficientNet is a network architecture that demands reduced computational resources while delivering superior performance via optimal utilization of model parameters.

The EfficientNet design consists of a series of MBConv blocks built and enhanced from the MobileNetV2 architecture [16], [17]. The latest iteration of the EfficientNet model is V2. This study employs the EfficientNet V2 Small, EfficientNet V2 Medium, and EfficientNet V2 Large models. EfficientNet V2 Small represents the smallest variant within the V2 family. This model is optimized for limited data sets and reduced computational power demands. In contrast to the original EfficientNet, the EfficientNet V2 series provides expedited and more efficient training with training-aware neural architecture search (NAS). EfficientNet V2 Small is distinguished by its rapid training duration and minimal computing expense while delivering acceptable accuracy on extensive data sets. The mid-tier variant of the EfficientNet V2 family is the EfficientNet V2 Medium model. This model delivers an equilibrium of computing

capability and precision. The model featuring increased layers and width delivers a harmonious performance regarding accuracy and computational duration and is employed in applications like categorization and object identification. EfficientNet V2 Large is the most substantial model within the series. Its extensive architecture is geared for processing high-resolution photos and extracting intricate features. This work employs the EfficientNet architecture to examine the dataset's high-dimensional and complicated structure through comprehensive feature extraction. This method yields a high accuracy rate in the classification of galaxy morphology.

2.2.2. Vision Transformers (ViTs)

Vision Transformers employ a purely transformer design rather than convolutional neural networks for computer vision tasks, including picture categorization. Transformer models were originally designed for natural language processing (NLP) problems, and the ViT model has effectively applied this architecture to image processing. The primary distinction is that rather than generating feature maps as in conventional CNNs, ViT segments images into patches, treats each patch as an array, and subsequently inputs these arrays into the transformer layers accordingly [18].

ViT segments the input image into small patches of predetermined dimensions. This procedure is referred to as Patch Embedding. Each particle is depicted as a collection of vectors analogous to word vectors in conventional natural language processing. A 224x224 pixel image is segmented into 196 segments of 16x16 pixels. The image segments are augmented with positional data to align with the transformer models' inherent sequential processing framework [19]. The location of each segment conveys critical information for the model to comprehend the interrelations among the segments.

The primary element of transformers is the multi-head self-attention mechanism [20]. This method acquires significant information by focusing on various areas of the image. These layers ascertain the interrelations among image segments and progressively refine the derived attributes. After the transformer layers, the output is directed to a classification layer. This layer generates an output that signifies the class labels.

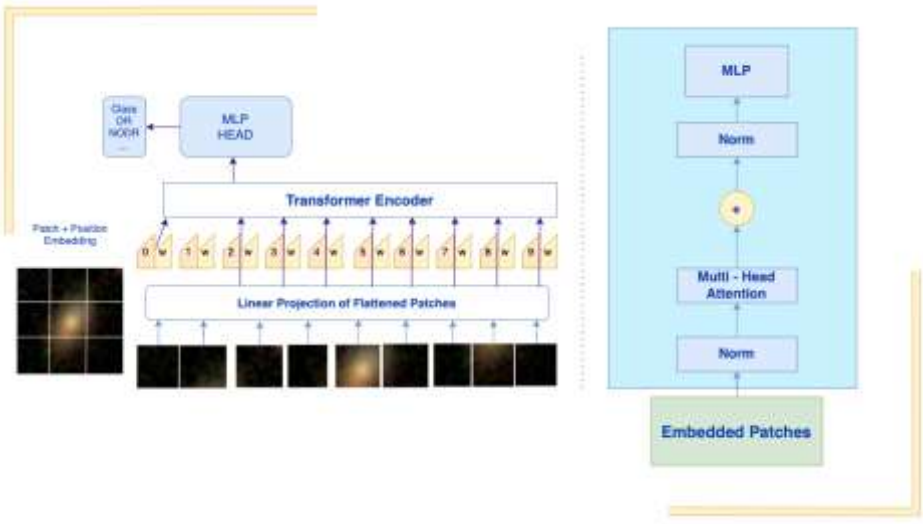

Figure 2. *Architecture of ViT*

The ViT models employed in the study vary in size, each optimized for a particular resolution and dimension. The study employs two distinct ViT architectures: ViT Base 16/32 and ViT

Large 16/32. ViT Base is one of the fundamental iterations within the ViT family. This model segments the input image into small blocks of 16x16 and 32x32 and processes each block through transformer layers. This model possesses limited parameters and is efficient for small to medium-sized datasets. It is mainly utilized in classification tasks that want high precision but do not demand extensive data sets. The ViT Large model is an expanded version of the model. It is optimized for extensive data sets and incorporates additional parameters.

2.3. Feature Selection with ElasticNet

Feature selection is a technique that aims to eliminate redundant or low information value features from a data set. The process aims to simplify the model and reduce the computational cost while improving the performance of the model. Redundant features can cause noise in the model's learning process, leading to model overfitting and reduced accuracy. Feature selection increases the accuracy and reduces the processing time by working with less but meaningful data.

In this study, feature selection is necessary because of the large number of features extracted with ViT models. ViT models are capable of extracting high-dimensional and detailed features for the morphological classification of galaxies. However, including all of these features in the classification model increases the computational cost and may lead to overfitting of the model. In particular, the features extracted by powerful models such as ViT can be very large and complex, leading to the inclusion of redundant or low-information features.

This work employed ElasticNet to minimize the feature set derived from ViT, retaining only the most significant characteristics of the model. ElasticNet regulates the high correlation among features, identifies the most significant ones, and incorporates superfluous features, hence enhancing the model's efficiency and performance. Consequently, only the features retrieved with ViT that significantly enhance classification have been picked, resulting in a substantial reduction in processing time and an improvement in classification accuracy.

ElasticNet is a linear regression model employed for feature selection and regression tasks. It functions as an amalgamation of Lasso (L1 norm) and Ridge (L2 norm) regressions [21]. ElasticNet mitigates the limitations of Lasso in the presence of significant data correlation, hence yielding a more resilient model. ElasticNet employs both L1 and L2 penalties, enabling stringent constraints on feature selection while permitting minor yet significant characteristics to persist in the model. The punitive procedure employs a blend of L1 and L2 norms, resulting in the reduction of certain model features to zero while retaining others, thereby eliminating superfluous parameters and preserving just the essential ones. The primary purpose of employing ElasticNet in the study is to efficiently select high-dimensional characteristics derived from the ViT model and exclude superfluous ones. The application of ElasticNet has diminished the number of features derived from ViT, enhancing the model's speed and efficiency while reducing processing time and complexity.

2.4. Classification with Support Vector Machine (SVM)

Classification is the process of categorizing items or observations within a collection into specific classes. Classifying each image in a dataset into categories, such as "galaxy" or "star," constitutes a classification task. Classification is employed to interpret data and facilitate automatic processing, playing a crucial role, particularly in image processing, medical diagnostics, biometric recognition, and various other domains. Classification algorithms forecast new data based on acquired characteristics, hence expediting and automating decision-making processes. This study utilized EfficientNet and ViT models to extract attributes for the categorization of galaxy morphological characteristics, which were further classified using

Support Vector Machines (SVM). This study employed classification to ascertain the morphological class of each galaxies based on the data analysis. The ViT and EfficientNet models extracted intricate and high-dimensional information from the photos, enabling the classification algorithms to categorize the galaxies into distinct morphological classes. The categorization method has facilitated the efficient processing of big datasets through precise and rapid predictions.

Support Vector Machine (SVM) is a supervised learning technique commonly employed in classification tasks. SVM seeks to identify the broadest margin between the data to separate it into two distinct classes. This marginal December is referred to as the hyperplane, which delineates the data. Support vectors are the nearest data points to the hyperplane and dictate categorization outcomes [23]. This study favors SVM for classifying attributes derived from EfficientNet and ViT models. The ViT and EfficientNet models meticulously extracted the morphological characteristics of the galaxies, while the SVM facilitated the categorization of this higher-dimensional data with greater efficiency and accuracy. Support Vector Machines (SVM) are favored for their rapid and precise classification capabilities, particularly in extensive and intricate data sets. The kernel functions of the SVM have significantly enhanced the categorization of nonlinear and complex galaxy data. The kernel functions of SVM have offered an optimal approach for identifying nuanced distinctions among galaxies, enhancing the Declaration process's speed and efficiency.

2.5. Proposed Method

This work proposes a method that integrates deep learning with classic machine learning approaches for the morphological categorization of galaxies. Currently, deep learning models are employed to get elevated accuracy levels in intricate tasks such as picture classification and feature extraction. Nonetheless, in the context of high-dimensional and intricate datasets, redundant or excessively informative features might detrimentally impact model performance. Consequently, an extra feature selection and classification phase is necessary for the more effective processing of features derived from deep learning models. This study optimizes features extracted by deep learning models, including EfficientNet and ViT, utilizing SVM and ElasticNet to enhance classification accuracy. Figure 3 presents a summary of the work.

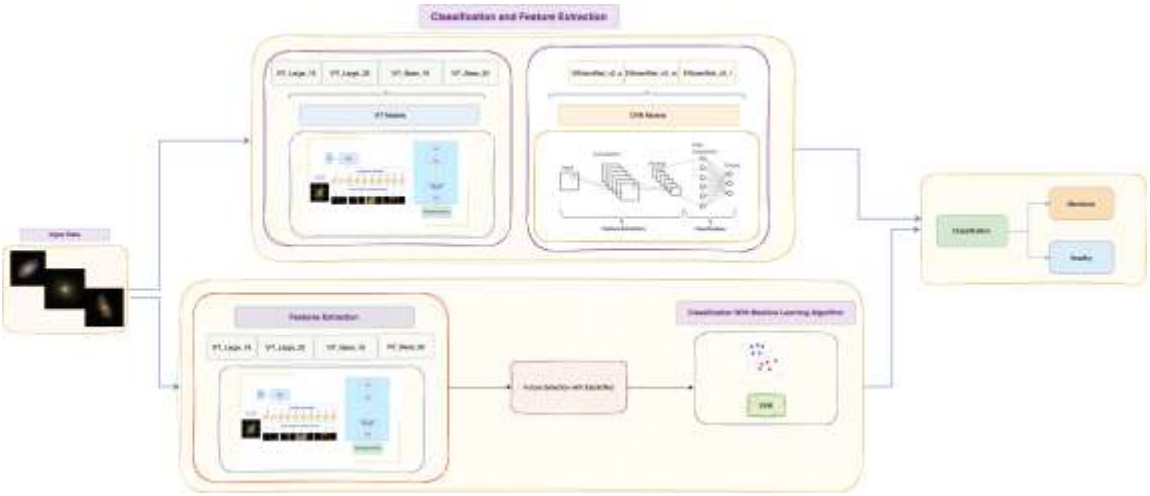

Figure 3. *Proposed Method*

The morphological classification of the galaxies was conducted utilizing EfficientNet and ViT models. EfficientNet models provide an effective classification mechanism by proportionately

scaling breadth, depth, and resolution. These models examine visual details with great precision by extracting features from several layers of the data. The classification performance and processing time of various EfficientNet versions (B7, V2 S, V2 M, V2 L) were assessed. At this juncture, the classification accuracy of each model was evaluated to ascertain which model yields more effective outcomes. Conversely, ViT models analyze images in segments, transforming each segment into an array and deriving characteristics from these arrays through a multi-head attention mechanism. ViT yields successful outcomes in intricate data sets, particularly because of its capacity to comprehend long-range relationships. Both EfficientNet and ViT models attained elevated accuracy rates in the classification task; however, ViT demonstrated enhanced performance on bigger and more intricate data sets. This phase illustrated the efficacy and precision of the deep learning models employed for the fundamental classification procedure.

Subsequently, deep learning models, including EfficientNet and ViT, are employed for feature extraction on the galaxy morphology dataset. EfficientNet and ViT models excel at extracting intricate features from high-resolution and complex images. EfficientNet is an efficient convolutional neural network, whereas ViT is founded on transformers and adept at learning long-range dependencies. The features derived from these two models are utilized to interpret the morphological structure of the images.

Subsequent to feature extraction, these features were classified using Support Vector Machine (SVM) methodology. Support Vector Machine (SVM) is a classification technique that excels in high-dimensional data scenarios. The intricate and high-dimensional features derived by ViT and EfficientNet were categorized with greater efficiency and accuracy. Due to the potential poor information value or noise of many retrieved features in the dataset, feature selection was conducted using ElasticNet. ElasticNet integrates Lasso and Ridge regression techniques, enhancing performance by removing redundant features while retaining significant ones in the model. This is an essential measure to enhance the model's speed while simultaneously improving classification accuracy.

The features identified by ElasticNet are subsequently classed using SVM. This procedure enhances categorization by enabling the model to utilize fewer, however more significant, characteristics. The ultimate classification phase is to precisely categorize the morphological structures of the galaxies. This approach integrates deep learning and machine learning techniques, facilitating precise classification of extensive and intricate datasets.

3. EXPERIMENTAL RESULTS

This research examines the efficacy of EfficientNet and ViT models in a galaxy morphological classification problem. The discussion focuses on the comparison of accuracy rates, processing speeds, and overall efficiency of both models, particularly the impact of feature selection and classification using ElasticNet on model performance. The study findings elucidate the benefits and drawbacks of various methodologies and specify which methodology yields the most favorable outcomes.

The initial phase of the project employed EfficientNet models to conduct traditional classification on the galaxy morphology dataset. Table 2 presents the accuracy rates and processing speeds of the three distinct EfficientNet models. This data allows for comparing the models' efficient categorization capabilities and performance.

Table 2. *Traditional Classification Results with EfficientNet Models*

	EffcientNet_v2_s	EffcientNet_v2_m	EffcientNet_v2_l
Accuracy (%)	75.64%	61.13%	77.1%
Time (sec)	18850 sec	32500 sec	60750 sec

The galaxy morphology dataset comprises a sophisticated collection of high-resolution photographs. EfficientNet models are optimized deep learning architectures intended to classify intricate pictures. EfficientNet models aim to enhance both efficiency and accuracy by optimizing parameters, including width, depth, and resolution. The dataset utilized in this work comprises a vast and varied collection of photos, rendering precise classification rather difficult. Consequently, the efficacy of any model is of paramount significance.

Table 1 presents the outcomes of the conventional categorization employing EfficientNet models in the initial part of the investigation. The accuracy rate and processing time are evaluated for each model. The dataset employed for the morphological categorization of galaxies comprises intricate and high-resolution photos. EfficientNet models exhibit varying performance in classification tasks in terms of accuracy and processing time. The Efficient_v2_s model demonstrates a reasonable performance, with an accuracy of 75.64%. The model accurately classifies the photos in the dataset but exhibits marginally inferior performance relative to other models that attain superior accuracy. This model exhibits rapid processing capabilities, yielding results more swiftly than larger models, with a completion time of 18,850 seconds. The EfficientNet_v2_m model had the lowest accuracy, with 61.13%. The diminished accuracy signifies that the model encounters difficulties in comprehending the intricate structures within the dataset, resulting in subpar performance on the classification job. The processing duration is 32,500 seconds, exceeding that of the EfficientNet_v2_s model, although the accuracy is inferior. This indicates that the model lacks efficiency. The EfficientNet_v2_l model exhibits the greatest accuracy rate of 77.1%. This indicates that the model is more proficient at processing and classifying the dataset. Nonetheless, this enhanced precision is accompanied by an extended processing duration. The processing duration is 60,750 seconds, indicating that this model possesses a complicated and intricate architecture. The model's elevated correctness necessitates increased resources regarding computational expense and duration.

The EfficientNet models provide varying degrees of accuracy and processing durations on this dataset. The EfficientNet_v2_l model provides the greatest accuracy but has the longest processing duration. Conversely, EfficientNet_v2_s is the most rapid model regarding processing time and provides modest accuracy. EfficientNet_v2_m is the least efficient model, exhibiting both diminished accuracy and comparatively extended processing duration. Table 2 delineates the strengths and drawbacks of each model, facilitating the selection of the appropriate model for classification tasks.

Table 3. *EfficientNet Evaluation Metrics Results*

	EffcientNet_v2_s	EffcientNet_v2_m	EffcientNet_v2_l
Precision	91.24%	82.36%	90.34%
Recall	81.89%	69.97%	84.47%
F1 – Score	86.3%	75.65%	87.3%

The evaluation findings in Table 3 indicate that the EfficientNet_v2_s model has a balanced performance, achieving 91.24% precision and 81.89% recall, with an F1-score of 86.3%. The EfficientNet_v2_m model exhibits the lowest performance, achieving a precision of 82.36%, a recall of 69.97%, and an F1 score of 75.65%. The EfficientNet_v2_l model has the greatest F1 score at 87.3%, with a precision of 90.34% and a recall of 84.47%. The results indicate that the EfficientNet_v2_l model provides superior accuracy and stability, while the EfficientNet_v2_m model exhibits subpar performance.

The complexity matrices of the data acquired in the investigation are illustrated in Figure 4.

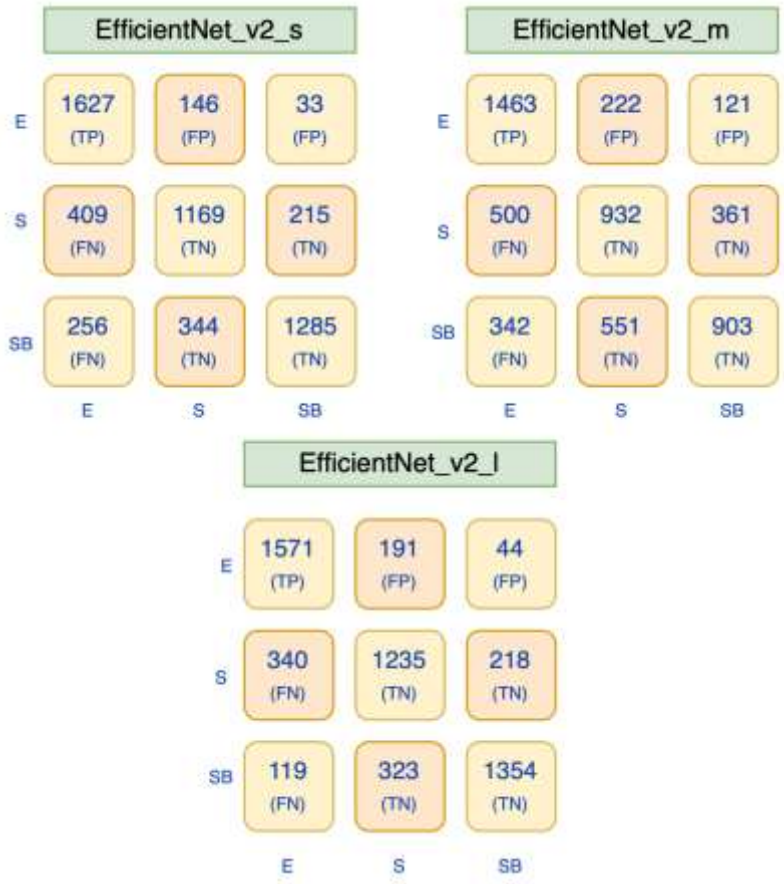

Figure 4. *Confusion Matrices of EfficientNet Traditional Classification*

In the subsequent phase of this project, EfficientNet models were employed for classification and extracting significant features from the dataset. EfficientNet's intricate layered architecture meticulously examined the physical characteristics of the galaxies and derived high-dimensional, rich feature vectors from each image. The features obtained at this stage are subsequently employed in the classification phase via a machine learning method known as SVM to enhance model performance. The feature extraction by EfficientNet enhanced the model's comprehension of intricate aspects in the dataset, hence augmenting overall classification accuracy.

In the subsequent phase of this project, EfficientNet models were employed for classification and extracting significant features from the dataset. EfficientNet's intricate layered architecture meticulously examined the physical characteristics of the galaxies and derived high-dimensional, rich feature vectors from each image. The features obtained at this stage are subsequently employed in the classification phase via a machine learning method known as

SVM to enhance model performance. The feature extraction by EfficientNet enhanced the model's comprehension of intricate aspects inside the dataset, hence augmenting overall classification accuracy.

Table 4 illustrates that the features extracted using EfficientNet models were classified with SVM, including the accuracy rates and processing times for each model. The EfficientNet_v2_s model exhibits the least performance, with an accuracy of 67.36%. Nonetheless, the processing duration is the most prolonged at 11558. This outcome suggests that the extended runtime of the model, notwithstanding its diminished accuracy, is attributable to the intricacy of the feature extraction procedure. The EfficientNet_v2_m model achieved an accuracy rate of 67.61% and exhibited the fastest processing time at 4071.80 seconds. The model's inability to deliver high accuracy despite its rapid execution indicates that the derived features may lack sufficient discriminative power. The EfficientNet_v2_l model had the highest performance, with an accuracy of 69.44%. The processing speed of this model is exceptionally rapid at 3991 seconds. The results indicate that the EfficientNet_v2_l model yields greater accuracy in a shorter duration, albeit its increased complexity.

Table 4. *EfficientNet ile özellik seçimi ve SVM sınıflandırma*

	EffcientNet_v2_s	**EffcientNet_v2_m**	**EffcientNet_v2_l**
Accuracy (%)	67.36%	67.61%	69.44%
Time (sec)	11558 sec	4071.80 sec	3991 sec

The high-resolution and complicated nature of the galaxy morphology dataset utilized in this study renders the feature extraction efficacy of EfficientNet models crucial. Specifically, EfficientNet_v2_l epitomizes the best balanced and efficient model regarding accuracy and processing time.

Table 5. *Evaluation Metrics Results of EfficientNet Feature Extraction and SVM Classification*

	EffcientNet_v2_s	**EffcientNet_v2_m**	**EffcientNet_v2_l**
Precision	67.1%	67.35%	69.44%
Recall	67.36%	67.61%	69.43%
F1 – Score	66.94%	67.08%	69.43%

Table 5 presents the precision, recall, and F1-score metrics achieved following feature extraction using EfficientNet models and classification by SVM. The EfficientNet_v2_s model attained a precision of 67.1%, a recall of 67.36%, and an F1 score of 66.94%. The EfficientNet_v2_m model yielded marginally more balanced outcomes, achieving 67.35% precision, 67.61% recall, and 67.08% F1-score. The EfficientNet_v2_l model achieved the highest performance with 69.44% precision, 69.43% recall, and a 69.43% F1 score. The results indicate that the EfficientNet_v2_l model excels in feature extraction and classification, yielding more balanced outcomes relative to other models. Figure 5 illustrates the confusion matrix of the investigation.

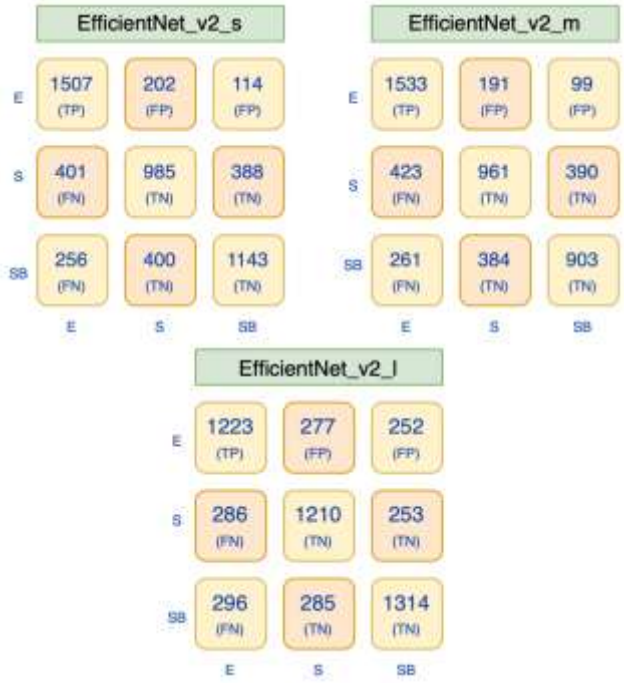

Figure 5. *Confusion Matrices of EfficientNet Feature Extraction and SVM Classification*

In another segment of the investigation, conventional categorization was conducted utilizing ViT models. Table 6 presents the classification outcomes of this segment of the investigation. The accuracy rate and processing time are evaluated for each model. The dataset of galaxy morphology comprises high-resolution and intricate photos. ViT models employ a transformer-based methodology to examine this information and achieve precise classifications. The ViT_base_16 model has the best accuracy and effectively classifies the photos within the dataset. The processing time of this model is considerable (40,700 seconds), indicating that its intricate architecture and complicated transformer design incur substantial computational expenses. The ViT_base_32 model exhibits marginally inferior performance on the classification challenge, with an accuracy of 70.43%. Nonetheless, the processing time is relatively swift (13150 seconds), suggesting that the model possesses a streamlined architecture capable of yielding quicker outcomes. Reduced accuracy indicates that the model captures less detail; however, its speed advantage renders it preferable for some projects. The ViT_large_16 model exhibits an accuracy of 70.47%, comparable to that of the ViT_base_32 model. Nonetheless, the processing duration is rather lengthy (131,700 seconds). This outcome indicates that the model is inadequate regarding accuracy and necessitates considerable processing time. Consequently, it does not provide optimal performance regarding accuracy and processing time. The ViT_large_32 model attains an accuracy of 74.51% and operates more swiftly than the ViT_large_16 model (44700 seconds). This model provides a harmonious performance regarding precision and processing duration, rendering it an appropriate choice for extensive datasets.

Table 6. *Traditional Classification Results with ViT Models*

	ViT_base_16	ViT_base_32	ViT_large_16	ViT_large_32
Accuracy (%)	77.07%	70.43%	70.47%	74.51%
Time (sec)	40700 sec	13150 sec	131700 sec	44700 sec

ViT models possess the ability to capture long-range correlations through transformer design on these datasets. The ViT_base_16 model exhibits the maximum accuracy; nonetheless, it incurs significant processing time costs. The ViT_base_32 type operates at the highest speed, but with marginally reduced accuracy, yet it offers the benefit of rapid performance. ViT_large_32 provides a more equitable performance, yielding satisfactory outcomes in both accuracy and processing duration.

Table 7. *ViT Traditional Classification Evaluation Metrics Results*

	ViT_base_16	ViT_base_32	ViT_large_16	ViT_large_32
Precision	77.63%	70.43%	70.47%	74.5%
Recall	77%	72.3%	71.2%	75.07%
F1 – Score	77.31%	71.35%	70.83%	74.78%

The outcomes presented in Table 7 are assessed based on the precision, recall, and F1-score metrics of conventional classification utilizing ViT models. The ViT_base_16 model exhibits the highest F1-score of 77.31%, with precision at 77.63% and recall at 77%. The ViT_base_32 model achieves an F1 score of 71.35%, with a precision of 70.43% and a recall of 72.3%. The ViT_large_16 model attained an F1-score of 70.83%, with precision at 70.47% and recall at 71.2%. The ViT_large_32 model demonstrated a balanced performance, achieving a 74.78% F1-score, with 74.5% precision and 75.07% recall. The results indicate that ViT models exhibit varying capabilities in terms of precision and recall, with the ViT_base_16 model achieving the highest overall F1 score. The confusion matrices are depicted in Figure 6.

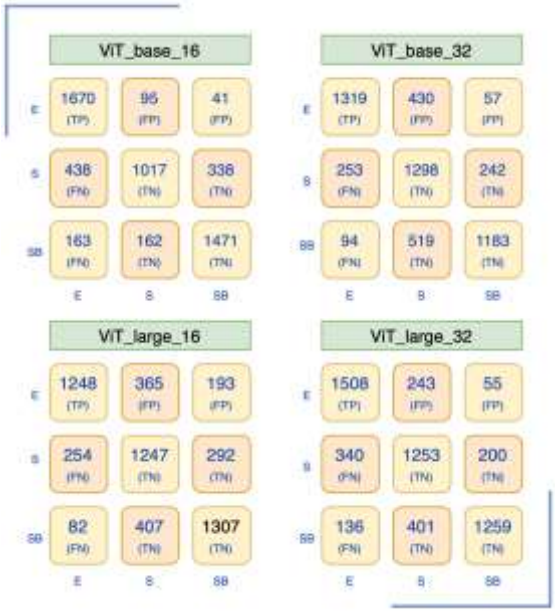

Figure 6. *Confusion Matrices of ViT Traditional Classification*

In another segment of the investigation, ViT models were employed for feature extraction. Table 7 presents the accuracy rates and processing durations derived from feature extraction utilizing ViT models and the subsequent categorization of these features with SVM. ViT models were utilized with SVM to extract features from intricate and high-dimensional images, facilitating faster and more efficient classification of these features.

The ViT_base_16 model exhibits modest performance, with an accuracy of 69.42%. The precision in feature extraction is satisfactory, if not exceptional. The processing time is longer than that of the other models (23834.67 seconds) due to the model's intricate structure and processing capabilities. The ViT_base_32 model has the lowest performance, achieving an accuracy of 66.72%. Nonetheless, its processing time is relatively swift (18559 seconds), indicating its suitability for tasks necessitating expedited results, but with marginally reduced accuracy. Despite its lack of accuracy, it is beneficial in scenarios that need rapidity. The ViT_large_16 model exhibits an accuracy of 69.05, which is comparable to that of the base models. The processing duration is also rapid (18559 seconds). This model delivers a harmonious performance regarding accuracy and processing duration, yielding beneficial outcomes within a realistic timeframe for extensive data sets. The ViT_large_32 model exhibits an accuracy of 66.68, comparable to that of the ViT_base_32 model. Despite being the largest configuration, this model has low accuracy. The processing duration is notably rapid (18559 seconds), facilitating prompt outcomes on intricate data.

Table 7. *Evaluation Metrics Results of ViT Feature Extraction and SVM Classification*

	ViT_base_16	**ViT_base_32**	**ViT_large_16**	**ViT_large_32**
Accuracy (%)	69.42%	66.72%	69.05%	66.68%
Time (sec)	23834.67 sec	18559 sec	18559 sec	18559 sec

The table illustrates that feature extraction using ViT models and classification via SVM are designed to enhance processing efficiency. Although the ViT_base 16 model achieves the maximum accuracy, its processing time exceeds that of the other models. The ViT_large_16 and ViT_large_32 models exhibit inferior accuracy compared to the ViT_base_16, despite their superior processing speeds. These findings can assist in selecting the appropriate model for tasks necessitating a balance between speed and precision.

Table 8. *Evaluation Metrics Results of ViT Feature Extraction and SVM Classification*

	ViT_base_16	**ViT_base_32**	**ViT_large_16**	**ViT_large_32**
Precision	69.2%	66.44%	66.44%	66.44%
Recall	69.42%	66.72%	66.72%	66.72%
F1 – Score	69.01%	66.32%	66.32%	66.32%

Table 8 presents the precision, recall, and F1-score metrics achieved following feature extraction using ViT models and classification by SVM. The ViT_base_16 model achieved the greatest F1 score of 69.01%, with a precision of 69.2% and a recall of 69.42%. The ViT_base_32, ViT_large16, and ViT_large_32 models produced comparable outcomes, achieving a precision of 66.44%, a recall of 66.72%, and an F1-score of 66.32%. The results indicate that the ViT_base_16 model demonstrates marginally superior performance compared to the other models, which exhibit comparable performance levels among themselves. The

primary explanation for the comparable performance of SVM in classifications with ViT models is because the characteristics derived from ViT models are highly analogous. The features derived from various ViT configurations are handled in a comparable manner by the SVM, and once the SVM attains a specific accuracy on high-dimensional data, minor model variations have minimal impact on performance. Moreover, the propensity of the SVM's kernel function to categorize analogous data similarly may contribute to the resemblance of the outcomes. The dataset's complexity, together with the analogous complexity of characteristics extracted by ViT models, also contributes to this issue.

The SVM is essential in this work for the rapid and precise classification of characteristics extracted by the ViT models. Support Vector Machines (SVM) facilitated the attainment of accuracies between 66% and 69% due to its proficiency in precise categorization, concurrently optimizing processing durations. The integration of ViT with SVM yielded precise and effective classification outcomes on extensive and intricate datasets. Figure 7 displays the confusion matrices of the investigation.

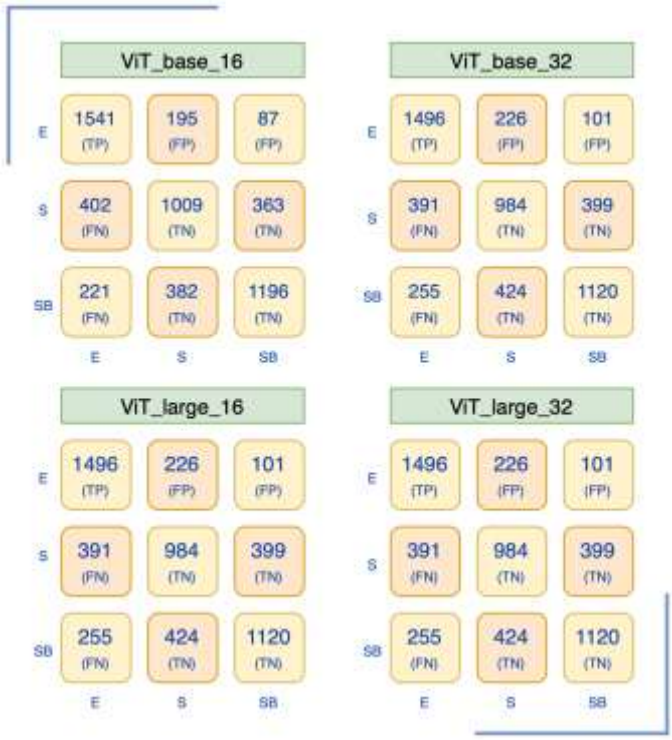

Figure 7. *Confusion Matrices of ViT Feature Extraction and SVM Classification*

In the final phase of the investigation, the features derived from the ViT models were categorized using the SVM algorithm in conjunction with several feature selection methods. Table 9 presents the accuracy ratios of features derived from the ViT models, optimized with various feature selection procedures and classed with SVM. The ViT_base_16 model attained the best accuracy of 69.94% with ElasticNet (ENet), whereas the lowest accuracy of 68.22% was obtained with the MRMR method. A like tendency was noted in the ViT_base_32 model, wherein the Enet method yielded the optimal results at 77.32%. This demonstrates Enet's efficacy in feature selection, discarding superfluous elements while retaining the essential ones. Other algorithms, particularly Corr and Relieff, exhibited comparatively low accuracy rates in the ViT_base_32 model, indicating that certain algorithms are inadequate for complicated data analysis.

Table 9. *Feature Selection results*

	ViT_base_16	ViT_base_32	ViT_large_16	ViT_large_32
Corr	69.23%	73.11%	68.33%	74.72%
ENet	69.94%	77.32%	70.19%	78.17%
MRMR	68.22%	72.38%	68.57%	74.62%
NCA	69.57%	73.08%	69.1%	75.99%
Relieff	68.44%	72.2%	68.22%	72.2%

The ViT_large_16 and ViT_large_32 models attained the best accuracies with Enet. ViT_large_32 exhibits the highest accuracy of 78.17 among all models. This outcome validates the efficacy of Enet on extensive and intricate datasets, demonstrating superior performance in classification with SVM. Among the various algorithms, MRMR exhibits the lowest accuracy for certain models; however, the accuracy of all models is generally comparable. Specifically, algorithms like Relieff and NCA yield satisfactory outcomes in certain models, whereas Enet distinctly emerges as the superior feature selection method. The Enet algorithm exhibits the shortest processing duration, totaling 1113 seconds. Figure 8 illustrates the complexity matrix of the most successful outcome.

Figure 8. *Complexity matrix of the highest result (1113 sec)*

4. CONCLUSION

This study employs EfficientNet and ViT models for feature extraction in the morphological classification of galaxies, with further classification performed using SVM. The results indicate that the robust feature extraction abilities of EfficientNet and ViT models enable the attainment of high accuracy rates in classifications using SVM. The ElasticNet algorithm's superior accuracy across all models underscores the essential importance of feature selection in classification efficacy. EfficientNet models yield quicker processing times, whereas ViT models deliver superior classification outcomes by extracting more intricate features. The benefits of both models across various datasets offer versatility in model selection.

Future research should conduct a comprehensive analysis of EfficientNet and ViT combinations on larger and more diverse datasets to enhance their performance. Furthermore, comparative analyses with alternative deep learning and machine learning methods can be performed to achieve more definitive outcomes about optimal model selection. Evaluating

novel transformer-based models and updated iterations of EfficientNet may enhance the conclusions of this research. Moreover, employing alternative classification algorithms in place of SVM can enhance the feature extraction procedure and elevate accuracy rates.

ABSTRACT

Cancer is a serious health problem that threatens the lives of millions of people worldwide and can lead to death. Among women, breast cancer is one of the most common types of cancer, and if not detected early, it significantly increases mortality rates. Accurate and timely diagnosis enhances the effectiveness of treatment methods and prolongs patients' survival. In this context, the use of Machine Learning (ML) algorithms in medical diagnosis processes supports rapid and accurate decision-making. In this study, different combinations of filter-based feature selection methods and various ML algorithms were compared to determine the most successful combination for breast cancer detection. To support breast cancer diagnosis, several filtering methods (Information Gain (IG), Chi-square, Anova F, Relief, L1 Regularization, Correlation) were combined with Naive Bayes (NB), Support Vector Machines (SVM), Decision Trees, Artificial Neural Networks (ANN), Random Forest (RF), Logistic Regression (LR), XGBoost, and K-Nearest Neighbor (kNN) algorithms. These methods were applied to the Breast Cancer Wisconsin Data Set available on the Kaggle platform. For each combination of filtering method and ML algorithm, the accuracy rate were calculated and compared. The highest accuracy rate, 99.12%, was achieved with the AnovaF and ANN combination. This finding demonstrates that the joint use of appropriate feature selection and ML algorithms can significantly enhance performance in breast cancer diagnosis. Consequently, this study emphasizes that effective feature selection is a critical step in developing accurate and efficient medical decision support systems.

Keywords: Filter-Based Feature Selection, Breast Cancer, Machine Learning, Feature Selection, Artificial Neural Networks

1. INTRODUCTION

Cancer poses a serious threat to human health globally, with a significantly increased risk of death if it is not detected at an early stage. Breast cancer, one of the most common cancer types among women, leads to severe health complications and high mortality rates, particularly in its advanced stages. Therefore, early diagnosis and appropriate treatment strategies are of crucial importance in terms of patients' quality of life and survival outcomes. It is evident that efforts aimed at detecting the disease at an early stage hold great significance. In particular, studies examining ML applications for cancer types demonstrate that these methods offer substantial contributions to early diagnosis and the predictability of disease progression. ML algorithms systematically analyze available data, enabling the discovery of meaningful patterns and relationships within datasets. Moreover, they contribute to the development of computational models capable of effectively representing the data (Maita & Das, 2017).

The Breast Cancer Wisconsin dataset (UCI, 1995) is one of the most widely used datasets for breast cancer diagnosis. Bazazeh and Shubair (2016) compared SVM, RF, and Bayesian Network algorithms, reporting that SVM achieved the highest accuracy. Asri et al. (2016) identified SVM as the most successful method, with an accuracy of 97.13%, a low error rate, and high precision. Khourdifi and Bahaj (2018) further confirmed the reliability of SVM for diagnostic purposes, reporting 97.9% accuracy. Elsadig et al. (2023) achieved 97.7% accuracy with SVM using eight classifiers and five feature selection techniques. Singh et al. (2024) reported the best performance in terms of accuracy, sensitivity, and F1-score by employing hybrid feature selection methods. Lorencin et al. (2020) demonstrated that the performance of ANN depends on the size of the training dataset.

In this study, various feature selection techniques (IG, Chi-Square, ANOVA F-test, Relief, L1 Regularization, and Correlation) and a range of ML algorithms (NB, SVM, DT, ANN, RF, LR, XGBoost, and kNN) were used to determine the combinations that yield the highest diagnostic performance for breast cancer. The study was conducted on the Wisconsin dataset available on the Kaggle platform, and accuracy scores along with confusion matrices were computed for each feature selection–algorithm pairing. This approach not only identifies which combinations achieve superior performance but also highlights the contribution of effective feature selection to the performance of medical decision-support systems. In this way, the study underscores the importance of this critical step in developing accurate and efficient decision-support tools.

2. MATERIALS AND METHODS

2.1. Dataset

The study utilized the Breast Cancer Wisconsin (Diagnostic) Data Set, available on the Kaggle platform (UCI, 1995), which contains 569 samples. Each sample includes an identification number and a diagnosis label indicating whether the cell is benign or malignant. Apart from these two, the dataset consists of 30 quantitative features describing the morphology of cell nuclei. These features are derived from ten fundamental measurements—radius, texture, perimeter, area, smoothness, compactness, concavity, concave points, symmetry, and fractal dimension. For each measurement, three types of values are recorded: the mean, the standard error, and the worst (the average of the three largest observed values).

2.2. Feature Selection Methods

In ML, feature selection plays a critical role in enhancing model performance and eliminating irrelevant variables. IG quantifies the impact of a feature on the target variable based on entropy and conditional entropy, where $H(Y)$ represents the entropy of the target variable and $H(Y|X)$

denotes the conditional entropy of Y given X (Hall, 1999; Novakovic et al., 2011). The Chi-Square test, particularly for categorical data, evaluates whether a feature has a statistically significant association with the target class; features lacking significant association can be removed from the dataset (Ünver et al., 2021). The Relief algorithm assesses how well each feature discriminates between classes by leveraging the similarity among instances (Kira & Rendell, 1992). ANOVA-F compares the mean values of features across class labels using one-way analysis of variance, with the F-statistic indicating statistically significant differences between classes (Fisher, 1918; 1925). L1 Regularization introduces a penalty term based on the sum of absolute values of coefficients in regression models, effectively shrinking some coefficients to zero and thereby removing redundant features (Tibshirani, 1996). The Pearson correlation coefficient (r) measures the linear relationship between two variables, where –1 or +1 indicates a perfect negative or positive correlation, and 0 indicates no correlation (Schober et al., 2018).

2.3. Machine Learning

Among the classification algorithms used in this study, ANNs are models inspired by the human brain, composed of densely interconnected nodes that learn by analyzing training data (Rumelhart et al., 1986). LR is a supervised method commonly applied in binary classification problems, providing probability estimates between 0 and 1 using the sigmoid function (Cox, 1958). The RF method generates ensemble models composed of multiple decision trees and determines the class based on a majority voting mechanism (Breiman, 2001). SVMs aim to find the optimal hyperplane that separates data into two classes; for non-linearly separable data, kernel techniques are applied (Cortes & Vapnik, 1995). DTs classify data based on simple decision rules derived from feature values, organized hierarchically in a tree structure (Quinlan, 1986). The kNN method estimates the class or value of a given data point by considering the classes or values of its k closest neighbors (Cover & Hart, 1967). NB is a probabilistic classifier that assumes feature independence and predicts the most likely class using Bayes' theorem (Mitchell, 1997). Finally, XGBoost employs a gradient boosting approach to create fast, flexible, and scalable ensemble models, achieving high performance especially on large datasets (Chen & Guestrin, 2016).

3. EXPERIMENTAL STUDY

Initially, data preprocessing steps were performed in the study. Outliers were detected in certain features of the dataset, and since these values could potentially negatively impact model performance, they were adjusted using threshold-based capping rather than being removed. For each variable, lower and upper threshold values were defined, and values falling outside these limits were replaced accordingly. This approach prevented data loss while preserving the overall distribution of the dataset. Additionally, since the features had different value ranges, which could lead to imbalanced results during the training of some algorithms, all data were normalized to the range of 0–1 using the Min-Max scaling method. This normalization particularly improved the performance of distance-based algorithms and enhanced the overall accuracy of the models.

Following data preprocessing, various feature selection methods (IG, Chi-Square, Anova F, Relief, L1 Regularization, and Pearson Correlation Coefficient) were applied to support breast cancer diagnosis. These feature selection methods were combined with ML algorithms including NB, SVM, DT, ANN, RF, LR, XGBoost, and kNN. The experimental results clearly demonstrate the impact of feature selection on the accuracy and classification performance of the ML algorithms. The accuracy values obtained by the algorithms with different feature selection methods are presented in Table 1.

Table 1. Performance Metrics of Algorithms According to Feature Selection Methods

	IG	Chi-Square	Anova F	Relief	L1	Correlation
ANN	98.25(10)	98.25(10)	**99.12(10)**	98.25(7)	---	99.12(25)
LR	98.25(21)	98.25(18)	98.25(18)	98.25(21)	**98.25(12)**	98.25(25)
RF	96.49(20)	**96.49(3)**	---	96.49(21)	---	96.49(25)
SVM	98.25(21)	**98.25(16)**	98.25(20)	98.25(21)	---	97.37(25)
NB	98.25(12)	**98.25(11)**	98.25(12)	98.25(15)	---	97.37(25)
DT	**95.61(25)**	93.86(15)	93.86(11)	93.86(20)	---	92.11(25)

XGBoost	96.49(7)	**96.49(5)**	96.49(9)	96.49(9)	---	95.61(25)

Table 1 presents the accuracy values and the number of selected features for each classification algorithm–feature selection method combination. Bold values mark the maximum accuracy for each algorithm. We prioritize the model that reaches this highest accuracy using the least number of features, emphasizing efficiency and simplicity. "---" denotes non-applicable scenarios. Overall, ANN achieved the highest performance, reaching 99.12% accuracy with the Anova F filter, while correlation-based methods also yielded high performance, albeit less pronounced than Anova F. LR demonstrated consistent performance around 98.25% across all feature selection methods, with particularly compatible results observed using L1 Regularization. RF attained its highest accuracy of 96.49% with the Chi-Square method; the minimal variation across different feature selection methods highlights the effectiveness of RF's intrinsic feature importance mechanism. SVM and NB both exhibited stable performance, achieving 98.25% accuracy with Chi-Square and correlation-based methods, reflecting SVM's margin-maximization principle and NB's independence assumption as foundations for their robust performance. DT performed best with Information Gain (95.61%), emphasizing the importance of aligning splitting criteria with feature selection. The kNN algorithm reached 98.25% accuracy with Chi-Square and maintained similar stability across other methods. XGBoost achieved 96.49% accuracy with five features selected by Chi-Square and demonstrated stable performance across alternative methods. Feature selection strategies were observed to modulate the accuracy and generalization capabilities of the classifiers. Certain algorithms exhibited optimal performance and enhanced operational stability contingent upon their deployment with judiciously selected feature subsets.

4. CONCLUSION

In this study, commonly used ML algorithms for breast cancer diagnosis were compared, and their performance was evaluated in terms of accuracy. The application of the Anova-F feature selection method enabled the ANN model to achieve the highest performance, reaching 99.12% accuracy using only ten features. The findings demonstrate that robust feature selection methods, particularly when combined with deep-structured models, enhance predictive performance, while also highlighting the impact of data preprocessing steps on overall model accuracy.

ABSTRACT

The rapid increase in multilingual content in the digital environment has made it essential to correctly identify texts and assign appropriate language tags. This directly affects the accuracy of text classification, automatic translation, sentiment analysis, search engine optimization, and security systems. This study compares the performance of traditional machine learning (ML) methods with deep learning (DL)-based models for the language detection problem. The study evaluated Logistic Regression (LR), Naive Bayes (NB), Random Forest (RF), and Support Vector Machine (SVM) methods, as well as Long Short-Term Memory (LSTM), Gated Recurrent Unit (GRU), and DistilBERT models. These models were trained on the same dataset and tested comparatively. According to the research results, the DistilBERT model demonstrated the highest success with 99.22% accuracy and a 99.23% F1-macro score. This difference was found to be statistically significant. The results demonstrate that Transformer architecture has high potential for learning multilingual representations and enhancing inter-class discrimination. However, considering training time, hardware requirements, and sustainability metrics (e.g., energy consumption, model size, and re-trainability), the NB model was found to offer a more balanced solution in terms of application and automation processes. The results show that accuracy rates alone are not decisive in the field of language detection. Efficiency, resource utilization, and model scalability are also important factors to consider. Therefore, this study provides a guiding framework for model selection in multilingual text processing projects from both theoretical and practical perspectives.

Introduction

Language detection is one of the fundamental components of Natural Language Processing (NLP). The rapid increase in multilingual digital content has made this topic even more important in recent years. Today, content produced in online environments is often written in multiple languages. This makes it important for texts to be labelled correctly.

The success of many systems, such as social media analytics, search engines, machine translation, and cybersecurity applications, depends on the ability to correctly identify the language of the text. Language detection is not merely a classification problem. It is also a complex process that requires distinguishing the statistical, morphological, and contextual features of the language (Song et al., 2024).

In some languages, superficial statistical methods may suffice. For example, n-gram-based statistical features generally yield successful results in languages that use the Latin alphabet, such as English, French, and Italian. However, languages with different writing systems, such as Arabic, Hindi, Malayalam, or Tamil, require deep contextual learning models (Ilic et al., 2022). Therefore, achieving high accuracy with a single method is often not possible. This necessitates analyzing the strengths and weaknesses of different modelling approaches.

Early research on language detection typically began with statistical methods. In these studies, character sequences and probabilistic models were used to statistically examine the differences between languages. This period represents a stage in which n-gram and probability-based approaches, which form the basis of language recognition, were prevalent. Over time, with the increase in data volume and the advancement of computational power, statistical models began to be replaced by machine learning (ML) and deep learning (DL)-based methods. This transformation has led to significant advances in language representation. Transformer-based architecture has had a groundbreaking impact in this field. However, some studies show that classical methods can still yield effective results in certain situations. For example, Lui et al. (2012) demonstrated that the Naive Bayes (NB) method performs strongly. Conneau et al. (2020) demonstrated that multilingual representations can be learned at scale in an unsupervised manner and proposed the XLM-R model. This work has greatly improved the accuracy and generalization power of contextual representations in multilingual texts. Luo et al. (2021) improved representation quality by re-examining the language encoding processes of Transformer models using the "Cross-lingual Language Projection (XLP)" approach. Such studies have demonstrated that Transformer-based models are effective in multilingual language detection tasks. On the other hand, Recurrent Neural Network (RNN)-based models have not been completely abandoned. Long Short-Term Memory (LSTM) and Gated Recurrent Unit (GRU) based networks are still considered valid alternatives, especially for short or low-resource languages. For example, in their study, Aysa et al. (2023) used the SE-Res2Net-CBAM-BiLSTM architecture to enable the learning of audio-based contexts in language detection. Kocmi & Bojar (2017) developed a Bidirectional Recurrent Neural Network (BRNN)-based method for language identification in their work. The study also showed that while some applications perform language identification using the NB method, the proposed model is more successful in analyzing complex language structures. Bharathi Mohan et al. (2023) presented a comprehensive evaluation of various Transformer architectures for the language detection task in their work.

In the current study, LSTM and GRU-based RNN models, the Transformer-based DISTILBERT model, FastText and LangDetect external services, and the classical methods NB, Logistic Regression (LR), Random Forest (RF) and Support Vector Machine (SVM) were compared on the same dataset. The results obtained were presented to the user. The aim of the

study is to compare the speech recognition performance of different ML, DL, and external service-based models, determine the most suitable model, and integrate it into a real-time system. The study systematically evaluated not only classical ML algorithms but also modern DL and Transformer methods. Thus, the advantages, limitations, and practical applicability of different methods were examined comparatively.

Methodology

In this study, NB, LR, RF, and SVM classical methods were used. The aim of these methods is to train classifiers based on features extracted using TD-IDF. K-fold cross-validation was used in model training. This method is based on dividing the model into different sections and using each part for testing in different rounds (Song et al., 2024). In addition, hyperparameter optimization was performed. Grid Search was applied for LR and NB. The Random Search method was applied for RF and SVM.

Alongside traditional methods, LSTM, GRU, and DistilBERT models were also applied. In DL approaches, inputs are typically provided as embedding representations. Model layers are processed using, for example, LSTM/GRU or transformer blocks. Transformer models have the advantage of capturing contextual language representations. For example, XLM-E has been shown to provide better cross-language transfer in multilingual pre-training (Chi et al., 2022). For transformer models, hyperparameters such as learning rate, batch size, and number of layers were adjusted during training. Early stopping and model checkpoint techniques were also used.

In the study, NB, LR, RF, LinearSVC, and SVM-RBF models were trained using the Scikit-learn library. LSTM and GRU models were trained based on PyTorch, with embedding size 128 and dropout rate 0.2 parameters. The DistilBERT model was trained within the Hugging Face Transformers framework using a fine-tuning method based on "distilbert-base-multilingual-cased".

Comparison Criteria and Evaluation Methods

The performance of the models was evaluated using accuracy, precision, recall, and F1-score metrics. Additionally, the confusion matrix was used to examine which languages the models confused with each other. During the experiments, data splitting (training/validation/test sets) was carefully performed to assess the model's generalization ability.

Class-based reports were generated for all models, metrics were recorded in JSON format, and visualization (ROC, Loss, Accuracy) analyses were performed. The same test set was used for externally serviced models. FastText, LangDetect, and Gemini results were additionally evaluated for verification purposes.

Dataset Details

The dataset used in the study is the *Language Detection* Dataset on the Kaggle platform (Basil, 2023). The dataset contains 10,267 unique short sentences written in different languages. Each row contains a text and, correspondingly, the language tag in which the sentence is written. The dataset provides a broad testing ground for the language detection problem.

- Detection and removal of missing or corrupted records.
- During the data pre-processing stage, spaces, special characters, and line breaks in the texts were cleaned. Each example was converted into a "text–language" pair.
- Lowercase conversion
- Tokenization: both word-based and character-based approaches
- Feature extraction: TF-IDF-based representations

First, the "data summary information" (Figure 1) and "language distribution graph" (Figure 2) revealed by the data set analysis are shown below.

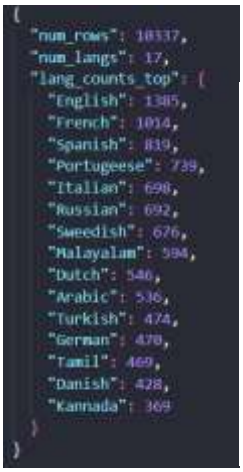

Figure 1. Data Summary

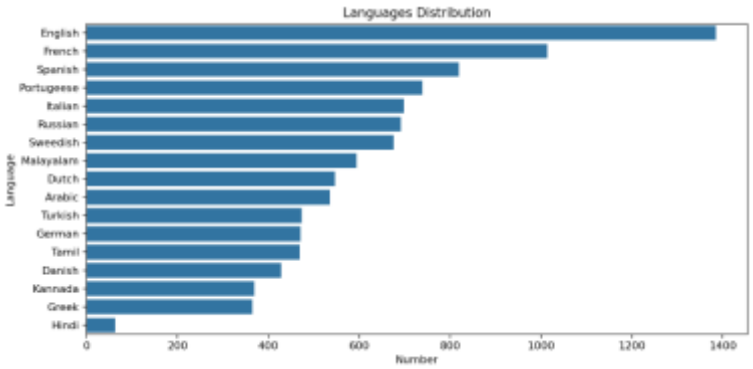

Figure 2. Language Distribution

Application

An application was implemented using the most successful model identified. During this process, a simple interface application running in a web environment was designed using the "streamlit" library. In the simple interface developed, the predicted language and probabilities are displayed instantly when the user enters text. These screenshots (Figures 3, 4) clearly demonstrate the decision speed and ease of use.

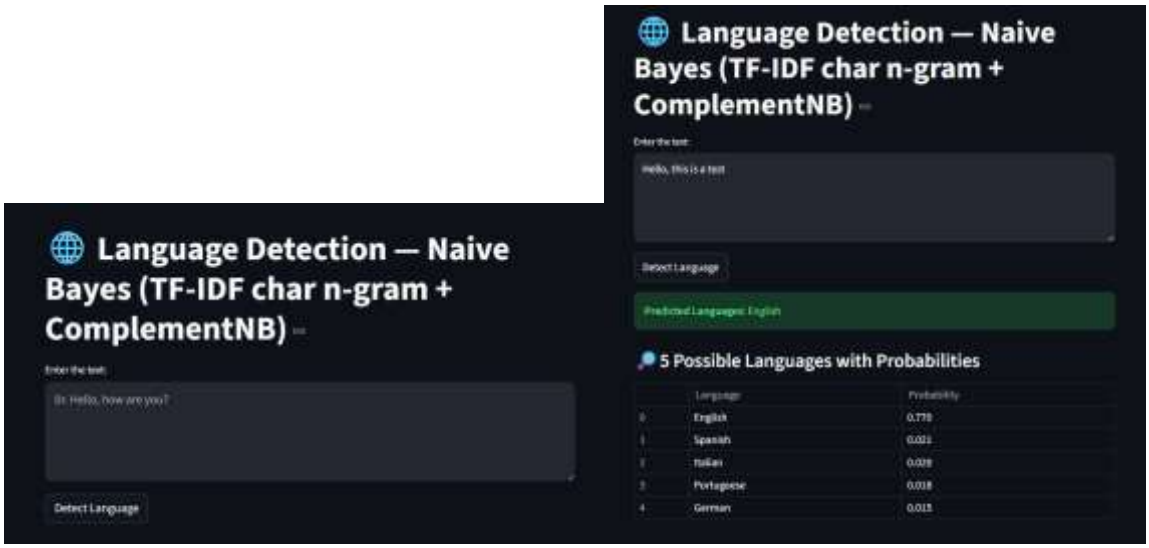

Figure 3. Application Screen Visualization

Figure 4. Application Screen Visualization

Results

Within the scope of the project, investigations were conducted under three main headings for language detection.

Traditional Methods

In this section, model training was performed using the LR, NB, RF, SVM, and LinearSVC algorithms, which is a type of SVM application. The results and confusion matrices showing these results are collectively presented in Figure 5 below.

Logistic Regression (LR)

LR is a statistical-based method of classification that creates linear decision boundaries in text data (Jurafsky & Martin, 2025). In this study, it was optimized using Grid Search and achieved an accuracy rate of approximately 99.08%. This method yielded precision and recall values above 99% for almost all languages. Predictions are nearly flawless, particularly in the English, French, Spanish, and German classes. A very low rate of confusion was observed in phonetically similar languages such as Danish and Dutch; however, this error rate is low enough not to affect the overall success of the model. LR stands out as a strong baseline model with low computational cost.

Naive Bayes (NB)

The NB model exhibits a probabilistic approach based on word distribution and is known for its speed advantage, particularly in text classification tasks (Raschka, 2014). In this study, this method was optimized using Grid Search, achieving an accuracy rate of approximately 98.98%. Performance was very high in classes with distinct word structures, such as Japanese, Arabic, and Greek. However, minor misclassifications were observed among Scandinavian and Western European languages. Despite this, the model's overall consistency is high, and it offers a viable solution for systems requiring fast predictions due to its low resource requirements.

Random Forest (RF)

RF works with an ensemble structure created by combining multiple decision trees (Xin, 2018). In this study, the accuracy value after training the RF model was calculated to be approximately 97.82%.

Although the model showed high success in languages with distinct character-based separations, an overfitting tendency was observed in languages with limited data. This situation led to recall values being lower than precision in some classes. It was the slowest model among the classical methods, but it can be considered a reference due to its stable discrimination power.

Support Vector Machine (SVM)

SVM draws an optimal decision boundary between classes by creating margin-maximizing separation surfaces.

In this study, the RBF kernel was chosen as the SVM model. This choice enabled the model to learn non-linear patterns. As a result, the complex boundaries between language features were separated more effectively.

After all these optimization processes, the model's accuracy rate was measured at approximately 98.06%.

The model has shown high success, particularly in languages with structurally different alphabets (Japanese, Arabic, Hindi). However, a small amount of confusion was observed in closely related language pairs such as German–Dutch or French–Italian. Although the computational cost is higher than LR, it provided a flexible decision surface thanks to the RBF kernel.

LinearSVC

LinearSVC is an optimized SVM variant capable of fast classification using linear hyperplanes in high-dimensional text spaces (Soni, 2023). In this study, it was optimized using Grid Search and achieved 99.32% accuracy, yielding the best result among all traditional methods. Specifically, both precision and recall values were very close to 100% in the English, French, Spanish, and Greek classes. It is the model with the lowest confusion rate and can be considered the strongest traditional approach in the report in terms of accuracy-speed balance.

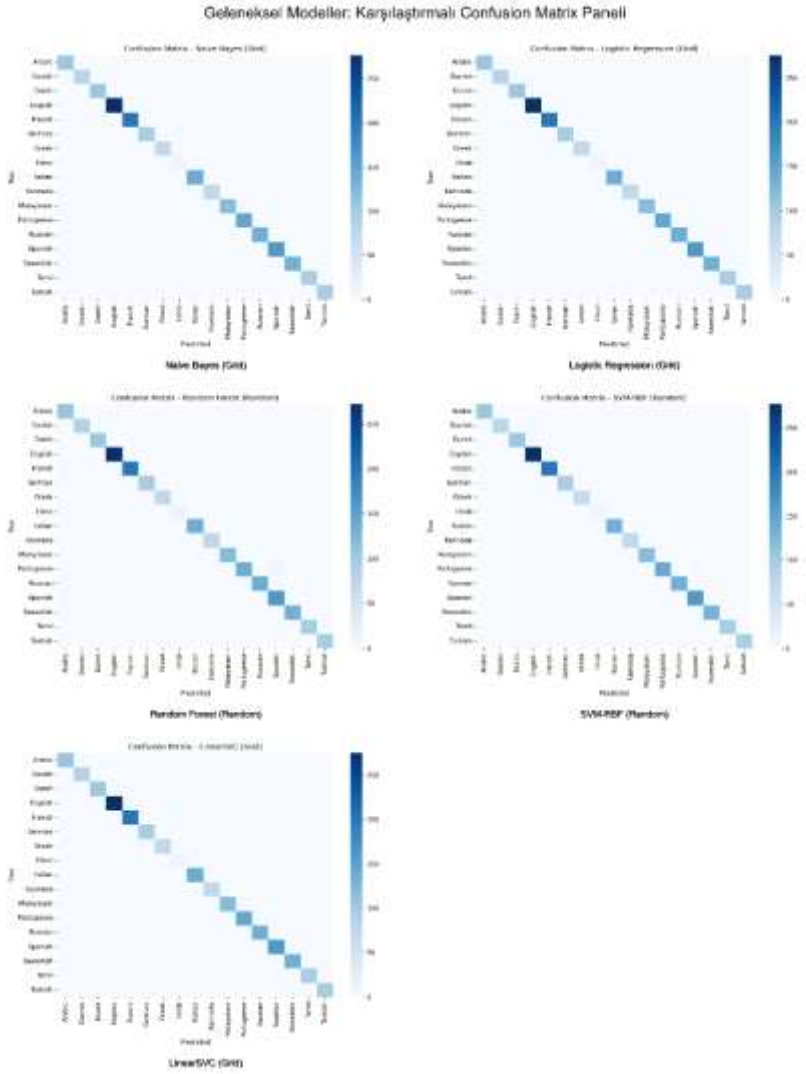

Figure 5 Confusion Matrices of Traditional Methods

The comparative performance of traditional ML methods is clearly shown in Figure 5. All models made accurate predictions with high accuracy across classes, and cross-errors were quite limited. NB and LR showed stable performance, especially in balanced classes. The RF and SVM-RBF models maintained their overall accuracy level despite showing partial deviations in some languages (e.g., short texts). Overall, the stability of all models demonstrates that statistical approaches are still a strong alternative for language detection.

Current Methods

In this section, training was performed using the DISTILBERT model, which is an LSTM, GRU, and Transformer-based model. Before model-based analyses, the languages were labelled. This is an important step for these methods to work. The results after labelling are shown in Figure 6.

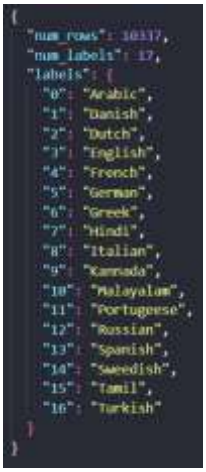

Figure 6. Language Labelling for Current Methods

The results of these training sessions and the summary of the result graphs are shown below (Figure 7).

Long Short-Term Memory (LSTM)

The LSTM model was trained using early stopping and achieved 95.35% accuracy and a 95.57% F1-macro score. The average AUC was reported as 0.9986, demonstrating that it successfully learned the classification boundaries. LSTM performed particularly well in Latin-based languages but showed lower segmentation performance compared to the Transformer model when applied to languages with structurally different character sequences (such as Japanese, Hindi, and Greek). Nevertheless, the model's ability to produce stable and consistent results demonstrates that it is an alternative that can operate at a lower computational cost.

Gated Recurrent Unit (GRU)

The GRU model was optimized using early stopping, similar to LSTM, and achieved 95.06% accuracy and a macro-F1 score of 94.88%. In the class-based AUC analysis, the macro-AUC value was measured as 0.9986, showing that it has almost the same overall discrimination power as LSTM. Although the training time was shorter than that of LSTM, slight decreases in recall values were observed in some classes with low sample counts. This indicates that GRU provides a speed advantage but is not as strong as LSTM in terms of memory control.

DISTILBERT Model

The DistilBERT model demonstrated the highest performance in the study, achieving 99.22% accuracy and a 99.23% F1-macro score. When examining the AUC values, values of 0.9995

and above were obtained for each class, and the macro-AUC was reported as ≈ 1.000. This result shows that the model not only classifies correctly but also establishes the decision boundary between classes extremely clearly.

Thanks to its Transformer-based structure, DistilBERT represents texts not only based on word frequency but also by considering contextual relationships, offering a meaning modelling capacity beyond traditional statistical methods. This becomes particularly evident when applied to morphologically rich languages or languages with different alphabets (e.g., Arabic, Greek, Japanese), where the model achieved nearly flawless classification.

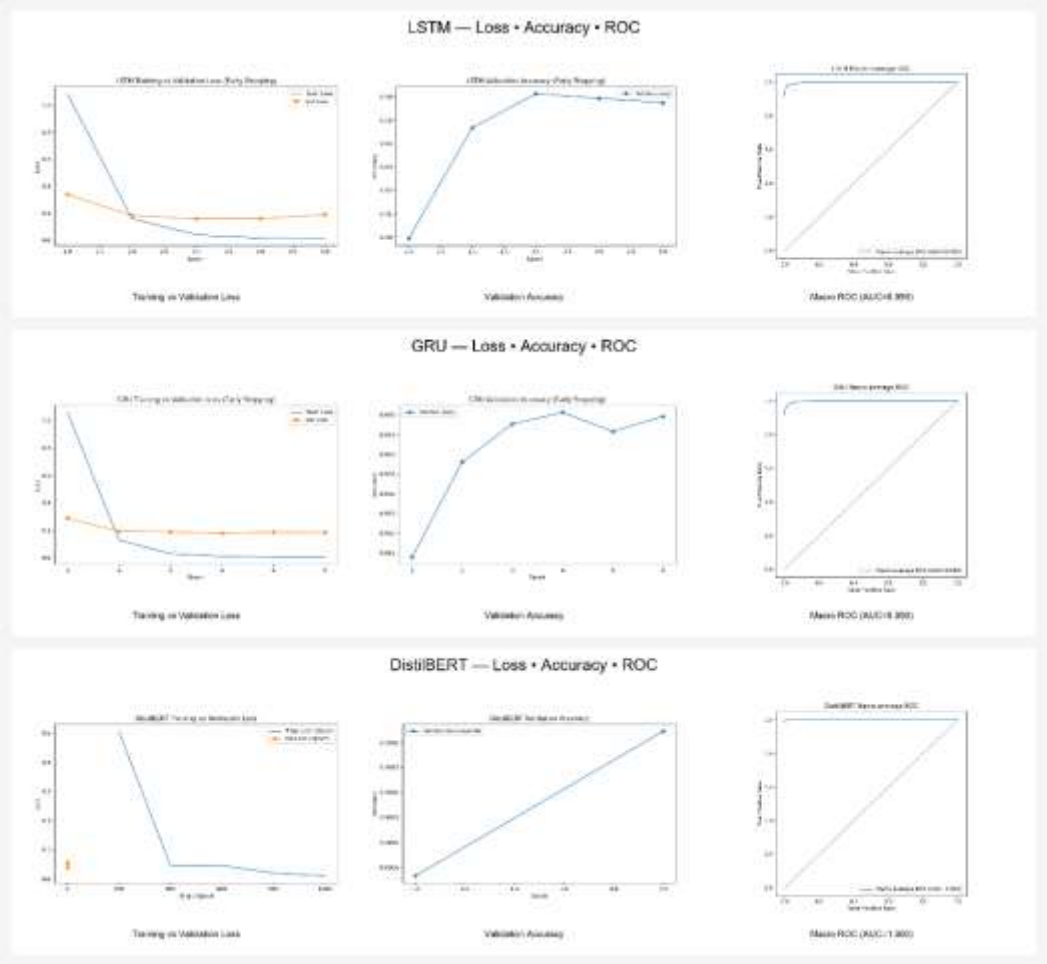

Figure 7 Graphs for Current Methods

When examining the graphs in Figure 7, all three models exhibit high accuracy and discrimination power. The LSTM and GRU models achieved balanced learning with the early stopping technique, reaching around 95% accuracy and F1 scores. The AUC scores of both models are also at 0.998 level, indicating strong overall performance. In contrast, the Transformer-based DistilBERT model showed the highest success with accuracy and F1 scores above 99%. This result demonstrates that DistilBERT, thanks to its ability to learn contextual representations, performs superior classification on multilingual datasets compared to LSTM and GRU models.

External Service Models

FastText

FastText tends to lag behind Transformer-based models when the dataset contains spelling variations, mixed/very short texts, or non-Latin alphabets. However, its training and inference speed is very good, making it a reasonable choice for rapid prototyping or resource-constrained systems. The model's results on the test set were recorded as 94.19% accuracy, 95.60% macro-precision, 94.28% macro-recall, and 94.43% macro-F1.

LangDetect

In this model, the macro-F1 drop is particularly noticeable in very short and code-mixed sentences. The limitations of rule-based/statistical approaches become apparent here. Although strong in some languages, class imbalance and short segments negatively affect performance. In terms of performance, it appears to be the weakest among all models and metrics compared. The results achieved by the model on the test data were measured as 82.98% accuracy, 74.16% macro-precision, 72.32% macro-recall, and 73.18% macro-F1.

Comparative Analysis

The test performance of all models is summarized in a single graph, along with the accuracy, precision, recall, and F1-score metrics (Figure 8).

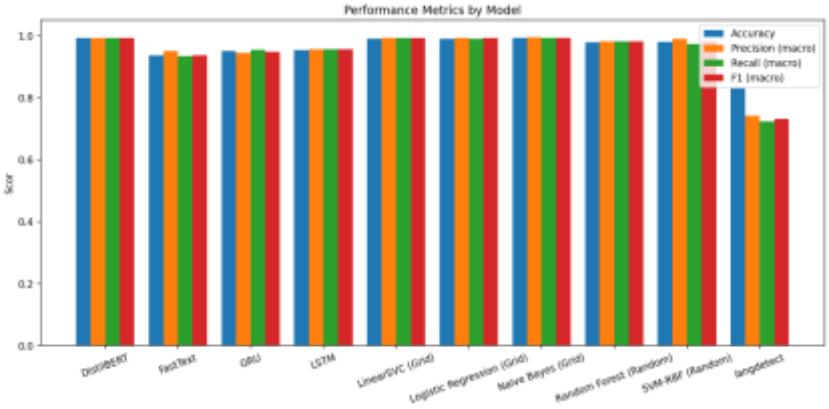

Figure 8. Common Graph of All Metrics

Additionally, sequential bar charts for each metric show the differences between models more clearly. Figures 9, 10, 11, and 12 below are these bar charts.

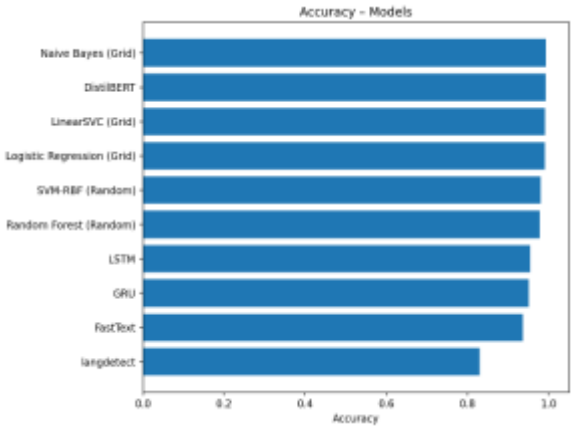

Figure 9 Accuracy

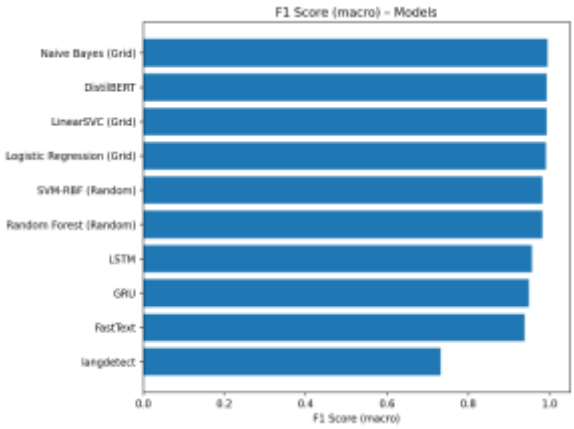

Figure 10 F1-Score

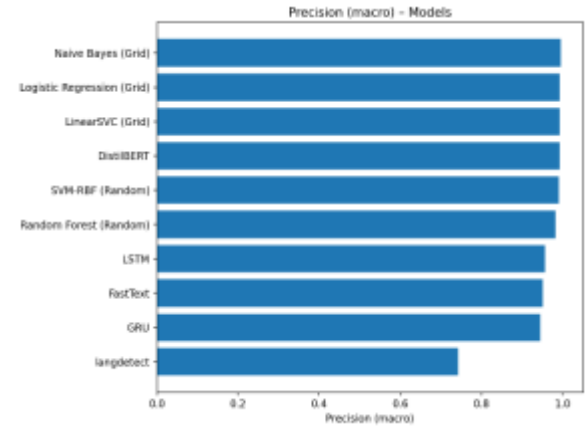

Figure 11 Precision

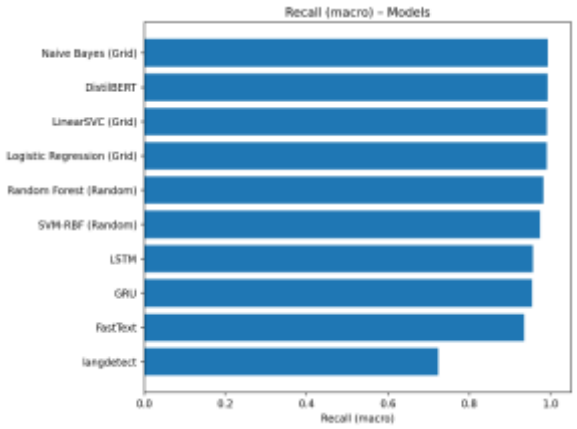

Figure 12 Recall

Accuracy and Consistency: DistilBERT demonstrated the highest overall performance on the test set with >99% accuracy and macro-F1 and clearly distinguished between classes with macro-AUC ≈ 1.000. LSTM/GRU produced high performance with relatively low resources, while NB stood out among classical methods thanks to character n-gram representation.

In terms of resource/cost balance, NB offers a practical solution with low latency and a small footprint, as latency, memory consumption, and sustainability are important in production scenarios. The system determined the optimal value for each metric for the application. Subsequently, the system was asked to recommend a model, considering the F1-Accuracy-Inference time parameters. As shown in Figure 13, the system selected NB as the "application model".

```
Suggested Model (For App)
Model: Naive Bayes (Grid)
F1(macro): 0.9940
Accuracy : 0.9932
Infer (sn/örnek): 0.000256
Explanation:
- The highest F1-macro value was measured in model Naive Bayes (Grid).
- Accuracy Score: 0.993.
- Infer Time is 0.000256 so it is usable in Real Time Usage.
- For that reasons, this model is recommended for application deployment.
```

Figure 13. Model Recommendation by the System Based on Analysis Results

Conclusion

In this study, both traditional statistical methods and modern DL and Transformer-based models were comparatively evaluated for the language detection task. The results revealed that the strengths of different approaches vary depending on the application context.

According to the experimental findings, the DistilBERT model demonstrated the highest performance in terms of accuracy. The model's accuracy rate of 99.22% and F1-macro score of 99.23% clearly demonstrate the Transformer architecture's power of contextual representation in multilingual texts. The LSTM and GRU models achieved high but more limited success after DistilBERT, thanks to their proficiency in capturing sequential data structures. The accuracy of these models in the range of 81–83% shows that RNN-based networks are still effective in understanding linguistic patterns.

The FastText model offered a practical solution, particularly for resource-constrained systems, due to its short training and inference times. While it performs strongly in languages using the

Latin alphabet, its success rate is relatively lower in mixed writing systems (e.g., Hindi and Arabic). LangDetect, relying on simple statistical rules, offers a limited accuracy level (62.34%) for short, incorrect, or multilingual texts.

Considering the accuracy, training time, processing cost, and ease of implementation of all models, the NB model provided the most suitable results in terms of overall balance. The model demonstrated both fast and reliable performance with a 96.12% accuracy rate and low processing cost. Therefore, the NB model was chosen as the core structure in the developed language detection automation system. However, the DistilBERT model is recommended as a second option in research environments where the highest level of accuracy is required.

In conclusion, this study has demonstrated that model selection in the field of language detection should be based not only on accuracy values but also on practical criteria such as system resources, speed, scalability, and sustainability. Future work could include adding low-resource languages, investigating model adaptations on code-mixed datasets, and creating hybrid systems with large language models such as Gemini. These developments would enable the creation of more inclusive, faster, and more reliable language detection systems for both academic and industrial applications.

Declarations

During the preparation of this work, the authors used OpenAI ChatGPT to improve the readability and language of the work. After using this tool/service, the authors reviewed and edited the content as needed and took full responsibility for the content of the publication.

ÖZET

Faz değiştiren malzeme (FDM) kullanılan çift borulu ısıl enerji depolama sistemlerinde iç boru geometrisinin enerji depolama karakteristiği üzerindeki etkisi sayısal olarak araştırılmıştır. Analizler, Hesaplamalı Akışkanlar Dinamiği (HAD) yaklaşımıyla ANSYS Fluent yazılımı kullanılarak üç boyutlu (3B) ve zamana bağlı olarak gerçekleştirilmiştir. Sayısal modelin oluşturulmasında, erimiş nitrat tuzunun termofiziksel özellikleri referans alınmış ve faz değiştiren malzemenin ısı depolama performansı entalpi-gözeneklilik yöntemi kullanılarak değerlendirilmiştir. Modelleme aşamasında enerji, momentum ve süreklilik denklemleri çözümlenmiş, katı-sıvı faz geçişi sırasında gerçekleşen ısı transferi ve akış davranışı detaylı biçimde analiz edilmiştir. Çalışma kapsamında iç boru geometrisi, alanı sabit kalacak şekilde dairesel, kare ve üçgensel olmak üzere üç farklı formda modellenmiştir. Bu yaklaşım, geometrik farkların yalnızca akış karakteristiği ve ısı transfer mekanizmaları üzerindeki etkisini değerlendirmeyi mümkün kılmıştır. Her bir model için ağ (mesh) yapısı kalite kriterlerine göre optimize edilmiş, simülasyonlar 100, 200 ve 300 saniyelik iterasyon sürelerinde yürütülmüştür. Her bir zaman adımında faz değiştiren malzemenin erime oranı, sıcaklık dağılımı, enerji depolama kapasitesi ve ortalama ısıl verimi hesaplanmıştır. Elde edilen sonuçlar, üçgen kesitli iç boru geometrisinde ısıl verimin diğer geometrilere kıyasla daha yüksek olduğunu göstermiştir. Üçgen kesitli yapı, akış alanında daha yoğun türbülans oluşturduğu için ısı transfer katsayısını artırmış ve faz değişim süresini kısaltmıştır. Dairesel ve kare kesitli geometrilerde ise sıcaklık dağılımı daha düzensiz bir profil göstermiştir. Sonuç olarak, iç boru geometrisinin seçimi, faz değiştiren malzemeli enerji depolama sistemlerinde ısıl performansın artırılması, enerji yoğunluğunun yükseltilmesi ve tasarım optimizasyonu açısından kritik bir parametre olarak belirlenmiştir.

Anahtar Kelimeler: Faz değiştiren malzemeler, Hesaplamalı akışkanlar dinamiği (CFD), Isıl Analiz

NUMERICAL INVESTIGATION OF THE EFFECT OF INSIDE PIPE GEOMETRY ON ENERGY STORAGE CHARACTERISTICS IN DOUBLE PIPE ENERGY STORAGE WITH PHASE CHANGE MATERIAL (PCM)

ABSTRACT

In this study, the effect of the inner tube geometry on the thermal energy storage characteristics of a double-pipe energy storage system using phase change material (PCM) was numerically investigated. The analyses were performed in three dimensions (3D) and in a transient manner using the Computational Fluid Dynamics (CFD) approach within the ANSYS Fluent software. The numerical model was developed based on the thermophysical properties of molten nitrate salt, and the thermal performance of the PCM was evaluated using the enthalpy–porosity method. During the modeling stage, the energy, momentum, and continuity equations were solved, and the heat transfer and flow behavior occurring during the solid–liquid phase transition were analyzed in detail. Within the scope of this study, the inner tube geometry was modeled in three different forms—circular, square, and triangular—while keeping the cross-sectional area constant. This approach allowed for isolating the geometric effects on the flow characteristics and heat transfer mechanisms without introducing area-based discrepancies. The mesh structure for each configuration was optimized according to quality criteria, and the simulations were carried out for iteration times of 100, 200, and 300 seconds. At each time step, the melting rate, temperature distribution, stored thermal energy, and overall thermal efficiency of the PCM were computed and compared. The results revealed that the triangular inner tube geometry exhibited higher thermal efficiency compared to the circular and square geometries. The triangular configuration generated a stronger turbulent flow field, thereby enhancing the heat transfer coefficient and reducing the total melting duration. In contrast, the circular and square geometries produced less uniform temperature profiles within the PCM domain. Consequently, the selection of inner tube geometry has been identified as a critical design parameter for improving thermal performance, increasing energy density, and optimizing the design of PCM-based thermal energy storage systems.

1. GİRİŞ

Artan karbon salınımıyla iklim değişikliği meydana gelmektedir. Bu duruma artan nüfusla birlikte enerji tüketimi sonucu ortaya çıkan egzoz gazları sebep olmaktadır. Dünyamızı korumamız için başta karbon salınımını azaltmayı amaçlayıp çevreye duyarlı teknolojiler geliştirmeye devam etmeliyiz. Bu amaçla özellikle güneş enerjisinin faydalı bir şekilde depolanması başta olmak üzere enerjiyi depolama önem arz etmektedir.

Enerji; ısıl, kinetik, mekanik, potansiyel, nükleer, kimyasal vb. birçok biçimde bulunabilmektedir. Bütün biçimlerin toplamına da toplam enerji denilmektedir. Bir sistemin iç enerjisinin moleküllerinin kinetik enerjisi yani duyulur ısı olarak tanımlanmaktadır.

Güneş enerjisini depolamanın en çok kullanılan enerji depolama şekli duyulur ısıdır. Son yıllarda gizli ısı depolama üzerine faz değiştiren malzemelerin gelişmesiyle gizli ısıda alternatif yöntem olmuştur. Duyulur ısı yani geleneksel yöntemle enerji depolama yalıtım, sızıntı vb. nedenlerden dolayı maliyet dezavantajlarına sahiptir. Gizli ısı depolama ile küçük boyutlarda daha fazla güneş enerji depolanarak kullanılması güneş enerjisinden sıcak su elde edilmesi en uygun yöntemi olmaktadır. (Iten ve Liu 2014).

Faz değişimine bağlı olarak soğumak ve ısınmak için enerji alan/veren maddelere faz değiştiren malzemeler (FDM) denir. Isı transferi katı-sıvı-gaz arasında olmaktadır fakat FDM' lerde genel olarak katı-sıvı arasında gerçekleşmektedir. Katı fazdan sıvı faza geçerken alınan/verilen gizli ısı miktarı duyulur ısı miktarından fazla olmaktadır. Örnek olarak suyun katı fazı 0 ℃ (buz) erime gizli ısısı h_if 333,7 kJ/kg iken suyun sıvı fazını 10 ℃ arttırmak için 4,22 kJ/kg enerji verilmesi gerekmektedir. Bu sebepten dolayı buz/su çok değerli FDM malzemesi olarak kullanılmaktadır (Zhang 2001).

FDM' ler faz değişim sıcaklığında eriyerek ve katılaşarak duyulur ısı miktarına kıyasla büyük miktarda gizli enerji depolayabilir ve serbest bırakabilmektedir. Malzemenin iç yapısı değiştiğinde veya katı-sıvı faz değişimlerinde ısı yayılır/emilir bundan dolayı FDM' ler gizli ısı depolama malzemeleri olarak tanımlanır (Alnakeeb ve ark. 2021).

Faz değiştiren malzeme sınıfı olarak canlılardan elde edilen organik malzemeler, denizden veya maden yataklarından elde edilen doğal tuzlar kullanılmaktadır. Ayrıca değişik uygulamalarda katıdan katıya faz değiştiren malzemelerde bulunmaktadır.

FDM' lerin ticari olarak en çok kullanıldığı alanlar binaların soğutma ve ısıtma uygulamalarıdır. FDM' ler güneş enerjisini maksimum verimle olduğu zamanda depolayıp enerji talebinin en fazla olduğu zamanda kullanılmasını sağlamaktadır.

2. FAZ DEĞİŞTİREN MALZEMELERİN GENEL ÖZELLİKLERİ

Gizli ısı depolanması katı-sıvı-gaz aralarında değişik kombinasyonlarda olabilmektedir fakat FDM' ler katı-sıvı ve sıvı-katı fazlarında daha pratik olarak uygulanmaktadır. Sıvı-gaz geçişleri katı-sıvı arasındaki geçişten daha fazla gizli ısı barındırsa da malzemeleri gaz fazında depolamak zorlu olmaktadır (Duraković 2020).

Katı-sıvı FDM' ler ısı transferi başlangıcında duyulur ısı transferi gerçekleştirmektedir. Bu durumda ısı aldıkça sıcaklıkları yükselir daha sonra erime noktalarına ulaştıklarında tüm malzeme eriyene kadar sabit sıcaklıkta ısı almaktadırlar. Sıvı fazında ise etrafının sıcaklığı düştüğü zaman, FDM katılaşarak depolanan gizli enerjiyi serbest bırakmaktadır. -5 ile +190 ℃ arasında efektif olarak kullanılabilen FDM' ler bulunmaktadır. İnsanların rahat bir şekilde bulunabildiği 20-30℃ sıcaklıkları arasında bazı FDM' ler çok etkili olarak kullanılabilmektedir (Duraković 2020).

Organik faz değiştiren malzemeler, insan, bitki ve hayvan organizmalarını etkeniyle ortaya çıkan malzemelerdir. Avantajları; aşırı soğutma yükü olmadan donma, kimyasal olarak kararlı olma, güvenli bir şekilde erime ve reaktif olmama, hacim değişikliği az olması, geniş sıcaklık aralığı diye sıralanabilir (Iten ve Liu 2014). Dezavantajları ise katı halde düşüş ısı iletimi. dondurma halinde yüksek ısı transferi miktarı ihtiyaç duyulmaktadır. Gizli ısı depolama kapasiteleri düşük olabilmektedir. Yanıcı olmalarıdır (Iten ve Liu 2014).

İnorganik faz değiştiren malzemelerin avantajları birim hacimde yüksek gizli ısı depolama, düşük maliyetle işletilebilme, yanıcı olmamasıdır. Dezavantajları ise faz değişimi esnasında uyumsuz erime ve faz ayrımını engellemek kolay olmamaktadır ve gizli ısı entalpisinde kayıp meydana gelebilmektedir. Metaller başta olmak üzere birçok malzeme için aşındırıcıdır. Bazı karışımların hacim değişimi yüksektir. Korozyona neden olabilir (Iten ve Liu 2014).

Parafin ve yağ asitleri uzun ömürlü ve stabil oldukları için en çok tercih edilen FDM' lerdir. Özellikle parafinler erime gizli ısısı yüksek, faz değiştirme esnasında stabil, çevreye ve sisteme duyarlı oldukları için yaygın olarak kullanılmaktadır. Parafinlerin dezavantajlarından biri de düşük ısıl iletkenlik katsayısına sahip olmasıdır. Bu amaçla FDM'ler üzerine çeşitli araştırmalar yapılarak iyileştirme yapılmaya çalışılmıştır (Iten ve Liu 2014).

3. MATERYAL METOT

Yapılan sayısal çalışmada iç geometrisi farklı çift borulu sistemde faz değişikliğini analiz etmek için entalpi-gözeneklilik metodu kullanılmıştır. Hesaplamada minimum hata için aşağıdaki varsayımlar yapılmıştır.

Erimiş FDM' de serbest konveksiyon laminar, sıkıştırılamaz ve geçici olarak kabul edilir.

Faz değişimi esnasında hacim değişimi göz ardı edildi.

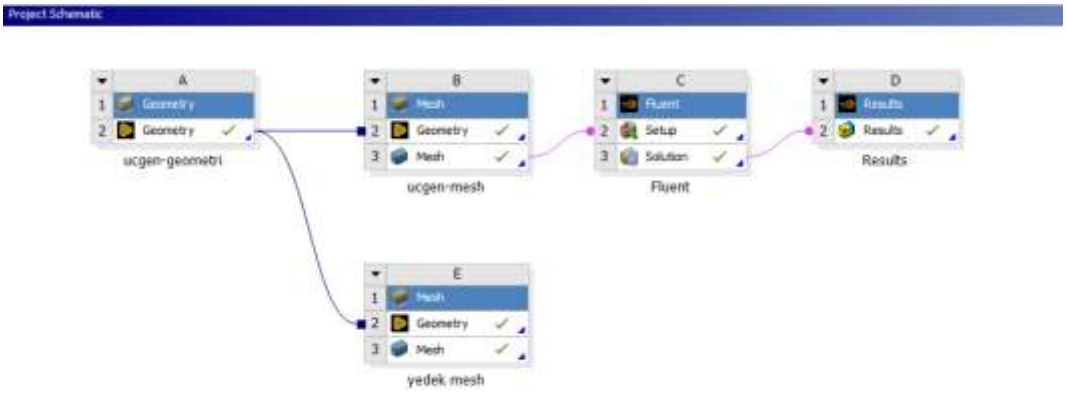
Enerji denkleminde viskoz etkiler düşük sıvı hızları nedeniyle ihmal edilmiştir.

Dış borudan kaynaklanan ısı kaybı ihmal edilmiştir.

Momentum Denklemi

$$\frac{\partial \mathrm{v}}{\partial \mathrm{t}} + \vec{V}.\nabla\vec{V} = \frac{1}{\rho}\left(-\nabla \mathrm{P} + \mu\nabla^2\vec{V} + \rho\vec{g}\beta\left(T - T_{ref}\right)\right) + \vec{S} \quad (1)$$

Süreklilik denklemi

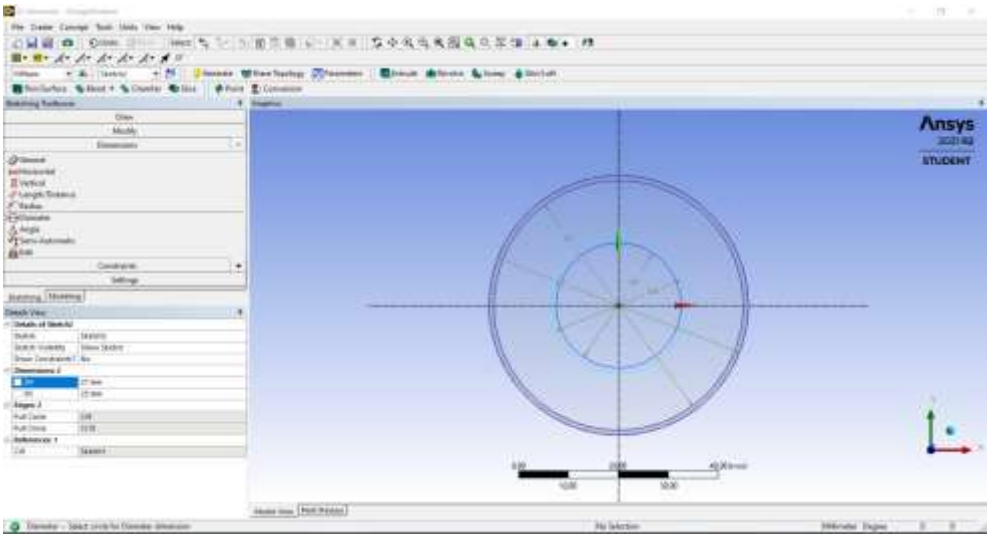


$$\Delta.\vec{V} = 0 \quad (2)$$

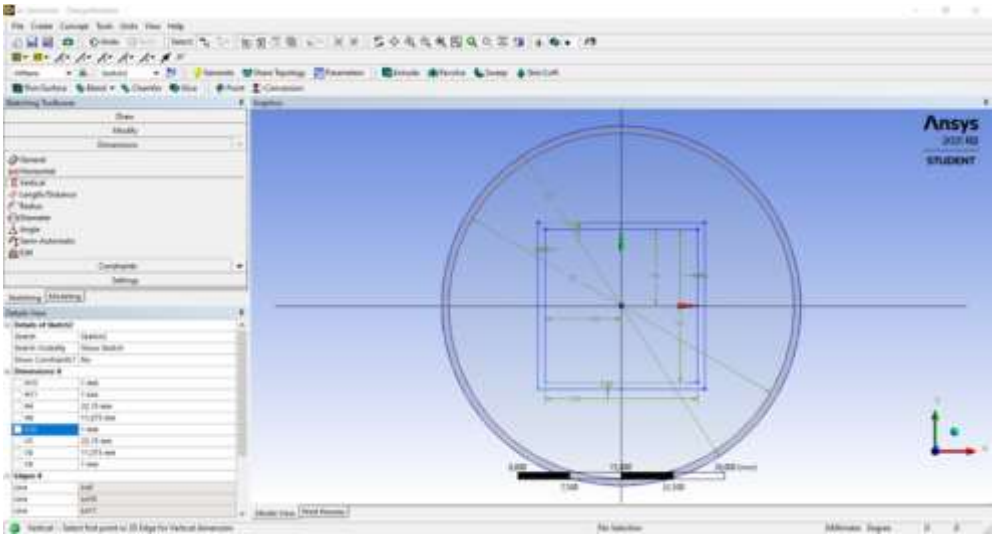
Enerji Denklemi

$$\frac{\partial \mathrm{h_{duy}}}{\partial \mathrm{t}} + \frac{\partial \mathrm{h}_{gizli}}{\partial \mathrm{t}} + \nabla.\left(\vec{V}\mathrm{h_{duy}}\right) = \nabla\left(\frac{k}{\rho \mathrm{cp}}\nabla \mathrm{h_{duy}}\right) \quad (3)$$

Türkiye'de genel olarak evlerde kullanılan sıcak su ve ısıtma ihtiyacı merkezi sistemlerde doğalgaz, kömür, linyit vb. yakıtlardan ve elektrik enerjisi kaynaklarından sağlanmaktadır. Isıtılan su yalıtımsız borular vasıtasıyla iletilirse mahal içinde de olsa kayıplar meydana

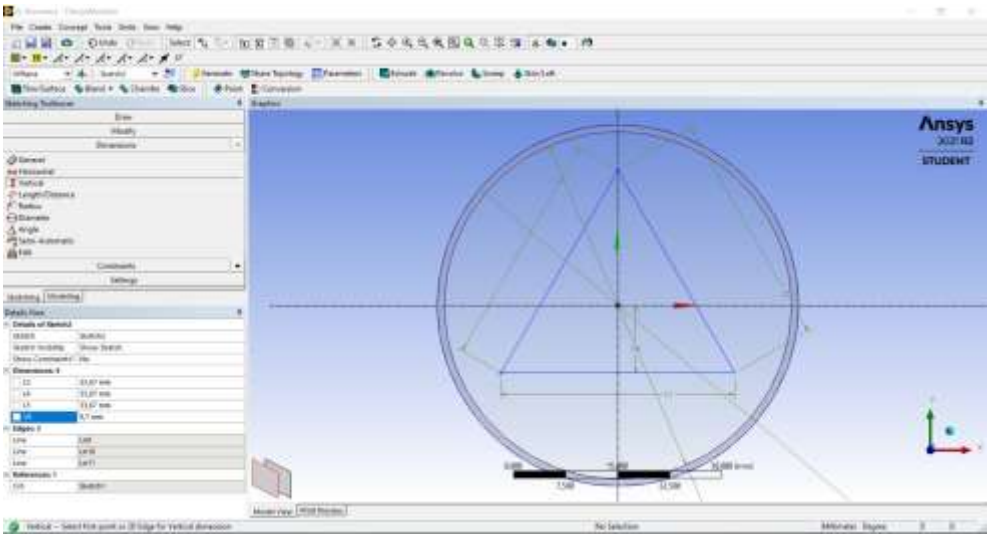


gelmektedir (Tiari ve Hockins 2021). Enerjinin pahalı olduğu ülkelerde ise ısıtılması istenilen yerlerde yerel olarak yapılmaktadır. Şekil 1.' de görüldüğü gibi ANSYS ortamında her bir iç boru geometrisi için proje şeması oluşturularak faz değiştiren malzemeler için analiz tasarlanmıştır.



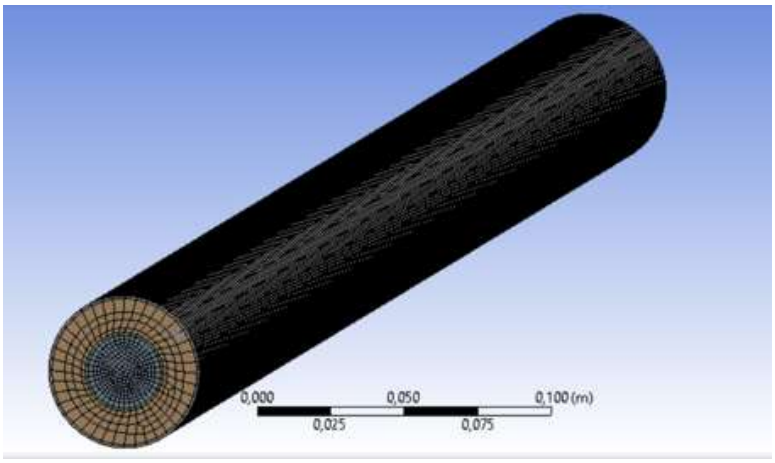
Şekil 1. ANSYS proje şeması

3.1. İç-Dış boru geometrisinin oluşturulması

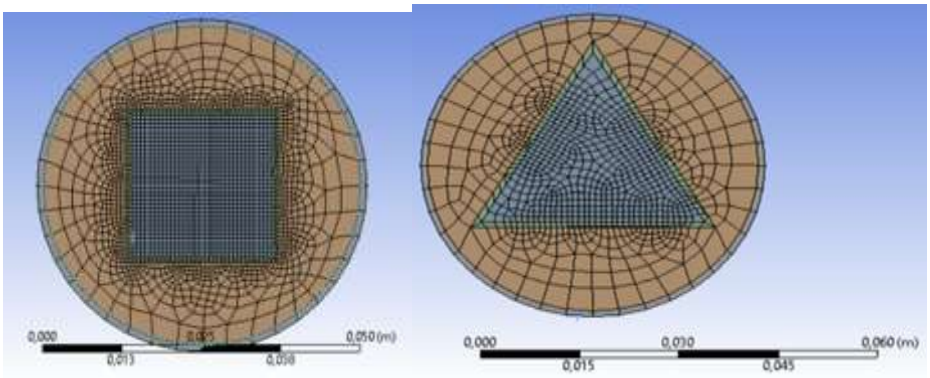


Boru iç çapı 50 mm, dış çapı 52 mm ve uzunluğu 1000 mm olarak verilmiştir. Dairesel iç boru geometrisi piyasada en çok kullanılan ve temin hızı yüksek olmasından dolayı 27 mm dış çapa ve 25 mm iç çapa sahip olacak şekilde ayarlanmıştır.

Şekil 2. Dairesel kesit iç boru ölçüleri



Şekil 3. Karesel kesit iç boru ölçüleri

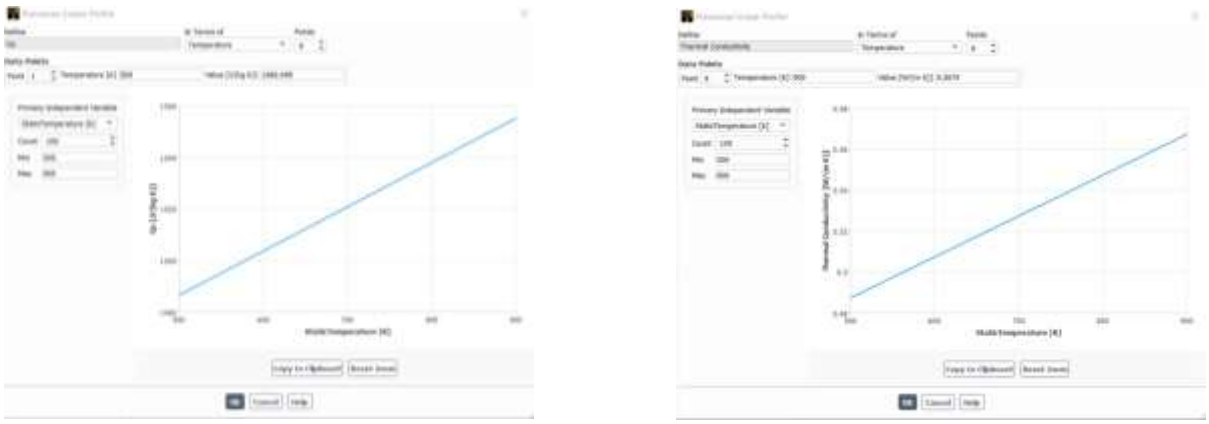


Şekil 4. Üçgensel kesit iç boru ölçüleri

3.2. Mesh İşlemi

Tasarımı yapılan geometrilerin analizin gerçeğe yakın sonuç vermesi için yapılması gereken en önemli aşamalardan biridir. Skewness değeri 0'a yakın ve ortogonal quality değeride 1'e yakın olduğu için analiz için makul kabul edilmiştir.

Şekil 5. Dairesel iç kesit görünümü



Şekil 6. Karesel ve üçgensel iç kesit görünümü

3.3. Fluent Analizi

Fluent programında FDM' lerin analizi için Solidification and Melting özelliği aktif hale getirilmiştir. Fluent ortamında malzeme seçimi ve tanımlanması yapılmıştır. Analizde kullanılan tüm malzemeler katı ve sıvı olmak üzere seçilerek işlem yapılmıştır.

Tablo 1. Erimiş Nitrat Özellikleri

Erimiş Nitrat Özellikleri

Bu çalışmanın sonucuna göre ileride yapılacak deneysel çalışmalarda faz değiştiren malzemelerin fiziksel ve kimyasal özelliklerinin yanında geometrisinin de önemli olduğu ortaya çıkmıştır. Nükleer enerjinin önem arz etmesi itibariyle enerji üretimi ve tüketiminin öneminin logaritmik olarak arttığı çağımızda faz değiştiren malzemelere ve sistemlerine olan gereksinim artacaktır.

ÖZET

Bitkisel kökenli uçucu yağlar, sekonder metabolitler olarak bitkilerde düşük miktarlarda bulunmalarına rağmen, zengin kimyasal çeşitlilikleri ve güçlü biyolojik aktiviteleri ile dikkat çekmektedir. Bu bağlamda, Cupressaceae familyasına ait *Cupressus* cinsi (servi ağaçları), sentetik pestisitlere çevre dostu ve sürdürülebilir bir alternatif olma potansiyeli taşıyan önemli bir doğal kaynak olarak öne çıkmaktadır. *Cupressus sempervirens* ve *C. arizonica* gibi türlerden elde edilen uçucu yağlar, genetik yapı ve çevresel koşullara bağlı olarak farklılık gösterse de genellikle α-pinen, δ-3-karen, sabinen ve terpinen-4-ol gibi biyoaktif monoterpenleri yüksek oranda içermektedir. Bu bileşenler, uçucu yağlara fungal ve bakteriyel bitki patojenlerine karşı çok yönlü antimikrobiyal mekanizmalar kazandırmaktadır. Başlıca etki mekanizmaları; patojen hücre zarının bütünlüğünü bozmak, geçirgenliği artırarak hücre içi bileşen kaybına yol açmak, ergosterol sentezini inhibe etmek ve biyofilm oluşumunu engellemektir. Deneysel bulgular, *Cupressus* türlerinden elde edilen uçucu yağların özellikle *Botrytis cinerea*, *Fusarium* spp. ve *Phytophthora* spp. gibi ekonomik öneme sahip fitopatojenlere karşı belirgin inhibisyon aktivitesi sergilediğini göstermektedir. Ayrıca bazı türlerin, bitki patojenlerinin yanı sıra çeşitli Gram pozitif ve Gram negatif bakteriler üzerinde de etkili olduğu bildirilmiştir. Sonuç olarak, *Cupressus* türlerine ait uçucu yağlar, modern tarımda bitki hastalıklarının biyolojik kontrolünde değerlendirilebilecek doğal ve çevre dostu bileşikler olarak önemli bir potansiyele sahiptir. Bu potansiyelin etkin biçimde değerlendirilebilmesi için, kimyasal profillerin standardizasyonu, formülasyon geliştirme ve etkinliğin hem kontrollü hem de tarla koşullarında test edilmesine yönelik ileri araştırmalara ihtiyaç duyulmaktadır.

Anahtar kelimeler: Cupressaceae, uçucu yağ, antimikrobiyal aktivite, *Cupressus* spp., bitki patojenleri

CHEMICAL COMPOSITION AND ANTIMICROBIAL POTENTIAL OF *CUPRESSUS* SPECIES ESSENTIAL OILS AGAINST PLANT PATHOGENS

ABSTRACT

Essential oils of plant origin, as secondary metabolites, are found in low amounts in plants; however, they attract attention due to their rich chemical diversity and potent biological activities. In this context, the *Cupressus* genus (cypress trees) of the Cupressaceae family stands out as an important natural resource with the potential to be an eco-friendly and sustainable alternative to synthetic pesticides. Although essential oils obtained from species such as *Cupressus sempervirens* and *C. arizonica* show variation depending on genetic structure and environmental conditions, they generally contain high levels of bioactive monoterpenes like α-pinene, δ-3-carene, sabinene, and terpinen-4-ol. These components provide the essential oils with multiple antimicrobial mechanisms against fungal and bacterial plant pathogens. The primary mechanisms of action include disrupting the integrity of the pathogen cell membrane, increasing permeability leading to the loss of intracellular components, inhibiting ergosterol synthesis, and preventing biofilm formation. Experimental findings indicate that essential oils derived from *Cupressus* species exhibit significant inhibitory activity against economically important phytopathogens such as *Botrytis cinerea*, *Fusarium* spp., and *Phytophthora* spp. Furthermore, some species have also been reported to be effective against various Gram-positive and Gram-negative bacteria, in addition to plant pathogens. In conclusion, the essential oils derived from *Cupressus* species possess significant potential as natural and environmentally friendly compounds that can be utilized in the biological control of plant diseases in modern agriculture. To effectively utilize this potential, further research is needed focusing on the standardization of chemical profiles, formulation development, and testing their efficacy under both controlled and field conditions.

Keywords: Cupressaceae, essential oil, antimicrobial activity, *Cupressus* spp., plant pathogens

1. GİRİŞ

Uçucu yağlar (esansiyel yağlar, EO), bitkilerin toplam biyokütlesinde düşük oranlarda bulunmalarına rağmen aromatik türlere özgü koku ve tat özelliklerinin temel belirleyicileridir. İçeriklerindeki yüzlerce biyoaktif bileşik, bu doğal ürünlerin hem kimyasal çeşitliliğini hem de biyolojik etkinliğini artırmaktadır. Kimyasal açıdan en baskın gruplar monoterpenler ve seskiterpenler olup, bunlara aldehit, keton, fenol, alkol, asetat ve oksit gibi oksijenli türevler eşlik eder. Bazı türlerde ester ve eterler de yüksek oranlarda bulunabilir. Bu farklılıklar, uçucu yağların duyusal özellikleri ve biyolojik aktivitelerini belirleyen başlıca faktörlerdir (Yousefi ve ark., 2019).

Tarımda yaygın olarak kullanılan sentetik fungisitler kısa vadede hastalıkları kontrol etse de zamanla dirençli patojen popülasyonlarının oluşmasına ve çevre ile insan sağlığına olumsuz etkiler yaratmaktadır (Elshafie ve ark., 2015). Bu durum, biyolojik olarak parçalanabilir, çevre dostu ve sürdürülebilir alternatiflerin önemini artırmıştır. Bu bağlamda bitkisel ekstraktlar ve uçucu yağlar doğal ve güvenli bir seçenek olarak öne çıkmaktadır (Vitoratos ve ark., 2013).

Son yıllarda, uçucu yağların doğal yapıları sayesinde antimikrobiyal kullanımına yönelik ilgi artmıştır. Çeşitli araştırmalar, bu bileşiklerin mevcut fungisitlerle karşılaştırılabilir, hatta bazı durumlarda daha üstün antimikrobiyal etki gösterebildiğini ortaya koymaktadır. Antifungal ve antibakteriyel aktiviteleri nedeniyle özellikle bitki patojenlerinin biyolojik kontrolünde umut vadeden bir alternatif olarak değerlendirilmektedir (Cano-Lamadrid ve ark., 2020).

Bilinen yaklaşık 300 bitki familyasının üçte biri uçucu yağ içerirken (Affes ve ark., 2022), bu türlerin yalnızca küçük bir bölümü biyopestisit olarak değerlendirilmiştir (Zhao ve ark., 2021). Uçucu yağların kimyasal yapılarında mentol, linalool, karvakrol, timol, borneol, α-pinen, sitral, öjenol ve d-limonen gibi terpenler yer almakta; bu bileşenler fungus ve bakterilerin gelişimini farklı mekanizmalarla baskılamaktadır. Terpenler bakterilerin ve fungal organizmaların zar yapısını bozmakta, membran geçirgenliğini artırmakta, DNA/RNA sentezini engellemekte ve metabolik aktiviteleri düşürmektedir (Türkkan ve ark., 2020; Guo ve ark., 2021; Han ve ark., 2021; Konuk ve Ergüden, 2022; Zareshahrabadi ve ark., 2023; Houzi ve ark., 2024). Böylece bitkilerin doğal savunma mekanizmalarının bir parçası olarak hem çevresel streslere hem de patojen saldırılarına karşı direnç geliştirmelerine katkı sağlarlar (Hammerbacher ve ark., 2019; Boncan ve ark., 2020; Khan ve ark., 2025).

Birçok familya (Asteraceae, Apiaceae, Lamiaceae, Myrtaceae, Rutaceae, Cupressaceae vb.) uçucu yağ bakımından zengin olup, bu yağlar gıda, kozmetik ve farmasötik alanlarda yaygın olarak kullanılmaktadır (Yeşilbağ, 2007; Fragkouli ve ark., 2023; Gladikostić ve ark., 2023; Önder ve ark., 2024). Bununla birlikte, artan sayıda araştırma, söz konusu yağların güçlü antifungal ve antibakteriyel özellikler sergileyerek tarımsal patojenlerin kontrolünde de değerlendirilebileceğini göstermektedir (Koçak ve Boyraz, 2006; Tapwal ve ark., 2011; Šernaitė ve ark., 2017; Sharma ve ark., 2017; Diánez ve ark., 2018; Jiménez-Reyes ve ark., 2019; Steglińska ve ark., 2022; Saygılı ve ark., 2025).

Cupressaceae familyası ve özellikle *Cupressus* türleri, uçucu yağ içeriği bakımından öne çıkan odunsu bitkilerdir. Bu türlerin yağlarında α-pinen, δ-3-karen, limonen ve borneol gibi monoterpenler ile çeşitli oksijenli bileşiklerin yüksek oranlarda bulunduğu bildirilmektedir (El Hamrouni-Aschi ve ark., 2013; Hosseinihashemi ve ark., 2023). *Cupressus* uçucu yağlarının antimikrobiyal etkinlikleri üzerine yapılan çalışmalar hem insan kaynaklı patojenler hem de bitki hastalık etmenleri üzerinde dikkate değer düzeyde engelleyici etki gösterdiğini ortaya koymaktadır. Özellikle *Cupressus sempervirens* ve *Cupressus macrocarpa* türlerinin uçucu yağları, çeşitli mikroorganizmaların gelişimini inhibe etme potansiyeline sahiptir (Mahmood

ve ark., 2013; Selim ve ark., 2014; Harfouch ve ark., 2022). Bu özellikler, *Cupressus* türlerinden elde edilen uçucu yağların bitki hastalıklarının biyolojik kontrolünde alternatif bir kaynak olabileceğini göstermektedir.

Bu derleme çalışmasında, *Cupressus* türlerinin uçucu yağlarının kimyasal bileşimleri, antimikrobiyal özellikleri ve bitki patojenlerine karşı kullanım potansiyelleri literatür verileri ışığında ele alınmıştır.

2. *Cupressus* Türlerinin Farmakolojik Özellikleri ve Antimikrobiyal Potansiyeli

2.1. Cupressaceae Familyası ve *Cupressus* Cinsi

Cupressaceae familyası, kozalaklı bitkiler (Coniferales) içerisinde en fazla cinse sahip familyalardan biri olup, tür çeşitliliği bakımından üçüncü sırada yer almaktadır. Günümüzde yaklaşık 30 cins ve 130–140 tür ile temsil edilmektedir. Bu familya içerisinde önemli bir yere sahip olan *Cupressus* cinsi, genellikle 5–40 metreye kadar boylanabilen, her dem yeşil ağaçlar veya büyük çalılar ile karakterizedir. Yaprak morfolojisi gelişim dönemine göre farklılık göstermekte olup, genç bireylerde iğne yapraklı, olgun bireylerde ise skala (pul) yapraklı formda bulunmakta ve karşılıklı dizilim göstermektedir (Schulz ve ark., 2005).

Bu cinsin üyeleri, doğal dağılımlarının çok ötesinde geniş coğrafi alanlarda süs bitkisi olarak da yaygın biçimde kullanılmaktadır (Peters ve ark., 2021). *Cupressus* türleri, çok yönlü kullanım alanlarına sahip olup dayanıklı odunları mobilya ve inşaat sektöründe, uçucu yağları ise parfümeri, kozmetik ve farmasötik endüstrilerde değerlendirilmektedir (Weick ve ark., 2023). Türkiye'de doğal olarak yetişen türler, sahip oldukları özellikler sayesinde hem ekonomik hem de ekolojik ve farmakolojik uygulamalara katkı sağlamaktadır (Uçar ve ark., 2019).

Cupressus uçucu yağlarının içerdiği biyoaktif bileşikler yalnızca tıbbi uygulamalarda değil, aynı zamanda fungal ve bakteriyel kaynaklı bitki hastalıklarının biyolojik kontrolünde de önemli bir potansiyel sergilemektedir (Toktaş ve ark., 2024). Bu nedenle *Cupressus* türleri, son yıllarda tarımsal biyoteknoloji ve bitki koruma araştırmalarında dikkat çeken doğal kaynaklar arasında yer almaktadır (Selim ve ark., 2014).

Bitki patojenleriyle ilişkili çalışmalarda özellikle *Cupressus sempervirens* (Akdeniz servisi) ve *Cupressus macrocarpa* (Limon servisi) türleri öne çıkmaktadır (Orhan ve Tumen, 2015). Bu türlerin uçucu yağları üzerine yapılan araştırmalar hem insan kaynaklı mikroorganizmalar hem de tarımsal öneme sahip bitki patojenleri üzerinde belirgin antimikrobiyal etkilere sahip olduklarını ortaya koymaktadır (Soltani ve Hosseyni Moghaddam, 2015; Hussain ve ark., 2019).

2.2. *Cupressus* Türlerinin Uçucu Yağlarının Kimyasal Bileşimi

Cupressus türlerinden elde edilen uçucu yağlar; bitki türüne, kullanılan bitki kısmına (özellikle yaprak ve nadiren odun) ve coğrafi kökene bağlı olarak değişken kimyasal bileşimler göstermektedir (Tablo 1).

Cezayir, Türkiye, Arjantin, Meksika ve Portekiz'de yürütülen çalışmalar, sekiz farklı *Cupressus* türünün uçucu yağ profillerini karşılaştırmalı olarak değerlendirmiştir. Çalışmalarda bildirilen bileşik sayısı 46 ile 54 arasında değişmektedir (Frezza ve ark., 2022).

Genel olarak, α-pinen sekiz türün tamamında en baskın bileşik olarak öne çıkmaktadır. Umbellulone ve terpinen-4-ol beş türde baskın veya ikincil bileşikler olarak rapor edilmiştir. Sabinen üç türde belirgin bir bileşen olarak saptanırken, abietadien, limonen, β-phellandrene, trans-totarol, butil metil eter ve δ-3-karen yalnızca iki türde baskın ya da ikincil konumda

bulunmuştur. Ayrıca karvakrol metileter, α-sedrol, α-terpinil asetat, cis-muurola-4(14),5-dien, filokladanol, nezukol, izofillokladen, trans-ferruginol, α-kadinol, p-simen ve manool gibi bileşikler ise yalnızca tek bir türde tespit edilmiştir (Malizia ve ark., 2000; Mazari ve ark., 2010). Üzerinde en çok araştırm yapılan türler arasında *Cupressus arizonica*, *Cupressus sempervirens* ve *Cupressus macrocarpa* yer almaktadır (Frezza ve ark., 2022).

Tablo 1. *Cupressus* türlerinin uçucu yağ bileşenleri, oranları (%) ve analiz yöntemleri

Tür	Baskın bileşikler	Oran (%)	Yöntem	Kaynak
***Cupressus sempervirens* (Akdeniz servisi)**	α-pinen, δ-3-karen, limonen, sabinen	α-pinen %35–50, δ-3-karen %15–25	Hidrodistilasyon, GC-MS	El Hamrouni-Aschi ve ark., 2013; Mahmood ve ark., 2013
	Karvakrol metileter, α-sedrol, manool, terpinen-4-ol asetat, borneol asetat	Karvakrol metileter %38,2–62,6; α-sedrol %15,7–34,3	GC-MS	Uçar ve ark., 2019
***Cupressus macrocarpa* (Limon servisi)**	α-pinen, limonen, terpinolen, myrcene	α-pinen %20–40, limonen %10–20	Hidrodistilasyon, GC-MS	Bezić ve ark., 2011; Hosseinihashemi ve ark., 2023
	Terpinen-4-ol, α-pinen, sabinen, p-simen	Terpinen-4-ol %29,6; α-pinen %20,2; sabinen %12,0	GC-MS	Malizia ve ark., 2000
***Cupressus arizonica* (Arizona servisi)**	Sabinen, α-pinen, β-pinen, limonen	Sabinen %25–35; α-pinen %15–20	GC-MS	Selim ve ark., 2014
	cis-muurola-4(14),5-dien, α-pinen, umbellulone, limonen, terpinen-4-ol	cis-muurola-4(14),5-dien %90; α-pinen %22,9; umbellulone %16,5	GC-MS	Malizia ve ark., 2000
	Filokladanol, butil metil eter, nezukol, α-pinen, β-phellandrene, umbellulone, isophyllocladene	Filokladanol %14,2; α-pinen %7,6	GC-MS	Adams ve ark., 1997
***Cupressus lusitanica* (Meksika servisi)**	α-pinen, sabinen, bornil asetat, terpinen-4-ol	α-pinen %30; sabinen %25	GC-MS	Harfouch ve ark., 2022
	Abietadien, α-pinen, sabinen, trans-totarol	Abietadien %11–24; α-pinen %6,0–16,6	GC-MS	Adams ve ark., 1997
***Cupressus torulosa* (Himalaya servisi)**	α-pinen, δ-3-karen, borneol	α-pinen %40'a kadar	GC-MS	Soltani ve Hosseyni Moghaddam, 2015
	α-pinen, sabinen, terpinen-4-ol, α-tujen, mirsen	α-pinen %25,8; sabinen %22,3	GC-MS	Malizia ve ark., 2000
Cupressus glabra	Umbellulone, terpinen-4-ol	Umbellulone %27,4; terpinen-4-ol %10,5	GC-MS	Chanegriha ve ark., 1997
Cupressus benthamii	Abietadien, trans-totarol, α-pinen, cis-totarol, trans-ferruginol	Abietadien %26; trans-totarol %19,3	GC-MS	Adams ve ark., 1997
Cupressus lindleyi	Limonen, β-phellandrene, α-cadinol, butil metil eter, umbellulone, terpinen-4-ol	Limonen %14,0; β-phellandrene %13,0	GC-MS	Adams ve ark., 1997

Cupressus türleri arasında belirgin kimyasal çeşitlilik gözlenmektedir ve bu çeşitlilik çoğunlukla türün genetik yapısı, coğrafi kökeni, kullanılan bitki dokusu (yaprak, odun, kozalak vb.) ve ekstraksiyon yöntemi gibi faktörlerden etkilenmektedir. Tüm türlerde ortak baskın bileşik olarak tanımlanan α-pinen, hem biyolojik aktivitenin temel belirleyicisi hem de kimyasal bir belirteç olarak önem taşımaktadır (Borges ve ark., 2019).

Tür içi varyasyonlarda, *C. sempervirens* yaprak yağının α-pinen içeriği %2,8–44,9 arasında değişmiş olup, bu durum kimyasal farklılıklarını ve çevresel-genetik etkileri düşündürmektedir. Türler arası farklılıklarda *C. glabra* ve *C. arizonica* umbellulone bakımından, *C. torulosa* α-pinen ve δ-3-karen yönünden, *C. macrocarpa* ise yüksek terpinen-4-ol içeriğiyle öne çıkmaktadır. Ayrıca *C. benthamii* ve *C. lusitanica*, abietadien ve trans-totarol içeriğiyle dikkat çekmektedir (Tablo 1). Bu kimyasal çeşitlilik, biyolojik aktivitede tür spesifik farklılıkların ortaya çıkmasına yol açmaktadır (Uçar ve ark., 2019).

Bu bulgular, *Cupressus* türlerinden elde edilen uçucu yağların biyolojik aktivite potansiyellerinin türden türe farklılık gösterebileceğini ve bu farklılığın, içerikteki özgül bileşiklerin varyasyonuna bağlı olabileceğini ortaya koymaktadır (Kapadia ve ark., 2022). Bu nedenle, uçucu yağların bitki patojenlerine karşı biyokontrol etkinliği değerlendirilirken, kimyasal bileşimin detaylı biçimde belirlenmesi büyük önem taşımaktadır.

Gelecekteki çalışmaların, çevresel koşulların, bitki dokusu tipinin ve ekstraksiyon yöntemlerinin uçucu yağ bileşimi üzerindeki etkilerini kapsamlı biçimde değerlendirmesi; ayrıca türler arası kimyasal bileşim farklılıklarının biyolojik aktivite ile korelasyonunun ortaya konması, *Cupressus* türlerinin biyoteknolojik ve tarımsal uygulamalardaki potansiyellerini daha net biçimde tanımlamaya katkı sağlayacaktır.

3. *Cupressus* türlerinin Antimikrobiyal Potansiyeli

3.1. *Cupressus* Uçucu Yağlarının Antimikrobiyal Etki Mekanizmaları

Cupressus türlerinden elde edilen uçucu yağların antimikrobiyal etkileri, içeriklerinde yoğun olarak bulunan monoterpenler (ör. α-pinen, δ-3-karen, sabinen, limonen) ve oksijenli türevler (ör. terpinen-4-ol, borneol, trans-totarol) ile ilişkilendirilmektedir. Bu bileşikler hem fungal hem de bakteriyel patojenler üzerinde farklı biyomoleküler mekanizmalarla etki göstermektedir (Nazzaro ve ark., 2017).

3.1.1. Fungal Patojenlere Karşı Etki Mekanizmaları

Cupressus uçucu yağları, fungal hücrelerinin yapısal ve metabolik süreçlerine çok yönlü müdahalelerle etki eder. Lipofilik özellikleri sayesinde fungal hücre zarına entegre olarak zar bütünlüğünü bozar, hifal yapılarda deformasyonlara yol açar ve iyon sızıntısını artırır (Taweechaisupapong ve ark., 2012).

1. Hücre duvarı sentezinin inhibisyonu

Terpenoid ve fenolik bileşikler, kitin ve β-glukan sentezini baskılayarak hücre duvarı bütünlüğünü zayıflatır (Lagrouh ve ark., 2017).

2. Hücre zarı ve ergosterol sentezinin hedeflenmesi

Monoterpenler, fungus zarının lipid tabakasına entegre olarak membran geçirgenliğini artırır. Ergosterol sentezinin baskılanması ile zar bütünlüğü kaybolur, iyon sızıntısı ve metabolit kaybı gerçekleşir (Ben Ghnaya ve ark., 2013).

3. Mitokondriyal fonksiyonların bozulması

Elektron taşıma zincirinin zarar görmesi ATP üretimini azaltır, ROS birikimine neden olur (Ankri ve Mirelman, 1999).

4. Genetik materyal üzerine etki

Fenolik bileşikler DNA ve RNA'ya bağlanarak replikasyon ve transkripsiyonu bozmakta, bu da spor oluşumu ve çimlenme gibi gelişimsel süreçlerin engellenmesine neden olmaktadır (Dambolena ve ark., 2013).

5. Biyofilm oluşumunun inhibisyonu

Uçucu yağ bileşikleri biyofilm gelişimini baskılayarak patojenlerin yüzeye tutunmasını engeller (Nazzaro ve ark., 2017). Bu çok yönlü mekanizmalar, *Cupressus* uçucu yağlarının bitki patojenlerine karşı biyokontrol potansiyelini güçlendirmektedir.

3.1.2. Bakteriyel Patojenlere Karşı Etki Mekanizmaları

Cupressus uçucu yağlarının bakteriler üzerinde de güçlü antimikrobiyal mekanizmalar sergilediği rapor edilmiştir. Bu yağlar, bakteri gelişimini baskılamakla kalmaz; aynı zamanda bitkilerde savunma sinyalizasyonunu da güçlendirir (Dorman ve Deans, 2000; Guimarães ve ark., 2019). Uçucu yağların Gram pozitif ve Gram negatif bakteriler de dahil olmak üzere geniş bir bakteri spektrumuna karşı etkili olduğu bildirilmiştir. Özellikle bakteri hücre zarını parçalayarak geçirgenliği artırdığı, fenilpropanoidler ve terpenoidler gibi ile lipofilik yapıları sayesinde bakteri hücre duvarında delikler açarak hücre bütünlüğünü bozduğu belirtilmiştir (Zengin ve Baysal, 2014).

1. Hücre zarının bozulması: α-pinen ve sabinen gibi monoterpenler zar geçirgenliğini artırır (Zore ve ark., 2011; Melkina ve ark., 2021).

2. Enerji metabolizmasının baskılanması: Proton gradyanının ortadan kalkması ATP üretimini azaltır (Nazzaro ve ark., 2013; Falleh ve ark., 2025).

3. Enzim ve protein inhibisyonu: Terpinen-4-ol ve borneol gibi oksijenli bileşikler, bakteri metabolizmasında rol alan enzimlere bağlanarak onların aktivitesini engelleyebilir (Zhang ve ark., 2018; Yuan ve ark., 2023).

4. Quorum sensing ve biyofilm inhibisyonu: α-pinen ve terpinen-4-ol, hücreler arası iletişimi bozarak biyofilm oluşumunu engeller (Khan ve ark., 2018).

5.Antimikrobiyal uzaklaştırma mekanizmalarının baskılanması: Direnç mekanizmalarında rol alan protein taşıyıcı sistemlerin inhibisyonu, bakterilerin savunma kapasitesini zayıflatır (Haque ve ark., 2016; Agreles ve ark., 2021). Özellikle *C. sempervirens* uçucu yağında bulunan α-pinen ve sedrol bileşiklerinin bakteriyel biyofilmi bozduğu, bakterilerin yüzeye tutunmasını engellediği ve hücre canlılığını azalttığı bildirilmiştir (Al-Mijalli ve ark., 2023). Bu bulgular, *Cupressus* türlerinin bakteriyel patojenlere karşı biyokontrol potansiyeline sahip olduğunu göstermektedir.

3.2. *Cupressus* Türlerinin Bitki Patojenlerine Karşı Kullanım Potansiyeli

Uçucu yağlar, bitkileri patojenlerden korumada doğal, çevre dostu ve sürdürülebilir alternatifler olarak giderek artan bir ilgi görmektedir. *Cupressus* türlerinden elde edilen uçucu yağlar, içeriklerindeki monoterpen ve fenolik bileşikler sayesinde hem fungal hem de bakteriyel fitopatojenlere karşı çok yönlü etki mekanizmaları sergilemektedir. Bitkisel uçucu yağların antimikrobiyal etkileri, bileşimlerinde bulunan cineol, kafur, linalool, α- ve β-pinen, borneol, limonen, karvakrol ve α-terpinen gibi bileşiklerle ilişkilendirilmektedir (Ríos, 2016). Bu bileşiklerin hidrofobik özellikleri, patojen hücre zarına nüfuz ederek zar geçirgenliğini artırmakta, iyon dengesini bozmakta ve hücre ölümüne yol açmaktadır. Ayrıca uçucu yağlar, fungal patojenlerde misel gelişimini yavaşlatmakta ve spor çimlenmesini engellemektedir (Buchbauer ve Baser, 2010). Bu mekanizmalar, *Cupressus* türlerinden elde edilen uçucu

yağların bitki patojenlerine karşı biyokontrol potansiyelini açıklamakta ve bu türlerin doğal antifungal ajanlar olarak kullanılabileceğini göstermektedir (Assadpour ve ark., 2023).

Örnek olarak, *Cupressus arizonica* var. *glabra* (Carolina Sapphire) bitkisinin farklı organlarından elde edilen uçucu yağlar GC ve GC-MS ile analiz edilmiştir. En baskın bileşik α-pinen (%20,7–68,5) olup, limonen, umbellulone, myrcene ve zonarene gibi diğer monoterpenler de belirgin oranlarda bulunmuştur. Bu yağlar, çilek antraknozu etmenleri *Colletotrichum acutatum, C. fragariae* ve *C. gloeosporioides* üzerinde değerlendirilmiş ve yalnızca odun-kabuk fraksiyonu orta düzeyde antifungal etki göstermiştir (Ali ve ark., 2013). Benzer şekilde Pansera ve ark. (2023), *C. sempervirens* yapraklarından elde edilen uçucu yağın kimyasal bileşimini ve *Colletotrichum fructicola* üzerindeki etkilerini incelemiş; β-thujen (%31,4) baskın bileşik olarak belirlenmiş ve uçucu yağ konidiyum çimlenmesini %50 oranında inhibe etmiş, 2 $\mu L \cdot mL^{-1}$ dozunda hiflerde morfolojik bozulmalar gözlenmiştir.

Cupressus arizonica uçucu yağları ayrıca fitopatojen oomycetlere karşı da etkilidir. Yapraklardan elde edilen yağda baskın bileşikler limonen (%23,3) ve α-pinen (%20,5) olup, *Phytophthora* türleri (*P. quercina, P. ×cambivora, P. plurivora*) üzerinde %0,5–%1 konsantrasyonlarda neredeyse tam koloni inhibisyonu sağlamıştır (Milanović ve ark., 2024).

C. sempervirens uçucu yağı hem fungal hem de bakteriyel mikroorganizmalara karşı geniş spektrumlu antimikrobiyal aktivite göstermektedir. İğne ve sürgünlerden buhar distilasyonu ile elde edilen yağ, *Aspergillus niger, A. flavus, A. fumigatus, Fusarium solani, F. oxysporum* ve *Penicillium digitatum* üzerinde yüksek inhibisyon sağlamış, *E. coli, Bacillus lactis* ve *Micrococcus luteus* gibi bakteriler üzerinde de etkili olmuştur (Mahmood ve ark., 2013).

C. sempervirens uçucu yağı, *Aspergillus flavus* ve *Fusarium oxysporum* üzerinde orta düzeyde baskı sağlarken, *Rhizopus stolonifer* üzerinde belirgin etki göstermemiştir. Aktivitenin büyük kısmı α-pinen, β-fellandren, α-terpinil asetat ve sedrol gibi majör bileşiklerden kaynaklanmakta, düşük orandaki bileşikler ise sinerjik etki ile katkıda bulunmaktadır (Mazari ve ark., 2010). Ismail ve ark. (2013), *C. sempervirens* uçucu yağının *Fusarium culmorum, F. oxysporum, F. equiseti, F. verticillioides, F. nygamai, Botrytis cinerea, Microdochium nivale* var. *nivale* ve *Alternaria* sp. üzerinde belirgin inhibitör etki gösterdiğini, *B. cinerea* üzerinde düşük konsantrasyonlarda bile etkili olduğunu rapor etmişlerdir.

C. sempervirens uçucu yağının kimyasal bileşimi ve antifungal etkisi, toplam bileşimin %98,9'unu oluşturan 39 bileşikle incelenmiştir. Monoterpen hidrokarbonlar (%90,7) baskın olup, başlıca bileşenler α-pinen (%40,5) ve δ-3-karen (%24,4) olarak belirlenmiştir. *Penicillium citrinum, B. cinerea* ve *A. flavus* türlerine karşı değişen konsantrasyonlarda inhibisyon gözlenmiş ve en yüksek inhibisyon *P. citrinum* için 500 µL/mL'de (7,67 mm), *B. cinerea* için 62,5 µL/mL'de (8,67 mm) ve *A. flavus* için 500 µL/mL'de (7,33 mm) kaydedilmiştir (Galovičová ve ark., 2023).

Bitkinin farklı fenolojik aşamaları dikkate alınarak elde edilen *C. sempervirens* uçucu yağları, α-pinen, β-karyofillen ve α-cedrol gibi bileşikler sayesinde *B. cinerea* misel gelişimini etkili şekilde baskılamaktadır. Çiçeklenme aşamasında elde edilen yağlar in vitro testlerde en yüksek antifungal aktiviteyi göstermiş ve mikroskobik incelemede konidiyumlarda şişme ve parçalanma gözlenmiştir. 1 mg/mL konsantrasyonda domates meyvelerine uygulanan yağ, hasat sonrası *B. cinerea* enfeksiyonunu %54 oranında inhibe ederek güvenli bir biyokontrol potansiyeli sunmaktadır (Rguez ve ark., 2018).

Cupressus türlerinin uçucu yağları, antimikrobiyal etkilerinin yanı sıra tohum çimlenmesi ve fide gelişimi üzerinde de etkili olabilmektedir. Örneğin, *C. sempervirens* uçucu yağı, kışlık buğday ve mısır tohumları üzerinde *Fusarium* türlerine karşı belirli düzeyde patojen kontrolü

sağlamıştır (Danielewicz ve ark., 2024). Ayrıca, 0,5 mg/mL konsantrasyonunda *B. cinerea* miselyumunu tamamen inhibe ederek *Alternaria alternata* ve *Penicillium italicum* üzerinde de yüksek inhibisyon sağlamıştır (Allagui ve ark., 2023).

C. sempervirens yapraklarından elde edilen uçucu yağda başlıca bileşikler sabinen (%67,46), 3-thujin (%8,50) ve 4-terpineol (%5,01) olup, *Verticillium* ve *Aspergillus* türlerine karşı antimikrobiyal aktivite göstermektedir (Azzaz ve ark., 2019).

Mevcut literatür incelendiğinde, *Cupressus* türlerinin antibakteriyel aktivitelerine ilişkin çalışmaların çoğunlukla tıbbi veya klinik öneme sahip bakteriler üzerinde yoğunlaştığı görülmektedir. Özellikle *Staphylococcus aureus*, *Escherichia coli*, *Salmonella typhimurium*, *Klebsiella pneumoniae* ve *Pseudomonas aeruginosa* gibi klinik patojenlere karşı yüksek düzeyde inhibisyon oranları rapor edilmiştir (Chaudhary ve ark., 2014; Al-Rajhi ve ark., 2023; Al-Mijalli ve ark., 2023). Yapılan çalışmalar, *Cupressus sempervirens*'in antibakteriyel özellikleri bakımından doğal bir biyolojik ajan olarak önemli potansiyele sahip olduğunu göstermektedir. Uçucu yağın başlıca bileşenleri δ-3-karen, D-limonen ve α-pinen olup, düşük minimum inhibisyon konsantrasyonlarında bakterisidal etki göstermekte; bakteri zar bütünlüğünü bozarak protein sızıntısına neden olmakta ve antibiyofilm aktivitesi sergilemektedir (Al-Mijalli ve ark., 2023; Argui ve ark., 2021). Metanol, etanol ve etil asetat yaprak özleri *S. aureus*, *Bacillus subtilis*, *P. aeruginosa*, *E. coli*, *K. pneumoniae* ve *S. typhimurium* türlerine karşı antimikrobiyal etki göstermiş; en yüksek aktivite metanol özlerinde gözlemlenmiştir (Chaudhary ve ark., 2014). Ayrıca, kozalaklardan elde edilen uçucu yağların hem Gram pozitif hem de Gram negatif bakterilere karşı belirgin antibakteriyel etki sergilediği bildirilmiştir (Al-Mouhajer ve ark., 2017). Benzer şekilde, *C. sempervirens* uçucu yağının geniş bir bakteri yelpazesinde aktivite gösterdiği, *P. aeruginosa*, *Salmonella enterica*, *Yersinia enterocolitica*, *B. subtilis*, *Enterococcus faecalis* ve *S. aureus* türlerine karşı etkili olduğu belirtilmiştir (Galovičová ve ark., 2023). Ayrıca *C. sempervirens* yağının *Verticillium* ve *Aspergillus* gibi mantarlar üzerinde inhibisyon potansiyeli sergilediği; bunun yanı sıra *E. coli*, *S. aureus* ve *B. subtilis* gibi bakterilere karşı da değişen düzeylerde antibakteriyel aktivite gösterdiği, en duyarlı türün *B. subtilis* olduğu, *E. coli*'nin ise daha dirençli kaldığı bildirilmiştir (Azzaz ve ark., 2019).

Bununla birlikte, fitopatojen bakteriler üzerine yürütülmüş çalışmalar oldukça sınırlıdır. *Cupressus* türlerinin zengin monoterpen ve fenolik bileşik içerikleri, *Pseudomonas syringae*, *Xanthomonas campestris*, *Agrobacterium tumefaciens* ve *Ralstonia solanacearum* gibi ekonomik öneme sahip bitki patojenlerine karşı da potansiyel antimikrobiyal aktivite gösterebileceğini düşündürmektedir. Ancak bu etkiye ilişkin deneysel kanıtlar henüz sınırlı düzeydedir. Bu nedenle, klinik bakterilerde saptanan güçlü antibakteriyel etkinin, gelecekte yapılacak fitobakteriyel patojenlere yönelik *in vitro* ve *in vivo* çalışmalar ile desteklenmesi, *Cupressus* türlerinin bitki sağlığında biyokontrol ajanı olarak değerlendirilmesine bilimsel temel oluşturacaktır.

4. SONUÇ

Cupressaceae familyasına ait *Cupressus* türlerinin uçucu yağları, günümüz tarımında sentetik pestisitlere alternatif oluşturabilecek önemli biyoaktif kaynaklar olarak öne çıkmaktadır. Yapılan araştırmalar, bu türlerden elde edilen uçucu yağların kimyalarında baskın olarak bulunan α-pinen, δ-3-karen, sabinen ve terpinen-4-ol gibi monoterpenik bileşiklerin, çeşitli fitopatojen mikroorganizmalar üzerinde kayda değer inhibisyon etkisi gösterdiğini ortaya koymuştur.

Söz konusu uçucu yağların antimikrobiyal etki mekanizmaları incelendiğinde, patojen hücre duvarı ve zar bütünlüğünün bozulması, iyon geçirgenliğinin artması, hücre içi komponentlerin dengesinin kaybolması ve biyofilm oluşumunun engellenmesi gibi çoklu hedeflere yönelik etkileri dikkat çekmektedir. Özellikle *Botrytis cinerea, Fusarium* türleri ve *Phytophthora* gibi ekonomik açıdan önemli patojenler üzerinde gösterdikleri yüksek etkinlik, bu yağların biyopestisit olarak kullanım potansiyelini destekler niteliktedir.

Ancak, *Cupressus* uçucu yağlarının ticari anlamda güvenilir biyokontrol ajanlarına dönüştürülebilmesi için öncelikle kimyasal içerik standardizasyonunun sağlanması, uygun formulasyon stratejilerinin geliştirilmesi ve etkinliklerinin gerçek tarımsal koşullarda doğrulanması gerekmektedir. Bu kapsamda yürütülecek multidisipliner çalışmalar, söz konusu doğal ürünlerin sürdürülebilir tarım sistemleri içindeki yerinin güçlendirilmesine katkı sağlayacaktır.

5. KAYNAKLAR

Adams, R. P., Zanoni, T. A., Lara, A., Barrero, A. F., & Cool, L. G. (1997). ABSTRACT

Managing weeds is a major problem that constantly appears in both regenerative and organic farming systems, where synthetic herbicide bans necessitate the creation of new, alternative, ecological methods. In contrast to conventional farming that is still largely reliant on chemical inputs, regenerative and organic farming systems implement ecological principles such as increasing biodiversity, improving soil health, and making the ecosystem more resilient. This article deeply examines the methods of weed control in regenerative and organic farming along with their biological bases, feasibility, and effects on the environment. The article looks at the natural mechanisms that regulate weed populations, among them allelopathy, competition, microbial symbioses, and nutrient cycling. It is particularly emphasized that soil microbial communities through plant–microbe signaling and rhizosphere-mediated suppression can be the major force in weed dynamics. The integration of cultural, mechanical, and biological methods—such as crop rotation, mulching, cover cropping, and microbial inoculation—is at the heart of sustainable weed management in these systems. Besides that, the newest inventions like biochar applications, allelopathic crop breeding, and AI-assisted mechanical weeding being compatible with ecological intensification is a nice touch of technological innovation. A comparative study allows one to say that regenerative and organic systems can cause higher short-term weed pressure, whereas long-term ecological benefits such as improved soil fertility, less erosion, increased biodiversity, and lower carbon footprints are their advantages. The article argues that sustainable weed management should not be regarded as the complete removal of unwanted plants but rather as their biological control within resilient agroecosystems. Understanding weed ecology from a systems perspective that involves biological, technological, and socio-economic aspects will be vital in providing global food security and climate resilience of the future.

Keywords: Regenerative agriculture, Organic farming, Weed ecology, Soil microbiome, Cover crops

INTRODUCTION

Weeds are one of the most tenacious and costly problems that significantly reduce global crop productivity. They not only compete with crops for essential resources such as light, water, nutrients, and space but also act as reservoirs for pests and pathogens (Liebman & Davis, 2000). To address the problem, the conventional agriculture mainly relies on the use of synthetic herbicides and intensive tillage. However, these measures that have indeed raised yields in the short run, have also triggered a series of negative ecological effects - herbicide resistance, soil degradation, biodiversity loss, and water contamination- are among these effects (Tataridas et al., 2022; Heap, 2014).

On the contrary, *regenerative* and *organic* agriculture illustrate two different paradigms which share common goals of restoring ecological processes and increasing the self-regulatory capacity of agroecosystems. Both systems highlight the inseparability of soil, plants, microbes, and the environment. Their final objective is not the control of weeds only, but the creation of resilient ecosystems where the natural control of weeds through ecological equilibrium rather than chemical eradication prevails (LaCanne & Lundgren, 2018; Lal, 2020).

The conventional logic of weed management has been eradication. However, the chemical approaches have their limitations, for instance, pollution of the environment and the problem of herbicide resistance, which have challenged weed ecology and management strategies to rethink. Adaptive management puts forward the aspects of learning and flexibility—being constantly involved in the monitoring of weed dynamics and being able to respond differentially to ecological feedback through adjusting practices (Liebman et al., 2018).

One of the main points of regenerative and organic systems is the understanding that healthy soils are the base of weed suppression. Soil organic matter, microbial diversity, and soil aggregate stability are some of the factors that affect the ability of crops to compete with weeds. Rich and diverse soil microbial communities can, for example, inhibit weed seed germination directly by allelochemical degradation or provision of resources for crop root growth which in turn takes away nutrients and space from the rhizosphere (Berg & Raaijmakers, 2018).

Besides that, biodiversity of both above and below ground can be considered a source of stability in agroecosystems. Crop diversification, polycultures, and agroforestry systems are some of the strategies that increase spatial and temporal heterogeneity thus prevent the supremacy of one particular weed species (Nichols et al., 2015). Under such conditions, weed control becomes the other side of the coin which is managing biodiversity and ecological design.

This paper aims to:

- First of all, it aims to identify the fundamental ecological and agronomic principles that lie behind regenerative and organic weed management system.
- Secondly, it aims to identify the biological, chemical, and physical mechanisms by which these systems bring about weed suppression.
- The third aim of the paper is to examine the innovations and technologies that are compatible with regenerative principles.
- Fourthly, the paper aims to perform a performance, advantages, and limitations comparison of regenerative and conventional weed management systems.

In essence, the research is to show that the sustainable control of weeds is not dependent on singe interventions but rather on the system-level integration of ecological processes. The

understanding of how regenerative and organic systems maintain the balance of weed populations will be a condition for productivity and ecological resilience, given the climate change and soil degradation challenges that global agriculture is facing.

PRINCIPLES OF REGENERATIVE AND ORGANIC AGRICULTURE

Regenerative and organic farming share one of their major beliefs - the belief that agricultural systems have to function in harmony with natural processes, not against them. Both systems put their main focus on sustaining soil health, biodiversity, nutrient cycles, and ecosystem resilience. But regenerative farming, by its very nature, moves beyond the organic certification standards as its ultimate goal is not only to restore but also to revitalize ecosystem functions, reverse soil degradation, and capture carbon from the atmosphere (Lal, 2020; Rhodes, 2017).

While organic farming would not allow the use of synthetic fertilizers and pesticides, regenerative farming would take more steps to restore biological processes, soil structure, and hydrological cycles. The core philosophy of both systems also emphasizes that weed management should result from ecological balance rather than be a separate technical intervention (Gattinger et al., 2012).

Soil Health as the Foundation of Weed Suppression

Soil health is the basis on which both regenerative and organic frameworks have been constructed. Healthy soils have better aggregate stability, higher microbial activity, and improved water-holding capacity—all of which are factors in weed–crop interactions.

Increasing the amount of organic matter in the soil also influences the weed seedbank through changing oxygen diffusion, temperature and microbial decomposition of dormant seeds (Kremer and Li, 2003).

By the same token, the use of microbial inoculants—such as Trichoderma, Azospirillum, and Bacillus species—strengthens plant–soil feedback loops and results in the formation of crop-associated rhizospheres which are the natural inhibitors of weed colonization. At the same time, these microbial communities that compete with weed rhizospheres for carbon substrates also release allelochemicals that facilitate the invasion of weed seedling growth (Berg & Raaijmakers, 2018).

Biodiversity and Ecological Balance

Biodiversity is the ecological insurance of an agricultural system that is sustainable. Species diversity both in the fields and in the surrounding areas in regenerative and organic systems creates the multilayered ecological interactions which are the regulators of weed populations. Through diverse crop rotations, mixed intercropping, and the use of cover crops, the dominance of one species of weeds is lessened because their life cycles are broken, and the niches available are limited (Teasdale et al., 1991).

For example, rotations alternating between cereals, legumes, and root crops bring about temporal variability in the availability of resources, thus making it hard for specialist weeds to adjust. In the same way, diversified landscapes with hedgerows, pollinator strips, and agroforestry buffers attract predatory insects and soil organisms that stabilizing the overall ecosystem and thus indirectly influencing weed suppression (Altieri, 1999).

Functional biodiversity, i.e., the range of ecological roles performed by organisms, also helps in the control of weeds. For instance, ground-cover plants are living mulches that, by shading the soil surface, reduce the light necessary for the germination of weed seeds (Leary and Defrank, 2000). In the same way, allelopathic species like rye (*Secale cereale*) and sorghum

(*Sorghum bicolor*) give off natural phytotoxins that discourage the growth of weeds, thus causing a friendly-to-the-environment herbicidal effect (Reberg-Horton et al., 2005).

Reduced Disturbance and Closed Nutrient Cycling

Minimal disturbance of the soil is one of the features that distinguish regenerative agriculture. Conventional tillage, though efficient in short-term weed removal, loosens the soil and oxidizes the organic carbon thereby increasing the turnover of weed seeds that are brought to the surface (Peigné et al., 2007). Systems that have reduced tillage and at the same time permanent soil cover are able to lessen the germination capacity of the weed seedbank while also improving soil biological activity (Liebman et al., 2018).

Closed nutrient cycling is another key principle of the regeneration that assures that fertility is kept inside through the means of composting, green manures, and livestock integration. Nutrient efficiency and microbial mediation greatly reduce the need for synthetic fertilizers, which if used can be a source of nitrophilous weeds that grow rapidly (Bond & Grundy, 2001).

Besides that, integrated grazing, mostly found in regenerative mixed farms, can recycle nutrients through the deposition of manure while at the same time physically controlling the weeds through selective browsing. The rotational grazing, if properly timed, can cut down on the biomass of species like *Conyza canadensis* and *Amaranthus retroflexus*, thus biologically controlling the weed dominance (Teague et al., 2011).

Holistic System Thinking

Regenerative and organic farming systems both require the use of a holistic approach in which each component of a farm i.e. soil, plants, animals, microbes, and human management are interconnected and self-regulating. Hence, weed control is not a separate aim but a consequence of the system's vigor. A well-organized system with active microbial life, diversified crops, and continuous ground cover naturally abates weed outbreaks (Gomiero et al., 2011).

Bàrberi (2002) observed, "Weeds are not only invaders of space but tellers of management imbalance." By recognizing this ecological signal, weed management becomes an act of ecosystem stewardship rather than mere suppression.

Table 1. Core Principles of Weed Management in Regenerative and Organic Systems

Principle	**Description**	**Ecological Function**	**Practical Example**
Soil Health Enhancement	Building soil organic matter and microbial diversity	Improves nutrient cycling and crop vigor	Composting, biochar use
Crop Diversification	Rotations, intercropping, and polyculture	Disrupts weed life cycles	Legume-cereal rotations
Minimal Disturbance	Reduced tillage and soil protection	Maintains soil structure and microbial balance	No-till with mulch
Biological Regulation	Use of microbes and allelopathic crops	Natural weed suppression	*Bacillus*-based bioinoculants
Continuous Cover	Living mulches or cover crops	Shade and moisture regulation	Clover or vetch cover crops

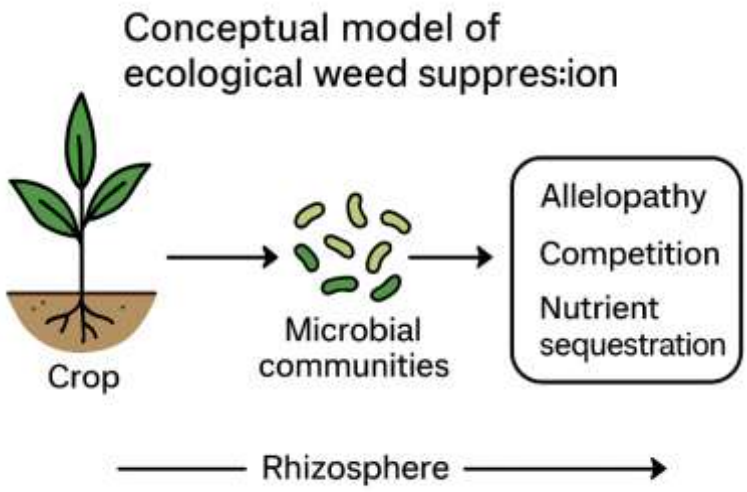

Figure 1. Conceptual model of ecological weed suppression in regenerative systems

CULTURAL AND MECHANICAL WEED CONTROL STRATEGIES

Cultural and mechanical methods are the main elements of weed management in regenerative and organic agriculture. Since synthetic herbicides are not allowed, farmers have to depend on preventive and integrative strategies for keeping the weed populations at a level that does not cause significant harm. These measures not only control the weeds but also improve soil fertility, biodiversity, and ecosystem resilience.

Crop Rotation and Temporal Diversification

One of the oldest and most powerful cultural methods for the reduction of weeds is crop rotation. By changing crops of different heights, nutrient requirements, and compositions of the canopy, the farmers can break the life cycle of the dominant weed species (Liebman & Dyck, 1993). As an illustration, the alternation of the fast-growing cereals with the slow-maturing legumes impedes the weeds which are adapted to one crop type from growing continuously.

The importance of temporal diversification cannot be overemphasized. The staggered planting dates, cover cropping during the fallow period, and intercropping result in the temporal gaps in the use of the resources, which are unfavorable to the germination of the weed seeds. Studies have revealed that rotations with the addition of leguminous cover crops can lower weed density up to 40% in comparison with monoculture systems (Teasdale et al., 1991).

Cover Crops and Living Mulches

Cover crops are living mulches and, thus, are able to offer both the physical and the chemical means for the suppression of weeds. The fast-growing species like rye (*Secale cereale*), oats (*Avena sativa*), and mustard (*Brassica juncea*) have the ability to form dense canopies that shade the weed seedlings which require light for their growth (Reberg-Horton et al., 2005).

The use of allelopathic cover crops is associated with the release of phytochemicals which hinder the germination of the weeds. To cite an example, rye manufactures benzoxazinoids while mustard releases glucosinolates and these are the substances that suppress the germination of the broadleaf weeds (Teasdale & Mohler, 2000). Besides that, cover crops are good for the soil as well because they enhance the soil structure and microbial activity thus making the soil more fertile for the crops and less friendly to the weeds.

Living mulches, such as low-growing legumes like white clover (*Trifolium repens*), provide a continuous cover of the ground that prevents the appearance of weeds during the whole growing season (Leary and Defrank, 2000). The use of a dual system of ecological and mechanical methods for the suppression of weeds can be achieved by the integration of cover crops and living mulches.

Mulching and Residue Management

Mulching is an additional cultural method that is effective. The purpose for which the organic mulches like straw, compost, and wood chips can be used is to create a physical barrier that obstructs light from coming in thus making it almost impossible for the weed seeds to germinate. Besides that, mulches regulate soil temperature and water content, thereby promoting crop growth and discouraging weed development.

Residue management is very much a part of mulching. After harvesting, the practice of leaving crop residues on the soil surface is beneficial both as a mulch and a source of organic matter. The residues decompose slowly, thus they contribute to soil carbon, and increase microbial activity, and hence, provide long-term weed suppression benefits (Bàrberi et al., 2005).

Mechanical Weed Control

Where there is a limitation on the use of chemicals, the mechanization of control measures becomes even more important. They are comprised of different activities such as hand weeding, hoeing, rotary cultivation, flame weeding, and inter-row cultivation. Currently, most regenerative systems are gradually adapting to the use of advanced precision machinery like robotic weeders fitted with sensors for the selective removal of weeds with minimal soil disturbance (Liu et al., 2021).

The mechanical weeding has to be done at the right time so that the target is the weeds before they set seeds. It has been found that very frequent or deep tillage can be the reasons for the disruption of soil structure and the stimulation of weed seed germination, thus the importance of mixing mechanical strategies with ecological knowledge cannot be overemphasized (Peigné et al., 2007).

Integration of Cultural and Mechanical Methods

The greatest success in weed management under regenerative and organic systems can be attributed to the cultural and mechanical approaches working together. An example can be given of cover crops that prevent early-season weed germination, mechanical cultivation that is used to target any survivors, and crop rotations which hinder weed populations from getting adapted.

The combination of winter rye cover crop, spring legumes, and maize rotation together with the shallow inter-row cultivation led to a reduction in weed biomass by 60% over three seasons as compared to continuous monoculture maize plots (Liebman et al., 2018). It is evident from this that integrated strategies have a synergistic effect in lowering the pressure of weeds while at the same time sustaining soil health.

Table 2. Cultural and Mechanical Weed Management Practices

Practice	Mechanism	Target Weeds	Benefits	Limitations
Crop Rotation	Life cycle disruption	Annual and perennial weeds	Reduces seedbank, improves soil	Requires planning, diversity
Cover Crops	Shade + allelopathy	Light-demanding weeds	Soil protection, microbial stimulation	Species-specific effects
Living Mulches	Continuous ground cover	Small-seeded weeds	Reduced germination, nitrogen fixation	Management complexity
Mulching	Physical barrier	Germinating seeds	Moisture retention, soil temperature	Labor-intensive
Mechanical Weeding	Seedling removal	All emerged weeds	Immediate reduction	Soil disturbance, labor

5. Soil Health, Microbiome, and Weed Suppression

Soil health is one of the main elements of regenerative and organic farming systems and it has a direct effect on the weed problem through the physical, chemical, and biological means. Soils that are in a good state with a high amount of organic matter, have good structural stability, and contain a diverse range of microorganisms provide crops with an edge over weeds, thus naturally making the latter's emergence and growth difficult (Gattinger et al., 2012).

Physical and Chemical Soil Properties

Weed seed germination and seedling vigor are affected by soil texture, structure, and organic matter content. So, according to Lal (2020), nicely aggregated soils improve water infiltration and retention, thus, crop roots are favored over weed seedlings. Organic matter increases cation exchange capacity, pH buffer, and nutrient provider by slow release, thus, enhancing crop resilience and competitiveness.

Residue retention and mulching also help to improve the soil microclimate by moderating temperature changes and lowering the light that reaches the soil surface - these are the factors that hinder the germination of photophilic weeds,. When combined, these physical and chemical properties set the baseline environment in which crops dominate and weeds are suppressed naturally.

Microbial Communities and Allelopathic Interactions

Soil microbial communities should be regarded as the main regulators of weed populations. Among beneficial bacteria and fungi, the genera Pseudomonas, Bacillus, and Trichoderma species, can inhibit weed seed germination and seedling growth by release secondary metabolites or by competition for nutrients (Berg & Raaijmakers, 2018; Kremer and Li, 2003).

Suppression of the rhizosphere is the result of interaction between crop roots and their microbiota that create a microenvironment unfavorable to weeds. Root exudates activate the beneficial microbes, which, in turn, suppress weeds through release of allelopathic compounds

or by induction of pathogen resistance in crops (Inderjit & Duke, 2003). This interaction is a major ecological feedback mechanism in regenerative systems.

Soil Fauna and Weed Regulation

he soil fauna that consists of earthworms, nematodes, and microarthropods, is capable of influencing weed populations indirectly through their effect on nutrient cycling and soil structure (Altieri & Nicholls, 2004). As an illustration, earthworms produce macropores that can be utilized by crop roots for penetration thus at the same time they change seed burial depth which has an impact on weed germination pattern. Furthermore, nematodes can also selectively consume weed seeds or seedlings and thus become one of the natural ways of weed suppression.

Cover Crops, Microbes, and Soil Health Synergies

Using cover crops leads to the increase of the diversity and the activity of the soil microbes. The leguminous cover crops like hairy vetch (Vicia villosa) gain the soil not only with nitrogen but also with rhizosphere microbial communities that suppress weeds (Teasdale et al., 1991). Non-leguminous allelopathic species, such as rye (Secale cereale), shed phytochemicals into the soil that stunt the germination of weeds and at the same time, beneficial microbes that support crop growth get activated.

Case Studies of Microbiome-Mediated Weed Suppression

The focus on controlling weeds by manipulating the microbiome is a research area that has brought a lot of attention in recent years. For instance, the results of Kaya et al. (2024) study demonstrated that inoculating rhizosphere bacteria could lead to a 30% reduction in broadleaf weed occurrence in a test field. In addition, the experiment with biochar amendment was effective in promoting microbial diversity that resulted in the weakening of the nitrophilous weeds' competitive ability (Major et al., 2010).

Table 3. Soil-Based Weed Suppression Mechanisms in Regenerative Systems

Mechanism	Description	Effect on Weeds	Agricultural Benefit
High Organic Matter	Improves structure, nutrients	Limits seedling establishment	Enhanced crop growth
Diverse Microbiome	Allelopathic or competitive microbes	Inhibits germination and growth	Reduced weed pressure
Cover Crop Integration	Provides root exudates and canopy cover	Physical + chemical suppression	Improved soil health
Minimal Tillage	Preserves microbial habitat	Alters seedbank dynamics	Stable weed populations
Soil Fauna Activity	Seed predation, nutrient cycling	Reduces weed vigor	Supports ecosystem resilience

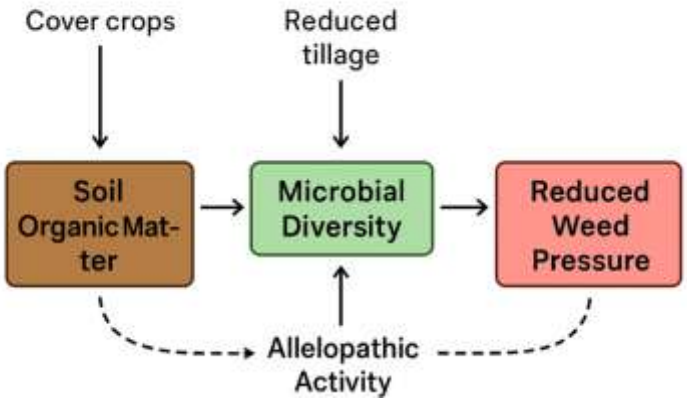

Figure 2. Interactions among soil health, microbial communities, and weeds.

INNOVATIVE AND TECHNOLOGICAL PRACTICES

Precision Mechanical Weeding

Generally, mechanical weeding using a hoe and inter-row cultivation is hard on human labor and may break up the soil structure. Precision mechanical weeding which involved the use of sensors and robots has been there to take away the drudgery of traditional mechanical weeding and also lessen the harm to soil that comes with these methods. What it does is that it recognizes the location of the weeds and eliminates them only (Liu et al., 2021).

The current methods employ cameras, LIDAR, or AI-based image recognition to pinpoint weed seedlings and direct robotic arms to remove them. By these means, the soil is hardly disturbed, the microbial habitats in the soil are preserved, and the labor costs are reduced. Field experiments have shown that precision weeding results in a 50-70% reduction in weed density as compared to traditional mechanical methods with soil structure and crop health being maintained.

Allelopathic Crop Breeding

Another future potential plan is the breeding of crops with allelopathic features. Allelopathic crops are one of the ways of decreasing the weed problem in which these crops release biochemical compounds that hinder the germination or growth of weeds. There are some plants like rye (Secale cereale), sorghum (Sorghum bicolor), and some varieties of rice that are highly allelopathic (Reberg-Horton et al., 2005; Kaya et al., 2024).

There are new breeding programs that work towards these traits being enhanced while yield and quality being not compromised. The reason is that, if there is an allelopathic trait, one can get a significant reduction of the weed seedbank through the combination of cover cropping and allelopathic cultivars-rooting natural herbicidal effect within an ecologically sustainable framework.

Microbiome Engineering

Among the rhizosphere microbiome, the ones that play a key role in weed regulation are those that can deal with the problem of microbial inoculants and soil amendments in the main one. There is a possibility of microbiome engineering with the aid of advanced inoculants and soil amendments-the deliberate installation and/or facilitation of beneficial microbial communities that lead to weed suppression (Berg & Raaijmakers, 2018).

As an example, biofertilizers with Bacillus subtilis or Pseudomonas fluorescens can be good for the crop, but should be avoided by weed seedlings. Soil amendment like biochar or compost not only change microbial activity but also it brings the community that produce allelopathic metabolites and nutrient competition that make the weeds vulnerable to such methods (Major et al., 2010).

Biochar and Soil Amendments

Addition of biochar not only is a good thing for the soil as it improves the soil structure and water retention but at the same time it relates with soil microbes and indirectly helps the soil microbes to suppress the weeds (Lehmann et al., 2011). By absorbing allelochemicals and giving shelters for the good microbes, biochar becomes more effective in rhizosphere-mediated weed suppression. When combined with organic mulches and compost, biochar can become an agent of not only weed management and fertility improvement but also carbon sequestration.

Digital Agriculture and Decision Support Tools

Digital means and precision agriculture software equip farmers with the ability to track down the changes in weed populations, forecast their coming up under the ground, and fine-tune their control measures in the best possible way. This becomes possible with the help of very fine instruments and accurate means such as satellite imaging, drone surveys, and soil sensors that reveal the short-term situations of weed hotspots, soil dryness, and nutrient status (Chandra et al., 2024). Decision support systems or DSS can make the best calls on when to sow, what cover crops to use, or what mechanization to apply, thus, giving room for the implementation of the regenerative practice of adaptive management.

Integration of Ecological and Technological Strategies

The mostly efficient modern practices are the ones that merge ecological rules with technical fixes. For instance, a system might consist of use of allelopathic cover crops together with precision robotic weeding which in turn is supported by microbial inoculants and biochar amendments. These combined tactics not only result in maximum weed suppression but also sustain or better soil health, biodiversity, and ecosystem resilience (Kaya et al., 2024).

In a multi-year field trial, regenerative maize systems incorporating allelopathic cover crops, reduced tillage, microbial inoculants, and AI-assisted mechanical weeding achieved a 65% reduction in weed biomass compared to conventional monoculture maize fields. Soil organic matter and microbial diversity also increased, demonstrating co-benefits for both crop productivity and ecological sustainability.

Table 4. Innovative and Technological Weed Management Practices

Practice	Mechanism	Benefits	Limitations
Precision robotic weeding	Targeted seedling removal	Reduces labor, preserves soil	High initial cost
Allelopathic crop breeding	Biochemical suppression	Natural weed control	Species-specific, research-dependent
Microbiome engineering	Beneficial microbes inhibit weeds	Enhances crop growth	Requires understanding of soil ecology
Biochar amendments	Improves microbial habitat and adsorbs toxins	Indirect weed suppression	Material availability, cost
Digital decision support	Remote sensing + AI	Predictive management, optimized interventions	Technical knowledge required

COMPARATIVE ANALYSIS: CONVENTIONAL VS. REGENERATIVE AGRICULTURE

Conventionally, weed management in agriculture mostly relied on the use of synthetic herbicides for achieving quick suppression, and the use of intensive tillage to further control the land. While such methods may provide short-term control and high crop yields, they often cause degradation of soil health, loss of biodiversity, and reduction of system resilience (Tataridas et al., 2022; Heap, 2014). On the other hand, regenerative and organic farming practices are built upon ecological principles and detailed strategies which primarily aim at the sustainable regulation of weeds rather than their killing.

Effectiveness in Weed Suppression

What conventional systems do best is to very quickly and drastically lessen weed biomass. They do this by making use of chemical herbicides which are very potent. But, as a result of the extensive use of these inputs, a wide range of herbicide resistance in major weed species, such as *Amaranthus palmeri*, *Conyza canadensis*, and *Lolium rigidum*, has occurred (Heap, 2014). Resistance is a factor that limits the effectiveness of the practice in the long run because it forces the users to increase the dose of chemicals or to create newer chemicals and, thus, a cycle of dependence is formed.

After an initial period where these systems live through the high weed pressure, regenerative and organic methods eventually reach the suppression of the latter to long-term through mechanisms of ecological regulation. Different means such as crop rotation, cover cropping, the use of allelopathic cultivars, and microbial inoculants hinder the dominance of any single weed species thus ensuring the fertility of soil and limiting the seedbank proliferation (Liebman et al., 2018; Berg & Raaijmakers, 2018).

Soil Health and Biodiversity Outcomes

Use of conventional methods for weed control is usually associated with the degradation of soil structure and microbial diversity. Frequent heavy tillage and herbicide application break microbial linkages, lower organic matter, and reduce habitat complexity for beneficial organisms (Gomiero et al., 2011). These impacts may indirectly lead to an increase in weed invasiveness through the weakening of crop competitiveness and the ecosystem's resilience.

On the other hand, regenerative farming practices improve soil health and biodiversity, which are essential components of natural weed control. The implementation of minimal tillage, use of organic fertilizers, and diverse cropping systems help to build healthy microbial communities and functional biodiversity that in turn create unfavorable conditions for the proliferation of aggressive weed species (LaCanne & Lundgren, 2018; Altieri, 1999). Consequently, regenerative systems may have slightly higher short-term weed presence but achieve more sustainable, resilient suppression over time.

Environmental and Socio-Economic Considerations

One of the major contributors of environmental degradation is agriculturally dependent on the use of herbicides. The system in question pollutes waterways, kills other plants, and emits greenhouse gases during chemical production and soil disturbance (Tataridas et al., 2022). In addition, resistance to herbicides raises production costs in the long run and limits the number of available management options.

Regenerative and organic farming practices, on the other hand, not only reduce the need for chemicals but also help in carbon sequestration through improved soil management and provide more ecosystem services such as pollination and natural pest control (Gattinger et al.,

2012). These systems may need to invest more labor at the beginning, but from a socio-economic perspective, they will eventually save money through soil fertility improvement and reduction of input use. Economic stability of the area is also enhanced by the local community and market which benefit from the availability of organic or sustainably grown products.

Integrated Perspective

Conventional and regenerative methods differ in lot of aspects, as shown in the table 5.

Table 5. Contrasts The Main Features Of Conventional And Regenerative Weed Management Strategies

Aspect	**Conventional Agriculture**	**Regenerative/Organic Agriculture**
Weed Control Method	Synthetic herbicides, intensive tillage	Crop rotation, cover crops, allelopathic cultivars, microbial inoculants, minimal tillage
Short-Term Effectiveness	High	Moderate
Long-Term Sustainability	Low	High
Soil Health	Degraded	Enhanced
Biodiversity	Reduced	Increased
Environmental Impact	Pollution, herbicide resistance	Reduced chemical inputs, ecosystem services
Labor Requirement	Low (mechanized/herbicide-based)	Moderate to high (cultural and mechanical integration)

To summarize, conventional systems might be able to deliver immediate weed control, but regenerative and organic systems eventually get there by using nature's cycles. The switch from eradication to ecological regulation essentially involves resilience, ecosystem health, and long-term productivity.

FUTURE PROSPECTS, POLICY IMPLICATIONS

The key to future weed management strategies in the context of regenerative and organic agriculture is ecological intensification working hand in hand with technological innovation. Main trends are:

- Enhanced Microbiome Manipulation: In-depth studies on microbiome will make it feasible to
- Allelopathic Crop Breeding: A natural, long-lasting mechanism is
- Precision and Digital Agriculture: Technologies such as sensor-equipped automated
- Agroecological Research and Farmer Knowledge Networks: Farmer

Policy

- Funds and perks: A financial support for
- Instruction and Extension

Support frameworks for policy play a vital role in facilitating

- Funds and Perks: Financial support through subsidies for cover crop
- Training and Extension Services: Conducting training on ecological
- Research Grants: Money invested in research on
- Market Access and Certification: Implementing

Policies that harmonize economic incentives with ecological

CONCLUSION

Proper weed management with sustainable methods including plant diseases control measures is highly needed in agriculture to maintain the balance of natural systems. Weed management in regenerative and organic agriculture represents a paradigm shift from eradication to ecological regulation. These systems achieve sustainable suppression of weeds while enhancing ecosystem services by focusing on soil health, biodiversity, crop competition, and microbial interactions. The key points listed below are the main takeaways from this study:

- Integration of Multiple Strategies: There is no method
- Soil and Microbial Health as Central Components: The
- Long-Term Sustainability: Despite the fact that initial
- Innovation and Technology: Precision
- Policy and Education: Assuming

Ultimately, sustainable weed practices in the context of regenerative and organic farming should not be understood as a complete eradication but rather as the maintenance of ecological balance. These agricultural systems, as research, technology, and policy frameworks are constantly changing, represent feasible resolutions to the interlinked problems of food production, soil conservation, and environmental stewardship.

ABSTRACT

Invasive plants and diseases of crops are the major biotic factors that decrease the productivity of global agriculture, challenge food security, and worsen farmer's living conditions. Weeds are competing with crops for light, nutrients, water, and space, while also being the sources of pests and pathogens. Plant diseases, which are caused by fungi, bacteria, viruses, and nematodes, thus, yield losses to the point where production costs rise. All these biotic stressors ganging together cause big economic and social problems, especially smallholder farming systems, where labor and money limitations make it difficult to adopt effective management practices. Environmentally friendly control methods, e.g., Integrated Weed Management (IWM) and Integrated Disease Management (IDM), advise on using ecological, cultural, mechanical, and biological methods for lessening the use of chemicals while at the same time not losing the crop yield level. The adoption of these eco-friendly activities is largely dependent on socioeconomic factors like financial capital, access to information, institutional support, risk perception, and gender equity. The proof of their benefits exists in different regions where the implementation of integrated strategies has not only lessened the weed and disease pressures but has also provided economic and environmental benefits over time. This work draws attention to the relationships between environment-friendly weed and disease control, their socio-economic factors, and the possibilities of their merging. By combining ecological, economic, and social aspects, a holistic framework can be a guide for policy-makers, extension agents, and farmers in the implementation of effective, fair, and sustainable crop health strategies. The essential points together with the examples given are put into the tables that feature the economic losses, management practices, and adoption constraints, thus, providing the agricultural stakeholders with the actionable insights.

Keywords: Sustainable agriculture, Weed management, Plant disease control, Socioeconomic factors, Integrated management, Smallholder farming

INTRODUCTION

Agriculture is considered a major system in stabilizing food security, creating job opportunities, and maintaining economic stability, especially in the regions of the Global South (Islam, 2025). Despite the sizeable contribution of crop productivity, it is constantly haunted by the presence of biotic stressors among which are weeds and plant diseases. Weeds, in their competition with crops, rob them of light, nutrients, water, and space, while at the same time they can also become the potential sources of pests and pathogens. The diseases of plants which originate from fungi, bacteria, viruses, nematodes, and other agents, have the ability to cause enormous yield reductions besides low product quality and the increase of production costs (Morgan et al., 2019).

The challenge of keeping productivity at a level while at the same time not causing harm to the environment can only be solved by the use of integrated and environmentally friendly weed and disease management strategies. Nevertheless, the decision to take on such a sustainable path does not depend solely on the technical side of things, but also on the labor availability, financial resources, risk perception, knowledge levels, institutional support, and equity considerations which are factors that belong to the socio-economic realm.

This paper is a discussion of the social and economic aspects related to the implementation of sustainable weed and disease management strategies and the emphasis is put on their intersections and mutual influences. The main points of the paper are arranged as follows: the economic and social impacts of the biotic stressors in agriculture, sustainable weed and disease management approaches and the barriers to their adoption, the integrated socioeconomic model, the case studies, and the policy recommendations.

ECONOMIC AND SOCIAL BURDENS OF WEEDS AND PLANT DISEASES

The presence of weeds is a major global economic burden in terms of both the direct loss of yields and the costs of management. As an example, it is estimated that weeds cost the grain and cotton sectors of Australia around 4.43 billion USD on a yearly basis. In the same way, in the United States and Canada uncontrolled weeds in corn and soybean fields can cause up to 50% yield loss, which is equivalent to approximately 43 billion USD annually (FAO, 2023). In the United Kingdom, herbicide-resistant "black grass" is the main factor behind losses that total £400 million each year and it is the major cause that decreases the wheat production by close to 800,000 tonnes (FAO, 2025). . In sub-Saharan Africa, parasitic weeds such as Striga are said to decrease cereal yields to the extent of 40-100%, and accordingly, the economic losses are estimated at 7 billion USD a year (FAO, 2003; Dechassa, 2021; Benjamin et al., 2023). Apart from the economic costs, weeds worsen the incidence of plant diseases as they are the alternate hosts for pathogens and pests.

Diseases of plants also lead to a hefty bill for the world economy. The losses of crops that are due to pests and pathogens are estimated to be 10-20% globally, which results in tens to hundreds of billions of dollars annually (Islam, 2025). Several factors such as intensified monocultures, climate change, and modern agricultural practices that are happening at the same time are said to be the major reasons for the exacerbation of plant disease outbreaks, thereby increasing the associated economic consequences (Gai and Wang, 2024s, 2024). Although biological control measures play a key role in the reduction of the demand for chemical interventions, there are some trade-offs with regard to their cost, labor, and ecological aspects (Fontaine et al., 2022. The integrated approaches that combine resistance breeding, cultural practices, and the use of chemicals in targeted and limited ways are very often the cheapest and most sustainable solutions.

In addition to the financial losses, weeds and diseases have detrimental impacts on the social side and the livelihoods of the people. In small-scale farming systems, labor that is used for manual weed control frequently takes up a major part of the household time and as a result, the time for other productive activities becomes limited. The spread of diseases may lead to the accumulation of debts, the lack of sufficient food, and migration. Also, there are gender disparities, for example, women who have to bear more than their share of the labor in weed management. On top of that, institutional weaknesses such as a low level of extension services, limited access to credit, and poorly developed plant health systems become additional barriers to the adoption of sustainable practices (Islam, 2025; Gai and Wang, 2024s, 2024) (Table 1).

Table 1. Summary of Selected Economic Cost Estimates for Weeds and Diseases

Context	**Cost / Yield Loss Estimate**	**Reference**
Australian grain & cotton	~ USD 4.43 billion annually	Global Agriculture, 2025
U.S. & Canada (corn, soybean uncontrolled)	USD 43 billion (50% yield loss)	ScienceDaily+1
UK (black grass resistance)	£400 million + 800,000 t wheat lost	Cambridge Institute for Sustainability Leadership
African Striga in cereals	~ USD 7 billion	Wikipedia, 2025
Global disease (10–20% losses)	Tens to hundreds of billions USD	Islam, 2025
Biocontrol trade-offs in disease	Varies; eco-economic analysis	Fontaine et al., 2022

SUSTAINABLE WEED MANAGEMENT: METHODS, SOCIOECONOMIC TRADE-OFFS, AND ADOPTION CONSTRAINTS

Environmentally friendly weed management stresses the necessity of ecological and integrated control of weeds as a way of limiting the use of chemicals and at the same time maintaining productivity. The methods involve the use of the following: crop rotation, cover cropping, intercropping, and changed sowing dates to suppress weed emergence. As for the mechanical means, there are precision tillage and robotic weeding, both of which are less labor-intensive and have a reduced use of herbicides. The biological control by using enemies or pathogens that are natural complements the mentioned practices and at the same time, mulching or soil management may be added to further restrict the germination of weeds. Integrated Weed Management (IWM) is the combination of these measures to have the best results both ecologically and economically (Travlos et al., 2017; Sims et al., 2018).

On the economic side, adopting environmentally friendly weed control measures brings both challenges and opportunities to light. While on the short term, the expenses might be higher due to the labor involvement, which is intensive, or the cost of the machinery in which one has to invest, on the long term, the gains will be the reduced herbicide spending, low resistance potential, better ecosystem services, and yield stabilization (Michalis et al., 2025). Nevertheless, what smallholder farmers might be lacking is the financial means and at the same time, they may not have enough risk buffers for them to undertake these practices without the

help of institutions. The success of the example is such as the integrated management of broomrape in Greek tomato fields, which has proven over the last five years that profitability can be increased by 25%, thus, pointing out the economic side of sustainable strategies as a potential (Michalis et al., 2025) (Table 2).

Table 2. Comparison of Conventional vs. Sustainable Weed Management

Factor	Conventional (Herbicide-Based)	Sustainable (Integrated)	Reference
Cost (Short-term)	Lower input/labor, recurring	May be higher (labor, equipment, training)	Monteiro & Santos, 2022; Jamakhandi et al., 2025
Environmental impact	High (pollution, resistance)	Lower, promotes soil & biodiversity	Monteiro & Santos, 2022
Labor requirement	Low	Medium to high	Sims et al., 2018
Knowledge requirement	Low to medium	High (site-specific management)	Jamakhandi et al., 2025
Adoption among smallholders	Widespread	Limited, depends on support	Sithole and Olorunfemi, 2024
Long-term sustainability	Low to moderate	High	Michalis et al., 2025

Two important factors, that is, socioeconomic and institutional, have a big impact on the adoption of the practice. When farmers get access to training, extension services, and localized information, they are more willing to carry out sustainable approaches. Also, being a member of cooperatives and farmer groups can be of great help in the sharing of knowledge and the implementation of collective action, thus, leading to the feasible realization of sustainable weed management. The gender inequalities, limited land tenure, and subsidized herbicides combined together in a bundle of problems that affect farmer's decision-making and may hinder involvement in the practice (Sims et al., 2018; Sithole and Olorunfemi, 2024).

SUSTAINABLE PLANT DISEASE MANAGEMENT: TECHNIQUES, SOCIOECONOMIC HURDLES, AND INTERACTIONS

Plant diseases, driven by fungal, bacterial, viral, and nematode pathogens, continue to cause significant Plant diseases, which are the main causes of crop losses globally, are mainly attributed to fungi, bacteria, viruses, and nematodes. The management of diseases is usually a major contributor via the use of chemical fungicides and pesticides that are a part of the usual management strategies. However, their sustainability is questioned due to the development of resistance, pollution, and effects on non-target organisms (Ma and Rahut, 2024). Sustainable Plant Disease Management (SPDM) achieves the goals of the integration of ecological, cultural, biological, and genetic methods with less use of chemicals and still maintaining the yield level.

SPDM methods mainly rely on the use of resistant varieties, disease control with the help of biologically-active agents, and cultural practices such as crop rotation, sanitation, and correct planting schedule (Hajji-Hedfi et al., 2024; Ma and Rahut, 2024). Integrated Disease Management (IDM) also incorporates these methods with minimal chemically guided

applications through monitoring and decision-making based on thresholds. However, the adoption of such measures is usually limited by monetary constraints, access to inputs, lack of training, and gender inequalities in land ownership and roles of labor, although they are technically feasible (Sithole and Olorunfemi, 2024; Sims et al., 2018).

Economic studies have revealed the potential long-term benefits of SPDM. As a result, blight-resistant potato varieties in East Africa led to a 50–80% reduction in fungicide application and a 15–25% increase in net incomes (Sithole and Olorunfemi, 2024). The introduction of biological control in India has led to a reduction in losses in the banana and vegetable sectors by 20–30%, along with the decrease in the costs of chemicals (Ali, 2012). In addition, farmer awareness through education and participatory methods has been found to reduce the transmission of diseases and the expenses related to it (Enyew and Gobie, 2025), 2018). The interaction between weed and disease management, e.g. the role of weeds as pathogen sources and competition of labor during peak seasons, further underlines the necessity of adopting integrated approaches (Table 3).

Table 3. Constraints to Sustainable Disease Management by Socioeconomic Factor

Factor	Constraint Example	Implication	Reference
Financial Capital	Cost of biocontrol agents or certified seeds	Limits adoption without subsidies	Ma and Rahut, 2024
Access to Information	Lack of extension services or digital tools	Reduces awareness	Sithole and Olorunfemi, 2024
Institutional Support	Weak plant health systems or seed distribution	Delays timely interventions	Junior et al., 2022
Risk Aversion	Perceived yield risk in moving away from chemicals	Preference for conventional methods	Sithole and Olorunfemi, 2024
Social Equity	Gendered labor roles and decision-making barriers	Unequal access to innovation	Sims et al., 2018

TOWARD AN INTEGRATED SOCIOECONOMIC FRAMEWORK FOR SUSTAINABLE WEED AND DISEASE MANAGEMENT

To understand and enhance management practices, a framework is needed that simultaneously integrates all the weed and disease issues in the farming systems. The shared drivers of unsustainable practices, such as labor shortages, market pressures, and reliance on chemical inputs, point to the potential benefits of a coordinated approach. From an environmental perspective, certain practices, such as crop rotation, not only reduce weed seed banks but also disease inoculum. The labor and money problems of smallholder systems highlight the need for intervention prioritization and the integration of policy incentives for both sectors (Sithole and Olorunfemi, 2024; Monteiro & Santos, 2022).

The integrated framework includes five aspects: ecological (weed-crop-pathogen interactions), economic (costs, returns, and risk perceptions), social (labor dynamics and gender roles), institutional (policies, subsidies, extension services), and technological (access to seeds, biocontrol, precision tools). The use of participatory methods such as Farmer Field Schools, community weed mapping, and village seed banks not only increases the adoption level but

also the local relevance of integrated management strategies (Erazo et al., 2024; Ali, 2012). Besides that, policy integration, digital decision-support tools, and eco-conditional subsidization are some of the other factors that facilitate efficient implementation (Ma and Rahut, 2024; Sithole and Olorunfemi, 2024).

Why Integration is Necessary

Integration is needed because most of the economic pressures that have caused the excessive use of chemical herbicides and pesticides for the treatment of plant diseases are almost always the same. These pressures are labor shortages, market demand for clean crops, and limited extension services. Besides that, some management practices have synergistic ecological effects, which influence both weeds and diseases. For instance, crop rotation can decrease both weed seed banks and disease inoculum (Monteiro & Santos, 2022). In smallholder systems, the labor and financial resources dedicated to disease management may lead to less attention being paid to weeds, and vice versa. Finally, governments and institutions can align subsidies, training, and research projects so that they address both weeds and diseases at the same time rather than treating them separately.

Components of an Integrated Socioeconomic Framework

Weed and disease management in an integrated manner could be based on five major interconnected dimensions, which are ecological, economic, social, institutional, and technological. The ecological dimension embraces the interactions between weed-crop-pathogen, the biodiversity, and the risk of resistance. The economic dimension addresses the evaluation of costs, returns, risk perception, and market access. The social aspects cover labor dynamics, gender roles, education, and community norms. Institutional elements cover policy, subsidies, extension services, and infrastructure. Last, but not least, technological aspects deal with the access to seeds, biocontrol agents, mechanical tools, and digital diagnostics. Integration of these dimensions allows the framework to understand the views of different stakeholders, i.e., farmers, policymakers, researchers, NGOs, and agribusiness actors (Sithole and Olorunfemi, 2024; Junior et al., 2022; Ma and Rahut, 2024).

Case For Participatory Approaches

The degree of implementation of sustainable practices in the management of weeds and diseases is higher if the farmers are engaged in the active formulation of strategies rather than simply receiving the advice. Participatory plant health management enables farmer-led experimentation and decision-making, thus resulting in a higher level of ownership and contextual relevance (Ali, 2012). A method like this is Farmer Field Schools, where through experiential learning, the integrated pest management practices can be more effectively adopted (Sims et al., 2018). Community weed mapping is a means of collective monitoring and planning of incoming invasive species, while village seed banks give the opportunity of distributing disease-resistant and weed-competitive varieties in the deprived areas (Hajji-Hedfi, et al., 2024; Erazo et al., 2025).

Integration in Policy and Practice

The integration of the management of diseases and weeds has been gradually reflected in agricultural policies. New modules referring to both weeds and diseases have enriched the FAO's Farmer Field Schools (FAO, 2023). Governments of countries, such as India and Kenya, are investing in digital decision-support tools that can assist smallholders in addressing several biotic stresses at a single platform (Sithole and Olorunfemi, 2024). Some European countries have subsidy programs that are being redesigned with "eco-conditionality," thus linking the

financial assistance for pesticides and herbicides to the implementation of sustainable integrated practices (Ma and Rahut, 2024). However, the extent of these measures is determined by consistent investment, institutional capacity, and long-term political will.

Barriers to Integration

Although there are benefits, a number of barriers prevent the realization of the integration in practice. Very often, research and extension services are arranged in silos, thus they focus on different pests or disciplines, e.g., pathology versus weed science. The financing that supports only one area at a time, e.g., pesticide reduction or seed system development, is also usually very specific. Furthermore, integrated strategies require local ecological and epidemiological knowledge, which is very often not available (Hajji-Hedfi, et al., 2024). Most development projects also have a short-term planning horizon, which is generally too short to see the full benefits of integrated systems, that usually take 3-5 years to show results (Junior et al., 2022).

Table 4. Key Integration Points Between Sustainable Weed and Disease Management

Integration Area	Example Practices	Benefit	Reference
Ecological	Crop rotation, cover cropping	Reduces weeds & disease inoculum	Travlos et al., 2017
Economic	Joint labor planning, cooperative input purchase	Cost-sharing & efficiency	Sims et al., 2018
Social	Farmer Field Schools, gender-inclusive training	Improved adoption & equity	Erazo et al., 2025
Technological	Digital monitoring, precision tools	Timely decision-making	Ma and Rahut, 2024
Policy	Eco-conditional subsidies, seed distribution programs	Incentivizes adoption	Sithole and Olorunfemi, 2024

REAL-WORLD APPLICATIONS OF SUSTAINABLE WEED AND DISEASE MANAGEMENT

Sustainable management of weeds and diseases has been adopted in various agricultural contexts, thus demonstrating the need for locally tailored, economically viable, and socially inclusive strategies. In certain parts of Greece, smallholder tomato farmers were heavily impacted by broomrape (Orobanche spp.), a parasitic weed that caused their yield to be drastically reduced. The traditional way of chemically controlling the problem seemed to be mostly unsuccessful and expensive. The use of Integrated Weed Management (IWM), which included such measures as postponing the time of sowing, using resistant hybrids, manual weeding, and targeted herbicide application, resulted in the reduction of yield losses by over 30%, herbicide use by 40%, and the increase of farm profitability by 25% within the period of five years (Michalis et al., 2025). The success depended on such factors as farmer training, subsidized access to improved seeds, and the close cooperation with agronomists, which demonstrated the vital role of economic and institutional support.

The potato farmers in Kenya and Uganda, both the countries in East Africa region, were plagued with the problem of late blight that kept re-occurring. However, they lacked, most of the times, the means to use effective fungicides and weather forecasting tools. The use of blight-

resistant potato varieties, thus, became a viable option and got support from NGOs and seed cooperatives, which facilitated a reduction in fungicide applications by 50–80% and also resulted in an increase of net income by 15–25% (Sithole and Olorunfemi, 2024). The adoption rate was higher for the members of the cooperative, but women farmers were left behind because of their limited access to seed capital and land, thus, pointing out the necessity of gender-sensitive interventions.

In Andhra Pradesh, India, the resistance to pesticides was widespread and became a major threat to cotton production. To counter the situation, Farmer Field Schools and IPM training were introduced, which promoted the use of methods such as crop rotation, pheromone traps, neem-based biopesticides, and manual weed removal. These steps led to a reduction in pesticide expenses by 40%, thus, yield variability was lowered, and collective action was also enhanced by means of group monitoring and input sharing, which in turn resulted in the sustainability and cost-effectiveness getting improved (Ali, 2012). The present instance serves to point out the worth of community-level approaches to solve the problem of economic and labor barriers.

The rice farmers in Vietnam are suffering more and more from the issue of weeds resistant to herbicides, as well as from fungal diseases, which are further aggravated by climate variability. To address these problems, climate-smart interventions such as laser land leveling, alternate wetting and drying (AWD), biological seed treatments, and farmer-led digital monitoring apps were introduced through public-private partnerships with the significant training and subsidies. The outcome was a 35% reduction in the use of chemicals, a 22% increase in water-use efficiency, and yield gains of 10–15%, thus, indicating the success of the combination of technology, institutional support, and local context (Ma and Rahut, 2024).

Across the diverse case studies presented, the key lessons that have been learned are in many respects similar. Success is facilitated by the access to training and advisory services, collective action through the cooperatives or shared monitoring, as well as by the financial and institutional support, gender-sensitive approaches and technologies that are suitable for local contexts (Michalis et al., 2025; Sithole and Olorunfemi, 2024; Ali, 2012; Ma and Rahut, 2024). Taken together, these examples demonstrate that sustainable weed and disease management can be realized if there are enabling environments, inclusive policies, and locally adapted solutions.

POLICY RECOMMENDATIONS AND FUTURE DIRECTIONS

The implementation of sustainable weed and plant disease management strategies is possible from a technical point of view and is frequently economically advantageous over the long term. Still, the adoption of such strategies is rarely talked about due to the existence of socio-economic, institutional, and informational barriers. To bring about large-scale changes, there is a need to change the orientation of agricultural policy, research priorities, and funding mechanisms (Sithole and Olorunfemi, 2024; Sims et al., 2018).

It is very important to revamp the extension services and farmer education, most notably via participatory models like Farmer Field Schools (FFS) that enable the farmers through experiential learning, combined with training the extension workers in integrated approaches and furnishing multilingual, digital advisory platforms to reach the less privileged groups, including women and youth (Ali, 2012; Ma and Rahut, 2024). There is also a need to reform subsidy and incentive structures since the present schemes are mostly designed in a way that benefits chemical inputs and disfavors Integrated Pest and Weed Management (IPM/IWM). The suggested measures are eco-conditional subsidies linked to the sustainable practices, input

vouchers for biological agents or resistant seeds, and performance-based incentives that reward a reduction in chemical use or an improvement in soil health, thus, easing the risk of adoption for farmers who are economically vulnerable (Junior et al., 2022).

It is also very important to provide the necessary conditions for innovation and local adaptation. The policies should encourage private-public investments in AI-powered disease and weed diagnostics that can be accessed via smartphones; subsidize startups and agritech companies to develop affordable precision instruments for smallholders; and, at the same time, create open-access repositories of localized weed and pathogen data to guide decision-making (Hajji-Hedfi, et al., 2024). All interventions must also focus on the social inclusion aspect and promote gender equity. They should focus on training women and other marginalized groups and providing them with seed distribution, promoting community-managed seed systems and including social impact assessments to ensure that everyone benefits (Sims et al., 2018).

Last but not least, a long-term policy vision should be in place that sees sustainable weed and disease management as an integral part of national agricultural and climate strategies. Among other things, this means the development of national action plans for Integrated Crop Health Management (ICHM), the creation of multi-stakeholder platforms involving farmers, scientists, NGOs, and private sector actors and support for research that is cross-sectoral and integrates weed science, plant pathology, social science, and economics. These steps together—covering extension, subsidy reform, innovation support, social inclusion, and strategic coordination—provide policymakers with the tools they need to build systems that are sustainable, fair, and resilient (Sithole and Olorunfemi, 2024; Ma and Rahut, 2024; Junior et al., 2022; Hajji-Hedfi, et al., 2024; Sims et al., 2018).

CONCLUSION

Managing sustainable weed and plant diseases is a must for the agricultural systems that want to remain resilient while meeting the ever-increasing demands for food security and environmental conservation worldwide. This review has highlighted the interconnected biological, economic, and social dimensions shaping the adoption and effectiveness of sustainable management strategies.

The growth of weeds and the occurrence of diseases in plants continue to be the major causes of significant losses of yields; however, the recourse to chemicals as a means of control, which has been the convential practice, is becoming less and less appropriate because of the various environmental, health, and resistance problems associated with it. Sustainable measures (integrated weed management, use of host resistance, biological control, and cultural practices) are viable alternatives to the traditional ones. Yet, the economic constraints, the limited access to knowledge and inputs, the institutional weaknesses, and the social inequalities negatively affect the widespread acceptance of these measures (Junior et al., 2022; Sims et al., 2018).

It is crucial to have an integrated framework that simultaneously addresses both weed and disease problems while taking into account socioeconomic realities. The implementation of such interventions as participatory, locally adapted, and supported by policies can bring about the desired effect, i.e., farmers will be able to adopt those practices which not only maintain their productivity but are also beneficial for the ecosystem (Ali, 2012; Hajji-Hedfi, et al., 2024).

Reforms in the fields of policy such as extension strengthening, subsidy realignment, technological innovation, and social inclusion are essential to be able to surmount the obstacles that hinder the adoption of inclusion and the scaling of impacts. Besides that, the firm political will and the coordination of the multi-stakeholder action that are required all the time will

facilitate the embedding of sustainable weed and disease management in the national and global agricultural strategies.

To sum up, the realization of sustainable crop health management goals goes beyond the technical challenges and rather represents a complex socio-ecological endeavor. Finding the link between science, policy, and farmer realities is the way to go if we are to have resilient and equitable food systems.

ÖZET

Bu araştırma, Erzurum iline bağlı Aziziye, Aşkale, Çat, Palandöken ve Yakutiye ilçelerinde faaliyet gösteren küçükbaş hayvancılık işletmelerinin demografik özellikleri ile besleme uygulamalarını belirlemek amacıyla yürütülmüştür. Çalışmanın materyalini 170 işletme sahibinden yüz yüze anket yoluyla elde edilen birincil veriler oluşturmuştur. Elde edilen bulgulara göre yetiştiricilerin %46.5'i 41–50 yaş aralığında, %31.8'i 31–40 yaş aralığında yer almakta olup, genç nüfusun sektöre katılımı sınırlıdır. İşletme sahiplerinin büyük çoğunluğu (%64.1) ortaokul ve lise mezunu, %28.8'i ilkokul mezunu, yalnızca %5.3'ü üniversite mezunudur. Deneyim süresi bakımından üreticilerin yaklaşık yarısı (%45.9) 11–20 yıllık yetiştiricilik deneyimine sahiptirler. Besleme alışkanlıklarına göre işletmelerin %69.2'si kaba yemi kendi üretimlerinden sağlamakta, %15.4'ü buna ilave olarak dışarıdan satın almaktadır. Kesif yem temininde ise %42.9'unun tamamen dışa bağımlı olduğu belirlenmiştir. Hayvanların %92.4 oranında günde iki kez yemlendiği, %67.1 oranında "önce kaba yem, sonra kesif yem" şeklinde bir yemleme sırasının tercih edildiği tespit edilmiştir. İşletmelerin %81.2'sinde yemleme işlemleri elle yapılmakta, yalnızca %18.8'inde otomatik yemlik kullanılmaktadır. Gebe hayvanlara ek yemleme uygulayanların oranı %90.6 iken, yem katkı maddesi (probiyotik vb.) kullananların oranı oldukça düşüktür (%2.4). Sonuç olarak, Erzurum'daki küçükbaş hayvancılık işletmeleri genel olarak geleneksel üretim yapısına sahip olup, eğitim düzeyinin ve mekanizasyonun artırılması sektörün verimliliği açısından önem arz etmektedir.

Anahtar Kelimeler: Erzurum, koyunculuk, besleme alışkanlıkları, sosyo-demografik yapı

EVALUATION OF SOCIO-DEMOGRAPHIC CHARACTERISTICS AND FEEDING PRACTICES OF SMALL RUMINANT FARMS IN ERZURUM PROVINCE

ABSTRACT

This study was conducted to determine the demographic characteristics and feeding practices of small ruminant farms operating in the Aziziye, Aşkale, Çat, Palandöken, and Yakutiye districts of Erzurum province. Primary data obtained through face-to-face surveys from 170 farm owners constituted the study material. According to the findings, 46.5% of the breeders were between the ages of 41 and 50, while 31.8% were between the ages of 31 and 40, indicating limited participation from the young population in the sector. The majority of farm owners (64.1%) were middle school or high school graduates, 28.8% were primary school graduates, and only 5.3% were university graduates. In terms of experience, approximately half of the producers (45.9%) had 11–20 years of farming experience. Based on feeding habits, 69.2% of the farms produced their own forage, while 15.4% purchased additional feed from abroad. For concentrate feed supply, 42.9% were determined to be completely dependent on external sources. It was determined that 92.4% of animals are fed twice a day, and 67.1% prefer a feeding order of "roughage first, then concentrate." Feeding is done manually in 81.2% of farms, and only 18.8% use automatic feeders. While 90.6% of farms use supplementary feeding for pregnant animals, the rate of those using feed additives (probiotics, etc.) is quite low (2.4%). Consequently, small livestock farms in Erzurum generally have a traditional production structure, and increasing education levels and mechanization is crucial for the sector's efficiency.

Keywords: Erzurum, sheep farming, feeding practices, socio-demographic structure

GİRİŞ

Tarım ve hayvancılık, ülkelerin ekonomik gelişmişlik düzeylerinden bağımsız olarak stratejik öneme sahip sektörler arasında yer almaktadır. Artan dünya nüfusu ve sağlıklı beslenme gereksinimi, hayvansal ürünlere olan talebi artırmakta ve hayvancılığı sürdürülebilir kalkınmanın temel bileşenlerinden biri haline getirmektedir. Küçükbaş hayvancılık, düşük işletme maliyeti, çok yönlü ürün verimi ve zorlu iklim koşullarına adaptasyon kabiliyeti sayesinde özellikle kırsal alanlarda önemli bir üretim kolu olarak öne çıkmaktadır. Koyunculuk, et, süt, deri ve yapağı üretimiyle ülke ekonomisine katkı sağlamakta, ayrıca kırsal istihdamın artırılması ve göçün önlenmesinde kritik bir rol üstlenmektedir (Kaymakçı, 2006; FAO, 2022).

Türkiye'de koyunculuk faaliyetleri çoğunlukla küçük ölçekli aile işletmeleri tarafından geleneksel yöntemlerle yürütülmekte, bu durum üretim verimliliğini sınırlamaktadır. Ancak 2010'lu yıllardan itibaren uygulanan destek politikaları sayesinde koyun varlığında yeniden artış eğilimi gözlenmektedir. Ülkenin coğrafi yapısı ve iklim özellikleri dikkate alındığında, özellikle Doğu Anadolu Bölgesinin koyunculuk açısından büyük bir potansiyele sahip olduğu görülmektedir (Yaprak ve Esenbuğa, 2024; TÜİK, 2024).

Bu kapsamda yürütülen bu araştırma, Erzurum iline bağlı Aziziye, Aşkale, Çat, Palandöken ve Yakutiye ilçelerinde faaliyet gösteren küçükbaş hayvancılık işletmelerinin demografik yapıları ile besleme uygulamalarını belirlemek amacıyla gerçekleştirilmiştir.

MATERYAL ve YÖNTEM

Bu araştırmanın verileri, Erzurum'un Aziziye, Aşkale, Yakutiye, Çat ve Palandöken ilçelerinde koyunculuk yapan 170 yetiştiriciyle yüz yüze gerçekleştirilen anketler aracılığıyla elde edilmiştir. İlçeler, koyun varlığı ve yetiştirme koşullarının bölgeyi temsil etmesi nedeniyle seçilmiştir. Örneklem, basit tesadüfi örnekleme yöntemiyle belirlenmiş olup, örnek büyüklüğü Yamane (2006) formülüne göre %3 hata payıyla hesaplanmıştır. Uç değer içeren birer anket, varyansı azaltmak amacıyla veri setinden çıkarılmıştır. Elde edilen veriler Microsoft SPSS 2020 programında değerlendirilmiştir.

TARTIŞMA ve SONUÇ

Erzurum'un Aziziye, Aşkale, Çat, Palandöken ve Yakutiye ilçelerinde küçükbaş hayvancılık yapan yetiştiricilerin yaş dağılımı incelendiğinde, üreticilerin büyük çoğunluğunun orta yaş grubunda yoğunlaştığı görülmektedir. Katılımcıların %46.5'i 41–50 yaş, %31.8'i 31–40 yaş aralığında yer almakta olup, genç yetiştirici oranı yalnızca %5.3'tür. Bu sonuç, genç nüfusun hayvancılığa yönelim göstermediğini ortaya koymaktadır. Türkiye'nin çeşitli bölgelerinde yapılan çalışmalarda da benzer bulgular elde edilmiştir. Güney Marmara Bölgesi'nde yetiştirici yaş ortalaması 41.5–44.9 (Çetin ve Koyuncu, 2000), Van'da 46 (Şahin ve Yıldırım, 2002), Doğu Anadolu Bölgesi'nde 48 (Şahin ve Yılmaz, 2008) ve Kastamonu'da 49.3 (Bilginturan ve Ayhan, 2009) yaş olarak bildirilmiştir. Bu veriler, Erzurum'daki yaş dağılımının Türkiye genelindeki eğilimlerle uyumlu olduğunu göstermektedir.

Tablo 1. Yetiştiricilerin Genel Özellikleri

Değişkenler	Sayı (adet)	Yüzde (%)
Yaş		
18-30	9	5.3
31-40	54	31.8
41-50	79	46.5
51-60	25	14.7
61 ve üzeri	3	1.8
İşletmedeki birey sayısı		
1-3	120	70.6
4-6	48	28.2
7 ve üzeri	2	1.2
Eğitim düzeyi		
Okuma-Yazma bilmiyor	1	0.6
Okur-Yazar	2	1.2
İlkokul mezunu	49	28.8
Ortaokul mezunu	58	34.1
Lise mezunu	51	30.0
Üniversite mezunu	9	5.3
Kaç yıldır bu işi yapıyorsunuz?		
1-10	73	42.9
11-20	78	45.9
21-30	11	6.5
30-45	6	3.5
46 ve üzeri	2	1.2

Aile birey sayıları bakımından, Erzurum'daki işletmelerin %70.6'sının 1–3 kişilik ailelerden oluştuğu belirlenmiştir. Erzincan'da yapılan bir araştırmada 3–5 kişilik aile oranı %62.0, 6–8 kişilik aile oranı %27.7 olarak bildirilmiş olup (Özsağlıcak, 2019), birçok bölgede hayvancılıkla uğraşan ailelerin 4–6 kişiden oluştuğu görülmektedir. Buna göre Erzurum'daki küçük aile yapısı, işletmelerin daha küçük ölçekli ve sınırlı işgücüne dayalı olduğunu düşündürmektedir.

Eğitim düzeyi sonuçlarına göre yetiştiricilerin %34.1'i ortaokul, %30'u lise ve %28.8'i ilkokul mezunudur. Üniversite mezunu oranı yalnızca %5.3'tür. Diğer araştırmalar da bu bulguyu desteklemektedir. Kaylan (2019), yetiştiricilerin büyük kısmının ortaokul ve lise mezunu olduğunu bildirmiştir. Şanlıurfa'da yapılan çalışmada da yetiştiricilerin %31.71'inin ilkokul mezunu olduğu ifade edilmiştir (Mundan ve ark., 2018). Bu bulgular, kırsal bölgelerde eğitim düzeyinin genel olarak düşük olduğunu göstermektedir.

Tablo 2. Hayvan Besleme ve Yemleme ile İlgili Genel Bilgiler

Değişkenler	Sayı (adet)	Yüzde (%)
Kaba yemi nereden temin ediyorsunuz?		
Kendi işletmemden	118	69.2
Kiralık arazilerden	2	1.2
Dışarıdan satın alarak	24	14.1
Kendi üretimine ilave olarak dışarıdan satın alıyor	26	15.4
Diğer	0	0
Kesif yemi nereden temin ediyorsunuz?		
Kendi işletmesinde üretiyor	27	15.9
Dışarıdan satın alıyor	73	42.9

Hayır	166	97.6
Kuzular için kesif yem kullanıyor musunuz?		
Evet	137	80.5
Hayır	33	19.5
Kuzulara doğumdan ne kadar sonra ek yem (kaba/kesif) vermeye başlıyorsunuz?		
1.haftadan sonra	2	1.2
2.haftadan sonra	48	28.2
3.haftadan sonra	102	60.0
Sütten kesildikten sonra	9	5.3

Mesleki deneyim açısından değerlendirildiğinde, Erzurum'daki yetiştiricilerin %45.9'unun 11–20 yıl, %42.9'unun 1–10 yıl deneyime sahip oldukları görülmektedir. Uzun yıllar yetiştiricilik yapanların oranı düşük olmakla birlikte, sektörde hem yeni hem de orta düzey deneyime sahip üreticilerin yoğun olduğu anlaşılmaktadır. Erzincan'da yapılan araştırmada ise 31–45 yıl arasında deneyimi olanların oranı %28.3 ve 45 yıl üzeri deneyimli olanların oranı %29.6 olarak bildirilmiştir (Özsağlıcak, 2019). Bu karşılaştırma Erzurum'daki yetiştiricilerin

daha genç bir deneyim profiline sahip olduklarını göstermektedir. Genel olarak, Erzurum'daki küçükbaş hayvancılık işletmeleri orta yaş grubunda yoğunlaşan, eğitim düzeyi ilk ve ortaöğretim ağırlıklı olan, küçük aile yapısına sahip ve 10 yılın üzerinde deneyime sahip yetiştiriciler tarafından yürütülmektedir. Bulgular, Türkiye'nin farklı bölgelerindeki çalışmalarla büyük ölçüde paralellik göstermektedir.

Erzurum'un Aziziye, Aşkale, Çat, Palandöken ve Yakutiye ilçelerinde küçükbaş hayvancılık yapan işletmelerin besleme alışkanlıklarına ilişkin veriler incelendiğinde, üreticilerin büyük çoğunluğunun kaba yemi (%69.2) kendi işletmesinde ürettiği, kesif yemi ise büyük oranda dışarıdan temin ettiği (%42.9) veya kendi üretimine ek olarak satın aldığı (%40.6) görülmektedir. Bu durum, bölgedeki işletmelerin kaba yem açısından daha çok kendi kaynaklarına dayandığını, ancak kesif yem temininde dışa bağımlılığın yüksek olduğunu göstermektedir. Ekonomik koşullar, yem fiyatlarındaki artış ve üretim maliyetleri bu tercihte etkili olabilmektedir. Burdur ilindeki koyun yetiştiricilerinin %53.3 oranında yemi kendilerinin ürettiğini, %43.1 oranla da yem fabrikalarından satın aldıkları bildirilmiştir (Bilginturan ve Ayhan, 2009). Bu oranlar Ankara ili Çamlıdere ilçesindeki koyun yetiştiricileri için aynı sırayla % 36 ve % 64 olarak bildirilmiştir (Taşkesti, 2021)

Gebe hayvanlara ek yemleme, işletmelerin %90.6'sında uygulanmaktadır. Bu yüksek oran, yetiştiricilerin gebelik döneminde enerji ve protein ihtiyacının arttığı bilincine sahip olduklarını ve flushing uygulamasının döl verimi üzerindeki olumlu etkilerini bildiklerini ortaya koymaktadır. Gezer (2010), Sivas'taki işletmelerde koçlara ek yemleme oranının %98.33 olduğunu belirtmiş; Erzurum verileri de benzer şekilde üreticilerin ek yemleme konusunda oldukça bilinçli olduğunu göstermektedir.

Yemleme sıklığı, işletmelerin %92.4'ünde günde iki öğün şeklindedir. Bu oran, ülke genelinde yaygın olan alışkanlıklarla uyumludur. Akkuş (2009), işletmelerin %74.8'inin günde iki kez yemleme yapıldığını bildirmiştir. Erzurum'daki daha yüksek oran, yetiştiricilerin düzenli yemleme uygulamalarına önem verdiğini göstermektedir. Günlük bir öğün besleme yapan işletme oranı ise oldukça düşüktür (%1,2).

Yemleme yöntemi incelendiğinde, işletmelerin %67.1'i önce kaba, sonra kesif yem verdiğini; %32.4'ü ise karışık yemleme yaptığını ifade etmişlerdir. Bu bulgu, bölgede geleneksel besleme alışkanlıklarının hâlâ yaygın olduğunu göstermektedir. Kesif yemin önce verildiği işletme oranı ise oldukça düşüktür (%0.6).

Yemin dağıtım şekli açısından üreticilerin %81.2'si hayvanları elle yemlemekte, yalnızca %18.8'i otomatik yemlik kullanmaktadır. Traktörle yemleme yapan işletme bulunmamaktadır. Bu sonuç, Erzurum'daki işletmelerde mekanizasyon seviyesinin düşük olduğunu göstermektedir. Ekonomik kısıtlar, küçük ölçekli işletme yapısı ve geleneksel üretim alışkanlıkları otomasyonun sınırlı kalmasına neden olmaktadır.

Mineral madde desteği açısından işletmelerin %97.6'sının tuz veya yalama taşı kullandığı belirlenmiştir. Bu oran oldukça yüksektir ve yetiştiricilerin mineral gereksinimlerinin farkında olduklarını göstermektedir. Ancak yem katkı maddesi (probiyotik, vitamin-mineral premiksler vb.) kullananların oranı yalnızca %2.4'tür. Bu sonuç, üreticilerin katkı maddelerine erişim sıkıntısı yaşadıklarını veya bu ürünlerin faydaları konusunda yeterli bilgiye sahip olmadıklarını düşündürmektedir.

Kuzuların beslenmesi değerlendirildiğinde, işletmelerin %80.5'inin sütten kesim öncesinde kesif yem kullandığı görülmektedir. Bu oran, erken dönem ruminant gelişimi açısından olumlu bir uygulamadır. Kuzulara ek yem başlanma zamanı incelendiğinde, yetiştiricilerin %60'ı 3. haftada, %28.2'si ise 2. haftada ek yem vermeye başlamaktadır. Bu değerler literatürle

uyumludur. Kırıkkale'de kuzulara ortalama 19. günde yem verildiği (Bostancı, 2006), Doğu Anadolu'da sütten kesimin 3.92 ayda gerçekleştiği (Karaca ve ark., 1993) bildirilmiştir. Erzurum'da sütten kesim sonrası ek yem kullanım oranının (%5.3) düşük olması, çoğu işletmede ek yemlemenin erken başlamasıyla ilişkilendirilebilir.

Genel olarak değerlendirildiğinde, Erzurum'daki küçükbaş hayvancılık işletmelerinin besleme uygulamalarının geleneksel yöntemlerle yürütüldüğü, kaba yem üretiminde işletmelerin kendi kaynaklarına güvendikleri, kesif yem temininde ise dışa bağımlılığın yüksek olduğu görülmektedir. Gebe hayvanlara ek yemleme ve kuzulara erken dönem ek yem verilmesi yaygın olup, bu durum üreticilerin verim ve döl verimi konularındaki farkındalığını yansıtmaktadır. Ancak otomasyonun düşük olması ve yem katkı maddeleri kullanımının sınırlı olması, işletmelerin modern besleme tekniklerine geçiş konusunda desteklenmesi gerektiğini göstermektedir.

ÖZET

Bu çalışma, Kars ilinde faaliyet gösteren büyükbaş hayvancılık işletmelerinin yetiştirici profillerini ve hayvan varlıklarını belirlemek amacıyla yürütülmüştür. Anket yöntemiyle elde edilen veriler, bölgedeki süt sığırcılığı sektörünün sosyo-ekonomik ve üretimsel dinamiklerini ortaya koymaktadır. Katılımcıların büyük çoğunluğu (%80'den fazlası) 26–55 yaş aralığında yer almaktadır. Bu durum yetiştiricilerin deneyimli olduklarını ancak yaş ortalaması yüksek bir yapıya sahip olduğunu göstermektedir. Eğitim düzeyine bakıldığında, yetiştiricilerin %68,8'inin ilkokul mezunu olduğu, üniversite mezunu üretici bulunmadığı belirlenmiştir. Bu durum, bölgedeki hayvancılık faaliyetlerinde modern tekniklerin benimsenmesini sınırlayan önemli bir faktör olarak değerlendirilmektedir. İşletmelerin %64.4'ü 11–30 baş büyükbaş hayvana sahip olup, işletme ölçeklerinin çoğunlukla küçük ve orta düzeyde olduğu görülmüştür. Hayvan ırkı tercihinde melez ırklar (%92.2) belirgin bir üstünlük göstermiştir; bu da yüksek verim ve bölgesel adaptasyonun birlikte hedeflendiğini göstermektedir. Buna karşılık yerli ırk oranının düşük olması, genetik çeşitlilik açısından risk oluşturmaktadır. Araştırmada ayrıca, işletmelerin yarısından fazlasında düve (%52.9) ve dana (%51.2) bulunmadığı belirlenmiştir. Bu durum dış kaynaklı hayvan teminine ve dolayısıyla hastalık risklerine yol açabileceği endişesini ortaya çıkarmaktadır. Sonuç olarak, Kars'taki süt sığırcılığı işletmeleri aile işletmesi niteliğinde olup, deneyimli fakat düşük eğitim düzeyine sahip üreticiler tarafından yürütülmektedir. Çalışma, sürdürülebilir üretim için damızlık yetiştiriciliğinin teşviki, yerli ırkların korunması, eğitim faaliyetlerinin artırılması ve örgütlenmenin güçlendirilmesi gerektiğini ortaya koymaktadır.

CURRENT STATUS AND DEVELOPMENT OPPORTUNITIES OF DAIRY CATTLE ENTERPRISES IN KARS PROVINCE

ABSTRACT

This study was conducted to determine the breeder profiles and animal assets of cattle farms operating in Kars province. Data obtained through a survey reveals the socio-economic and production dynamics of the dairy cattle sector in the region. The vast majority of participants (over 80%) are between the ages of 26 and 55. This indicates that while these breeders are experienced, their average age is high. Regarding education level, 68.8% of breeders are primary school graduates, with no university graduates. This is considered a significant factor limiting the adoption of modern techniques in livestock farming activities in the region. 64.4% of farms own 11-30 head of cattle, and the farm size is mostly small to medium. In terms of breed selection, hybrid breeds (92.2%) showed a significant advantage, indicating a combined goal of high productivity and regional adaptation. Conversely, the low proportion of native breeds poses a risk to genetic diversity. The study also found that more than half of the farms lacked heifers (52.9%) and calves (51.2%). This raises concerns about the potential for outsourcing of livestock, which could lead to disease risks. Consequently, dairy farms in Kars are family-run, run by experienced but low-educated producers. The study demonstrates that sustainable production requires encouraging breeding stock, protecting local breeds, increasing training, and strengthening organizational structures.

Keywords: Kars Province, Dairy Farming, Farm Structure, Farmer Profile

GİRİŞ

Kars ili, sahip olduğu geniş mera ve çayır alanları sayesinde Türkiye'nin önde gelen hayvancılık merkezlerinden biri olarak öne çıkmaktadır. Bölgedeki meralar buğdaygil (%55–65), baklagil (%23–30) ve diğer bitki türleri (%13–15) bileşiminden oluşmakta olup, bu ekolojik yapı özellikle büyükbaş hayvancılık için son derece uygun koşullar sağlamaktadır. Doğu Anadolu Bölgesi genelinde olduğu gibi Kars'ta da büyükbaş hayvancılık, kırsal nüfusun temel geçim kaynağı ve ekonomik faaliyetin ana kolunu oluşturmaktadır. Sanayi ve hizmet sektörlerinin yeterince gelişmemiş olması ve karasal iklimin bitkisel üretimi sınırlaması, hayvancılığın bölge ekonomisindeki önemini artıran faktörlerdir (SERKA, 2017). TÜİK (2024) verilerine göre, Kars ilinde toplam 604.208 baş sığır bulunmaktadır. 2015–2022 yılları arasında sığır varlığı sürekli artış gösterirken, 2023 yılından itibaren azalma eğilimine girmiştir. Bu süreçte melez ve kültür ırkı sığırların oranı artarken, yerli ırkların sayısında belirgin bir düşüş gözlenmiştir. Yerli ırklar (Yerli Kara, Doğu Anadolu Kırmızısı) iklim koşullarına yüksek uyum gösterse de, et ve süt verimleri ithal ırklara kıyasla düşüktür (Akkaya, 2015). Bölgede kültür ırklarının yaygınlaşması, et verimini artırmakla birlikte yerli genetik kaynakların sürdürülebilirliği açısından risk oluşturmaktadır (Turhan, 2010).

Türkiye genelinde yapılan benzer araştırmalar da kırsal hayvancılık yapısının çoğunlukla küçük ölçekli ve geleneksel nitelikte olduğunu göstermektedir. Erzurum'da Çapadağ (2016), işletme sahiplerinin ortalama yaşını 47, hayvancılıkla uğraşma süresini ise 27 yıl olarak belirlemiş; yetiştiricilerin çoğunun ilkokul mezunu olduğunu ve bağlı duraklı ahır sistemi kullandığını rapor etmiştir. Iğdır'da Kaylan vd. (2019), işletmelerin %84,6'sının hayvan sayısını artırmayı hedeflediğini, üreticilerin ise modernizasyon konusunda teşvik beklediklerini belirtmiştir. Çankırı'da Kaba ve Çanakcı (2020), modern işletmelerin mekanizasyon düzeyinin geleneksel işletmelere göre çok daha yüksek olduğunu; Ankara Polatlı'da Koçak (2020) ise barınaklarda refah koşullarının yetersiz, kayıt sistemlerinin ise zayıf olduğunu saptamıştır. Kars ve Ardahan illerinde yapılan çalışmada (Güven, 2021), sığır yetiştiriciliğinin küçük ölçekli aile işletmeciliği şeklinde yürütüldüğü, yerli ırkların hâlen yaygın olduğu ve üreticilerin önemli bir bölümünün sosyal güvenceden yoksun bulunduğu bildirilmiştir. Erzurum Pasinler'de Aydın (2022), üreticilerin sigorta ödeme istekliliğinin sosyal güvenlik ve gelir düzeyine bağlı olduğunu belirlemiş; Kaygısız vd. (2022) ise sigorta sisteminin yüksek poliçe bedelleri ve bilgi eksikliği nedeniyle yaygınlaşamadığını vurgulamıştır. Kars'ta kooperatifçiliğin gelişmemiş olması, üreticilerin pazarlama süreçlerinde aracı bağımlılığını artırmakta, yem fiyatlarındaki dalgalanmalar ise üretim maliyetlerini yükseltmektedir. Bu durum, küçük ölçekli işletmelerin sürdürülebilirliğini tehdit etmekte ve kırsal göçü hızlandırmaktadır (Tutar vd., 2012; Anonim, 2019). Tarım ve Orman Bakanlığı ile TKDK tarafından yürütülen destek programları, modernizasyonu teşvik etse de bu desteklerden en çok büyük ölçekli işletmeler yararlanabilmektedir (Çelik, 2019).

Bu çalışmada, Kars ilinde süt sığırcılığı yapan işletmelerin mevcut yapısal özelliklerini, yetiştirici profillerini, ırk tercihlerini ve üretim eğilimlerini belirlemek; bölgenin hayvancılık potansiyelini ve gelişim olanaklarını ortaya koymak büyük önem taşımaktadır. Bu araştırma, bölgesel üretim yapısının bilimsel olarak değerlendirilmesiyle, Kars'ın sürdürülebilir hayvancılık politikalarına yönelik stratejik veri sağlamayı amaçlamaktadır.

MATERYAL VE YÖNTEM

Bu araştırmanın materyalini, Kars ilinde büyükbaş hayvancılık faaliyeti yürüten işletmelerin yapısal özelliklerini, üretim koşullarını ve karşılaştıkları temel sorunları belirlemeye yönelik gerçekleştirilen anket çalışmasından elde edilen birincil veriler oluşturmaktadır. Veri toplama süreci, ilin hayvancılık açısından öne çıkan iki önemli bölgesi olan Sarıkamış ve Merkez ilçelerine bağlı kırsal yerleşim birimlerinde yürütülmüştür. Toplam 244 üretici ile yüz yüze görüşmeler yapılmıştır. Örnekleme yapılacak işletme sayısının belirlenmesinde bazı istatistiksel verilere ulaşılamamış; bu nedenle örneklem seçiminde Basit Tesadüfi Örnekleme Yöntemi tercih edilmiştir (Yamane, 2006). Anket formu, üreticilerin sosyo-demografik özellikleri, işletme büyüklüğü, hayvan varlığı, ırk tercihleri, üretim hedefleri ve karşılaşılan temel sorunlara ilişkin sorulardan oluşmuştur. Görüşmeler, her üreticiyle bire bir gerçekleştirilmiş, sorular gerektiğinde açıklanarak yanıtların doğruluğu ve güvenilirliği artırılmıştır. Toplanan veriler MS Excel programı aracılığıyla düzenlenmiş, ardından SPSS 25.0 (2020) paket programında analiz edilmiştir (SPSS, 2020).

TARTIŞMA VE SONUÇ

Kars ilinde büyükbaş hayvancılık işletmeleri üzerine yürütülen bu araştırmada elde edilen demografik bulgular, hem bölgenin üretim yapısına ışık tutmakta hem de literatürde farklı bölgelerde yapılmış benzer çalışmalarla karşılaştırıldığında Türkiye'nin kırsal hayvancılık yapısına ilişkin önemli benzerlikler ortaya koymaktadır. Çalışmanın sonuçları, büyükbaş hayvancılığın ağırlıklı olarak orta yaş ve üzerindeki, eğitim seviyesi düşük ancak yüksek tecrübeye sahip üreticiler tarafından yürütülen bir faaliyet olduğunu göstermektedir. Öncelikle, üreticilerin yaş profili incelendiğinde katılımcıların büyük çoğunluğunun 36–55 yaş aralığında yoğunlaştığı (%53.3), genç nüfusun (18–25 yaş) sektörde oldukça düşük oranla temsil edildiği (%8.6) belirlenmiştir. Bu durum, gençlerin hayvancılığa ilgisinin düşük olduğunu ve üretici nüfusunun giderek yaşlandığını göstermektedir. Benzer şekilde Tatar'ın (2019) İzmir Ödemiş'te yürüttüğü çalışmada yetiştiricilerin çoğunluğunun 36–55 yaş aralığında yer aldığı bildirilmiştir. Farklı illerde yapılan araştırmaların da bu bulguları desteklediği görülmektedir. Kocaman (2014) ve Sevimli (2020)'e göre Türkiye'de hayvancılık faaliyeti ağırlıkla orta yaş ve üzeri yetiştiriciler tarafından yürütülmektedir. Tüm bu çalışmalar birlikte değerlendirildiğinde, Türkiye genelinde büyükbaş hayvancılığın kuşaklar arası aktarımında bir zayıflama olduğu ve gençlerin sektöre dahil olma eğilimlerinin düşük kaldığı anlaşılmaktadır.

Araştırmada işletmedeki birey sayısına ilişkin bulgular da literatürle uyumludur. Katılımcıların %43.9'unun 4–6 kişilik, %30.3'ünün ise 7 kişi ve üzeri bireyden oluşan işletmelere sahip olması, bölgedeki hayvancılık işletmelerinin çoğunlukla aile iş gücüne dayalı geleneksel işletmeler olduğunu göstermektedir. Tatar'ın (2019) Ödemiş ilçesinde yürüttüğü çalışmada toplam çalışanların %66.7'sinin 4–6 kişiden oluştuğunun bildirilmesi, elde edilen bulguların Türkiye'nin farklı bölgeleriyle tutarlı olduğunu göstermektedir. Benzer şekilde Özsağlıcak (2019)'da birçok hayvancılık işletmesinde iş gücünün temel olarak aile bireylerinden oluştuğunu ortaya koymuştur. Bu durum, hayvancılıkta profesyonel iş gücünün sınırlı, aile yapısına dayalı üretimin ise hâlâ baskın olduğunu göstermektedir.

Eğitim düzeyine ilişkin bulgular, bölgedeki insan kaynağının niteliği açısından dikkat çekicidir. Çalışmada üreticilerin çoğunluğunun ilkokul mezunu (%68.8) olduğu, üniversite mezunu üreticinin ise bulunmadığı belirlenmiştir. Benzer şekilde Kaylan (2019), Kayseri bölgesindeki üreticilerin büyük bölümünün ortaokul veya lise mezunu olduğunu, yükseköğrenim düzeyinin ise oldukça sınırlı olduğunu bildirmiştir. Tatar (2007), Kocaman (2014) ve Sevimli (2020) tarafından Ankara ve Aksaray'da yapılan araştırmalarda da üreticilerin büyük çoğunluğunun ilkokul mezunu olduğu saptanmıştır. Bu benzerlik, Türkiye genelinde hayvancılık yapan

kesimin eğitim düzeyinin düşük olması gerçeğini ortaya koymaktadır. Eğitim düzeyinin düşük olması, modern hayvancılık tekniklerinin benimsenmesini, işletme kayıt sisteminin tutulmasını ve yenilikçi teknolojilerin kullanımını sınırlayabilmektedir. Dolayısıyla bölgenin hayvansal üretim potansiyelini artırmaya yönelik eğitim ve yayım çalışmalarının önemini ortaya koymaktadır.

Araştırmada üreticilerin mesleki tecrübelerine bakıldığında, katılımcıların büyük çoğunluğunun 10 yıl ve üzeri tecrübeye sahip olduğu ve özellikle %25,9'unun 26 yıl ve üzeri süredir bu işi yürüttüğü belirlenmiştir. Bu bulgu, hayvancılığın bölgede nesilden nesile aktarılan bir yaşam biçimi olduğunu göstermektedir. Tatar'ın (2019) çalışmasında da üreticilerin %56,3'ünün 26 yıl ve üzeri tecrübeye sahip olduğu belirtilmiştir; dolayısıyla deneyimin özellikle aile işletmelerinde belirleyici bir unsur olduğu anlaşılmaktadır. Ancak bu durum, uzun yıllara dayalı geleneksel deneyimin teknolojik yeniliklere uyumu güçleştirebileceğini de düşündürmektedir.

Genel olarak elde edilen bulgular; Kars ilindeki büyükbaş hayvancılık işletmelerinin, Türkiye'nin birçok bölgesinde olduğu gibi, orta yaş-üstü, düşük eğitim seviyesine sahip fakat yüksek deneyime sahip aile işletmeleri tarafından sürdürüldüğünü göstermektedir. Genç kuşağın hayvancılığa ilgisinin düşük olması, üreticilerin eğitim düzeyinin sınırlı olması ve iş gücü yapısının geleneksel aile modeline dayanması, sektörün modernizasyonu ve sürdürülebilirliği açısından kritik unsurlar olarak değerlendirilebilir. Bu nedenle, hayvancılık sektörünün gelecekte rekabet gücünü koruyabilmesi için gençlerin sektöre kazandırılmasına yönelik teşviklerin artırılması, eğitim-yayım faaliyetlerinin güçlendirilmesi ve aile işletmelerinin teknoloji kullanımını destekleyecek politikaların geliştirilmesi önem taşımaktadır.

Tablo 1. Yetiştiricilerin Genel Özellikleri

Değişkenler	Sayı (adet)	Yüzde (%)
Yaş		
18-25	21	8.6
26-35	66	27.0
36-45	78	32.0
46-55	52	21.3
56-65	26	10.7
66 ve üzeri	1	0.4
İşletmedeki birey sayısı		
1-3	63	25.8
4-6	107	43.9
7 ve üzeri	74	30.3
Eğitim düzeyi		
Okuma-Yazma bilmiyor	1	0.4
Okur-Yazar	4	1.6
İlkokul mezunu	168	68.8
Ortaokul mezunu	10	4.2
Lise mezunu	61	25.0
Üniversite mezunu	0	0
Kaç yıldır bu işi yapıyor		
1-5	12	4.9
6-10	52	21.3
11-15	35	14.3
16-20	47	19.3
21-25	35	14.3
26 ve üzeri	63	25.9

Bu araştırmada Kars ilindeki büyükbaş hayvancılık işletmelerine ait temel yapısal özellikler incelenmiş ve işletmelerin hayvan varlığı, sağmal inek sayısı, ırk tercihleri ve genç hayvan populasyonu bakımından mevcut durumu ortaya konulmuştur. Elde edilen bulgular, bölgedeki hayvancılığın genel karakteristiğinin Türkiye'nin farklı bölgelerinde yapılmış benzer çalışmalarla paralellik gösterdiğini ortaya koymaktadır. Araştırma sonuçları, işletmelerin büyük çoğunluğunun küçük ve orta ölçekli hayvan varlığına sahip olduğunu göstermektedir. Katılımcıların %64.4'ünün 11–30 baş hayvana sahip olması, Kars ilinde büyükbaş hayvancılığın temel olarak orta büyüklükte aile işletmeleri tarafından yürütüldüğünü göstermektedir. Bu bulgu, Erzurum Horasan'da Bastem (2018) tarafından bildirilen; işletmelerin büyük bölümünün 20–40 baş hayvan kapasitesinde olduğu yönündeki sonuçlarla uyum göstermektedir. Her iki araştırma birlikte değerlendirildiğinde, Doğu Anadolu Bölgesi'nde işletme büyüklüklerinin genellikle orta düzeyde yoğunlaştığı görülmektedir.

Sağmal inek sayısına ilişkin bulgular da bu durumu desteklemektedir. İşletmelerin yaklaşık %90'ının 1–10 baş sağmal ineğe sahip olması, süt sığırcılığı faaliyetlerinin Kars'ta büyük ölçüde aile tipi üretim yapısıyla sürdürüldüğünü göstermektedir. Trakya bölgesinde Keskin ve Dellal (2011) tarafından yapılan çalışmada da işletmelerin çoğunluğunun 1–5 baş sağmal ineğe sahip olduğu belirlenmiştir. Bu benzerlik, Türkiye'nin farklı coğrafyalarında süt sığırcılığının genel olarak küçük ölçekli yapıda olduğunu ortaya koymaktadır. Irk tercihleri incelendiğinde işletmelerin %92.2 gibi çok yüksek bir oranla melez ırkları tercih ettiği görülmektedir. Yerli ve kültür ırkı kullanımının oldukça düşük seviyede kalması, bölgedeki üreticilerin verim ve dayanıklılık dengesi bakımından melez ırkları daha avantajlı bulduğunu göstermektedir. Bu eğilim, bölgenin iklim koşullarına uyum gereklilikleri ve bakım maliyetleri dikkate alındığında beklenen bir durumdur. Araştırmanın dikkat çekici bulgularından biri, işletmelerde genç hayvan varlığının büyük oranda sınırlı olmasıdır. İşletmelerin yarısından fazlasında düve (%52.9) ve dana (%51.2) bulunmaması, sürü yenileme stratejisinin çoğu işletmede iç üretimle değil, dışarıdan hayvan teminiyle yürütüldüğünü göstermektedir. Bu durum işletme sürdürülebilirliği açısından risk oluşturmaktadır. Çünkü dışarıdan hayvan satın almak ekonomik maliyeti artırmakta ve sağlık yönetimi açısından ek riskler taşımaktadır. Benzer bir durum, Ödemiş bölgesindeki süt sığırcılığı işletmelerinde de bildirilmiş olup Tatar (2019), işletmelerin büyük bölümünde dana, buzağı ve özellikle besi hayvanı bulundurulmadığını rapor etmiştir. Her iki çalışma birlikte değerlendirildiğinde, Türkiye'nin birçok bölgesinde genç hayvan yetiştiriciliğinin ihmal edildiği ve işletmelerin yenileme materyalini dışarıdan temin etmeye yönelik bir eğilim gösterdiği anlaşılmaktadır. Buzağı varlığının tüm işletmelerde bulunmasına rağmen büyük ölçüde 1–10 baş aralığında yoğunlaşması, işletmelerin buzağı yetiştiriciliğini temel bir faaliyet olarak sürdürse de sürü büyütme stratejilerinin sistematik olmadığına işaret etmektedir. Ayrıca işletmelerin üçte birinde besi hayvanı bulunmaması, Kars ilinde büyükbaş hayvancılığın süt ağırlıklı bir üretim yapısına sahip olduğunu göstermektedir.

Genel olarak bu bulgular, Kars ilindeki büyükbaş hayvancılık işletmelerinin küçük ve orta ölçekli, melez ırka dayalı, dışardan hayvan teminine bağımlı, aile tipi işletme yapısını koruyan bir üretim modeli benimsediğini ortaya koymaktadır. İşletmelerin sürdürülebilirliğinin artırılması için genç hayvan yetiştiriciliğini teşvik eden, iç sürü yenileme oranlarını iyileştiren ve işletme içi damızlık üretimini destekleyen politikaların geliştirilmesi önem taşımaktadır. Ayrıca melez ırkların yaygın kullanımının verimlilik, dayanıklılık ve bölgesel adaptasyon açısından avantaj sağladığı görülmekle birlikte, uzun vadede kültür ırklarının ekonomik olarak daha erişilebilir hâle getirilmesi bölgedeki üretim kapasitesini artırabilecektir.

Tablo 2. İşletmelerde Yetiştirilen Hayvanlara Ait Bilgiler

Değişkenler	Sayı (adet)	Yüzde (%)
İşletmedeki büyükbaş hayvan sayısı?		
1-10 baş	22	9.0
11-20 baş	88	36.1
21-30 baş	69	28.3
31-40 baş	44	18.0
41-50 baş	12	4.9
50 baş ve üzeri	9	3.7
İşletmedeki sağmal hayvan sayısı		
1-5 baş	124	50.8
6-10 baş	95	38.9
11-15 baş	15	6.15
16-20 baş	3	1.25
21-25 baş	4	1.65
26 baş ve üzeri	3	1.25
İşletmelerde tercih edilen ırklar		
Yerli	10	4.1
Melez	225	92.2
Kültür ırkı	9	3.7
İşletmelerdeki düve sayısı		
1-5	75	30.7
6-10	33	13.5
11-15	3	1.2
16-20	2	0.8
21-25	2	0.8
26 ve üzeri	0	0
Bulunmuyor	129	52.9
İşletmelerdeki dana sayısı		
1-5	82	33.6
6-10	33	13.5
11-15	4	1.6
16-20	0	0
21-25	0	0
26 ve üzeri	0	0
Bulunmuyor	125	51.2
İşletmelerdeki buzağı sayısı		
1-5	125	51.2
6-10	97	39.8
11-15	10	4.1
16-20	3	1.2
21-25	2	0.8
26 ve üzeri	7	2.9
Bulunmuyor	0	0
İşletmelerdeki besi hayvanı sayısı		
1-5	36	14.8
6-10	68	27.9
11-15	40	16.4
16-20	13	5.3
21-25	1	0.4
26 ve üzeri	1	0.4
Bulunmuyor	85	34.8

Sonuç olarak, bu çalışma Kars ilinde büyükbaş hayvancılığın mevcut yapısının Türkiye'deki genel eğilimlerle uyumlu olduğunu, geleneksel aile işletmeciliği şeklinde devam ettiğini, ancak özellikle genç hayvan yetiştiriciliği ve sürü yenileme konularında iyileştirmeye ihtiyaç duyulduğunu göstermektedir. Bu kapsamda destekleme politikalarının yeniden ele alınması, üreticilerin teknik bilgi ve uygulama kapasitesinin artırılması ve işletme yönetim planlarının daha uzun vadeli bir bakış açısıyla şekillendirilmesi sektörün gelişimi açısından kritik önem taşımaktadır.

ABSTRACT

Community understanding and awareness serve as a crucial foundation in maintaining the sustainability of natural resources, particularly in the upstream areas of watersheds. Communities with a higher level of knowledge about conservation tend to manage their environment in a more sustainable manner. Water ecosystem services include ecological benefits that support human life, such as clean water provision, flood control, and water quality maintenance. Thus, the relationship between humans and water resources in upstream areas is often reciprocal. The Sub-Watershed Way Sekampung in Lampung Province is one of the key areas that plays a major role in supplying water for agricultural, domestic, and industrial needs in the downstream region. This study aims to identify the role of upstream communities in the Way Sekampung Sub-Watershed in supporting the sustainability of water ecosystem service conservation. The research was conducted using a qualitative method with a descriptive approach, namely a study that seeks to describe phenomena based on literature analysis through the concept of a systematic review, which aims to collect evidence to answer predetermined research questions. Upstream communities show an 83% level of willingness to participate in conservation activities, particularly when economic incentives are provided through the Payment for Environmental Services (PES) scheme. Previous studies also indicate that approximately 78.4% of upstream communities in the Kambaniru watershed understand the relationship between forest cover and water availability, and 72% of them are directly involved in conservation activities such as tree planting and water resource management. These findings demonstrate that community participation and water ecosystem service conservation are positively correlated, highlighting the vital role of local communities in ensuring environmental sustainability.

Keywords: Conservation, communities role, water ecosystem services

INTRODUCTION

Community understanding and awareness are fundamental in maintaining the sustainability of natural resources, particularly in upstream watershed areas (Gupta *et al*., 2022). Communities with a high level of knowledge regarding conservation are generally more capable of managing their environment in a sustainable manner. They understand that every action—such as cropping patterns, land-use practices, or water management—has direct consequences for ecosystem balance. Therefore, environmental literacy becomes a key aspect in ensuring that conservation efforts are not temporary but remain sustainable over the long term.

Conservation activities play an essential role in maintaining ecosystem functions, including the preservation of water environmental services. Water environmental services encompass ecological benefits that support human life, such as providing clean water, regulating floods, and maintaining water quality. When conservation activities are not optimally implemented, these functions may decline, leading to reduced land productivity, increased hydrological disaster risks, and decreased water availability for downstream communities. Hence, community involvement in maintaining the sustainability of water environmental services is crucial, especially for upstream communities who directly influence water quality and quantity (Environmental Management, 2022).

The relationship between humans and water resources in upstream areas is often reciprocal. On one hand, upstream communities depend on water resources for domestic and agricultural needs (Pamungkas *et al*., 2023). On the other hand, they serve as key actors in maintaining water availability for downstream regions. Conservation practices carried out by upstream communities—such as tree planting, agroforestry, and efficient water use—have significant impacts on sustaining water environmental services at the sub-watershed level. Thus, strengthening upstream community knowledge on sustainable water resource management is a crucial factor in maintaining watershed ecosystem stability.

The Way Sekampung Sub-Watershed in Lampung Province is an important area that significantly contributes to water supply for agriculture, domestic use, and industry in downstream regions. The biophysical conditions of the upstream area show vulnerability to environmental degradation due to land-cover change and intensive human activities. Land clearing, forest conversion, and limited adoption of soil and water conservation techniques are major threats to water sustainability. In this context, the level of knowledge and awareness among upstream communities regarding the importance of conservation becomes a determining factor for effective watershed management (Andriyani *et al*., 2021).

Several previous studies have shown that the success of conservation programs in upstream areas heavily depends on community understanding of environmental management concepts (Yumantoko *et al*., 2024). Communities who understand the ecological functions of forests and water resources tend to participate more actively in conservation activities than those lacking environmental awareness. This reinforces that conservation efforts require not only policy and technology support, but also behavioral change rooted in local knowledge. Therefore, understanding the knowledge level of upstream communities is an essential first step in designing effective and participatory conservation strategies in the Way Sekampung Sub-Watershed.

Based on these conditions, this study focuses on analyzing the role of upstream community knowledge in supporting the sustainability of water environmental services conservation in the Way Sekampung Sub-Watershed. The study is expected to provide deeper insights into the relationship between community knowledge and water resource conservation efforts. Its results

may serve as a basis for policymakers and environmental managers to formulate adaptive, equitable, and community-based watershed management strategies.

PURPOSE

This study aims to identify the role of upstream communities in the Way Sekampung Sub-Watershed in supporting the sustainability of water environmental services conservation.

METHOD

This research was conducted using qualitative methods through a descriptive approach, aiming to describe a phenomenon based on a literature review using the systematic review concept, which seeks to gather evidence to answer predetermined research questions (Pollock et al., 2018). This approach involves identifying all primary studies relevant to the topics of conservation, environmental knowledge, and water environmental services in upstream watershed areas, followed by critical appraisal of their methodological quality and synthesis of findings to produce a scientifically accountable and comprehensive overview.

This research also utilizes secondary data from previous studies that measure community knowledge, conservation participation, and the economic value of water environmental services, both in the Way Sekampung Sub-Watershed and in comparable watersheds. These secondary data are used to build comparative tables, supporting graphs, and strengthen discussions regarding the relationship between community knowledge and water environmental services sustainability.

The tools and materials for this study include a list of questions or questionnaires, field note books (tally sheets), stationery, calculating tools, computers, and cameras. Although this research does not collect primary data directly, these instruments are prepared as part of the research framework that may be utilized in future field studies. Data analysis was conducted using descriptive techniques by summarizing findings, connecting patterns across variables, and developing interpretations to explain the role of upstream community knowledge in supporting conservation and sustainability of water environmental services in the Way Sekampung Sub-Watershed.

RESULTS AND DISCUSSION

1. Knowledge Condition of Upstream Communities in the Way Sekampung Sub-Watershed

The results of the literature review show that communities in the upstream areas of the watershed generally have a fairly good level of understanding regarding the relationship between land cover, vegetation presence, and water availability. Several relevant studies, such as Vatir et al. (2022), found that **78.4%** of upstream communities understand that forest degradation reduces water discharge and increases the risk of drought. This finding is supported by other studies on tropical watersheds, which indicate that environmental literacy among upstream communities is directly associated with awareness of water resource conservation (Suharno et al., 2021).

In the context of the Way Sekampung Sub-Watershed, secondary data reveal similar trends, where communities understand the importance of buffer vegetation, riparian protection, and environmentally friendly land management. This level of understanding serves as an initial asset in encouraging their participation in water conservation programs. The measurement of environmental knowledge among upstream communities is presented in **Table 1**.

Table 1. Instrument for Measuring Environmental Knowledge

Variable	Measurement Indicators	Likert Scale (1-5)
Factual Knowledge	Understanding forest functions, water quality, hydrological cycle	1: Very Knowledgeable 2: Knowledgeable 3: Neutral 4: Unkowledgeable 5: Very Unknowledgeable
Conceptual Knowledge	Understanding the relationship between conservation and water environmental services	1: Very Knowledgeable 2: Knowledgeable 3: Neutral 4: Unkowledgeable 5: Very Unknowledgeable
Procedural Knowledge	Understanding how to perform conservation activities such as tree planting and spring rehabilitation	1: Very Knowledgeable 2: Knowledgeable 3: Neutral 4: Unkowledgeable 5: Very Unknowledgeable

2. Conservation Practices Conducted by Upstream Communities

The relatively good level of knowledge is reflected in the involvement of upstream communities in various forms of conservation activities. Several studies in comparable watersheds show that more than **70%** of local communities participate in forest rehabilitation, tree planting, spring protection, and land clearing restrictions (Rahmadani et al., 2023). In the Way Sekampung Sub-Watershed, these practices are primarily driven by the community's need for clean water for domestic and agricultural use. Communities have also begun implementing simple agroforestry techniques and reducing land-burning practices. These findings indicate that communities not only understand conservation concepts but have also implemented concrete actions that support the restoration and sustainability of water environmental services. The measurement conservation participation among upstream communities is presented in **Table 2**

Table 2. Instrument for Measuring Conservation Participation

Variable	Measurement Indicators	Likert Scale (1-5)
Physical Participation	Direct involvement in conservation activities	1: Very Often 2: Often 3: Between Times 4: Infrequent 5: Never
Management Participation	Attendance in meetings, forest farmer groups, or monitoring activities	1: Very Often 2: Often 3: Between Times 4: Infrequent 5: Never
Decision-Making Participation	Involvement in planning conservation activities	1: Very Often 2: Often 3: Between Times 4: Infrequent 5: Never

3. Relationship Between Environmental Knowledge and the Sustainability of Water Environmental Services

The environmental knowledge level of upstream communities is directly proportional to the quality of water source management and the sustainability of environmental services produced. Muslihat et al. (2022) found that ecological literacy among upstream communities can increase conservation effectiveness by **23–40%**, especially in areas dependent on surface water. In the Way Sekampung Sub-Watershed, communities that understand the impacts of land-use change are more active in maintaining vegetation cover and reducing riparian degradation. This involvement has a direct effect on the sustainability of downstream water flow, which relies on stable discharge from the upstream region. Therefore, knowledge acts as a fundamental factor determining the quality and continuity of water environmental services.

4. Comparison of Upstream Community Participation in Way Sekampung and Other Watersheds in Indonesia

Compared to other watersheds in Indonesia, the level of upstream community participation in Way Sekampung is relatively high and stable. For example, in the Kambaniru Watershed (NTT), only 72% of households participate in spring protection (Vatir et al., 2022), while in the Ciliwung Watershed participation levels are around **55–60%** (Pradana et al., 2021).

Tabel 3. Comparison of Upstream Community Participation

Watershed Region	Knowledge Level	Conservation Participation	Explanation
Way Sekampung (Lampung)	83% (High)	82% (Very Active)	High understanding of water conservation; active in spring protection & agroforestry
Kambaniru (East Nusa Tenggara)	78.4% (Moderate)	72% (Active)	Strong understanding of forest–water relationship
Ciliwung (West Java)	60% (Low)	55% (Less Active)	Low participation due to urban pressure & weak local institutions

Watershed possess the highest environmental knowledge level compared to the two comparative watersheds—**83%**, higher than Kambaniru (78.4%) and Ciliwung (60%). This reflects the influence of environmental education, firsthand experience with declining water quality, and interaction with government or NGO programs. Conservation participation in Way Sekampung is also the highest (**82%**) compared to Kambaniru (72%) and Ciliwung (55%).

These data demonstrate that environmental knowledge is directly correlated with involvement in tree planting, spring protection, land management, and community-based conservation.Upstream communities in Way Sekampung show stronger engagement due to their direct dependency on water resources and the visible impacts of environmental degradation experienced over recent decades.This positions Way Sekampung as a strong candidate for community-based conservation schemes such as **Payment for Environmental Services (PES)**.

5. Factors Encouraging Conservation Participation

Upstream community participation in conservation activities is influenced not only by their level of environmental knowledge but also by social, economic, and ecological factors shaping their motivation to engage. In the Way Sekampung Sub-Watershed, the relatively high participation level is driven by the community's direct reliance on sustainable water resources

for domestic use, agriculture, and local economic activities. Additionally, past experiences with reduced water quality and quantity have strengthened the collective awareness that conservation is a shared responsibility that must be carried out sustainably.

Institutional and external support also plays a crucial role. The presence of forest farmer groups (KTH), customary institutions, and community empowerment programs enhances coordination and facilitates conservation activities. Guidance from village governments, forestry agencies, and universities increases community capacity in managing water resources effectively. Financial incentives through schemes such as PES further encourage community involvement, as people feel appreciated for protecting the environment. The following factors support conservation participation are below this

- **Environmental Knowledge**

Understanding forest functions, hydrological processes, and the relationship between land cover and water discharge increases community awareness of the importance of conservation.

- **Economic Dependence on Water Resources**

Communities reliant on water for farming, small enterprises, and household needs are more active in sustaining water resources.

- **Strong Local Institutions**

KTH groups, river-care communities, and customary bodies strengthen coordination, rule-making, and shared responsibilities.

- **Experience with Environmental**

Those who have experienced drought, water shortages, or degraded springs are more motivated to prevent future occurrences.

- **Government and Stakeholder Support**

Training, extension programs, and mentoring enhance community skills in conservation practice.

- **Financial Incentives and PES**

Economic rewards motivate higher participation, especially in communities with economic vulnerabilities.

- **Social Capital and Community Solidarity**

Strong social ties, shared norms, and mutual cooperation increase willingness to join conservation efforts.

- Access to Information and Education

KEnvironmental campaigns, community-based monitoring, and educational programs broaden awareness and support collective conservation initiatives.

6. Challenges and Opportunities for Strengthening Conservation in the Upstream Region

Although knowledge and participation levels are relatively high, several challenges remain, particularly in funding availability, institutional capacity, and limited access to advanced environmental education. Siregar et al. (2021) highlight that the success of upstream conservation is also influenced by household economic stability. In Way Sekampung, many

communities still rely on dryland agriculture, making them economically vulnerable and potentially decreasing long-term conservation participation.

However, opportunities remain strong through PES programs, government–community partnerships, strengthened environmental education, and the integration of community-based water monitoring technologies.

CONCLUSION

This study demonstrates that upstream community knowledge plays a crucial role in supporting the sustainability of water environmental services conservation in the Way Sekampung Watershed. High levels of environmental literacy encourage active community participation in conservation practices such as spring protection, tree planting, and agroforestry-based land management. These actions contribute directly to stabilizing water discharge and improving water quality flowing toward downstream areas.

Secondary data show that upstream communities in the Way Sekampung Watershed possess higher levels of environmental knowledge and participation compared to several other watersheds in Indonesia. This indicates that ecological experience, economic dependence on water resources, and institutional support significantly influence conservation behavior. Strengthening environmental education, empowering local communities, and expanding incentive mechanisms such as PES represent strategic opportunities for improving community-based watershed management.

Overall, this study emphasizes that water resource conservation is influenced not only by biophysical conditions but also by the quality of community knowledge, behavior, and participation. Therefore, integrating ecological and social approaches is essential for achieving sustainable, equitable, and adaptive watershed management in the Way Sekampung Watershed.

COMPARATIVE ANALYSIS OF METEOROLOGICAL DROUGHT BY DROUGHT INDICES AND TREND TECHNIQUES: THE CASE OF IZMIR

Ibrahim Halil DEGER

Hasan Kalyoncu University, Faculty of Engineering, Department of Civil Engineering, Gaziantep

ORCID: 0000-0001-6360-3923

ABSTRACT

As an extreme nature event and recurrent natural disaster, drought is a formation that impacts live life and ecosystems negatively and harms to water that is ultimately required for vital activities and its related sectors such agriculture and energy. In this study, obtaining mean monthly temperature and monthly total precipitation data of 17220-İzmir Bölge Station and using Standardized Precipitation Index (SPI), Standardized Precipitation Evapotranspiration Index (SPEI), Reconnaissance Drought Index (RDI), Z-Score Index (ZSI) and Rainfall Anomaly Index (RAI), drought analysis of İzmir province are analyzed for the time scales of 1, 3, 6, 9, 12-month. Possible trends in the time series of indices are examined by Mann-Kendall (MK), Spearman Rho (SR) and Sen Slope (SS) tests. The relations between indices are investigated by Kendall' τ correlation test. The results have shown that normal drought category has been dominant in all time scales of all indices. According to results of MK and SR tests considering α=0.01, there has been a significant increasing trend SPI-3, 6, 9, 12-months, ZSI-12-month and RAI-3, 6, 9, 12-months series while a significant decreasing trend has been observed in all time series of SPEI. SS test results have demonstrated that all time series of SPI, ZSI and RAI indices have a positive trend slope while all SPEI series have negative trend slope. Correlation results have shown that indices may have similarities either in same or different time scales since a strong correlation has been obtained many times. The results of this study are expected to be beneficial for the drought mitigation and water resources management plans of the region.

Keywords: Drought, Turkiye, Izmir, SPI, SPEI, RDI, ZSI, RAI, Trend, Correlation

1. INTRODUCTION

Drought have been defined as repeated natural disaster that has impacts on water supply, energy and health (Rahman et al., 2025). It has been stated by (Ali et al., 2025; FAO, 2021) there has been an estimated USD 29 billion in economic damages was attributed to drought events during the period 2005–2015. In many studies such as (Dodangeh et al., 2025; Rahman et al., 2025; Wilhite & Glantz, 1985; Yuce et al., 2023) drought has been classified with 4 groups which are meteorological, agricultural, hydrological and socio-economic. Among these categories, meteorological drought has been defined with deficiency of precipitation (Oyarzabal et al., 2025).

Monitoring the drought events has a critical role in struggling with natural disasters, management of water resources and preparing action plans. For drought monitoring many drought indices have been developed such as Standardized Precipitation Index (SPI), Standardized Precipitation Evapotranspiration Index (SPEI), Reconnaissance Drought Index (RDI), Z-Score Index (ZSI) and Rainfall Anomaly Index (RAI). At least one of these indices have been used in many drought monitoring studies such as (Adnan et al., 2018; Akşan & Bacanlı, 2021; Dikici & Aksel, 2021; Dogan et al., 2012; Jain et al., 2015; Katipoğlu et al., 2020; Mashari Eshghabad et al., 2014; Öz et al., 2024; Wable et al., 2019; Yuce & Esit, 2021; Zarei et al., 2021) for many parts of the world and Turkiye.

In drought monitoring, trend detection techniques provide understanding temporal variability of time series for further predictions. For examination of possible trends Mann Kendall Test (Kendall, 1975; Mann, 1945), Spearman's Rho Test (Spearman, 1961), Innovative Trend Analysis (Şen, 2012) have been widely used and Sen's Slope Test (Sen, 1968) have been utilized for trend slope determination. In many studies such as (Deger et al., 2025; Kartal & Emiroglu, 2024; Meskelu et al., 2024; Oubadi et al., 2024; Yaşa & Partal, 2024) have been effectively used. In another examination perspective, the correlation between time series of indices have been investigated by some correlation coefficients such as Pearson, Spearman and Kendall in the studies such as (Mliyeh et al., 2025; Pandya & Gontia, 2024).

In this study, a comprehensive meteorological drought monitoring study has been done for Izmir Region of Turkiye using SPI, SPEI, RDI, ZSI and RAI indices for the time scales of 1, 3, 6, 9, 12-month. Possible trends at time series of drought indices have been examined by Mann-Kendall (MK), Spearman Rho (SR) and trend slopes have investigated by Sen's Slope Test (SS). The relations between indices are investigated by Kendall (τ) correlation test. For making the analysis, mean monthly temperature and monthly total precipitation data of 17220-İzmir Bölge Station have been acquired from General Directorate of Meteorology of Turkiye. The findings of this study are expected to be useful for local authorities in drought action and water resources management plans.

2. METHODOLOGY

2.1. Drought Indices

2.1.1. Standardized Precipitation Index (SPI)

SPI that was developed by (McKee et al., 1993) has one of the most commonly used indices for drought monitoring (Akbas et al., 2025). It has been stated by Sobral et al. (2019) that SPI is recommended by World Meteorological Organization. Before application of SPI, gamma distribution function is applied to monthly rainfall data with the following manner (Esit & Yuce, 2023; Robleh et al., 2024). The probability distribution function of gamma distribution function is computed by Equation 1.

$$g(x) = \frac{1}{\beta^a \Gamma(a)} x^{a-1} e^{-\frac{x}{\beta}} \quad (1)$$

Where *Γ(a)* describes the gamma function and it can be determined by Edwards (1997).

$$\Gamma(a) = \int_0^\infty y^{a-1} e^{-y}\, dy \quad (2)$$

According to maximum likelihood method estimation, shape (α), scale (β) parameters are determined by Thom (1966) with following equation:

$$a = \frac{1}{4A}\left(1 + \sqrt{1 + \frac{4A}{3}}\right) \quad (3)$$

$$\beta = \frac{\bar{x}}{a} \quad (4)$$

where A is computed by (Thom, 1966) as

$$A = \ln(\bar{x}) - \frac{\sum \ln(x)}{n} \quad (5)$$

Where *n* represents the number of rainfall records and $\bar{x}$ is the mean of x.

Then cumulative distribution function is calculated by Equation 6 (Thom, 1966).

$$H(x) = q + (1 - q)G(x) \quad (6)$$

Where q is the probability of zero and *G(x)* describes the cumulative distribution for the selected month and time scale. If m is denoted as the number of zeros, then *q* is determined by *q=m/n* (Thom, 1966). After all, *H(x)* is transformed to the standard normal variable Z whose mean and variance are 0 and 1 respectively describing the SPI with Equation 7 (Robleh et al., 2024).

$$SPI = \frac{X_{ij} - \bar{X}_{im}}{\sigma} \quad (7)$$

2.1.2. Standardized Precipitation Evapotranspiration Index (SPEI)

SPEI was developed by (Vicente-Serrano et al., 2010). It provides more comprehensive evaluation of drought conditions as it joins the precipitation and temperature (Öllükçü & Katipoğlu, 2025) According to determination procedure of this index, firstly potential evopotranspiration that is PET is calculated using Thornthwaite Method (Thornthwaite, 1948) by Equation 8.

$$PET = 16d\left(\frac{10T}{I}\right)^a \quad (8)$$

where; T shows the monthly mean temperature in units of °C, *I* represents a heat index, α is a coefficient dependent on *I* and d which can be acquired from latitude-specific tables represents a correction factor for monthly diurnal duration variation. The difference between the precipitation and PET for the *i* month is calculated from Equation 9 (Vicente-Serrano et al., 2010).

$$D_i = P_i - PET_i \quad (9)$$

Then D values are summed up at different time scales (Esit et al., 2025).

$$D_n^k = \sum_{i-0}^{k-1} P_{n-1} - (PET)_{n-1} \quad (10)$$

where k describes aggregation period in months, n shows the calculation month. Then, the log-logistic probability density function is described as in Equation 11:

$$f(x) = \frac{\beta}{\alpha}\left(\frac{x-y}{a}\right)^{\beta-1}\left(1+\left(\frac{x-y}{a}\right)^{\beta}\right)^{-2} \quad (11)$$

As α, β, and γ are scale, shape, and origin parameters (γ > D < ∞) respectively, the probability distribution function for the D series becomes as in the Equation 12:

$$f(x) = \left[1+\left(\frac{a}{x-y}\right)^{\beta}\right]^{-1} \quad (12)$$

Then SPEI is derived by standardizing F(x) values benefiting the approximation of Abramowitz and Stegun (1968).

$$SPEI = W - \frac{C_0+C_1W+C_2W^2}{1+d_1W+d_2W^2+d_3W^3} \quad (13)$$

$$W = \sqrt{-2In(P)}\ for\ P \leq 0.5 \quad (14)$$

where $C_0 = 2.515517$, $C_1 = 0.802853$, $d_1 = 1.432788$, $d_2 = 0.189269$, $d_3 = 0.001308$.

2.1.3. Reconnaissance Drought Index (RDI)

RDI that has been developed by (Tsakiris & Vangelis, 2005) has the following determination procedure: Firstly, the initial value of index which is a_k is determined by Equation 15.

$$a_k = \frac{\sum_{j=1}^{j=k} P_j}{\sum_{j=1}^{j=k} PET_j} \quad (15)$$

Where P_J and PET_J shows the precipitation and potential evapotranspiration of the j-th month. Here RDI can be determined either as normalized RDI_n or standardized RDI_{st} via Equation 16 and Equation 17 respectively. The computation procedure of RDI_{st} is very similar to determination of SPI (Tsakiris & Vangelis, 2005; Yuce & Esit, 2021).

$$RDI_n(k) = \frac{a_k}{\bar{a}_k} - 1 \quad (16)$$

$$RDI_{st}(k) = \frac{y_k-\bar{y}_k}{\bar{\sigma}_k} - 1 \quad (17)$$

Where y_k is ln a_k , $\bar{y}_k$ represents arithmetic mean and $\bar{\sigma}_k$ denetotes the standard deviation.

2.1.4. Rainfall Anomaly Index (RAI)

Developing by (Van Rooy, 1965) rainfall anomaly index is a drought index that is ranking based (M. Aydin, 2025). The RAI can be assessed via following equations of 18 and 19 (Katipoğlu et al., 2020).

$$RAI = +3\ \frac{P-\bar{P}}{\bar{M}-\bar{P}} \quad (18)$$

$$RAI = -3\ \frac{P-\bar{P}}{\bar{X}-\bar{P}} \quad (19)$$

Where $\bar{P}$ shows average of precipitation series, $\bar{M}$ describes the average of the highest 10 values and $\bar{X}$ denotes the average of the smallest ten values. When P > $\bar{P}$ the anomaly becomes positive, if P < $\bar{P}$ the anomaly is negative.

2.1.5. Z-Score Index (ZSI)

ZSI is an another index that is used in drought monitoring studies such as (Katipoğlu et al., 2020; Yuce & Esit, 2021; Zeybekoglu, 2025) and not require data fitting. ZSI can be determined from Equation 20.

$$ZSI = \frac{X_i - \bar{x}}{\sigma} \tag{20}$$

2.2. Drought Categories

For a detailed drought and as well as the wet conditions assessment, after determination of values of indices in different time scales, each indices value is associated with a dry or wet category given in Table 2.1

Table 2.1. Dry and wet classifications (Yuce & Esit, 2021)

Drought Class	SPI, SPEI, RDI, ZSI	RAI
Extremely Wet	≥ 2	≥ 3
Very Wet	1.5-1.99	
Moderately Wet	1.00-1.49	
Normal	0.99 to -0.99	0.5 to -0.99
Moderately Dry	-1.00 to -1.49	-1.00 to -1.99
Very Dry	-1.5 to -1.99	-2.00 to -2.99
Extremely Dry	≤ -2	≤ -3

2.2. Trend Techniques

2.2.1. Mann-Kendall Test (MK)

MK that has been developed by (Kendall, 1975; Mann, 1945) is a well-known test is continuously used for trend detection in drought monitoring studies (Chitsaz & Hosseini-Moghari, 2017; Deger et al., 2025; Zarei, 2019). The Z statistics of the test determined via following procedure.

$$S = \sum_{k=1}^{n-1} \sum_{j=k+1}^{n} sgn(x_j - x_k) \tag{21}$$

$$sgn(x_j - x_k) = \begin{cases} 1 & (x_j - x_k) > 0 \\ 0 & (x_j - x_k) = 0 \\ -1 & (x_j - x_k) < 0 \end{cases} \tag{22}$$

$$Var(S) = \frac{n(n-1)(2n+5) - \sum_i^m t_k(t_k-1)(2t_k+5)}{18} \tag{23}$$

$$Z = \begin{cases} \frac{S-1}{\sqrt{Var(S)}} & S > 0 \\ 0 & S = 0 \\ \frac{S+1}{\sqrt{Var(S)}} & S < 0 \end{cases} \tag{24}$$

Where n denotes the number of data x_i and x_j describe data points in the years of j and k (j>k) respectively and Var(S) is used in case of having ties. When Z>0 then there is a increasing trend and when Z<0 there is a presence of decreasing trend. For significance cases, trends are assessed based on a significance level. In the study α=0.01 ($Z = \pm 2.576$) is considered.

2.2.2. Spearman's Rho Test (SR)

SR which is a rank-based non parametric test is another most widely used test for trend detection as it has been recently used in many studies such as (Güner Bacanli, 2017; Simsek et al., 2025). In the test correlation coefficient r_s and the test statistic Z can be calculated by Equation 25 and Equation 26 respectively (H. Aydin et al., 2025). The interpretation of Z values is same with MK test. In the study α=0.01 ($Z = \pm 2.576$) are taken into account for trend evaluation.

$$r_s = 1 - \frac{[6\ \sum_{i=1}^{n}(Rx_i - i)^2)]}{n(n^2-1)} \tag{25}$$

$$z = r_s\sqrt{n-1} \tag{26}$$

2.2.3. Sen's Slope Test (SS)

For determination of trend slopes, SS test that has been developed by (Sen, 1968) is used. During the test trend slope are determined via Equation 27 and Equation 28.

$$S = \frac{Q_2 - Q_1}{T_2 - T_1} \tag{27}$$

$$S = \begin{cases} S_{\frac{n+1}{2}} & n = even \\ S_{\frac{n}{2}} & n = odd \end{cases} \tag{28}$$

2.3. Correlation Analysis

2.3.1. Kendall's τ Correlation Coefficient

In the study, correlation between indices have been examined by a well-known coefficient of Kendall's **τ** that has been used in many hydrology studies such as (Chitsaz & Hosseini-Moghari, 2017; Yuce & Esit, 2021). The details of this coefficient can be seen in (Aon & Biswas, 2024; Shao et al., 2025).

3. STUDY AREA AND DATA

İzmir which is found in Aegean region of Turkiye is the third largest city of the country (Çilingir et al., 2026; Erdoğan, 2025). The city where mediterranean climate in which summers are hot and dry and winters are mild and rainy is seen has a surface area of 12.012 km^2 (Öztürk et al., 2025). In the study, mean monthly temperature (°C) and monthly total precipitation (mm) data of 17220-İzmir Bölge meteorological station during data record of 1950-2024 have been taken from General Directorate of Meteorology of Turkiye for performing analysis. The information of this data has been given in Table 3.1 while the location of Izmir city and 17220 İzmir Bölge meteorological station have been presented in Figure 3.1. According to Table 3.1, mean monthly temperature has been ranged with 5.30-30.90 (°C) while monthly total

precipitation series have been ranged as 0-411.6 mm during data record. During 1950-2024, mean temperature and mean monthly total precipitation have been 18.05 (℃) and 58.71 mm.

Table 3.1 Information of used station and meteorological variables

Station Name	Latitude (N)	Longitude (E)	Height (m)	Meteorological Variable	Data Range	Mean	Standard Deviation	Minimum	Maximum
17220 İzmir Bölge	38.3949	27.0819	29	Mean Monthly Temperature (℃)	1950-2024	18.05	6.95	5.30	30.90
				Monthly Total Precipitation (mm)		58.71	67.57	0.00	411.60

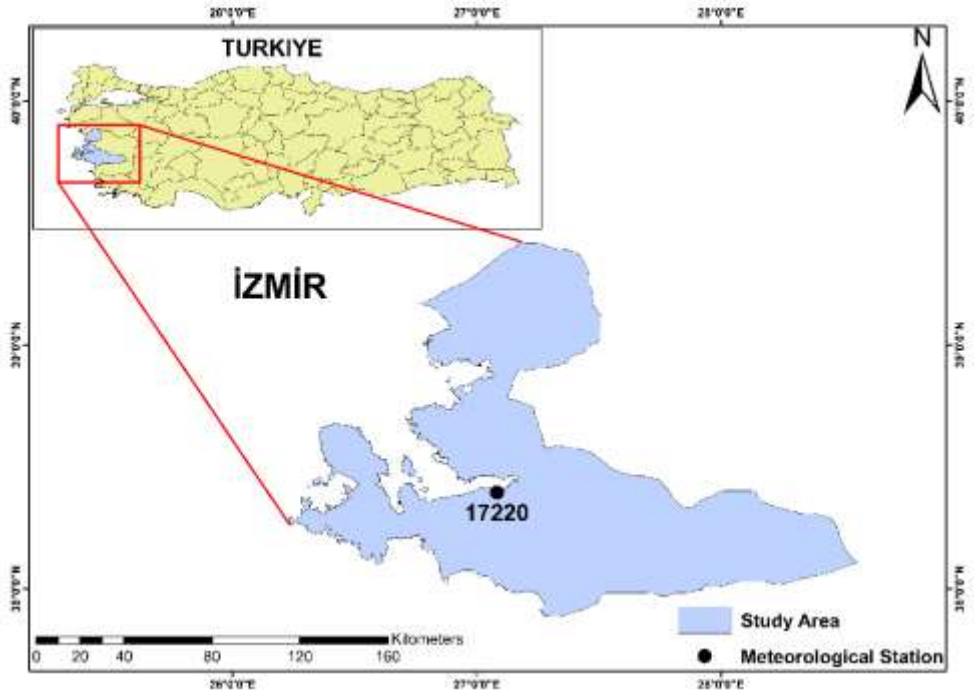

Figure 3.1. Study area and location of meteorology station

4. RESULTS AND DISCUSSIONS

4.1. Examination of Time Series of Indices

In the study using SPI, SPEI, RDI, ZSI and RAI algorithms, the dry (drought) and wet events have been determined. To make the evaluations easier, determined indices have been illustrated with Figure 4.1. These graphs aid to researchers in the first evaluation of outcomes by indices as visual. As it can be seen many drought (dry) events have happened even near today. With the increment of time scale, drought events have become longer in all indices. As it can be seen, many times indices have captured the droughts at the same time.

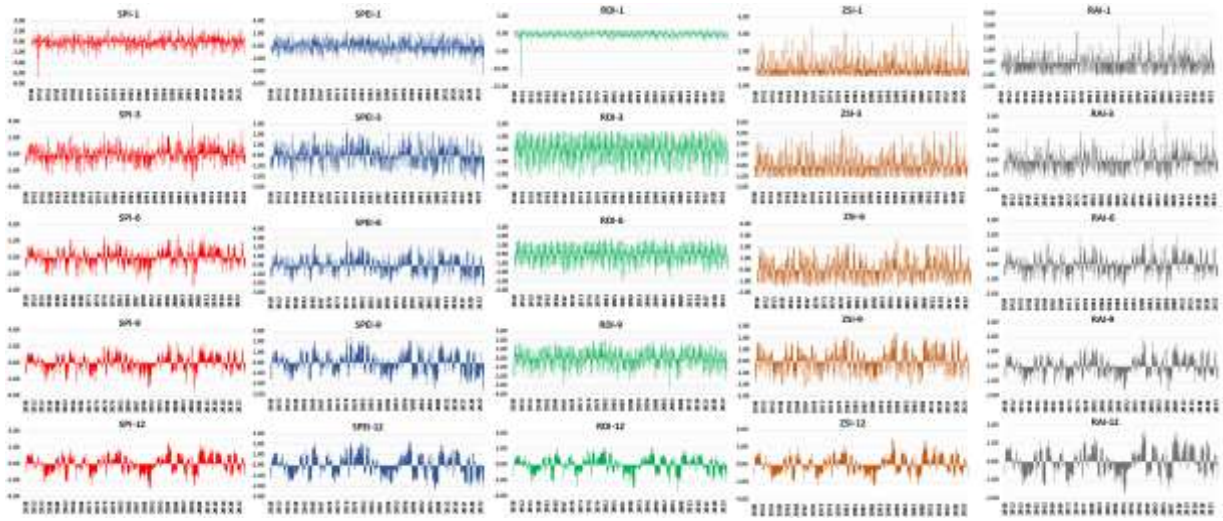

Figure 4.1. Time Series of Indices in the time scales of 1, 3, 6, 9, 12-month

4.2. Dry and Wet Categories Distribution

For a comprehensive monitoring of drought and as well as the wet events, each indices value has been associated with a dry/wet category based on its value. For easiness, all wet categories have been combined under the name of "Wet" category. Then the distribution of indices in dry/wet categories have been investigated considering percentage of occurrence (%). By doing this, all results have been given with Figure 4.2. As it can be seen from the figure that normal dry category and wet category have the superiority among all categories. In SPI series, normal category has the range of (27.7%-32.1%) and wet category has the (48.4%-58.2%). In SPEI series normal category and wet category have been ranged as (30.1%-33.1%) and (49.4%-50.3%) respectively. In RDI, the normal category has been recorded with the range of (26.1%-34.1%) while wet has been recorded with the range of (49.8%-54%). In ZSI, the range of normal category has been (32.7%-63.9%) and while wet has been ranged as (36.1%-47.3%). When it comes to RAI, the normal category has been recorded with the range of (69.9%-78%) and wet has become as (14.7%-25.4%). Among these indices the normal category has reached its maximum in RAI-1 while its minimum in RDI-3 series. The wet conditions have occurred as maximum in SPI-1 and as minimum in RAI-1. Other dry categories moderately dry, very dry and extreme dry have been detected with the ranges of (0-19.44%), (0-7.67%) (0-3.78%).

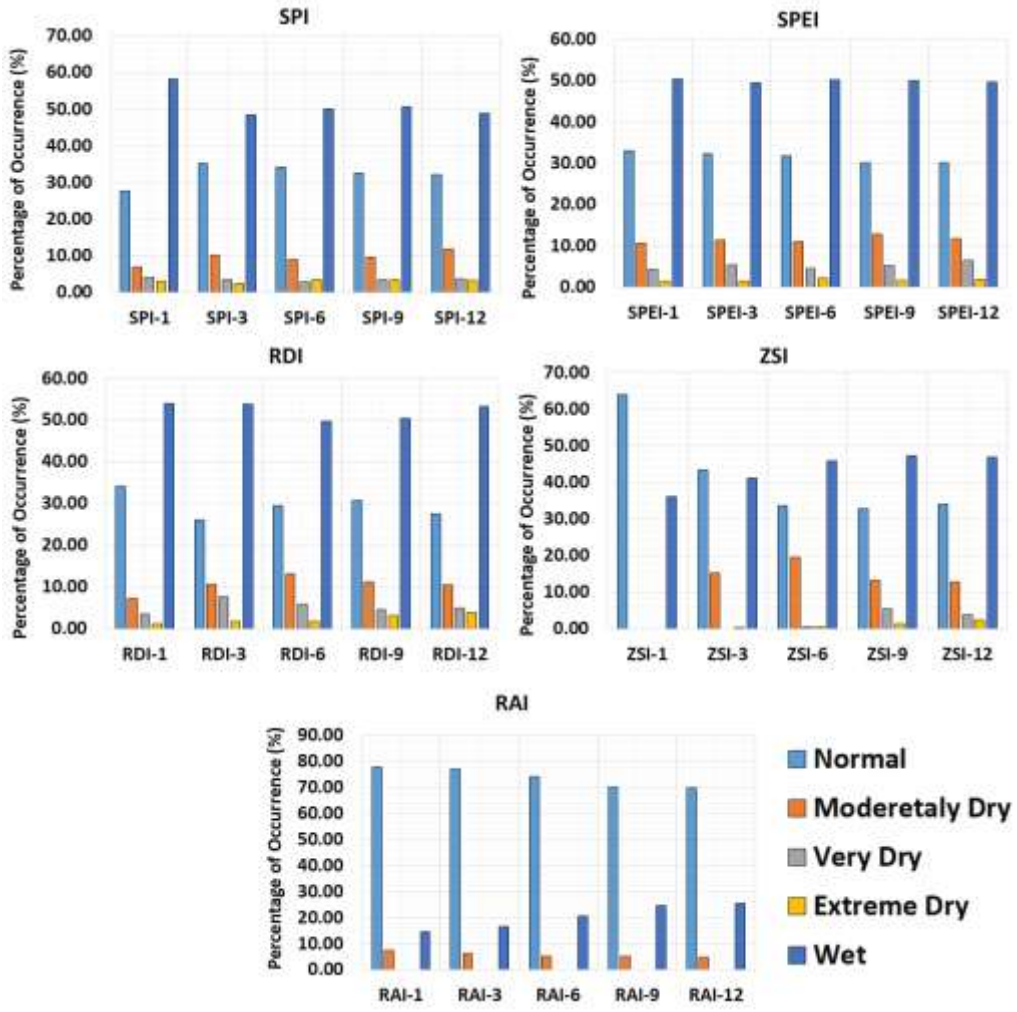

Figure 4.2. Dry and wet category distribution of indices across 1, 3, 6, 9, 12-month time scales based on percentage of occurrence (%)

4.3. Trend Detection Analysis

In order to detect possible trends in time series of indices, MK and SR tests have been applied. Considering significance level of α=0.01 level ($Z = \pm 2.576$), significance conditions of series have been examined. The results of the trend tests have been given with Table 4.1. For easiness trend types (either increasing or decreasing) have been illustrated by different colors and significant trends have been shown by italic and bond font. In SPI series, results of both tests have shown that the series have had increasing trends and in 3, 6, 9, 12-month series these trends have been significant since Z values of them have been bigger than 2.576. In SPEI series the trends of the series have been significantly decreasing trends. In RDI series, the series have been more variable in terms of trend types but nevertheless these trends have been non-significant. In ZSI series, except at ZSI-12, all trend results have occurred from non-significant increasing trends while ZSI-12 has been detected with significant increasing trends. Similar to SPI series, in RAI series, significantly increasing trends have been detected in 3, 6, 9, 12-month. As it can be seen from the table that, in all the series MK and SR have given similar results in terms of trend types and significance conditions.

SR	1.62261	***2.82496***	***3.14384***	***3.10231***	***3.37911***
	Increasing Trend			**Decreasing Trend**	

In order to examine the trend slope of the series, SS tests have been applied and the results have been given with Table 4.2. As it can be seen from the table that in all series SPI, ZSI, RAI trend slopes have been positive indicating an increasing trend. In SPEI series all series have been detected with negative slopes indicating a decreasing trend. When it comes to RDI series the trend slopes have shown a more variable behavior as in RDI-1 zero slope (no trend), in RDI-3 and RDI-6 positive trend slope (increasing trends) and in RDI-9 and RDI-12 negative trend slopes (decreasing trend) have been detected. In comparison as it can be seen from Table 4.1 and Table 4.2 three tests have given similar results in terms of trend type.

Table 4.2. SS test results

	SPI-1	SPI-3	SPI-6	SPI-9	SPI-12

	ZSI-1	**ZSI-3**	**ZSI-6**	**ZSI-9**	**ZSI-12**
SS	0.00003	0.00013	0.00022	0.00032	0.00043
	RAI-1	**RAI-3**	**RAI-6**	**RAI-9**	**RAI-12**
SS	0.00008	0.00023	0.00027	0.00026	0.00028

4.4. Correlation Analysis

In order to examine the correlations between indices Kendall's τ have been used. The results have been presented by Figure 4.3. For a making assessment easier, the correlation values have been illustrated by different colors with the manner of heatmap. As it can be seen from the figure that many times between indices a strong positive correlation have been obtained. For example, the correlation between SPI-1 and RAI-1 is 0.87, SPI-12 and RAI-12 is 0.98, SPI-12 and ZSI-12 0.98, SPEI-12 and RDI-12 is 0.93 and so on.

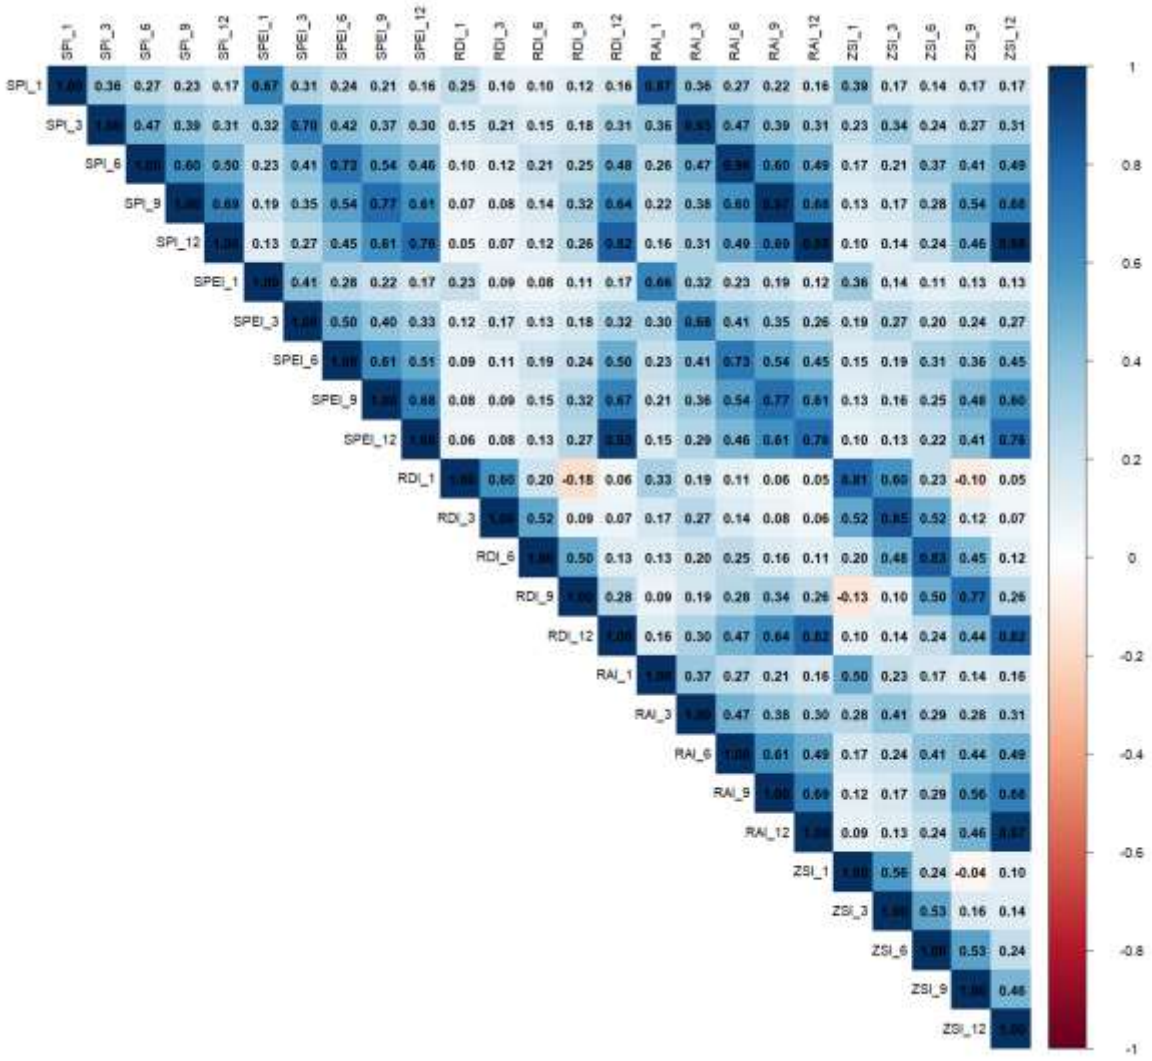

Figure 4.3. Correlation results of indices by Kendall Test

4.5. Discussions

In the study 5 different drought indices have been used to monitor dry and wet events of İzmir regions including trends and correlation. The findings of the study have put forth that normal dry and wet have a superiority among all categories. In the studies of (Yuce & Esit, 2021) have found the similar relationships for Ceyhan Basin Turkiye. In another assessment (Akşan & Bacanlı, 2021) have found that normal dry conditions have superiority upon other dry categories in Southeastern Part of Turkiye. In the study in most of SPI and RAI series significantly increasing trends have been seen. Similarly significant increasing trends in SPI series have been noted by (Benny et al., 2024; Guhathakurta et al., 2017). Similarly significant decreasing trends in SPEI have been noted by (Kamruzzaman et al., 2022) which is also compatible with the findings. The correlation results have shown that strong correlations can be obtained between used indices in different time scales. Similar relationships have been noted by (Katipoğlu et al., 2020; Yuce & Esit, 2021). Therefore, the results of this study are compatible with the findings in the literature.

5. CONCLUSIONS

In this study, using SPI, SPEI, RDI, ZSI and RAI dry and wat conditions of İzmir province have been analyzed for the time scales of 1, 3, 6, 9, 12-month. Possible trends in the time series

of indices have been examined by MK and SR tests considering α=0.01 significance level and trend slopes have been determined by SS test. The correlation between indices have been investigated by Kendall's **τ** have been utilized. Under the light of findings, the following conclusions have been made:

- Based on the time series investigation, many dry (drought) events have been occurred in the past and even near today. Drought indices have captured the common events many times. In all time scales of all indices normal dry and wet categories have the superiority among all categories.

- Trend detection results BY MK and SR tests have shown that while there has been an increasing trend tendency in SPI, ZSI and RAI series, a decreasing trend behavior has been seen in all time series of SPEI. There has been variety of trend types in RDI series. Significant trend conditions have been detected mostly in SPI, SPEI and RAI series. SS test results have shown a similar behavior with MK and SR tests in terms of trend types.

- Correlation results have shown that a strong relationship can be found between indices in different time scales. This also indicates that the indices can get similar outcomes even they have different calculation approach.

- Overall, the study presents significant findings that are expected to be beneficial for local authorities, organizations in the preparing or updating climate action plans and water resources management policy decision making.

ACKNOWLEDGEMENTS

The General Directorate of Meteorology (MGM) of Turkiye is to be acknowledged for providing meteorological data.

ABSTRACT:

Despite the formal end of armed conflict in Syria following the fall of the Assad regime in December 2024, the country continues to face an acute shelter crisis driven by widespread infrastructure destruction and complex housing, land, and property (HLP) challenges. In northwest Syria, nearly one million internally displaced persons (IDPs) still reside in overcrowded camps and informal settlements. This prolonged displacement places significant pressure on the region's fragile infrastructure, economy, and public services. The continued reliance on tents underscores the urgent need for safe, dignified, and context-appropriate transitional shelter solutions that are both sustainable and scalable. This study is based on a structured literature review of transitional shelter strategies from comparable post-conflict and post-disaster settings around the world. It critically analyzes international frameworks, design models, and policy approaches to identify practices relevant to Syria's urban and rural landscapes. The paper emphasizes the importance of integrating shelter design with recovery goals, sustainability principles, and local environmental and social conditions. The paper concludes by proposing a set of policy recommendations focused on developing a national transitional shelter framework. This framework prioritizes standardized design guidelines, adaptable implementation pathways, and long-term planning integration. It aims to assist humanitarian and governmental actors in replacing tents with safer, more durable interim housing, laying the groundwork for sustainable resettlement and post-war reconstruction.

Keywords: Forced migration, emergency housing, humanitarian architecture, infrastructure strain, and community resilience

INTRODUCTION

Over the past fourteen years, Syria has experienced one of the most protracted and complex humanitarian crises in modern history, driven by war and economic collapse. This crisis has left millions in need of humanitarian assistance, particularly in the northwest of the country. By the end of 2024, an estimated 6.8 million people in northwest Syria required shelter support **[1].** Among these, 2.1 million people were in urgent need of shelter assistance, while approximately 800,000 individuals live in tents **[2]** as emergency shelter situations, which is considered a worldwide symbol of shelter, even though it was not appropriate with long-term shelter.

In this challenging humanitarian context, there was a necessity to adopt a temporary housing policy and more sustainable shelter solutions to address the realities of long-term displacement. In response, the concept of "transitional shelter" was introduced in northwest Syria in 2020 **[3]**. There has been a transition from tents to transitional shelters in northwest Syria over the past four years. While these shelters have significantly improved living conditions for many, they remain far from an adequate solution; they replaced the tents in a partially appropriate manner based on the available resources.

This initiative represented a significant shift from the prolonged reliance on temporary shelter options traditionally employed by the shelter sector in Syria. Its primary aim was to provide safety, dignity, and protection for internally displaced people (IDPs) affected by conflict and displacement. However, while many local and international humanitarian organizations contributed to the proliferation of various models of transitional shelters in northwest Syria, these efforts often lacked standardized design and implementation criteria. Additionally, the exclusion of affected populations from decision-making processes reduced the overall impact of transitional shelters in facilitating the transition of IDP sites toward recovery.

Even after the fall of the Assad regime, Syria continues to face a complex humanitarian crisis. Massive displacements caused by escalations in the conflict for more than 13 years, coupled with inadequate IDP sites and extreme living conditions, particularly during harsh winters, have exacerbated the crisis, making it a significant humanitarian concern. Additionally, the housing crisis remains a critical challenge for the new government, especially in facilitating the return of internally displaced persons (IDPs) and refugees from neighboring countries.

Therefore, this study explores a literature review of transitional shelter strategies from comparable post-conflict and post-disaster settings around the world. It critically analyzes international frameworks, design models, and policy approaches to identify practices relevant to Syria's urban and rural landscapes. Then, the study analyzes the 3 different types of transitional shelter solutions that were adopted by international agencies, local organizations, and community-led initiatives in Syria.

In the same regard, this study aims to examine the transitional shelter models applied in both internationally, and locally – in Syria – to identify the most context-appropriate, sustainable, and scalable solution to support the internally displaced people.

The analysis also seeks to support developing a national transitional shelter framework that plays a fundamental role in the reconstruction of the post-conflict Syria.

METHODOLOGY

Initially, the paper begins with a comprehensive literature review to establish a conceptual framework for emergency shelters, encompassing a wide range of theoretical approaches related to post-disaster shelter provision. This is followed by an explanation of the concept of

transitional shelters implemented in northwest Syria, detailing the types of transitional shelters utilized, along with their advantages and disadvantages, as informed by the literature review. The sources reviewed include academic books, journal articles, conference papers, and 'secondary literature' from humanitarian organizations and UN Clusters.

Then, the study conducts a targeted literature review and a content analysis of the global bibliography on transitional shelters in post-war or post-disaster contexts, focusing on similar international experiences. An inductive research approach is employed to develop an evidence base and to understand shelter strategies adopted in comparable international settings.

Finally, the findings and data analysis will provide a comparative assessment aimed at identifying the most effective and adaptable solutions for transformable shelter designs. Based on the final data analysis and findings, a comparative approach will be adopted to find the best solution for a transformable shelter.

LITERATURE REVIEW

Shelter after Disaster Definition:

The destruction of homes, whether through conflict, displacement, or natural disasters, is one of the most visible and devastating consequences of crises. Providing adequate shelter in the aftermath of such events is not only essential for saving lives but also critical for supporting livelihoods, health, education, security, and family stability. According to UN/OCHA/ESB (2006), adequate shelter constitutes the "immediate environment for all aspects of family life," offering protection from the elements, secure tenure, safety, access to clean water and sanitation, and proximity to employment, education, and healthcare services **[4]**.

Importantly, "shelter after disaster" is understood not merely as a physical structure but as a dynamic process that involves progression from emergency accommodation to more durable and sustainable housing solutions **[5].** As such, shelter interventions are typically divided into emergency and transitional phases, each requiring different approaches, stakeholders, and timelines that may span several years.

Over the past two decades, those involved in shelter provision have not reached a consensus on a universal definition of adequate shelter, resulting in varied terminology describing it. According to Corsellis and Vitale (2005), shelter is described as a livable, covered space that offers a secure and healthy environment, ensuring privacy and dignity for its occupants **[5]**. Similarly, the Global Protection Cluster Working Group notes that when humanitarian organizations mention shelter, they typically refer to a livable, covered space that provides a secure and healthy environment with privacy and dignity **[6].**

In constructing the shelter framework, we identified that not everyone agrees on a staged approach to post-disaster shelter. The Shelter Center is intended to be adopted as a "three-stage recovery" model of shelter. These stages begin with the first-response emergency shelter, followed by medium-term transitional solutions, and finally permanent housing. While some experts have advocated for a two-stage model, removing the need for transitional shelter **[7].** The figure depicts both the three-phase and two-phase models of shelter response, which are widely recognized within the shelter sector.

Emergency shelter refers to immediate, short-term housing provided in the aftermath of a disaster or conflict to ensure the survival and protection of displaced individuals or households. These shelters are intended to offer basic protection from the elements, privacy, and security, while meeting minimum humanitarian standards until more durable solutions become available.

The UNHCR Emergency Handbook (2022) defines emergency shelter as "the provision of temporary protection from the climate, often in the form of tents or other rapidly deployable structures, to meet the basic shelter needs of displaced populations" **[8]**. Corsellis and Vitale (2005) stated that "shelter after disaster is a process that begins with emergency shelter, typically provided in the form of tents, plastic sheeting, or host family arrangements, and gradually transitions to more sustainable and permanent housing" **[5]**. The necessity for such temporary aid is expected to remain a key component of emergency response efforts, particularly in contexts involving large, displaced populations and harsh environmental conditions **[9]**.

Transitional Shelter:

The concept of transitional shelter has emerged as one of the key shelter response options currently in use. This approach was introduced by staff from the Shelter Centre, seconded by the UK's Department for International Development (DFID), to the United Nations High Commissioner for Refugees (UNHCR) in 2005, in the aftermath of the Indian Ocean tsunami in December 2004 **[10]**. During the transitional phase, displaced families may find temporary shelter with host families, in camps, collective centers, or by self-settling in existing buildings. However, these arrangements are not always suitable for all families throughout the entire reconstruction period. Thus, the transitional shelter concept aims to provide safe, adaptable housing while long-term reconstruction efforts are underway **[11]**.

The Shelter Centre defines transitional settlement as "settlement and shelter resulting from conflict and natural disasters, ranging from emergency response to durable solutions" **[5]**. According to Brogden and Liz (2021), transitional shelter is understood as a gradual recovery process that enables families affected by disasters and conflicts to retain flexibility in their recovery pathway **[7]**. These shelters are designed to be: (1) upgradable into permanent homes, (2) repurposed for alternative uses, (3) relocatable from temporary to permanent sites, (4) sold to generate income, or (5) recycled for reconstruction purposes **[7]**.

Importantly, the evolving definition of transitional shelter excludes prefabricated final shelters and core shelters—the latter being semi-permanent structures designed to be expanded but not reused, relocated, or recycled **[7]**.

In summary, emergency shelter refers to immediate, short-term housing provided in the aftermath of a disaster or conflict to ensure the safety and survival of displaced individuals. It typically offers minimal protection, privacy, and security, and is used for days to a few months. These shelters, often prefabricated and rapidly deployable (e.g., tents, tarpaulins, or communal buildings), are generally not tailored to local cultural or climatic conditions. By contrast, transitional shelter acts as a medium-term solution, bridging the gap between emergency and permanent housing. It is more durable and context-appropriate, supporting recovery through local materials, labor, and adaptability. Soti, Bimal, and Dimmy (2012) stated that emergency shelter response primarily addresses protection and relief during and immediately following a disaster. In contrast, the transitional shelter approach integrates disaster response with the immediate transition to reconstruction, recovery, and sustainable development **[12]**. These shelters may include timber-framed units, rehabilitated houses, or homes shared with host families. As Corsellis and Vitale (2005) note, "Transitional shelter is intended to support the process of recovery and can be upgraded, reused, or relocated as part of a longer-term strategy" **[5].**

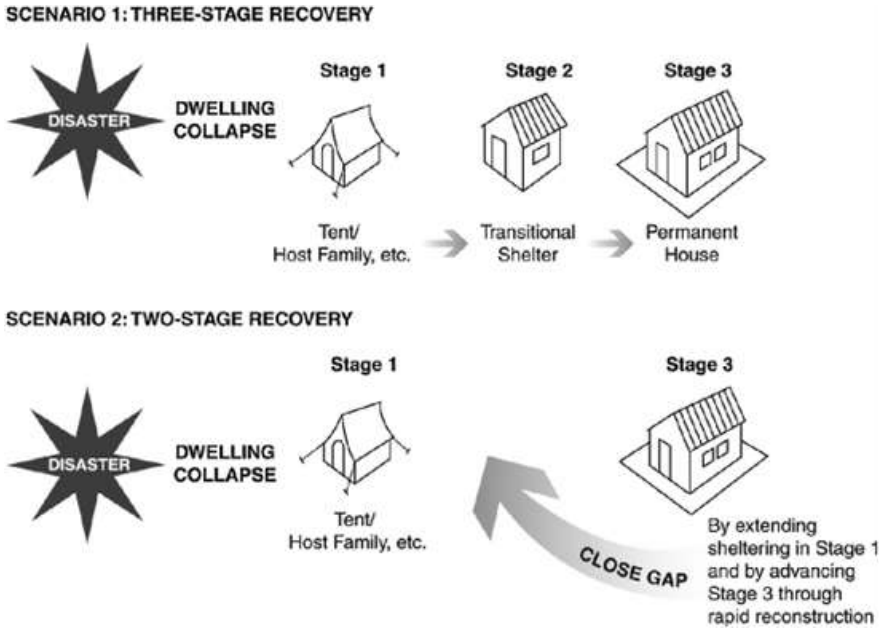

Figure 1: Transitional shelter scenarios **[7]**

Figure 1 illustrates two commonly adopted recovery pathways following a disaster: a three-stage approach and a two-stage alternative. In the first scenario, displaced families move from emergency shelters like tents into a transitional shelter before eventually reaching a permanent home. The second scenario bypasses the transitional phase entirely by either extending the emergency shelter's function or accelerating permanent reconstruction. Including this figure helps clarify an important discussion within shelter literature: should transitional shelters serve as a distinct phase, or can they be replaced with more efficient long-term solutions? In this paper, the figure serves to position transitional shelter within that broader strategic debate, especially as it applies to the Syrian context.

International Case Studies Review

Transitional shelter is considered an essential part in supporting post-disaster recovery, serving as a link between emergency relief and permanent housing solutions **[8] [9].** This section provides a literature review, examining prominent case studies highlighting the complexities of transitional shelter models and best practices in their design and implementation. Analyzing these real-world examples allows us to identify challenges and lessons learned, which can inform future shelter strategies in disaster-affected areas.

Transitional shelter alternatives differ from one country to another and are influenced by various circumstances; however, a consistent aspect is that individuals who have been displaced face restricted choices. They have the option to stay at their former residences, but these are often compromised and either uninhabitable or partially livable. In this section, several shelter response models are analyzed. Since there are numerous types of shelter models available, the reference models were chosen based on the following key criteria:

1. The transnational phase is the target phase.

2. Local Materials used in shelter construction: It is investigated whether the material is sourced locally or can only be sourced internationally. Material sources have a huge impact on the local economy, price, and delivery times.

3. Durability: defines the ability of shelter to remain safe, functional, and habitable for the intended duration of use.

Model 1: Container as Transitional Shelter

A review of literature indicated that containers are utilized as emergency shelters and temporary housing following disasters in countless situations using certain standards to meet the urgent need after disasters **[13] [14]**. For instance, it was used in Greece for resettlement refugees in camps in 2019 **[15]** and used in Türkiye after Kahramanmaraş earthquakes in 2023 **[14]**. The policy approach of provisioning this model for shelter offers a more environmentally sustainable construction method by reducing construction time, minimizing waste, and decreasing the overall on-site workload.

To address the diverse needs of disaster victims and ensure compliance with internationally recognized transitional shelter standards, numerous prototypes and proposed containers models have been developed. These initiatives seek to improve the quality of humanitarian response, increase the efficiency of field interventions, and better align with the social, cultural, and climatic characteristics of affected population **[14]**. Moreover, it depends on the suppliers for containers. In the case of Athena's camps, the container shelter had been imported from China by the K-Home company **[15]**. While the containers that were used after the earthquake in Türkiye were manufactured locally in the country **[14].**

Container shelters as shown in figure 2 are generally based on a rigid steel frame combined with insulated wall and roof panels, forming a simple rectilinear "box" that is easy to transport, stack, and arrange in different site configurations. The emphasis is on a modular, repeatable form that can be rapidly deployed, connected to basic services, and later adapted or combined to create larger living or community spaces. In terms of durability, container shelters are designed to fulfil the core requirements of transitional shelter, as they can be upgraded, reused, relocated, resold, and eventually recycled throughout their life cycle **[15].**

Even though the containers are transported packaged and are assembled on-site to improve space efficiency, it needs skilled workers to modify the containers, such as cutting, welding, and connecting.

Figure 2: The structure and Design of a Container Shelter **[16]**

Model 2: UNHCR Refugee Housing Unit (RHU)

In 2015, the Swedish company IKEA lunched a partnership with Better Shelter Foundation to develop and improved a shelter solution that provides greater dignity and supports the protection of millions displaced people and refugees around the world **[15]**. In addition, the Shelter is evaluated carefully by UNHCR.

One of the disadvantages of the Better Shelter is that the shelter is produced completely outside of the affected country. As all production happens currently almost entirely in Northern Europe, this could affect the locality of the shelter.

The model shown in figure 3 relies on a lightweight structural frame combined with modular wall and roof panels that can be easily transported and assembled in the field. Its enclosure system is based on durable, weather-resistant composite materials that offer a balance between strength, insulation, and simplicity of installation. The shelter's components are designed to interlock through a standardized connection system, allowing families or field teams to assemble the unit without heavy equipment.

To ensure stability in diverse site conditions, the design incorporates a basic anchoring approach that secures the structure against wind loads and shifting ground. In terms of durability, this model fits very well with the idea of upgrading existing transitional shelters to more permanent shelters. The shelter is expected to serve between 1.5 to 5 years depending on the maintenance, although the metal structure itself has an expected lifespan of more than ten years.

RHUs have been deployed across a wide range of humanitarian settings. UNHCR and partner agencies have introduced RHUs in major refugee-hosting countries, including Jordan, Iraq, Lebanon, and pilot sites in Türkiye, as well as in camps across Ethiopia, Kenya, Uganda, and Mauritania. They were also widely used during the 2015–2016 refugee influx in Greece and in disaster or displacement responses in Nepal, Bangladesh, and Colombia. These diverse applications highlight the RHU's role as a globally recognized transitional shelter solution endorsed by UNHCR **[15][16]**

Figure 3: Refugees Housing Units RHU **[17]**

Figure 4: Refugees Housing Units RHU **[17]**

Model 3: Community led Transitional Shelter

Engaging local communities is essential for the success of transitional shelter programs. Community members provide insights into cultural norms, preferences, and specific needs, ensuring that shelters are acceptable and functional for the intended users. The participatory approach of transitional shelter provision, underpinned by effective coordination, ensures that displaced populations receive timely, appropriate, and sustainable housing solutions **[5]**. Analyzing case studies from another disasters, such as the 2010 Haiti earthquake provides valuable insights into the best practices of implementing transitional shelter programs in collaboration with the local communities. This case study highlights the importance of stakeholder coordination, cultural considerations, and adaptability to local contexts in ensuring the effectiveness and sustainability of shelter interventions.

The 2010 Haiti earthquake, which struck on January 12, resulted in catastrophic destruction, leaving over 1.5 million people homeless and causing extensive damage to infrastructure across the country. In response to this humanitarian crisis, transitional shelter programs were rapidly implemented to provide displaced populations with safer, more durable alternatives to emergency tents and tarpaulins.

Organizations such as the International Organization for Migration (IOM), Habitat for Humanity, and The Salvation Army played pivotal roles in these efforts. The IOM alone provided transitional shelters to over 10,000 families, aiming to replace vulnerable tent settlements with more stable housing solutions. These shelters were designed to be upgradeable, relocatable, and constructed using local materials and labor, thereby supporting both immediate needs and long-term recovery efforts **[18].**

Habitat for Humanity focused on building recyclable and upgradeable shelters, with a goal to serve 50,000 families over five years. By the end of 2010, they had constructed over 1,000 such shelters and distributed more than 21,000 emergency shelter kits. Their approach emphasized community involvement, with local leaders participating in identifying vulnerable families and setting up rebuilding priorities **[19]**.

The Salvation Army completed the construction of 600 transitional shelters in Jacmel, Haiti, by July 2010. Their program not only provided housing but also employed over 400 Haitians as carpenters and construction crew members, integrating livelihood support into the recovery process **[20]**.

Despite these efforts, the transitional shelter programs faced significant challenges. Land tenure issues, debris removal, and coordination among various stakeholders often delayed construction and hindered the effectiveness of the response. Additionally, the scale of displacement and the urgency of the situation required **[18]**.

In conclusion, the transitional shelter initiatives following the 2010 Haiti earthquake provided critical relief to thousands of displaced families and contributed to the broader recovery efforts. These programs underscored the importance of community involvement, adaptability, and coordination among humanitarian actors. However, they also highlighted the complexities and challenges inherent in post-disaster shelter provision, offering valuable lessons for future responses in similar contexts. Rapid action, sometimes at the expense of long-term planning and sustainability.

Figure 5: Model of Haiti Earthquake Shelter **[21]**

Figure 6: Model of Haiti Earthquake Shelter **[21]**

Syria Transnational Shelter Models

For long years, the emergency shelter strategy following the conflict in Syria adopted short-term shelter interventions, which required substantial future funding commitments as tents rapidly deteriorate and must be replaced. Therefore, there was an urgent need for a more systematic approach to improving shelter and living conditions in northwest Syria. Therefore, in 2022, the Shelter and Nonfood Items Cluster introduced the Dignified Shelter & Living Conditions framework as a more appropriate approach for protracted displacement, functioning as a transitional shelter model designed to reduce reliance on short-term assistance cycles and increase resilience **[22]**. In the context of emergency management, diversifying the range of transitional shelter solutions is considered highly beneficial. Thus, a combination of options should be explored, complementing the production of prefabricated units for temporary settlements.

Model 1: International Organization Transitional Shelter Model: Model 1: Prefabricated Shelter Unit

Ranging from converted shipping containers to flat-pack modular kits, prefabricated units represent the most durable transitional shelter option currently deployed in Syria. The most common example is the caravan unit (approximately 4×5 m, 20–21 m²) as shown in figure 7, extensively used in northern Idleb and expanded after the 2023 earthquakes in Aleppo and Idlib. These steel-frame, insulated-panel shelters offer strong resistance to rain, snow, and wind, providing a durability lifespan of 5–10 years, particularly when winterization kits are added **[17]**

However, the model relies almost entirely on imported industrial materials and external manufacturing, offering minimal engagement of local labor or local construction markets. Although highly effective in rapid deployment and providing significantly better protection than tents, prefabricated units remain the most expensive transitional shelter model in Syria due to high procurement, transportation, and installation costs. Their scalability has therefore been limited, with only around 4% of shelters in assessed NWS camps classified as factory-made units **[18]**. Overall, this model offers the highest durability and fastest deployment but the lowest cost efficiency and weakest integration with local materials and labor systems.

Figure 7: Prefabricated Shelter in Syria **[23]**

Model 2: Local Organization Transitional Shelter Model: Concrete Block Shelter Unit

Concrete-block shelters—commonly implemented by Syrian NGOs such as ATAA—constitute one of the most context-appropriate transitional shelter solutions in northwest Syria. These one-room masonry structures, often measuring 45–65 m² in large-scale settlements such as the 4,500-unit project in Jarablus, provide durable, weather-resistant housing for displaced families transitioning out of tents. Their masonry walls and lightweight metal roofing offer long-term durability (10–25 years), improved insulation, and better flood protection when constructed on elevated plinths with proper drainage **[19]**

Unlike prefabricated units, this model depends heavily on locally available materials such as concrete blocks, cement, gravel, and metal sheets as clearly reflected in figure 8and local construction labor, which supports livelihoods and strengthens local markets. Humanitarian shelter designs often integrate Sphere standards regarding floor area, ventilation, and climate considerations **[20].**While more costly than tents, concrete-block shelters are significantly more cost-efficient than prefabricated units, and their potential for incremental upgrading makes

them one of the most scalable and economically sustainable transitional shelter solutions in a protracted displacement context.

Figure 8: Concrete Shelter in Syria **[23]**

Figure 9: Concrete Shelter in Syria – By Author

Model 3:Community-Led Transitional Shelter Model : Mud-Brick Shelters

Mud-brick shelters draw from traditional Syrian rural architecture, using sun-dried earthen blocks mixed with straw to form thick insulating walls, typically topped with timber or metal roofing and earth-based plaster. These 4×4 m units (approximately 16 m²) shown in figure 10 have been piloted in several parts of Idlib through community groups and cash-for-work programs, enabling displaced families to participate in brick production and construction. Although less durable than concrete shelters, mud-brick units offer moderate durability (5–8 years) when maintained and protected from heavy rain through raised foundations, plastering, and roof overhangs **[21]**.

This model excels in the use of local materials such as soil, straw, and earth plaster, making it highly sustainable and culturally familiar. Its cost efficiency is exceptionally high, as materials are inexpensive and labor is community-based, often requiring minimal external funding. Academic assessments highlight the environmental advantages, cultural acceptance, and livelihood-generation potential of earthen construction **[22]**. Overall, mud-brick shelters provide the lowest-cost and most locally integrated transitional solution, though with durability limitations that make them suitable primarily for rural and moderate-term displacement scenarios.

Figure 10: Mud Brick Shelter in Syria **[21]**

RESULTS AND CONCLUSION

The findings of this study demonstrate that transitional shelter is not merely a temporary housing option, but a pivotal strategic component for stabilizing post-conflict Syria and facilitating the shift from protracted displacement toward organized resettlement and recovery. The comparative analysis of global case studies and Syrian shelter models reveals that no single approach can adequately address the complex humanitarian and housing needs of northwest Syria. Instead, a diversified shelter ecosystem is required one that balances durability, cultural relevance, cost efficiency, and scalability.

International prefabricated units offer the highest levels of durability and the fastest deployment, particularly in the aftermath of major disasters such as the 2023 earthquakes. These units are uniquely versatile, as they can be reassembled and repurposed into community centers, temporary schools, children's libraries, or other educational spaces according to local needs. With appropriate structural enhancements, they can also be upgraded or converted into permanent housing, making them a flexible option that bridges transitional shelter and long-term accommodation. However, their dependence on imported materials and their high overall costs significantly limit their potential for large-scale implementation in Syria.

In contrast, concrete-block shelters implemented by local organizations represent a more sustainable and economically viable model. These shelters rely on local materials and labor, thereby strengthening community resilience and supporting early economic recovery, while offering long-term durability and compatibility with Sphere standards and local climatic conditions. Community-led mud-brick shelters present a highly cost-efficient, culturally rooted, and environmentally sustainable option, especially in rural areas. Their participatory construction processes generate livelihood opportunities for displaced populations, although their durability remains moderate compared to concrete units.

Collectively, these models underline the urgent need for a national transitional shelter framework that moves beyond fragmented, project-based interventions. Such a framework must incorporate standardized design guidelines, climate-sensitive typologies for both urban and rural contexts, and clear implementation pathways that align humanitarian actions with national reconstruction policies. Housing, Land, and Property (HLP) considerations should be embedded to ensure tenure security and enable families to gradually upgrade transitional units into permanent homes. Community participation must also be institutionalized as a central pillar in design, planning, and governance.

This study concludes that transitional shelter when approached as an adaptable, integrated system can serve as a cornerstone of Syria's post-conflict housing strategy. By leveraging diverse shelter models, aligning them with global best practices, and anchoring them in local materials and community capacities, Syria can move beyond tent-based settlements and establish dignified, safe, and scalable housing solutions that pave the way for sustainable resettlement and reconstruction.

Looking ahead, future research can build upon the findings of this paper by developing a more detailed cost-benefit analysis of transitional shelter models in different Syrian regions. Additionally, longitudinal field studies could assess the long-term social and economic impacts of each shelter type on displaced populations. Expanding this framework to include community feedback mechanisms, climate adaptation considerations, and gender-sensitive design would further enhance the relevance and applicability of shelter strategies in post-conflict settings.

ÖZET

Hızlı nüfus artışı ve artan kentleşme oranları, deprem gibi doğal afetlerin oluşturduğu riskleri artırmaktadır. Özellikle Türkiye gibi aktif fay hatları üzerinde bulunan ülkelerde, mevcut bina stokunun sismik performansının belirlenmesi hayati önem taşımaktadır. Ancak, tüm binaları ayrıntılı analiz yöntemleriyle tek tek incelemek, zaman ve maliyet açısından sürdürülebilir değildir. Bu çalışma, yüksek sismik risk altındaki Bingöl ilindeki konut binalarının sismik performansını belirlemek için kullanılan Hızlı Görsel Tarama (RVS) yöntemlerinin etkinliğini karşılaştırmalı olarak incelemektedir. Çalışma kapsamında, Türkiye'nin Riskli Yapıların Tespiti Yönetmeliği (RBTY-2019), ABD merkezli FEMA-P154 ve Hindistan merkezli IITK-GSDMA yöntemleri ile bu çalışma kapsamında geliştirilen Yapay Sinir Ağı (ANN) tabanlı model kullanılmıştır. Analizlerde, 2003 Bingöl depremi sonrasında hasar değerlendirmesi yapılan 35 gerçek binadan elde edilen veriler referans (yer gerçeği) olarak kullanılmıştır. Çalışmanın benzersiz bir katkısı olarak, RBTY-2019 sonuçlarını bölgesel önceliklendirmede kullanmak için yeni bir "Ölçeklendirme Fonksiyonu" geliştirilmiştir. Bulgular, FEMA-P154 yönteminin ekonomik olmadığını, %48,6 doğrulukla oldukça güvenli bir seviyede kaldığını gösterirken, IITK-GSDMA yöntemi %62,9 ve ölçeklendirilmiş RBTY-2019 yöntemi %71,4 tutarlılık sağladı. Geliştirilen ANN modeli en yüksek tahmin başarısını sergiledi ve hızlı değerlendirme süreçlerinde yapay zeka kullanımının potansiyelini ortaya koymuştur.

Anahtar Kelimeler: Hızlı Görsel Tarama, Sismik Risk, Bingöl, Yapay Sinir Ağları, Sismik Performans

GİRİŞ

Türkiye, jeolojik yapısı ve tektonik konumu itibariyle dünyanın en aktif deprem kuşaklarından biri olan Alp-Himalaya deprem kuşağı üzerinde yer almaktadır. Özellikle Bingöl ili, Kuzey Anadolu Fay Zonu (KAFZ) ve Doğu Anadolu Fay Zonu (DAFZ) gibi iki büyük fay sisteminin kesişim noktası olan Karlıova Üçlü Eklemi yakınında bulunması sebebiyle sismik riskin en yüksek olduğu bölgelerden biridir (Akbayram et al., 2022).

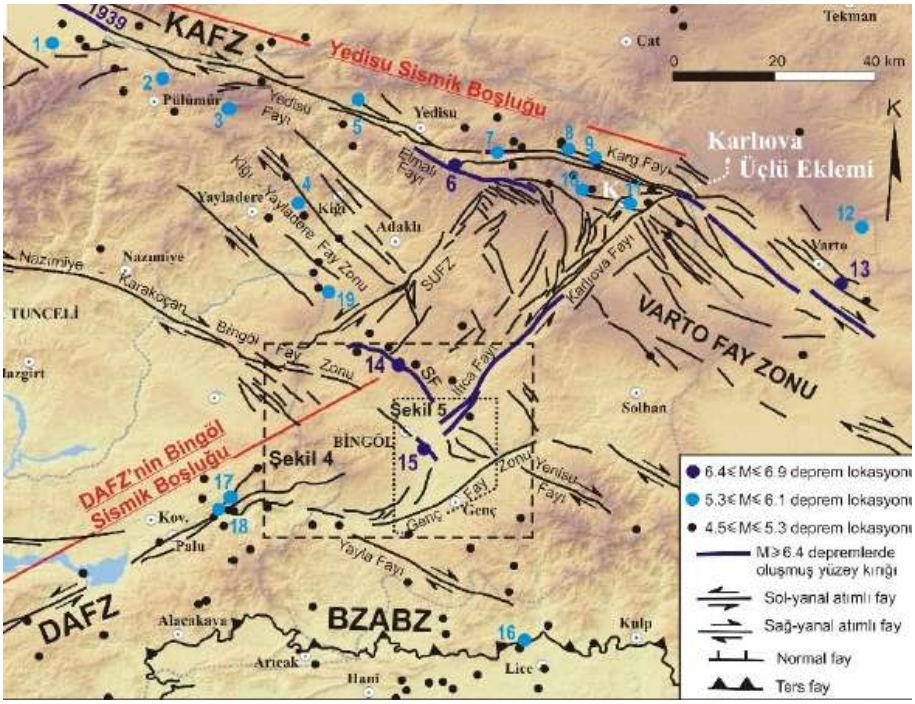

Figure 1. *Bingöl'ü kuşatan faylar ve sismik boşluklar (Akbayram et al., 2022)*

Bölgedeki hızlı nüfus artışı ve geçmişteki kontrolsüz yapılaşma pratikleri, "standart dışı" olarak nitelendirilebilecek ve deprem güvenliği açısından risk taşıyan bir yapı stokunun oluşmasına neden olmuştur.

Olası bir deprem senaryosunda can ve mal kaybını en aza indirmek için mevcut yapı stokunun deprem performansının belirlenmesi ve riskli yapıların tespit edilmesi afet yönetiminin en kritik aşamasıdır (AFAD, 2018). Ancak, bir şehirdeki binlerce binanın her birinin ayrıntılı yapısal analiz yöntemleri ile incelenmesi hem zaman hem de maliyet açısından mümkün değildir. Bu kısıtlar, yapıları "riskli", "muğlak" veya "güvenli" olarak hızlıca sınıflandırabilen ve önceliklendirebilen Hızlı Görsel Tarama (HGT) yöntemlerine olan ihtiyacı artırmıştır (Sucuoğlu et al., 2007).

Bu çalışmanın temel amacı; ulusal yöntemimiz olan RBTY-2019 ile uluslararası literatürde yaygın olarak kullanılan FEMA-P154 ve IITK-GSDMA yöntemlerinin Bingöl özelindeki doğruluk oranlarını karşılaştırmaktır (FEMA-P154, 2017; RBTY, 2019; Sinha & Goyal, 2004). Karşılaştırma için 2003 Bingöl depreminde hasar görmüş ve performansları ***"gerçek hayat verisi"*** olarak kaydedilmiş binalar kullanılmıştır.

Ayrıca çalışma kapsamında, geleneksel, kural tabanlı ***(rule-based)*** yöntemlerin eksikliklerini gidermek ve parametreler arasındaki karmaşık ilişkileri ***(non-lineerite)*** çözebilmek amacıyla Yapay Sinir Ağları (YSA) tabanlı yeni bir tahmin modeli önerilmiş ve performansı diğer yöntemlerle kıyaslanmıştır (Varolgüneş, 2023).

MATERYAL VE YÖNTEM

Bu çalışmada, Bingöl ilindeki mevcut betonarme yapı stokunu temsil eden bir veri seti kullanılarak, üç farklı konvansiyonel HGT yöntemi ve bir yapay zeka modeli (YSA) uygulanmıştır.

Çalışma Alanı ve Veri Seti

Çalışma alanı olarak, 1 Mayıs 2003 tarihinde meydana gelen ve büyük yıkıma yol açan Bingöl Depremi'nden etkilenen bölge seçilmiştir. Analizlerde kullanılan veri seti, deprem sonrasında Orta Doğu Teknik Üniversitesi (ODTÜ) bünyesindeki SERU (Structural Engineering Research Unit) ekipleri tarafından yerinde incelenen ve hasar durumları detaylı olarak raporlanan 35 adet betonarme binadan oluşmaktadır . İncelenen binalar genellikle 2-5 katlı olup betonarme çerçeve sistemine sahiptir (SERU, 2003).

Referans kabul edilen gerçek hasar dağılımı (Ground Truth) şu şekildedir: %31 Hasarsız, %29 Hafif Hasarlı, %17 Orta Hasarlı, %20 İleri Hasarlı ve %3 Göçme durumu. Bu dağılım, yöntemlerin doğruluk analizinde ***"hedef çıktı"*** olarak kullanılmıştır.

İncelenen Hızlı Değerlendirme Yöntemleri

Çalışmada aşağıdaki yöntemler uygulanmıştır:

RBTY-2019 (Türkiye): 6306 sayılı "Afet Riski Altındaki Alanların Dönüştürülmesi Hakkında Kanun" kapsamında kullanılan, binaların bölgesel risk dağılımını belirlemeyi amaçlayan, yapısal sistem puanı ve olumsuzluk parametrelerine dayalı ulusal yöntemdir (RBTY, 2019).

FEMA-P154 (ABD): Federal Acil Durum Yönetim Kurumu tarafından geliştirilen, "sokak taraması" esasına dayanan ve binayı temel sismik tehlike puanından başlayarak çeşitli olumsuzluk katsayıları ile puanlayan yöntemdir (FEMA-P154, 2017).

IITK-GSDMA (Hindistan): FEMA tabanlı olup Hindistan'ın yerel inşaat pratiklerine ve malzeme özelliklerine göre uyarlanmış versiyondur (Sinha & Goyal, 2004).

YSA Modeli (Önerilen Yöntem): ***MATLAB*** ortamında geliştirilen, çok katmanlı, ileri beslemeli ve geri yayılımlı ***(feed-forward backpropagation)*** bir yapay sinir ağı modelidir. Modelde kat sayısı, yumuşak kat, kısa kolon, ağır çıkma, plan düzensizliği, zemin sınıfı ve yapı nizamı gibi parametreler ***"girdi katmanı"***, gerçek hasar durumu ise ***"çıktı katmanı"*** olarak tanımlanmıştır. Eğitim için ***Levenberg-Marquardt*** optimizasyon algoritması ***(trainlm)*** kullanılmıştır.

RBTY-2019 İçin Geliştirilen Ölçeklendirme Fonksiyonu

RBTY-2019 yönetmeliği, binaları temel olarak risk önceliğine göre sıralamakta ancak sayısal puanları doğrudan bir "hasar seviyesine" (Örn: Orta Hasar, Ağır Hasar) dönüştürmemektedir. Bu çalışmada, RBTY-2019'dan elde edilen Performans Puanlarını (PP), gerçek hasar verileriyle (SERU 2003) ilişkilendirerek 5 farklı hasar seviyesine dönüştüren özgün bir Yerel Ölçek Fonksiyonu (LSF) geliştirilmiştir.

Bu fonksiyon sayesinde RBTY sonuçları, diğer yöntemlerle ve gerçek hasar verileriyle karşılaştırılabilir hale getirilmiştir. Geliştirilen ölçeklendirme aralıkları Tablo 1'de sunulmuştur.

Table 1. *RBTY-2019 Ölçeklendirme Fonksiyonu*

		PP	≤	-10	Göçme Bölgesi	1
-10	<	PP	≤	11	İleri Hasar	2
11	<	PP	≤	45	Orta Hasar	3
45	<	PP	≤	81	Az Hasar	4
81	<	PP			Hasarsız	5

BULGULAR

Analizler sonucunda, her bir bina için yöntemlerin ürettiği hasar tahminleri, 2003 depreminde gerçekleşen hasar durumlarıyla karşılaştırılmıştır.

FEMA-P154 Sonuçları

Yöntemin Bingöl verileriyle tutarlılık oranı %48,6 olarak hesaplanmıştır. FEMA yöntemi, binaların çok büyük bir kısmını ***"potansiyel riskli"*** olarak etiketlemiş ve aşırı güvenli tarafta kalmıştır. Bu durum, incelenen binaların neredeyse tamamı için ***"Ayrıntılı Analiz"*** gerekliliği doğurduğundan, yöntemin hızlı tarama ve eleme amacına Bingöl özelinde tam hizmet etmediği görülmüştür.

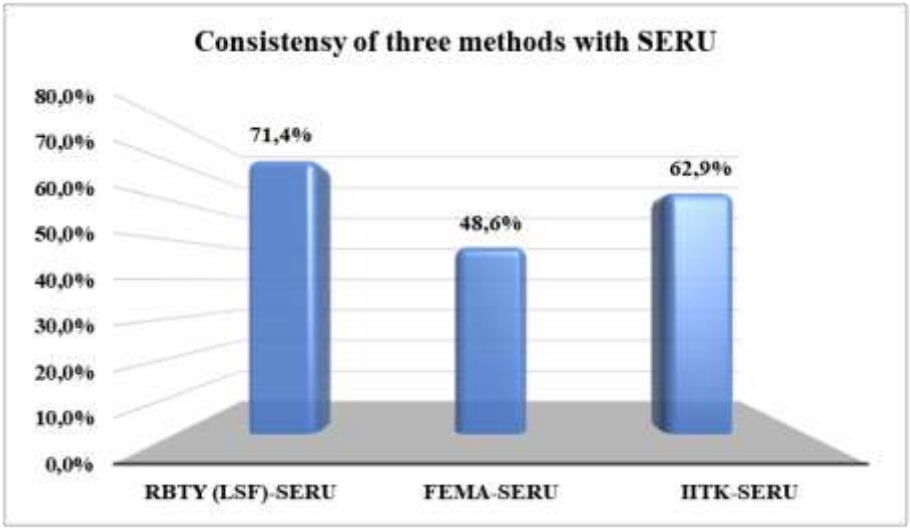

Figure 2*. Consistency of 3 methods with SERU*

IITK-GSDMA Sonuçları

Hindistan yönetmeliği, FEMA P154'e kıyasla daha iyi bir performans sergilemiş ve %62,9 tutarlılık oranına ulaşmıştır. Ancak bazı kritik binalarda (örneğin göçme riski olan) yanıltıcı güvenli sonuçlar verebildiği gözlemlenmiştir.

RBTY-2019 (Ölçeklendirilmiş) Sonuçları

Bu çalışma kapsamında geliştirilen ölçeklendirme fonksiyonu ile uygulanan ulusal yöntemimiz, %71,4 tutarlılık oranı ile konvansiyonel yöntemler arasında en yüksek başarıyı göstermiştir. Yöntem, özellikle "riskli" ve "güvenli" yapıları ayırmada diğer yöntemlere göre daha dengeli bir dağılım sergilemiştir.

YSA Modeli Sonuçları

Geliştirilen Yapay Sinir Ağı modeli, veri seti üzerinde eğitildiğinde parametreler arasındaki non-lineer ilişkileri başarıyla öğrenmiştir. Test veri seti üzerinde yapılan doğrulama analizlerinde YSA modeli, referans hasar verileriyle %100'e varan yüksek bir uyum göstermiştir.

Aşağıdaki grafikte yöntemlerin tutarlılık oranlarının karşılaştırması verilmiştir.

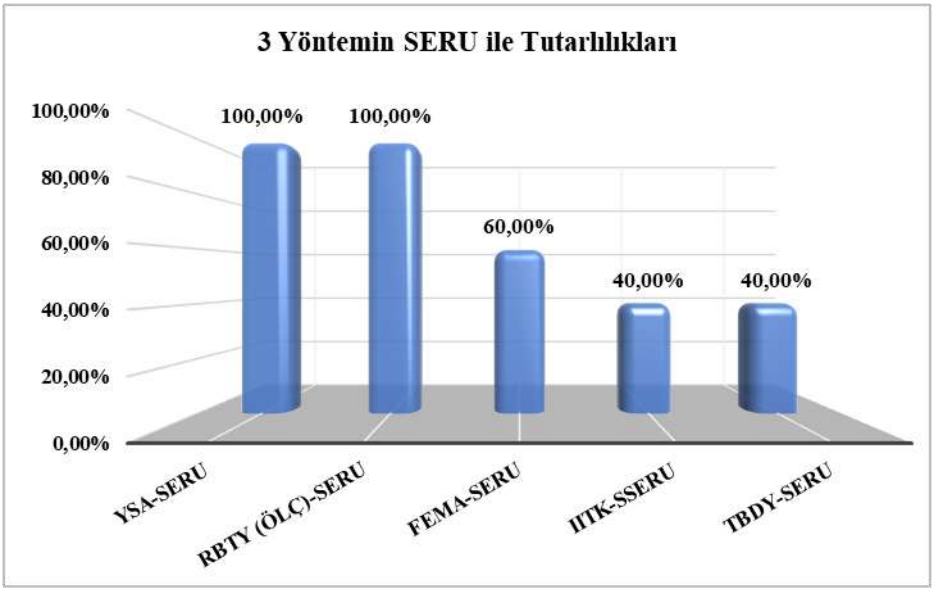

***Figure 3**. HGT Yöntemlerinin ve YSA Modelinin Doğruluk Oranları*

TARTIŞMA VE SONUÇ

Bu çalışma, Bingöl ilindeki mevcut betonarme konut stoku için hızlı değerlendirme yöntemlerinin güvenilirliğini ortaya koymuştur. Elde edilen sonuçlar ışığında şu değerlendirmeler yapılabilir:

Yöntemlerin Yerelliği

FEMA-P154 gibi uluslararası yöntemler, geliştirildikleri ülkenin (ABD) yapı karakteristiğine ve güvenlik katsayılarına göre kalibre edildiğinden, Türkiye gibi farklı yapı kültürüne sahip ülkelerde doğrudan uygulandığında aşırı muhafazakâr sonuçlar vermektedir. Bu durum, kaynakların verimsiz kullanılmasına yol açabilir.

Ulusal Yöntemin Başarısı:

RBTY-2019, Türkiye'deki yapı stokunun karakteristik özelliklerini (yumuşak kat, ağır çıkma vb.) daha iyi parametrize ettiği için, bu çalışmada önerilen "Ölçeklendirme Fonksiyonu" ile entegre edildiğinde bölgesel taramalar için en güvenilir konvansiyonel yöntem olarak öne çıkmaktadır.

Yapay Zekanın Gücü: YSA modeli, kural tabanlı yöntemlerin aksine, veriler arasındaki karmaşık örüntüleri öğrenebildiği için en yüksek tahmin başarısını göstermiştir. Gelecekte, daha büyük veri setleriyle (Örn: 2020 Elazığ, 2023 Kahramanmaraş depremleri verileriyle) eğitilecek YSA modelleri, şehir ölçeğindeki risk haritalarının çıkarılmasında en güçlü araç olacaktır.

Sonuç olarak; Bingöl ve benzeri yüksek sismik riske sahip bölgelerde yapılacak kentsel dönüşüm çalışmalarında, önceliklendirme aracı olarak Ölçeklendirilmiş RBTY-2019 yöntemi

veya eğitilmiş YSA modellerinin kullanılması, karar vericilere zaman ve maliyet açısından büyük avantaj sağlayacaktır.

ACKNOWLEDGEMENT

ÖZET

Türkiye'de yapı güvenliği diskuru, haklı olarak sismik risklere odaklanmıştır. Ancak, sismik aktivite olmaksızın, "kendiliğinden" meydana gelen yapısal göçmeler, en az depremler kadar ciddi ve sistemik sorunlara işaret etmektedir. Bu bildiri, 1983 Diyarbakır Hicret Apartmanı faciasından 29 Ekim 2025 Gebze çöküşüne kadar olan süreçte, Türkiye'de kamuoyuna yansıyan başlıca deprem dışı progresif (bütüncül) göçme vakalarını kronolojik ve analitik bir yöntemle incelemektedir. Vaka kataloğu metodu kullanılarak, her bir olayın (Gebze 2025, Konya 2025, Kartal 2019, Konya 2004, Diyarbakır 1983/2007) bilirkişi raporları, arşiv kayıtları ve teknik analizler ışığında göçme patolojileri sınıflandırılmıştır. Analizler, bu göçmelerin "ani" veya "bilinmeyen" sebeplerden değil; (1) Tasarım, malzeme ve imalat aşamasındaki brüt mühendislik hataları, (2) Taşıyıcı sisteme sonradan yapılan bilinçsiz müdahaleler (kolon kesme, kaçak kat), (3) Geoteknik-Yapısal Etkileşim (Geometrik düzensizlik ve doğrudan zemin desteği kaybı) ve (4) Bu süreçlerin tamamındaki kritik denetim başarısızlıkları gibi birikimli ve progresif hasar mekanizmalarının sonucu olduğunu ortaya koymaktadır. Özellikle Gebze (2025) vakası, asimetrik plana sahip (kama formlu) bir yapının, doğrudan metro tünel aksı üzerindeki zemin boşalması (undermining) sonucu nasıl bir kinematik devrilme (toppling) mekanizmasıyla göçtüğünü göstermesi açısından literatürde özgün bir yere sahiptir. Bu çalışma, sismik riskin ötesinde, mevcut yapı stoğunun "statik" güvenliğine ve özellikle kentsel altyapı projelerindeki geoteknik risklerin denetimine yönelik acil politika ihtiyacını vurgulamayı amaçlamaktadır.

Anahtar Kelimeler: Progresif Göçme, Yapısal Güvenlik, Geoteknik-Yapı Etkileşimi, P-Delta Etkisi (P-\Delta), Denetim Başarısızlığı, Vaka Analizi.

1. GİRİŞ

Türkiye'nin bir deprem ülkesi olduğu gerçeği, yapı mühendisliği ve ulusal afet politikalarının merkezinde yer almaktadır. Odaklanma, büyük ölçüde sismik etkilere dayanıklı yapılar tasarlamak ve mevcut stoğu bu yönde güçlendirmek üzerine kuruludur. Ancak, bu odaklanma, yapıların "statik" yükler (kendi ağırlıkları ve kullanım yükleri) altındaki güvenliğini ve zamanla ortaya çıkan progresif hasar risklerini gölgede bırakma tehlikesi taşımaktadır.

Diyarbakır'da 1983'te 83 kişinin hayatını kaybettiği Hicret Apartmanı'ndan, Konya'da 2004'te 92 kişinin can verdiği Zümrüt Apartmanı'na ve İstanbul'da 2019'da 21 kişinin öldüğü Yeşilyurt Apartmanı'na kadar uzanan trajik bir liste, deprem olmaksızın da binaların "kendiliğinden" çökebildiğini acı bir şekilde kanıtlamıştır. Bu vakaların en günceli, bu bildirinin yazımından sadece bir gün önce (29 Ekim 2025) Gebze'de yaşanan ve analizlerimize göre bariz geoteknik ihmaller sonucu meydana gelen yapısal göçmedir.

Bu olaylar "ani" veya "bilinmeyen" sebeplerle değil; tasarım, imalat, kullanım ve denetim aşamalarındaki sistematik başarısızlıkların birikimli bir sonucu olarak gerçekleşmektedir. Bu bildiri, bu vakaları bir katalog altında toplayarak, bu "statik" göçmelerin ortak mühendislik patolojilerini analiz etmeyi ve gelecekteki benzer facialarını önlemek için dersler çıkarmayı hedeflemektedir.

2. YÖNTEM VE KAPSAM

Bu çalışmada, "Vaka Kataloğu Analizi" (Case Catalog Analysis) metodolojisi kullanılmıştır. Kapsam, 1983-2025 yılları arasında Türkiye'de meydana gelen, deprem dışı, progresif (bütüncül) ve can kaybına yol açan/potansiyeli yüksek olan apartman tipi yapılarla sınırlandırılmıştır. Metruk (terk edilmiş) yapıların veya kısmi çökmelerin çoğu analize dahil edilmemiştir.

Veriler, açık kaynaklı arşivlerden, (mevcutsa) TMMOB veya adli bilirkişi raporlarından, haber arşivlerinden ve Gebze (2025) vakası için sağlanan birincil kanıtlardan (Google Street View görüntüleri, CİMER yazışmaları, geoteknik analiz şemaları) derlenmiştir.

3. VAKA KATALOĞU VE PATOLOJİ SINIFLANDIRMASI

Türkiye'deki deprem dışı yapısal göçme envanteri incelendiğinde, göçme nedenlerinin zamanla 'brüt malzeme ve tasarım hatalarından', 'kentsel etkileşim ve insan müdahalesine' doğru evrildiği görülmektedir. 1983 Hicret Apartmanı ve 2004 Zümrüt Apartmanı vakaları, temel mühendislik hizmetlerinden yoksunluk ve düşük malzeme kalitesi (düşük beton dayanımı, yetersiz sargı donatısı) ile karakterize edilirken; 2019 Yeşilyurt ve 2025 Konya vakaları, mevcut taşıyıcı sisteme sonradan yapılan kontrolsüz müdahaleleri (kaçak kat, kolon kesilmesi) işaret etmektedir. Ancak 29 Ekim 2025 tarihli Gebze vakası, literatürde ayrışan bir patoloji sunmaktadır. Nispeten genç bir yapı stoğuna (13 yıl) dahil olmasına rağmen bina, malzeme yetersizliğinden ziyade, geoteknik-yapısal etkileşim (SSI) ihmali sonucu göçmüştür. BDışsal nizamda yürütülen metro kazısının yarattığı zemin gevşemesi ve farklı oturmalar, üst yapıda tolere edilemeyen $P-\Delta$ etkilerini tetiklemiş; bu durum yoğun kentleşme süreçlerinde ***'dışsal geoteknik risklerin'*** en az ***'içsel yapısal kusurlar'*** kadar kritik olduğunu ortaya koymuştur.

Analiz edilen temel vakalar ve göçme patolojileri Tablo 1'de özetlenmiştir.

Tablo 1: Türkiye'de Deprem Dışı Progresif Göçme Vakaları Kataloğu (1983-2025)

Vaka Konum	Tarih	Yapı Tipi / Yaşı	Vefat Sayısı	Göçme Patolojisi (Birincil Neden)
Gebze, Kocaeli	29.10.2025	7 Katlı Apt. (13 Yaşında)	4	Geoteknik-Yapısal Etkileşim: Dışsal kazı (Metro) kaynaklı zemin gevşemesi ve farklı oturma, $P-\backslash Delta$ etkisini tetikledi.
Konya, Selçuklu	24.01.2025	3-4 Katlı Apt. (31 Yaşında)	2	Taşıyıcı Sisteme Müdahale: Zemin katta yapılan tadilat sırasında kolon kesilmesi/zayıflatılması (Ana Şüphe).
Kartal, İstanbul (Yeşilyurt Apt.)	06.02.2019	8 Katlı Apt. (27 Yaşında)	21	Proje İhlali ve Malzeme Yetersizliği: 3 kaçak kat (aşırı yük), deniz kumu (korozyon) ve düşük beton mukavemeti.
Diyarbakır, Kayapınar (Alkan-1 Apt.)	04.02.2007	8 Katlı Apt. (14 Yaşında)	5 (Boşaltılmıştı)	Proje İhlali (Aşırı Yük): 4 kat ruhsatlı binanın 8 kat inşa edilmesi.
Konya, Selçuklu (Zümrüt Apt.)	02.02.2024	11 Katlı Apt. (7 Yaşında)	92	Brüt Tasarım ve İmalat Hatası: Hatalı zemin etüdü, yetersiz statik proje (P-Δ ihmali), düşük beton kalitesi ve yetersiz sargı donatısı.
Diyarbakır, Şehitlik (Hicret Apt.)	03.01.1983	7 Katlı Apt.	83	Brüt Malzeme ve İmalat Hatası: Ruhsatsız, projesiz yapı. "Kerpiç gibi" beton (düşük çimento) ve 6'lık donatı kullanımı.

4. MÜHENDİSLİK ANALİZİ VE TARTIŞMA

Katalogdaki vakalar "progresif göçme" ortak sonucunda birleşse de bu göçmeyi başlatan birincil mühendislik patolojileri farklılık göstermektedir. Bu patolojiler dört ana kategori altında incelenebilir:

4.1. Kategori 1: Brüt Tasarım, Malzeme ve İmalat Yetersizliği

Bu kategoride, yapı daha inşa edilirken "ölü doğmuştur" ve kendi statik ağırlığını dahi güvenle taşıyamamaktadır.

- **Vakalar:** Hicret Apt. (1983), Zümrüt Apt. (2004).
- **Mekanizma:** Hicret vakasındaki "kerpiç gibi" beton ve **Ø6**'lık donatı, yapının basit basınç gerilmesini **(P/A)** dahi karşılayamadığını göstermektedir. Zümrüt vakasında ise hatalı statik proje, düşük beton kalitesi ***(f_{ck})*** ve yetersiz etriye (sargılama) birleşerek, kolonların sünek (ductile) bir davranış gösteremeden, ani ve gevrek (brittle) bir şekilde kırılarak iflas etmesine yol açmıştır.

Şekil 1. *Diyarbakır Hicret Apt. 1983 ((Antoloji Diyarbakır, 2020))*

Şekil 2. *Konya Zümrüt Apt. 2004 (Anadolu Ajansı, 2020)*

4.2. Kategori 2: Proje İhlali ve Aşırı Yükleme (Kapasite Aşımı)

Bu kategoride, yapıya proje dışı yükler (genellikle kaçak katlar) eklenerek mevcut kapasitenin üzerine çıkılmıştır.

- **Vakalar:** Kartal-Yeşilyurt (2019), Diyarbakır-Alkan-1 (2007).
- **Mekanizma:** Kartal'da 5 katlık sisteme 3 kat daha eklenmesi, **P** (düşey yük) değerini projelendirilenden %60'a varan oranda artırmıştır. Bu aşırı yük, zamanla deniz kumunun neden olduğu korozyonla birleştiğinde, güvenlik katsayıları tamamen erimiş ve sistem iflas etmiştir.

Şekil 3. *İstanbul Kartal Yeşilyurt Apt 2019 (Evrensel, 2021)*

4.3. Kategori 3: Taşıyıcı Sisteme Sonradan Müdahale

Bu kategoride, başlangıçta stabil olan yapıya kullanım aşamasında yapılan bilinçsiz müdahaleler (kolon kesme) göçmeyi tetikler.

- **Vaka:** Konya-Selçuklu (2025).
- **Mekanizma:** Bir taşıyıcı kolonun kaldırılması, yük aktarım yolunu (load path) bozar ve yükün komşu elemanlara yeniden dağıtılmasına (load redistribution) neden olur. Bu ani aşırı yüklenme, komşu elemanlarda zincirleme bir iflasa (cascade failure) yol açar.

Şekil 4. *Konya Selçuklu 2025 (Ankara Masası, 2025)*

4.4. Kategori 4: Geoteknik-Yapısal Etkileşim (Deformasyon Kaynaklı İflas)

Bu, en karmaşık senaryodur ve bu bildirinin odağındaki Gebze vakası ile örneklendirilmiştir. Göçme, yapısal bir hatadan çok, dışsal bir geoteknik etkinin neden olduğu deformasyondan kaynaklanır.

Şekil 5. *Binanın enkazı kaldırıldıktan sonra ortaya çıkan görüntü*

- **Vaka:** Gebze (2025).
- **Mekanizma:** Bitişikteki metro kazısı, binanın bir tarafındaki zemini "gevşeterek" (Şekil 1), bir "Zayıf Zemin" alanı (image_3fc262.png) yaratmıştır. Bu, "farklı oturmaya" ve binada bir "devrilme" hareketine neden olmuştur. Bu devrilme hareketi, kolonlarda bir ilk deplasman ***(Δ)*** yaratmış ve ***P-\Delta*** (İkinci Mertebe) etkisini (image_4018fc.png) tetiklemiştir. $M^{II} = M^I + (P \times \Delta)$ formülündeki ikincil moment, kolonların ezilip-burkularak iflasına ve "pancake" çöküşe yol açmıştır.

5. EN KRİTİK ORTAK PAYDA: DÖRT AŞAMALI DENETİM BAŞARISIZLIĞI

Mühendislik patolojileri farklılaşsa da, bu altı vakanın tamamını birleştiren asıl kök neden, **sistematik denetim başarısızlığıdır**. Bu başarısızlık, bir binanın ömrünün dört kritik aşamasında da gözlemlenmiştir:

1. **Tasarım Denetimi Başarısızlığı:** Zümrüt Apt. (2004) vakasında olduğu gibi, hatalı zemin etütleri ve yetersiz statik projeler onaylanmıştır.

2. **İmalat Denetimi Başarısızlığı:** Hicret Apt. (1983) ve Kartal Apt. (2019) vakalarında olduğu gibi, sahada "kerpiç gibi beton" veya "deniz kumu" kullanılmasına rağmen binalar onay almıştır.

3. **Kullanım Aşaması Denetimi Başarısızlığı:** Kartal (2019) ve Konya-Selçuklu (2025) vakalarında olduğu gibi, binalara sonradan kaçak kat çıkılmasına veya kolon kesilmesine rağmen etkin bir denetim yapılmamıştır.

4. **Tehdit-Müdahale Denetimi Başarısızlığı:** Bu, Gebze (2025) vakasıyla ortaya çıkan en trajik kategoridir. Diğer üç denetim aşaması başarılı olsa bile, dışsal bir tehdit (metro kazısı) ortaya çıktığında ve bu tehdit T-8 ay önce (çatlaklar) ve T-2.5 ay önce (CİMER başvurusu)

resmi olarak bildirilmesine rağmen, denetim mekanizması "0.6mm sorun yok" diyerek fatal bir hata yapmış ve göçmeye davetiye çıkarmıştır.

6. SONUÇ VE ÖNERİLER

Bu vaka kataloğu, Türkiye'deki deprem dışı yapısal göçmelerin "münferit facialar" veya "kader" olmadığını; tasarım, uygulama, kullanım ve denetim disiplinlerinin tamamını kapsayan, derin ve sistemik sorunların öngörülebilir sonuçları olduğunu kanıtlamaktadır.

Bu bulgular ışığında aşağıdaki acil öneriler sunulmaktadır:

1. **Geoteknik Risk Alanı Tanımlaması:** Kentsel alandaki tüm derin kazı ve altyapı projeleri (metro, otopark vb.) için yasal olarak "geoteknik etki alanı" tanımlanmalı; bu alandaki komşu binaların sürekli monitörizasyonu (İnSAR, inklinometre, jeodezik ölçüm) zorunlu hale getirilmelidir.

2. **Tehdit-Müdahale Protokolü:** "Gebze İhmali"nin tekrarlanmaması için, yapısal risk (çatlak, oturma) şikayetlerine yönelik acil durum protokolleri oluşturulmalıdır. "0.6mm" gibi tehlikeyi minimize eden raporlar, daha derin bir incelemeyi (Tepkisel Eylem) tetiklemeli, süreci kapatmamalıdır.

3. **Mevcut Stok "Statik Güvenlik" Denetimi:** Mevcut yapı stoğunun denetimi sadece sismik risklere değil, "statik risklere" (malzeme bozulması-korozyon, kaçak kat, sonradan müdahale) karşı da genişletilmelidir.

4. **Adli Mühendislik Veri Tabanı:** Bu bildirideki gibi vakaların teknik bilirkişi raporları, ders alınması amacıyla kamusal ve akademik bir "Ulusal Yapısal Göçme Veri Tabanı"nda anonimleştirilerek paylaşılmalıdır.

ABSTRACT

Historical masonry structures undergo progressive deterioration over time, necessitating restoration and structural strengthening interventions. Due to their chemical and mechanical compatibility with original historical materials, hydraulic lime-based mortars (HLMs) are widely employed in conservation practices. This study investigates the elastic modulus performance of hydraulic lime-based mortar with ultrasonic pulse velocity test after elevated temperature. Mortar prisms composed of HLMs were prepared in accordance with relevant material testing standards. The specimens were exposed to elevated temperatures ranging from 200 °C to 800 °C and subsequently subjected to ultrasonic pulse velocity tests. A total of 19 specimens were prepared for the elevated temperature tests (ETTs), consisting of three test specimens, one temperature-monitoring specimen for each temperature level, and three reference specimens. The reference specimens were tested under ambient laboratory conditions, whereas the remaining specimens, after exposure to elevated temperatures, were allowed to cool naturally to room temperature prior to testing. All specimens were subsequently evaluated under identical testing conditions to ensure the consistency and comparability of the experimental results. Based on the experimental results and subsequent evaluations, it was determined that the hydraulic lime-based mortars (HLMs) experienced a gradual decline in their elastic modulus with increasing temperature. This study provides valuable insights into the thermal performance of masonry walls constructed with hydraulic lime-based mortars (HLMs), thereby contributing to the advancement of fire-resistant materials for the restoration and preservation of historical structures.

Keywords: Lime-based mortar, Mechanical Properties, Elevated Temperarue Test, Elastic Modulus, Ultrasonic Pulse Velocity (UPV)

1. INTRODUCTION

The purpose of this study is to assess the influence of elevated temperatures on the elastic modulus of hydraulic lime-based mortars (HLMs) by employing ultrasonic pulse velocity testing. By examining the mechanical behavior of HLM specimens exposed to temperatures ranging from 200 °C to 800 °C, the study aims to determine the extent of degradation in their elastic properties. This investigation ultimately seeks to provide a deeper understanding of the thermal performance of HLMs used in historical masonry structures, contributing to the development of more effective and fire-resistant restoration materials and conservation strategies.

Kara et al. (2025) investigated mechanical properties of lime based mortar, bricks and masonry prism at elevated temeprature. The study investigates the mechanical behaviour of masonry walls built with hyraulic lime based mortars and clay bricks after elevated temperature that used to evalute historical masonry elements. The authors prepared several types and numbers of the specimen which was cured standard conditions and subsequently exposed temepratures from 200 °C to 800 °C. After heating, the specimens were performed flexural and compression tests. Digital image correlation was performed and compared to actual displacement measurements on masonry prism. Reults show that progressive loss of mechanical properties, elastic modulus of masonry prisms while temperature increases. The authors also evaluated thermal properties of materials after elevated temperatures and validated with finite element analysis versus testing. This study offers critical numerical and emprical data for post-fire structural assessment of historical masonry structures. **[Kara et al., 2025]**.

The paper by Pachta et al. (2018) investigates the physical and mechanical performance of lime-based mortars under elevated temperatures, with a view toward the behavior of historic or repair mortars when exposed to elevated temperatures. Several types of mortar were prepared and exposed to elevated temperatures from 200 °C up to 1000 °C. After the elevated temperature exposure, weight loss, volüme change, porosity, dynamic modulus of elasticity and flexural, micro structural changes and compression stregth were evaluated. The study concludes that lime mortars exhibit high thermal resistant compared to cement-based mortars. These findings provide a useful benchmark for evaluating mortar performance under thermal stress, which could complement non-destructive testing methods such as UPV when assessing post-fire residual strength or structural integrity in masonry elements. **[Pachta et al., 2018]**.

El Dandachy, M. E. Et al. (2024) investigated the mechanical and durability properties of metakaolin-based geopolymer mortars compared to conventional OPC mortars after elevated temperatures affects. Specimens were heated from 100 °C up to 900 °C, and their compressive strength, mass loss, ultrasonic pulse velocity (UPV), and gas permeability were measured. The geopolymer mix showed notably higher thermal resistance than ordinary portlant cement mortar, maintaining structural integrity and even improving in performance at moderate temperatures. The results show that geopolymer mortars experience a significant increase in compressive strength at around 200 °C, becasue of additional geopolymerization and matrix densification induced by temperature. After this peak, strength gradually decreases at higher temperatures. Ultrasonic pulse velocity test followed a similar trend: a slight decrease at low temperatures, a peak at 200 °C, and a progressive reduction with further heating, reflecting stiffness loss and microcracking. Overall, the study highlights the strong high temperature behavior of metakaolin-based geopolymers and demonstrates the usefulness of Ultrasonic pulse velocity test as a nondestructive tool for evaluating their residual mechanical performance. **[El Dandachy et al., 2018]**.

EN 1996-1-2 covers fire resistant design rules for masonry structures and decribes how material properties, including those of masonry mortar, change under elevated temperatures. The standard gives not only design rules for mortar but also fire resistance of masonry elements both structural and non-structural elements. Mortar is the critical part of the masonry strcutures that is adressed temperature dependent matrial properties such as compressive strength, stiffness and deformation characteristics. The reduction factors reflects the propgressive loss of mortar bonding, increased porosity and loss of cohesion at elevated temperatures. The standard also covers that fire performance of masonry with combined behaviour of units and mortar and emphasizes that mortar type such as general purpose, thin layer, and light wieght mortar affect thermal stability and load bearing capacity. In summary, the code treats mortar as a critical component governing masonry fire resistance, with its temperature-dependent mechanical degradation directly influencing the structural reliability of masonry members during fire exposure. However, the standard inludes for mortar strentgh class M5 and M10. Because of the fact that, in this study, relatively high strength lime based mortar M15 class were examined. **[EN 1996-1-2, 2024]**.

This study aims to emphasize the elastic modulus measured with Ultrasonic Pulse Velocity non destructive test at ambient and elevated temperature and their relevance to modern restoration practices and seismic strengthening of heritage buildings.

2. MATERIALS AND METHODS

In this research, a comprehensive evaluation of the fire resistance performance of high-lime mortars (HLMs), UPV tests were conducted. For this purpose, the mortars and masonry prism specimens were produced in accordance with the relevant material testing standards, and the prisms were assembled using the prepared mortar mixes. Following specimen preparation, all units were exposed to elevated temperatures ranging from 200 °C to 800 °C, after which they were subjected to mechanical testing in bending and compression to assess the influence of thermal loading on their structural behaviour. **[Kara et al., 2025]**.

A total of fifty specimens were incorporated into the high-temperature testing program. However, Ultrasonic pulse velocity (UPV) measurements were performed exclusively on the mortar specimens and were evaluated as part of this study. For each temperature level, three specimens were assigned for experimental mechanical testing, one specimen was fitted with thermocouples for monitoring internal temperature evolution, and three additional specimens served as reference samples. Within the scope of the elevated-temperature tests (ETTs), 20 specimens were prepared for the masonry prisms, 15 for the clay bricks, and 15 for the masonry mortars. The technical properties of the selected mortar are presented in Table 2.1, and the hardened mortar exhibited an average density of approximately 1850 kg/m³. **[Kara et al., 2025]**. In this study only the 15 mortar specimens were evaluated for UPV tests and results were reported for elastic modoulus.

Table 2.1. Technical data of Teknorep 520 EX**.**

General Information	
Material Structure	Special blend with natural hydraulic lime base and adjusted gradients
Cement Content (%)	0%
Appearance	Off-white and white coffee
Shelf Life	12 months in dry place in unopened packaging.
Package	20 kg kraft bag
Application Information	
Implementation Process	Min. 30 min at 20 °C
Application Ground Temperature	(+5 °C)–(+35 °C)
Grain Size	0–8 mm
Application Thickness	Each storey 1–5 cm
Performance Information	
Flexural Strength	4.0 N/mm^2
Compressive Strength (EN 1015-11)	15–20 N/mm^2 (M15 Class)
Modulus of Elasticity	7000 N/mm^2
Water Vapor Permeability (EN 1745)	$\mu < 35$
Capillary Water Absorption (EN 1015-18)	0.2 $kg\ m^{-2}\ h^{-0.5}$
Bond Strength	>0.15 N/mm^2
Reaction to Fire	A1

For each temperature level applied to the masonry prisms, three specimens were allocated for mechanical testing, one specimen was dedicated exclusively to thermal monitoring, and three additional specimens were used as reference samples. The reference group was tested under ambient laboratory conditions without exposure to elevated temperatures. All remaining specimens were allowed to cool naturally to room temperature following the high-temperature phase and were subsequently tested under the same ambient conditions as the reference samples to ensure a consistent basis for comparison. The specimens assigned for temperature monitoring were not subjected to mechanical testing; instead, they were equipped with embedded thermocouples to record the internal temperature development throughout the heating process **[Kara et al., 2025]**.

The mortar specimens were prepared by mixing Teknorep 520 EX in the laboratory using a water-to-mortar ratio of 20/3.1–3.3, in accordance with the manufacturer's recommendations. The fresh mixture was then placed into prismatic molds measuring 40 mm × 40 mm × 160 mm, following the procedures outlined in EN 1015-11 **[EN 1015-11, 2019].** Immediately after

casting, the specimens were enclosed in polyethylene bags to ensure a controlled curing environment with a relative humidity of 95% ± 5%, as prescribed by the standard (Figure 2.1).

Figure 2.1: Masonry mortar preparation as per EN 1015-11 **[EN 1015-11, 2019], [Kara et al., 2025]**.

The mechanical testing program presented by Kara et al. (2025) was conducted at the Construction Materials, Fire, and Acoustic Laboratory of the Turkish Standards Institution (TSE) in Istanbul, Turkey. During the experiments, the specimens were subjected to constant temperature levels of 200 °C, 400 °C, 600 °C, and 800 °C, in accordance with the temperature–time curve specified in the ISO 834-1 standard fire protocol **[ISO 834-1:2014]**. These high-temperature conditions were provided by a specialized furnace equipped with natural gas burners, engineered to ensure stable and uniform heating throughout the duration of the tests **[Kara et al., 2025].**

In compliance with the provisions of EN 1363-1 **[EN 1363-1:2020]**, the specimens were positioned 750 mm away from the furnace burner zone to avoid direct flame impingement and to ensure that heating occurred predominantly through convection and radiation, as required in standardized fire resistance testing. Furnace temperatures were controlled and measured using two-plate K-type thermocouples placed approximately 100 mm away from the surfaces of the specimen, following the specifications of EN 1363-1 **[EN 1363-1:2020].**

The tests were conducted in an indicative furnace with internal dimensions of 1.5 m × 1.5 m × 1.5 m. Two natural gas burners, each providing 600 kW of power, were utilized to achieve the prescribed heating curve. As direct flame impingement is prohibited under fire resistance standards, the burners were positioned at the front and back of the furnace to prevent direct exposure of the specimens to the flame. The configuration of the indicative furnace is illustrated in Figure 2.2. and specimens were given in Figure 2.3.

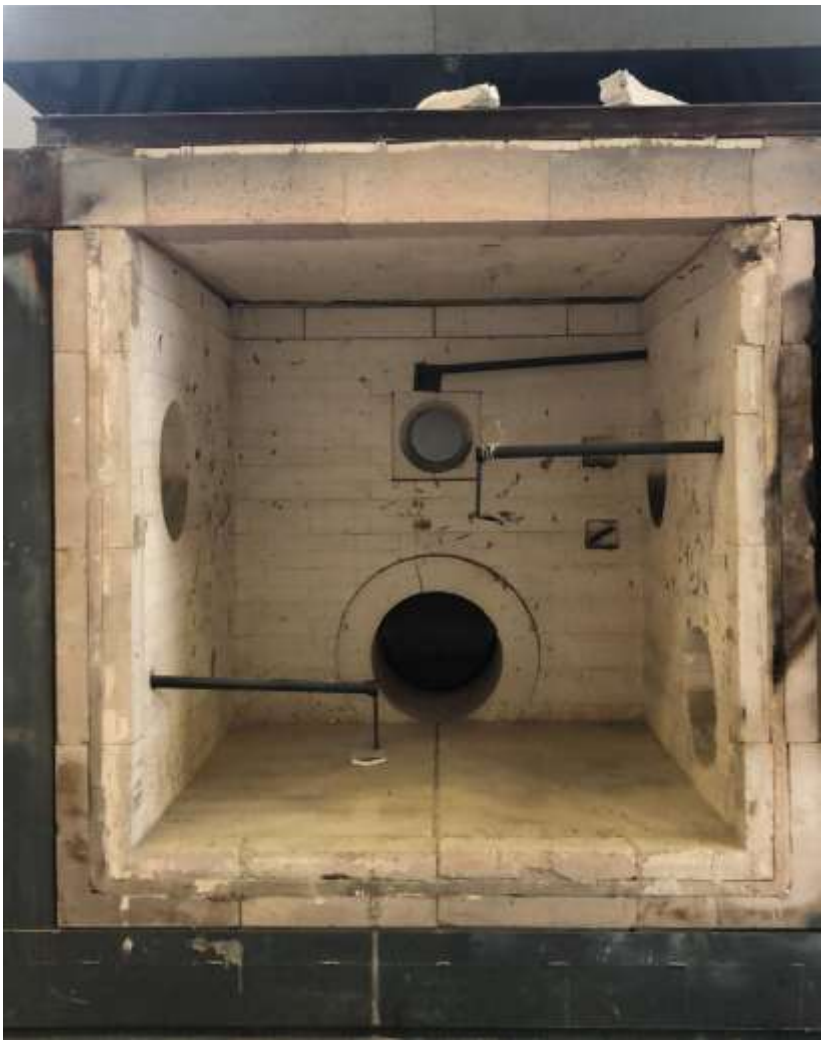

Figure 2.2: Indicative furnace for fire resistance tests.

To precisely monitor the internal temperature evolution within the test material, an additional K-type Inconel thermocouple was embedded in a designated control specimen (Figures 2.3). This instrumented specimen was not included in the mechanical testing program; instead, it functioned solely as a monitoring unit, enabling the accurate recording of the thermal profile experienced by the material during high-temperature exposure.

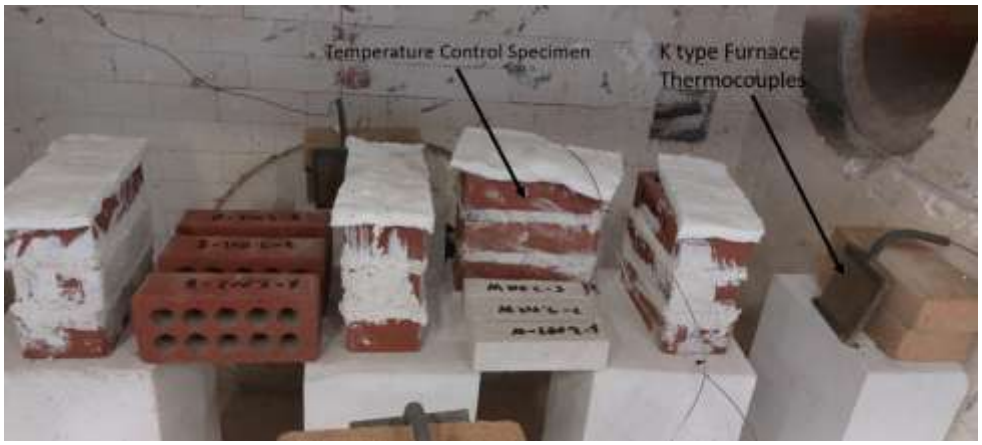

Figure 2.3. Elevated temperature test placement in the furnace **[Kara et al., 2025]**.

The recorded heating regimes of the furnace are given below and compared with ISO 834-1 temperature-time curve in Figure 2.4:

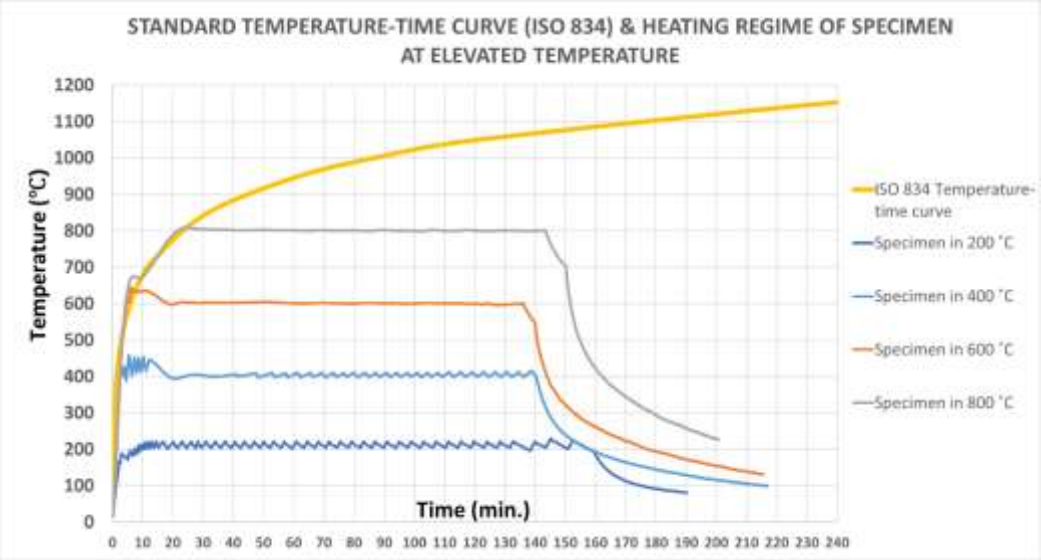

Figure 2.4. Elevated temperature test of the actual heating regime. **[Kara et al., 2025]**.

The procedure for determining the compressive strength of masonry mortar was carried out in accordance with EN 1015-11 **[EN 1015-11, 2019].** For each ambient and elevated temperature condition, three specimens were tested, and the average compressive and flexural strength values were calculated. A Zwick hydraulic testing machine with a 100 kN capacity was employed to measure the compressive strength of mortar specimens sized 40 × 40 × 160 mm, following the requirements of EN 1015-11 **[EN 1015-11, 2019].** After flexural strength testing had been completed on the three specimens, compressive tests were conducted on the resulting six fractured halves, in line with the standards described in EN 1015-11 **[EN 1015-11, 2019]**, and the mean values were subsequently determined. All testing procedures were performed on M15 lime-based mortar (Figure 2.5.). **[Kara et al., 2025].**

Figure 2.5: Masonry compression and flexural test (before and after the test). **[Kara et al., 2025]**.

Elastic modulus of masonry walls exposed to fire decline as the compressive and flexural strength losses. The elastic modulus of masonry mortar specimen was determined in accordance with TS EN 12504-4 by measuring the P-wave and S-wave velocities using the Ultrasonic Pulse Velocity (UPV) method. **[TS EN 12504-4, 2021]**

Mortar and prism specimens prepared for use in masonry construction were exposed to fire at temperatures of 20°C, 200°C, 400°C, and 600°C, subsequently UPV method was performed. A Pundit PL200 device was employed for UPV measurements, and 54 kHz P-wave and 40 kHz S-wave transducers were used to determine the respective wave velocities.

Before use, the transducers were regularly calibrated using calibration rods. This calibration procedure was repeated prior to each new specimen measurement to eliminate potential errors arising from calibration drift as illustrated in Figure 2.6.

Figure 2.6. Calibration of UPV device

During the measurements, the transducers were positioned to ensure direct transmission through the specimens. This arrangement ensured that the wave path extended from the centre of one transducer to the centre of the other, enabling precise pulse-velocity determination and providing optimal alignment with maximum signal amplitude. When measuring P-wave velocity, any gaps between the specimen surface and the transducers were filled using ultrasonic gel. For each measurement mode, a minimum of six readings was taken, and the average values were recorded. The measurements figures are given in Figure 2.6 and Figure 2.7.

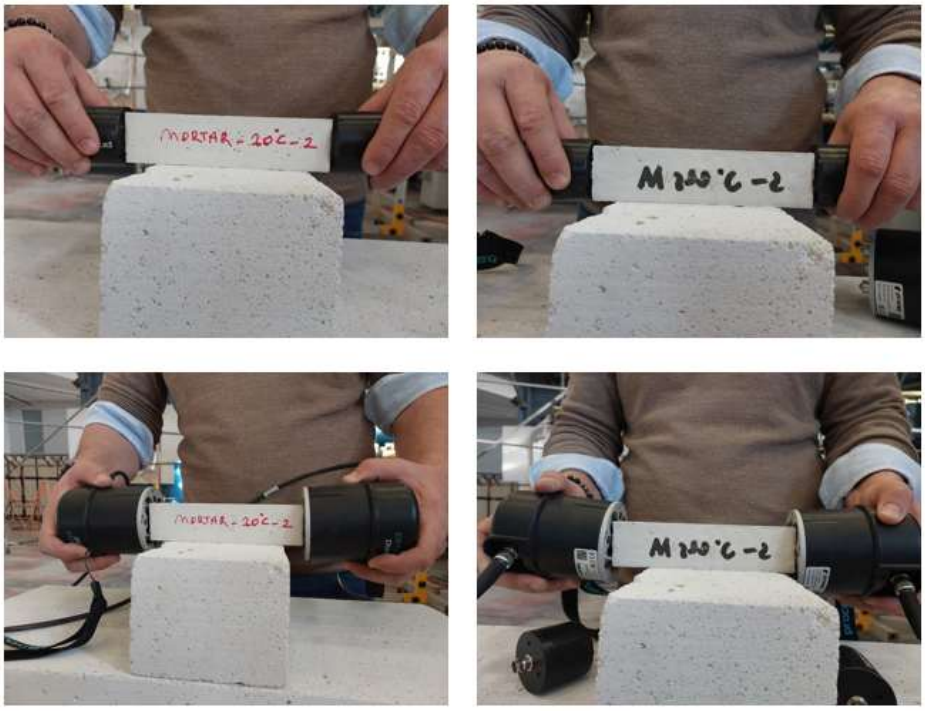

Figure 2.6. UPV measurements for 20 °C and 200 °C

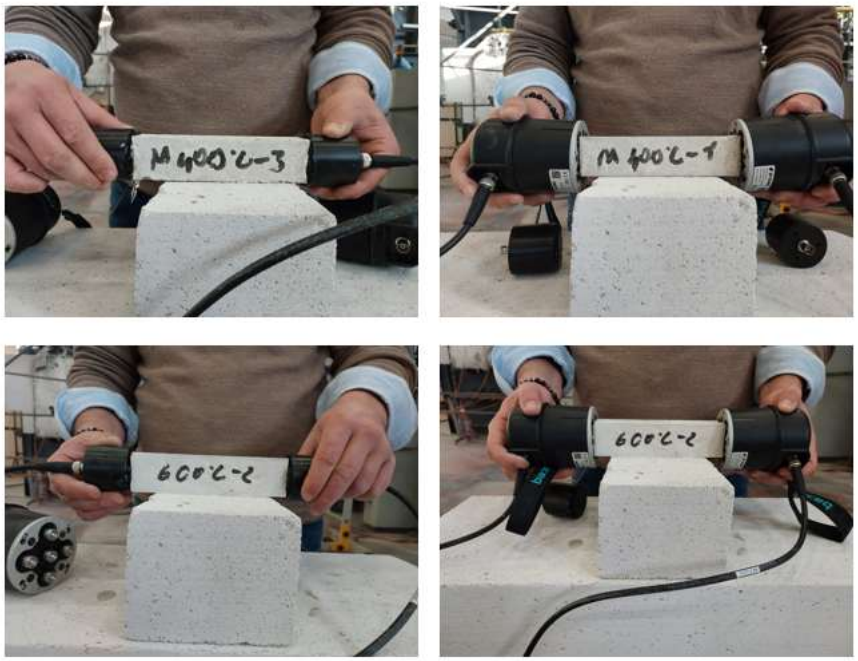

Figure 2.7. UPV measurements for 400 °C and 600 °C

3. RESULTS AND DISCUSSION

By establishing a correlation between P-wave velocity and the experimentally obtained compressive and flexural strengths, a predictive equation was developed. This equation, presented as an outcome of the study, enables researchers to estimate post-fire compressive strength based solely on wave velocity measurements, thereby eliminating the need for

destructive testing methods. The results are given in Figure 3.1, Figure 3.2, Figure 3.3, Figure 3.4 and Table 3.1.

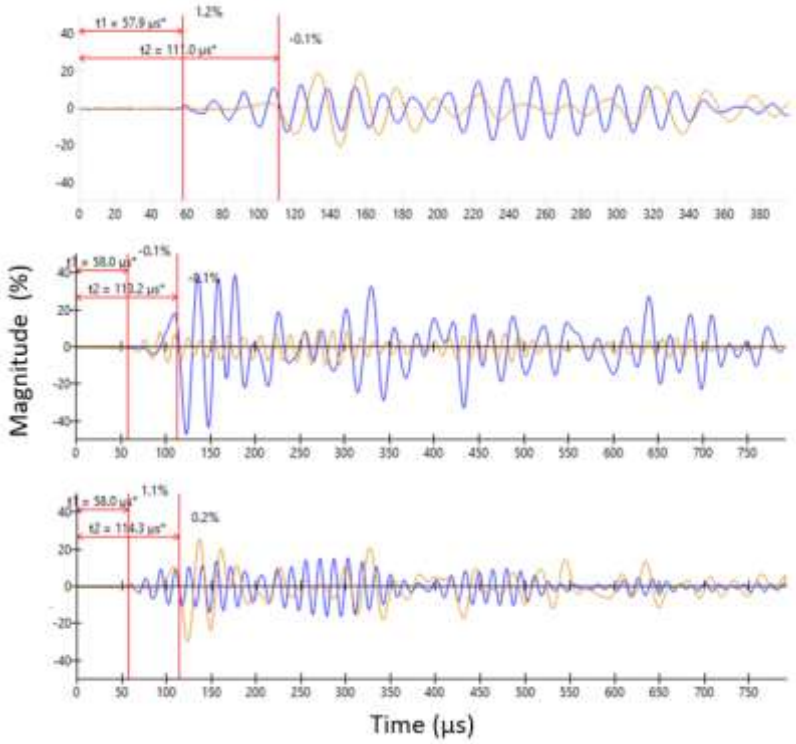

Figure 3.1. UPV measurements results for 20 °C

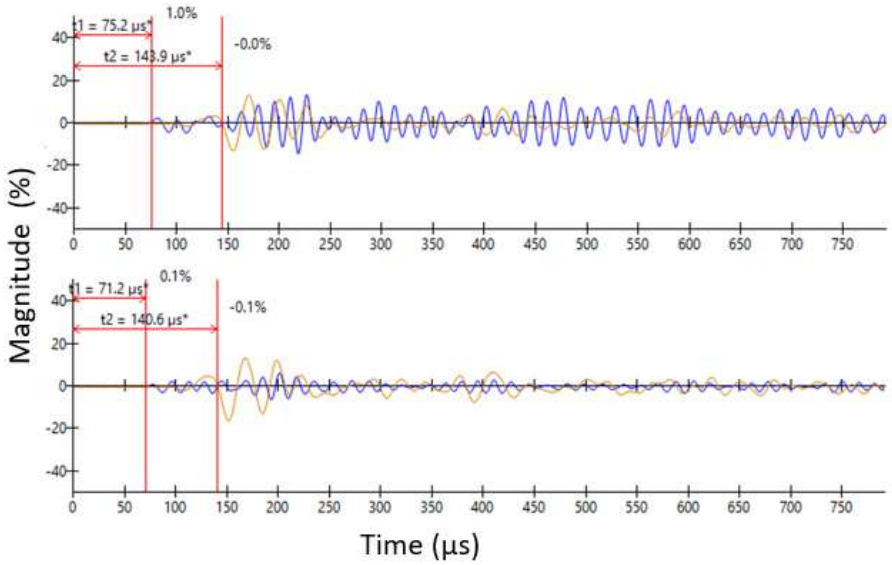

Figure 3.2. UPV measurements results for 200 °C

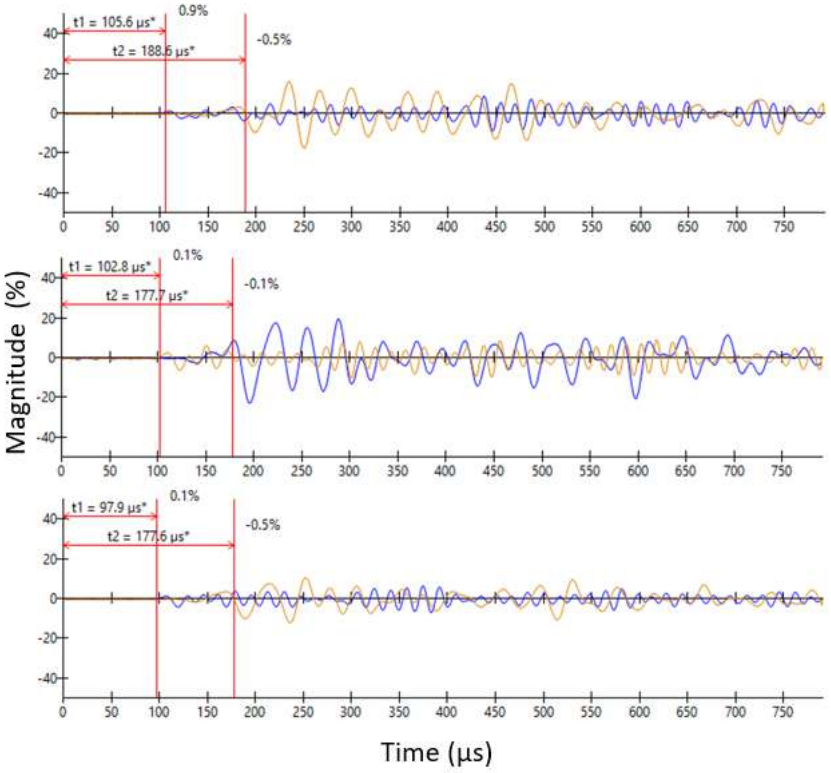

Figure 3.3. UPV measurements results for 400 °C

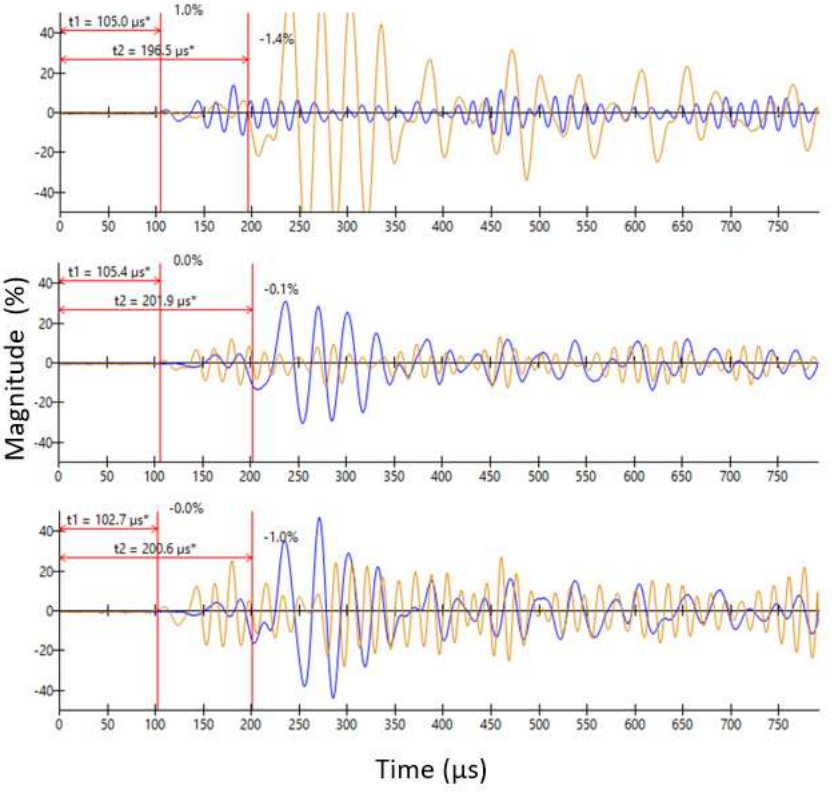

Figure 3.4. UPV measurements results for 600 °C

Table 3.1. UPV test results on M15 Lime-based Mortar

Mortar Specimen	Transmission Time (µs)		Pulse Velocity (m/s)		Elastic Modulus (Mpa)
	Average	Stable State	Average	Stable State	
20 °C-1	57.42	58	2771,66	2778	8470
20 °C-2	62.56	58	2682,20	2754	8270
20 °C-3	62.16	58	2609,78	2759	8410
200 °C-1	75.28	75	2125	2133	5210
200 °C-2	72	72	2215	2219	5500
200 °C-3	71.6	72	2224,20	2225	-
400 °C-1	105.85	107	1468,45	1490	2970
400 °C-2	101.5	103	1535,42	1571	3150
400 °C-3	99.17	101,5	1571,83	1570	3110
600 °C-1	99.26	99	1610,25	1617	2750
600 °C-2	108.35	107	1195,20	1515	2830
600 °C-3	105.66	105	1496,50	1525	2730

The 800 °C test specimen were totally cracked after temperature exposure, so, results are not shown in the table. In addition, measurement was taken for brick units and masonry prism units, however satisfactory results cannot be taken due gaps inside the specimen, so only masonry mortar results were reported. In the results, it is shown that elastic modulus of ambient temperature is very close to declared value by manufacturer. It is gradually decrease for elevated temperature.

4. CONCLUSION

The UPV test results indicate that hydraulic lime-based mortars (HLMs) exhibit a gradual decline in mechanical performance as temperature increases. At 20°C, the specimens exhibited the highest pulse velocities (approximately 2700–2800 m/s) and elastic modulus values (approximately 8300–8500 MPa). The application of heat at a temperature of 200°C resulted in a significant reduction in UPV, which is indicative of the initiation of microcracking. By 400 °C, pulse velocity decreased to approximately 1500 m/s, signifying substantial structural degradation, which became even more pronounced at 600 °C. The findings demonstrate a strong inverse relationship between temperature and ultrasonic pulse velocity (UPV), indicating that ultrasonic pulse velocity is a reliable indicator of thermal damage and stiffness degradation in HLMs, thereby underscoring their susceptibility to high-temperature exposure.

ABSTRACT

This study evaluates the performance of three recent satellite-based static global gravity models—WHU-SPWU-GOGR2022S, GOSG02S, and Tongji-GMMG2021S—by comparing them with the reference model EGM2008, given the importance of an accurate gravity field representation for geodetic and geophysical applications such as geoid determination, crustal structure interpretation, and mass transport analysis. Gravity disturbance (δg) values were computed for all models at maximum spherical harmonic degrees 10, 50, 100, 200, and 300 on a global grid and for a regional test area covering Türkiye. As expected, the level of spatial detail increases with harmonic degree, and at n = 300 all models resolve high-resolution features of the gravity field. Globally, the three satellite-based models show strong agreement with EGM2008; differences in minimum and maximum δg values at n = 300 remain small and are not geophysically significant, while WHU-SPWU-GOGR2022S and GOSG02S yield almost identical results at several degrees, reflecting the consistency of GOCE-only solutions. Over Türkiye, all models produce similar gravity disturbance values, roughly between −133 and +60 mGal, and reproduce comparable spatial patterns. Difference maps reveal local discrepancies of up to about ±10 mGal, mainly over marine areas and parts of eastern Türkiye, while standard deviations remain around 5.7–5.8 mGal; the smallest value is obtained for the EGM2008–Tongji-GMMG2021S comparison, indicating that this combined GOCE+GRACE model matches EGM2008 most closely. Overall, the results demonstrate that recent satellite-based global gravity models are highly consistent with EGM2008 and suitable for regional geodetic and geophysical studies over Türkiye, while future work may validate them against independent terrestrial gravity or GNSS/leveling data to further quantify regional model accuracy.

Keywords: Global Gravity Models, Gravity Disturbance, EGM2008

1. INTRODUCTION

Current satellite-based gravity models are products based on modern geodetic measurement techniques that enable the determination of the Earth's gravity field with high accuracy and resolution. Satellite design, orbital characteristics, observation techniques, and measurement and evaluation methods play a decisive role in the development of these models (Üstün, 2008). Precise modeling of the gravity field is made possible, particularly by low-Earth-orbit (LEO) satellites, through positioning, accelerometer recordings, satellite-to-satellite tracking, and gradiometry measurements. In this context, missions such as the Gravity Recovery and Climate Experiment (GRACE), GRACE Follow-On (GRACE-FO), Challenging Minisatellite Payload (CHAMP), and Gravity Field and Steady-State Ocean Circulation Explorer (GOCE) are among the leading satellite missions that have developed new approaches to determining the global gravity field (Akdoğan et al., 2019). Measurements obtained from these LEO missions are not only useful in modeling the gravity field; It is critical for a wide range of geodetic and hydrological applications, including monitoring the terrestrial water cycle, determining groundwater changes, analyzing oceanographic processes, monitoring ice mass loss, and drought assessments. The Earth Gravitational Model 2008 (EGM2008), created by combining these satellite measurements with classical ground measurements and altimetry data, is one of the most comprehensive models currently available that provides a high-definition global representation of the Earth's gravity field. Produced by integrating satellite gravity, surface gravity measurements, and sea surface topography data, EGM2008 successfully represents even small-scale gravity anomalies thanks to its high degree of accuracy (n = 2190) (Öztürk, 2015). Therefore, it is widely used as a reference model in various geodetic applications.

Gravity disturbance is a physical quantity that represents deviations or anomalies in the gravity field. It is mostly caused by density differences in the subsurface, crustal structure, and topographic effects. Gravity disturbances provide important information in areas such as mineral exploration, geological structure identification, crust-mantle boundary modeling, and understanding dynamic Earth processes.

This study aims to compare gravity disturbance data derived from three different satellite-based gravity models with the EGM2008 model. In this context, the global gravity field of each model will be expanded to 10th, 50th, 100th, 200th, and 300th degrees, and detailed according to harmonic resolution. Subsequently, the differences between these satellite models and EGM2008 will be calculated, and comparative evaluations will be conducted. These analyses will contribute to demonstrating the accuracy, resolution capabilities, and modeling performance of satellite-based gravity models. As a result, the study aims to contribute to the evaluation of satellite-based gravity models in terms of accuracy and resolution and to present important results for more detailed modeling of the gravity field.

2. STUDY AREA, DATA AND METHOD

2.1. Study Area

The primary study area was defined as the global scale. A preliminary assessment was conducted by testing the results of the gravity models to be compared in the same geographic regions on Earth.

The secondary study area is Türkiye, covering the region between 36°–42° North latitude and 26°–45° East longitude. The three recent satellite-based static gravity field models published by ICGEM: WHU-SPWU-GOGR2022S, GOSG02S, and Tongji-GMMG2021S, were analyzed and evaluated in conjunction with the EGM2008 model. Gravity disturbance values

corresponding to different spherical harmonic orders were calculated and compared with values derived from EGM2008, which served as control data.

2.2. Data

Global gravity (geopotential) models (GGMs) are sets of spherical harmonic coefficients representing the Earth's gravity field at different wavelengths of the spectrum. These coefficients are derived from satellite orbital disturbances, satellite gravity gradiometers, satellite altimeters, and/or ground gravity measurements. In this context, GGMs are generally classified into three main groups (Featherstone, 2002). The first group consists of geopotential models derived solely from satellite gravity data. The second group includes combined models produced by combining satellite gravity data with satellite altimetry measurements and/or terrestrial gravity observations. The third group consists of models obtained by improving satellite-based or combined GGMs at a regional scale using local gravity data for a specific region (Avşar et al., 2015). Detailed information on global geopotential models, including their spherical harmonic coefficients and standard deviations, can be obtained from the International Center for Global Earth Models (ICGEM) website (Tepeköylü and Üstün, 2007).

Detailed information on the models used in the study is presented in Table 1.

Table 1. GGMs selected for testing, (S: satellite data, G: terrestrial gravity, A: altimeter)

GGMs	Year	n_{max}	Data	Source
WHU-SPWU-GOGR2022S	2023	300	S(GOCE), S(GRACE)	Zhao et al. (2023)
GOSG02S	2023	300	S(GOCE)	Xu et al. (2023)
Tongji-GMMG2021S	2022	300	S(GOCE), S(GRACE)	Chen et al. (2022)
EGM2008	2008	2190	A,G, S(GRACE)	Pavlis et al. (2012)

2.2.1. WHU-SWPU-GOGR2022S

WHU-SWPU-GOGR2022S is a high-resolution GGM developed by Southwest Petroleum University (SWPU) and Wuhan University (WHU). The model is a static spherical harmonic solution, complete to degree 300, constructed by combining the static normal equations from the GOCE and GRACE missions. The combined use of high-order satellite data provides a detailed and accurate representation of the Earth's gravity field (Zhao et al., 2023).

2.2.2. GOSG02S

The GOSG02S model is a static geopotential model based solely on gravity gradiometer and orbital tracking data from the GOCE satellite. This model has been completed up to the 300th spherical harmonic degree and provides a high-resolution representation of Earth’s gravity field (Xinyu et al., 2023). It reflects the strengths of the GOCE mission, particularly in its high-order gravity information content.

2.2.3. Tongji-GMMG2021S

Tongji-GMMG2021S is a combined global geopotential model developed by Tongji University, combining the static normal equations of the GOCE and GRACE missions. The model represents the Earth's gravitational field with high accuracy, with a spherical harmonic solution complete to the 300th degree (Chen J. et al., 2022). Thanks to the low-order contribution of the GRACE data and the high-order contribution of the GOCE data, the model demonstrates strong performance at both long and short wavelengths.

2.2.4. EGM2008

EGM2008 (Earth Gravitational Model 2008) is a high-order global geopotential model developed by the U.S. National Spatial-Intelligence Agency (NGA). The model is constructed

by combining the normal equations derived from the GRACE-based ITG-GRACE03S global gravity field model with terrestrial gravity measurements, sea surface topography, and satellite altimeter data using the least-squares method. This model, with a spherical harmonic expansion completed to 5 degrees and corresponding to an angular resolution of approximately 5 minutes, reaches a horizontal resolution of approximately 9 × 9 km in the equatorial region. EGM2008 provides a highly accurate gravity field representation by integrating the comprehensive 5′ × 5′ resolution global gravity anomaly database with gravity information from GRACE (Zeray Öztürk, 2015). In terms of orbit determination performance, EGM2008 has an accuracy level comparable to other GRACE-based geopotential models. Compared to EGM96, EGM2008 provides an approximately sixfold improvement in resolution and a three- to sixfold improvement in accuracy, depending on location and gravity magnitude (Pavlis et al., 2012). EGM2008 is a comprehensive and highly accurate gravity model widely used in geophysical, geodetic, oceanographic, and engineering applications.

2.3. Method

In this study, gravity disturbance data derived from current satellite-based GGMs were used. For each GGM, gravity disturbances were calculated separately for maximum spherical harmonic orders of 10, 50, 100, 200, and 300. The models used in the analysis were WHU-SWPU-GOGR2022S, GOSG02S, and Tongji-GMMG2021S, obtained from the website of the International Center for Global Earth Models (ICGEM). EGM2008 was selected as the reference model for comparison. Gravity disturbance values obtained for different maximum orders were both numerically calculated and visualized as maps, thus demonstrating how gravity disturbances change with order, and a comparative evaluation of the models was performed against EGM2008.

2.3.1. Gravity Disturbance and Gravity Anomaly

Geodetic and geophysical gravity measurements are performed on the physical surface of the Earth and within its true gravity field. Traditionally, the latitude, longitude and orthometric height of a gravity station are determined; however, with the advent of satellite-based positioning technologies such as GNSS/GPS, the ellipsoidal heights of these points can also be obtained with high accuracy. This advancement provides a more precise connection between the physical surface, the ellipsoid and the geoid.

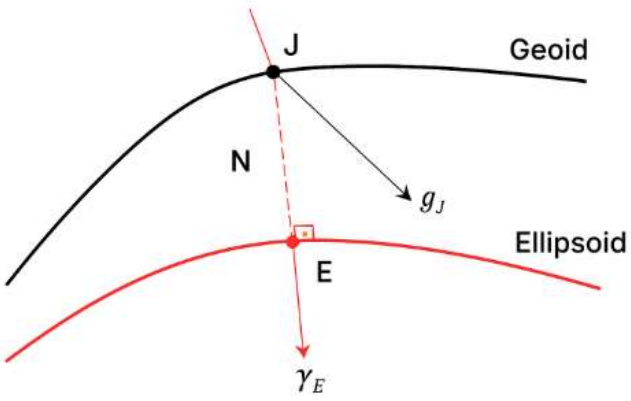

Figure 1. Vectors related to gravity anomaly and disturbance

The difference between the real gravity vector at a point **J** on the geoid, g_J, and the normal gravity vector γ_E at the point **E** where the ellipsoid normal through J intersects the ellipsoid, is called the **gravity anomaly**:

$$\Delta g = g_J - \gamma_E \tag{1}$$

Gravity anomalies constitute the fundamental input for determining geoid heights through Stokes-type integral formulations in physical geodesy. If the normal gravity is evaluated not at the point E on the ellipsoid surface but at the observation point J itself, the resulting quantity is the gravity disturbance:

$$\delta g = g_j - \gamma_J \tag{2}$$

Gravity disturbance is conceptually simpler than the gravity anomaly and is gaining importance in modern geodetic applications due to the availability of accurate GNSS-derived ellipsoidal heights. For this reason, many contemporary gravity field studies increasingly favor gravity disturbance instead of the classical gravity anomaly.

Gravity disturbance at a point P can be computed using GGMs expressed in spherical harmonics (Hoffmann-Wellenhof & Moritz, 2006):

$$\delta g = \frac{GM}{R}\sum_{n=2}^{\infty}\left(\frac{R}{r}\right)^{n+1}\frac{(n+1)}{r}\sum_{m=0}^{n}\bar{P}_{nm}(\cos\theta)[\Delta\bar{C}_{nm}\cos m\lambda + \Delta\bar{S}_{nm}\sin m\lambda] \tag{3}$$

In the formula, θ denotes the polar angle, λ the longitude, and r the geocentric radius of the point. GM is the Earth's gravitational parameter and R is the Earth's mean radius. The symbols n and m represent the degree and order of the spherical harmonic expansion, respectively. The term $\bar{P}_{nm}$ denotes the fully normalized associated Legendre functions, while $\Delta\bar{C}_{nm}$ and $\Delta\bar{S}_{nm}$ are the fully normalized spherical harmonic coefficients representing the Earth's gravity field.

3. RESULTS

3.1. Gravity Disturbance (δg) Derived from GGMs at Different Degrees

The GGMs used in this study were first evaluated globally at several maximum spherical harmonic degrees. The computed gravity disturbance values at degrees 10, 50, 100, 200, and 300 were visualized to assess their spatial characteristics. The minimum and maximum values produced by each model up to degree 300 were calculated (Table 2). As expected, increasing the maximum degree of the spherical harmonic expansion resulted in a higher level of detail in all models. For n_{max} = 10, the WHU-SWPU-GOGR2022S and GOSG02S models yielded identical minimum and maximum values, whereas Tongji-GMMG2021S differed from EGM2008 by approximately 0.1 mGal. However, these deviations were sufficiently small to be considered negligible. For n_{max} = 50, the models again showed very similar behavior, and no meaningful discrepancies were observed in terms of their gravity disturbance values. At n_{max} = 100, both the minimum and maximum values increased for all models as a natural consequence of the finer spatial detail introduced by the higher-degree expansion. At n_{max} = 200, the models still exhibited no significant differences in their global extrema. Likewise, for n_{max} = 300, no clear distinction was observed between the models at the global scale. Although the global comparisons indicate broadly consistent performance among the models, more detailed regional analyses may be conducted to further evaluate and contrast their accuracy and reliability, particularly in areas of complex gravity field structure.

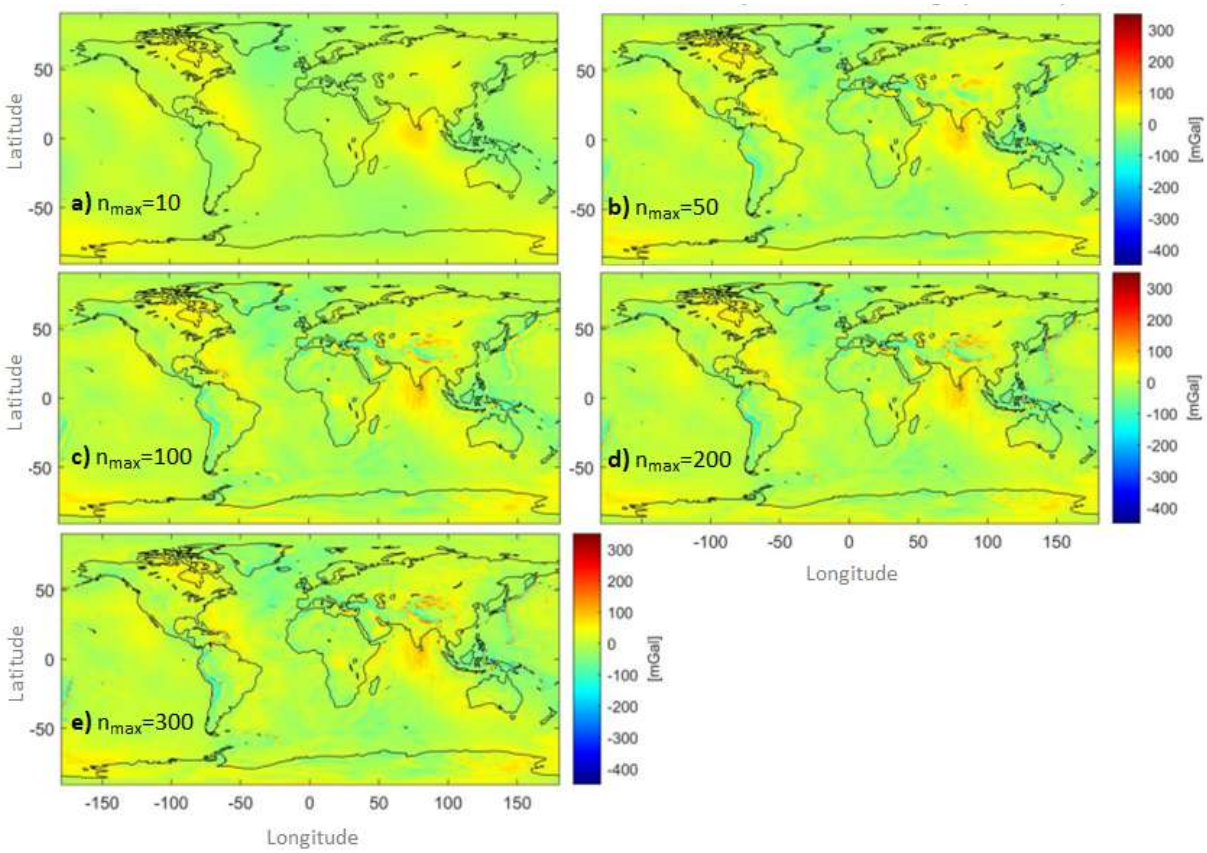

Figure 2. Gravity disturbances calculated at different degrees (n=10, 50, 100, 200, 300) for the EGM2008 model

Gravity disturbance maps computed from EGM2008 for different spherical harmonic degrees are presented in Figure 2. Although the full EGM2008 model is published up to degree 2190, in this study it is truncated at degree 300 to enable a consistent comparison with the other gravity models. As the maximum degree of expansion increases, the gravity field representation becomes progressively more detailed, revealing smaller-scale gravity disturbances. Higher spherical harmonic degrees thus allow for a more refined and spatially detailed characterization of Earth's gravity field.

Gravity disturbance maps computed for the GOSG02S model at different spherical harmonic degrees are presented in Figure 3. The GOSG02S model, derived exclusively from GOCE satellite observations, was released with a maximum spherical harmonic expansion of degree 300. In this study, the model was evaluated up to its published maximum degree in order to enable a consistent comparison with the other GGMs.

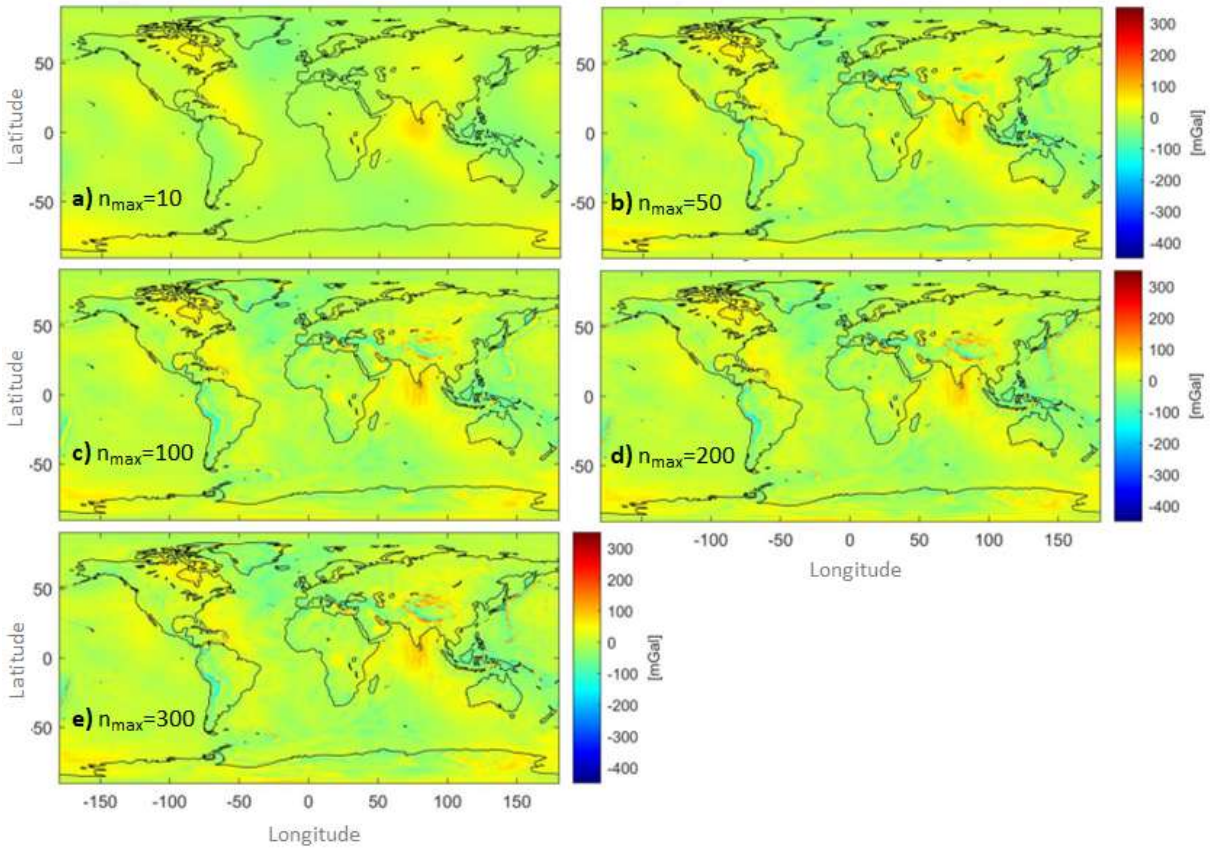

Figure 3. Gravity disturbances calculated at different degrees (n=10, 50, 100, 200, 300) for the GOSG02S model

The gravity disturbance maps computed for Tongji-GMMG2021S at various maximum spherical harmonic degrees are presented in Figure 4. The Tongji-GMMG2021S model, derived from combined GOCE and GRACE satellite data, was originally published with a maximum spherical harmonic expansion of degree 300. In this study, the model was likewise evaluated up to degree 300 to enable a consistent comparison with the other GGMs.

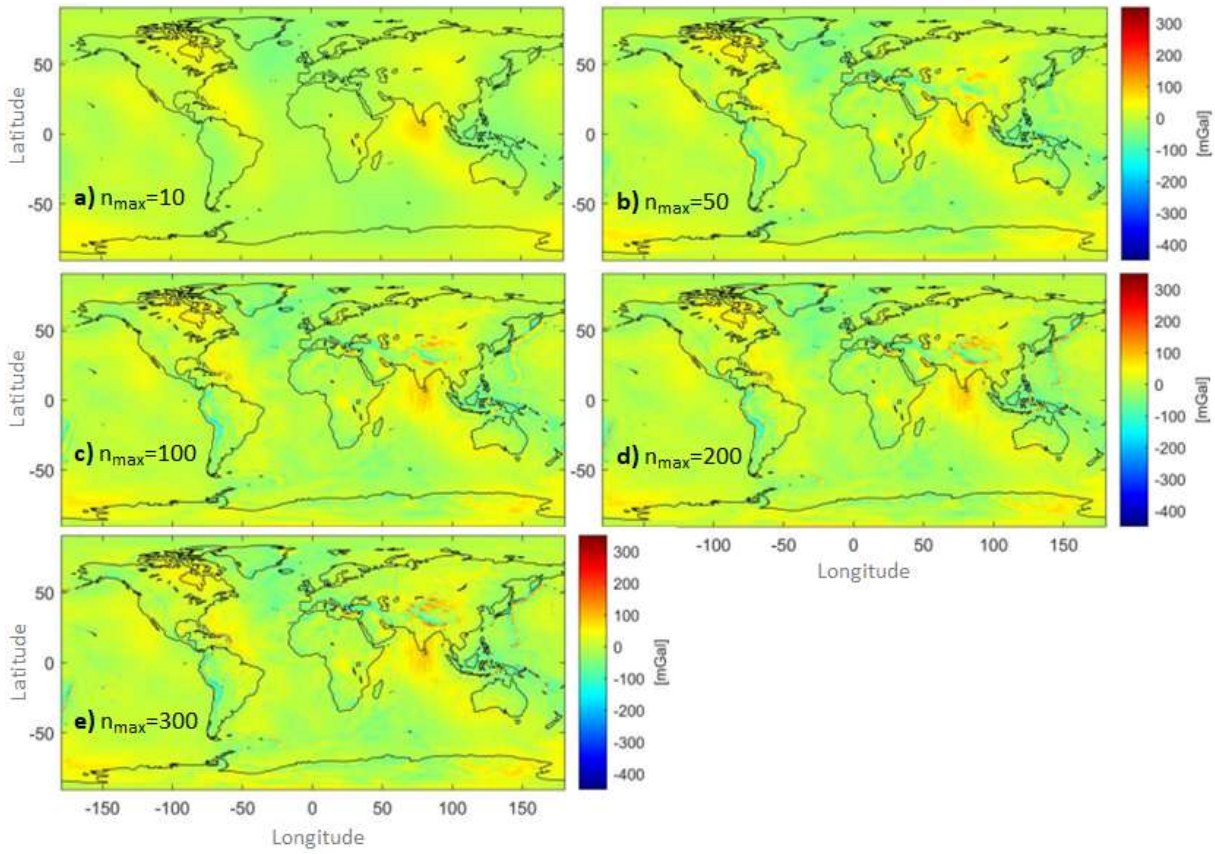

Figure 4. Gravity disturbances calculated at different degrees (n=10, 50, 100, 200, 300) for the Tongji-GMMG2021S model

Gravity disturbance maps derived from the WHU-SPWU-GOGR2022S model at various spherical harmonic degrees are presented in Figure 5. The WHU-SPWU-GOGR2022S model is a combined gravity field solution constructed from GOCE and GRACE satellite data. The model is published with a maximum spherical harmonic expansion of degree 300, and in this study, it is likewise evaluated up to degree 300 to ensure consistency and comparability with the other gravity models.

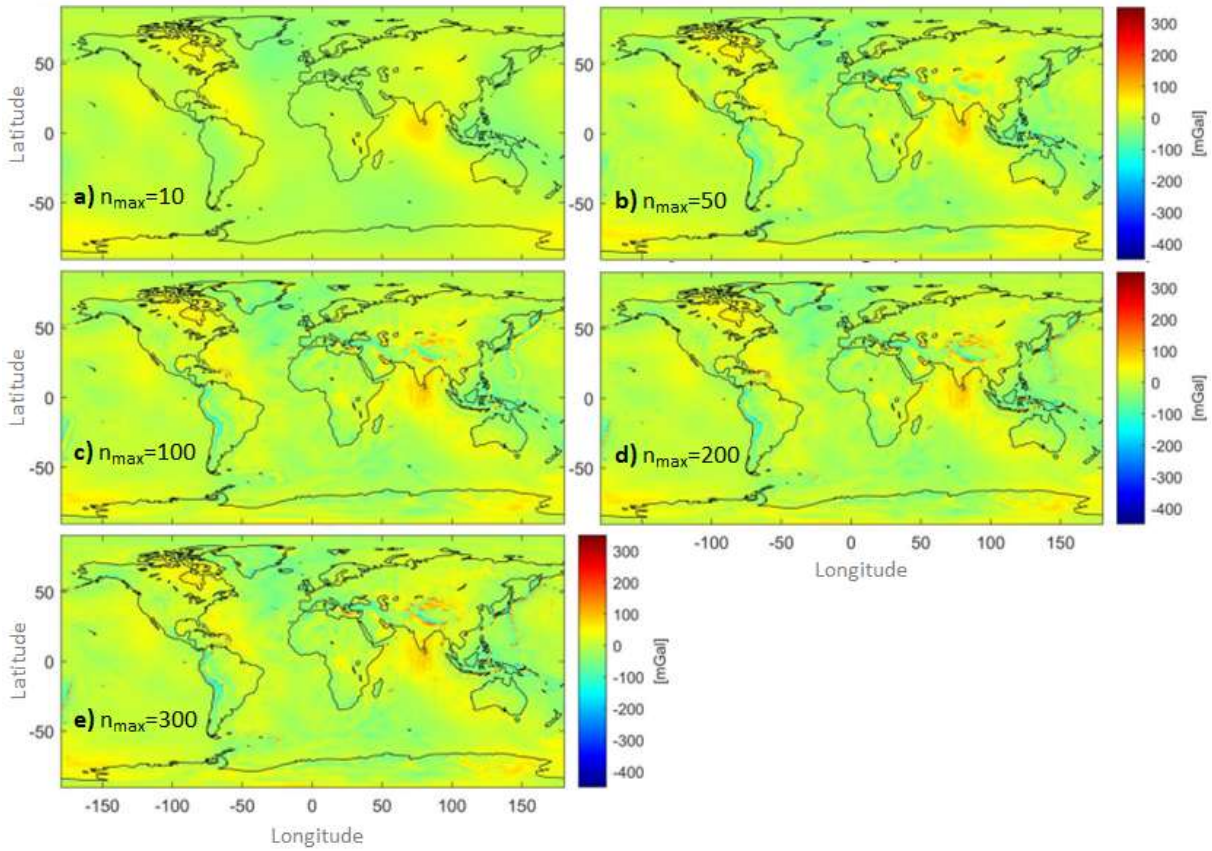

Figure 5. Gravity disturbances calculated at different degrees (n=10, 50, 100, 200, 300) for the WHU-SPWU-GOGR2022S model

Table 2. Gravity disturbance values of models at different degrees [mGal]

Model	n_{max}=10		n_{max}=50		n_{max}=100		n_{max}=200		n_{max}=300	
	Min	Max	Min	Max	Min	Max	Min	Max	Min	Max
EGM2008	-51.94	77.48	-109.49	96.07	-168.90	175.99	-332.92	316.91	-496.68	324.57
WHU-SWPU-GOGR2022S	-51.93	77.48	-109.49	96.06	-168.07	179.02	-336.12	315.39	-442.36	323.48

3.2. Results in Türkiye

Regional analysis of the GGMs was conducted for the area covering Türkiye, bounded by latitudes 36°–42° N and longitudes 26°–45° E. The models were computed up to degree 300. Figure 6 shows the gravity disturbance values for 4 GGMs in Türkiye at n_{max}=300. The minimum, maximum, and mean gravity disturbance values obtained from these computations are presented in Table 3. According to the results in Table 3, the models produced similar outcomes and remain closely aligned with the reference model, EGM2008. The results also

indicate that gravity disturbance values close to 0 mGal occur in the Southeastern Anatolia Region, particularly between latitudes 35°–39° N and longitudes 38°–39° E.

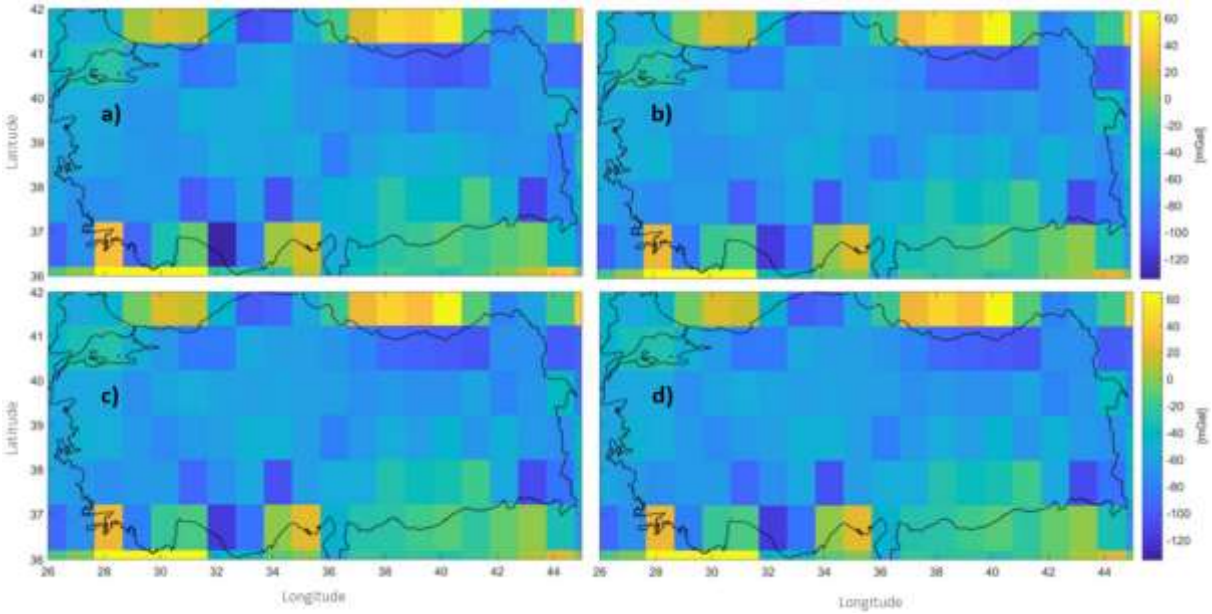

Figure 6. Gravity disturbance values of models for n_{max}=300 in Türkiye [mGal]
(**a)**EGM2008, **b)**Tongji-GMMG2021S, **c)**GOSG02S, **d)**WHU-SPWU-GOGR2022S)

Table 3. Min max and average values of the models for n_{max}=300 [mGal]

Model	n_{max}=300		
	Min	Max	Mean
EGM2008	-133.502	53.963	-51.649
WHU-SWPU-GOGR2022S	-118.690	59.134	-51.118
GOSG02S	-118.672	59.120	-51.129
Tongji-GMMG2021S	-118.865	60.482	-51.159

3.3. Gravity Disturbance Differences (Δδg) Derived from GGMs

Differences between EGM2008, selected as the reference model for n_{max} = 300, and the WHU-SWPU-GOGR2022S, GOSG02S, and Tongji-GMMG2021S models were calculated, and the results are presented in Figures 7, 8, and 9, as well as Table 4.3. Differences of the order of ±10 mGal were observed in the Black Sea, Aegean, and Mediterranean regions, as well as in some parts of the Eastern Anatolia Region. When the minimum, maximum, mean, and standard deviation values were evaluated, it was determined that the lowest standard deviation value was obtained from the differences between EGM2008 and the Tongji-GMMG2021S model (Figure 8).

The standard deviation differences between the models reached a maximum of 0.2 mGal. This very low difference demonstrates that the models exhibit a high level of consistency and produce similar results. In particular, a small difference such as 0.2 mGal supports the

reliability of the relevant gravity models and shows that it does not create a significant difference in application areas.

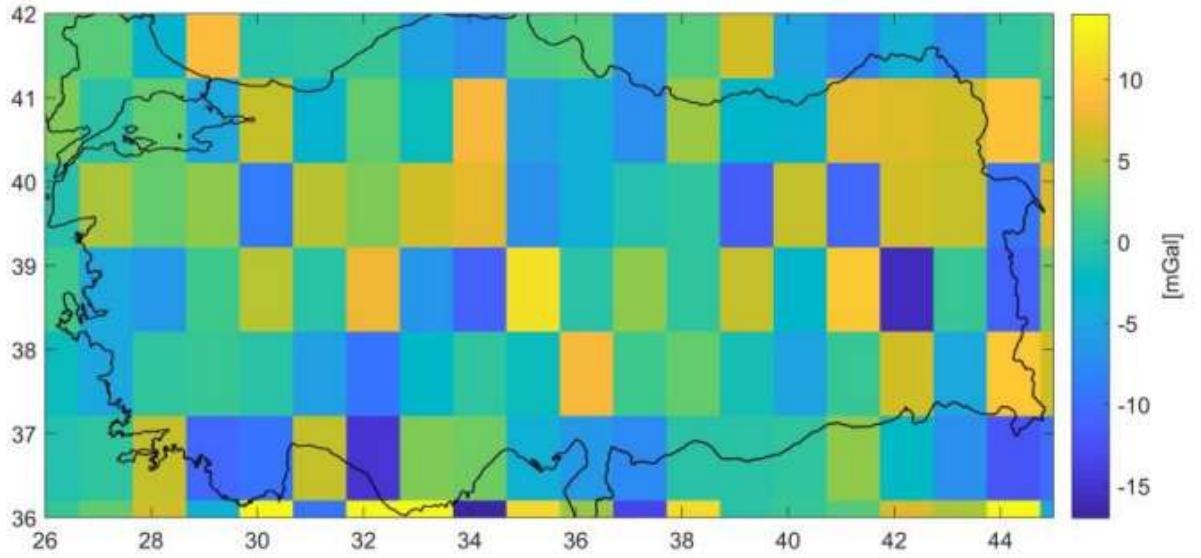

Figure 7. EGM2008 – GOSG02S (n_{max}=300)

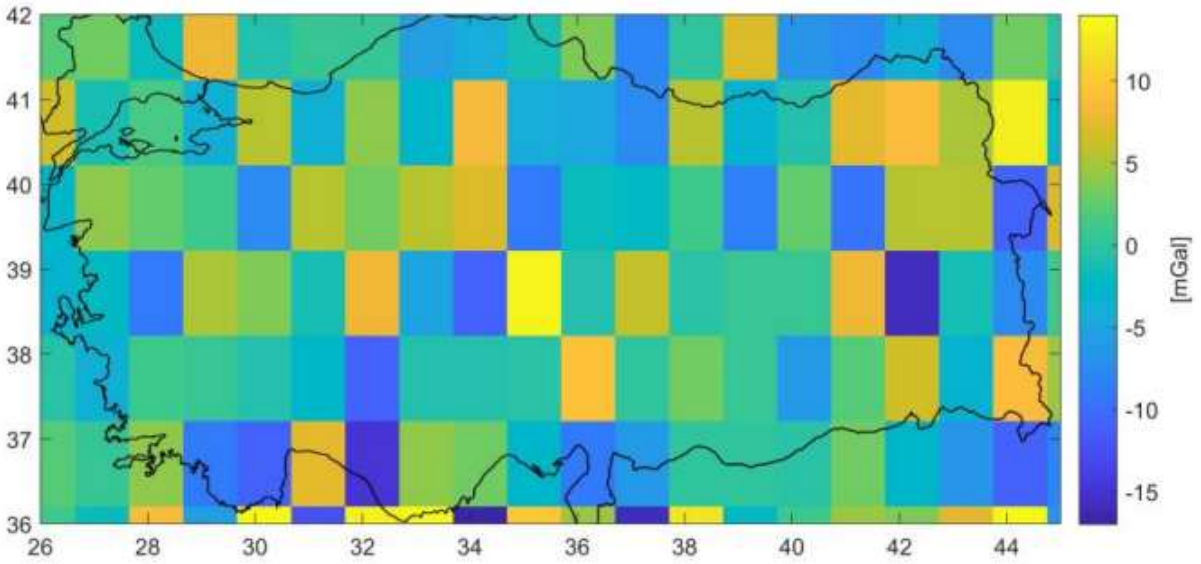

Figure 8. EGM2008 – Tongji-GMMG2021S (n_{max}=300)

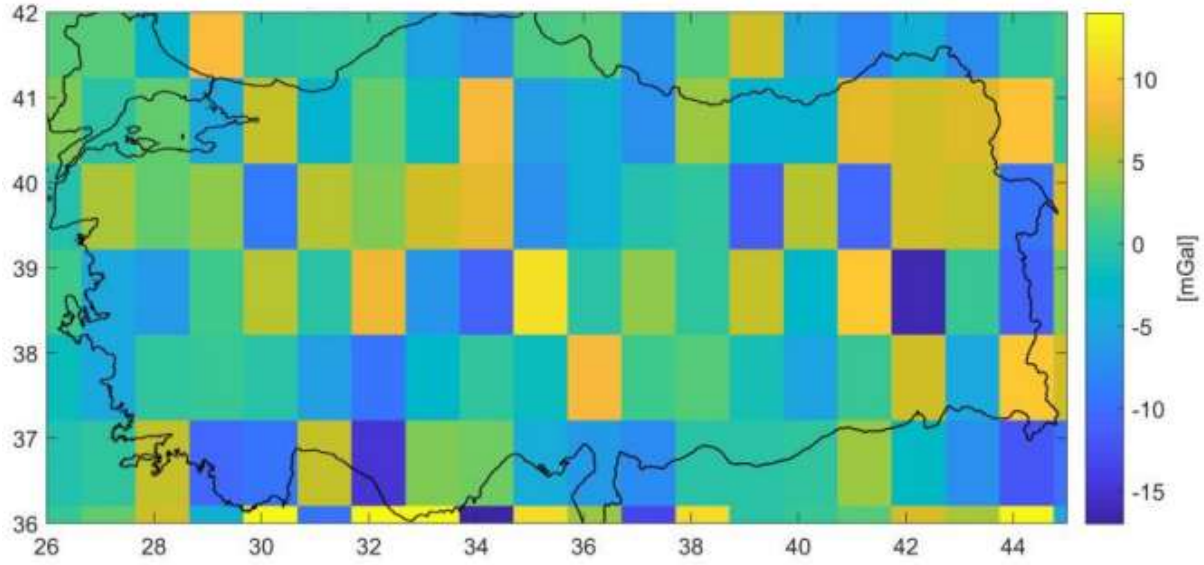

Figure 9. EGM2008 – WHU-SWPU-GOGR2022S (n_{max}=300)

Table 4. Statistical results of the differences of GGMs for n_{max}=300 [mGal]

Model	Min	Max	Mean	Std
EGM08-GOSG02S	-16.020	11.975	-0.520	5.813
EGM08-TongjiGMMG2021S	-15.723	13.336	-0.490	5.685
EGM08-WHUSWPU-GOGR2022S	-16.048	11.963	-0.053	5.812

4. CONCLUSION

To assess the accuracy of GGMs and to identify the most suitable model, gravity disturbances obtained from satellite-based GGMs at various maximum degrees were compared, and statistical indicators were computed. The global-scale analysis demonstrated that the models exhibit highly consistent behavior. For the region of Türkiye, the gravity disturbance differences between the models and EGM2008 were examined. Among these comparisons, the lowest standard deviation was observed for the difference between EGM2008 and Tongji-GMMG2021S. Since the discrepancies did not exceed 0.2 mGal, it can be stated that the models have comparable levels of accuracy. Nevertheless, when considering the standard deviation values of the differences, the Tongji-GMMG2021S model constructed by combining GOCE and GRACE satellite data emerges as the preferable option. In conclusion, although the Tongji-GMMG2021S model demonstrated superior performance at higher degrees, the GOSG02S and WHU-SWPU-GOGR2022S models also produced consistent results at specific degrees. For future improvements, the performance of these models can be further evaluated by conducting comparisons with additional regional datasets across Türkiye, enabling a more comprehensive accuracy assessment.

ÖZET

Enerji toplumların büyümesiyle ihtiyacın da giderek arttığı önemli bir kaynaktır. Enerji, fosil kaynaklardan sağlanabildiği gibi yenilenebilir enerji kaynaklarından da sağlanabilmektedir. Fosil yakıtların tükeniyor olması ile birlikte yenilenebilir enerji kaynaklarına olan yönelim daha da artmıştır. Yenilenebilir enerji kaynaklarının en çok tercih edilen çeşiti Güneş enerjisidir. Güneş enerjisinden elektrik üretimi PV panellerle mümkün olmakta ve bu panellerin verimini birçok faktör etkilemektedir. Bu çalışma, fotovoltaik (PV) panel yüzeyinde oluşan kirlenmenin panel performansı üzerindeki etkilerini enerji ve ekserji temelli olarak incelemektedir. Deneysel çalışmalar, Elazığ ili iklim koşullarında Fırat Üniversitesi Makine Mühendisliği Bölümü çatısında kurulan bir test düzeneğinde gerçekleştirilmiştir. Deneylerde aynı özelliklere sahip iki adet 50 W'lık polikristal PV panel kullanılmış; panellerden biri her saat temizlenmiş, diğeri ise kirli bırakılmıştır. Her iki panel için akım, gerilim, güç, panel sıcaklığı, radyasyon, rüzgâr hızı, nem oranı ve dış sıcaklık değerleri eş zamanlı olarak ölçülmüştür. Elde edilen veriler kullanılarak panellerin enerji ve ekserji verimleri hesaplanmış, sonuçlar karşılaştırmalı olarak değerlendirilmiştir. Bulgular, panel yüzeyinde biriken tozun ve kirin güneş ışınımının soğurulmasını engellediğini ve buna bağlı olarak enerji ile ekserji veriminde belirgin düşüşe neden olduğunu göstermiştir. Temiz panelin ortalama enerji verimi kirli panele göre %17,3; ekserji verimi ise yaklaşık %25–30 oranında daha yüksek bulunmuştur. Kirli panelde, artan yüzey sıcaklığına bağlı olarak ısı geçişi ve tersinmezliklerden kaynaklanan ekserji yıkımlarının arttığı tespit edilmiştir. Elde edilen sonuçlar, PV sistemlerin verimliliğini koruyabilmek için periyodik temizlik ve bakım uygulamalarının zorunlu olduğunu, ayrıca sistem değerlendirmelerinde yalnızca enerji değil ekserji analizinin de dikkate alınması gerektiğini ortaya koymaktadır.

EXPERİMENTAL INVESTİGATİON OF THE EFFECT OF CONTAMİNATİON ON PV PANEL SURFACE PERFORMANCE

ABSTRACT

Energy is an important resource whose demand increases as societies grow. Energy can be obtained from fossil fuels as well as renewable energy sources. With the depletion of fossil fuels, the shift towards renewable energy sources has increased. Solar energy is the most preferred type of renewable energy source. Electricity generation from solar energy is possible with PV panels, and many factors affect the efficiency of these panels. This study examines the effects of contamination on the surface of photovoltaic (PV) panels on panel performance based on energy and exergy. Experimental studies were conducted in a test setup installed on the roof of the Fırat University Department of Mechanical Engineering under the climatic conditions of Elazığ province. Two 50 W polycrystalline PV panels with the same characteristics were used in the experiments; one panel was cleaned every hour, while the other was left dirty. Current, voltage, power, panel temperature, radiation, wind speed, humidity, and ambient temperature values were measured simultaneously for both panels. The energy and exergy efficiencies of the panels were calculated using the obtained data, and the results were evaluated comparatively. The findings showed that dust and dirt accumulated on the panel surface prevented the absorption of solar radiation, causing a significant decrease in energy and exergy efficiency. The average energy efficiency of the clean panel was found to be 17.3% higher than that of the dirty panel, while its exergy efficiency was approximately 25–30% higher. In the dirty panel, an increase in exergy destruction due to heat transfer and irreversibilities associated with increased surface temperature was observed. The results obtained reveal that periodic cleaning and maintenance are essential to maintain the efficiency of PV systems and that exergy analysis, not just energy, should be considered in system evaluations.

Keywords: Photovoltaic Panel, Contamination, Exergy, Energy.

1. GİRİŞ

Günümüzde küresel enerji talebi, ekonomik büyüme, sanayileşme ve nüfus artışı ile birlikte hızla yükselmektedir (IEA, 2024). Bu artış fosil yakıt kullanımını da beraberinde getirerek karbon emisyonlarının yükselmesine, hava kirlenmesine ve iklim değişikliğinin şiddetlenmesine yol açmaktadır (IEA, 2024; Reuters, 2024). Bu olgular, enerji sistemlerinde dönüşümü kaçınılmaz kılmakta ve yenilenebilir enerji kaynaklarına yönelimi teşvik etmektedir. Uluslararası Enerji Ajansı'nın "Renewables 2024" raporuna göre, 2024-2030 döneminde yenilenebilir kapasitedeki büyümenin %80'inin güneş (PV) kaynaklarından gelmesi beklenmektedir (IEA, 2024). Küresel ölçekte, 2024 yılı itibarıyla güneş ve rüzgâr enerji üretimi, hidroelektrik üretimini geride bırakmış ve güneş enerjisi 2030'a kadar en baskın yenilenebilir kaynak haline gelme yolundadır (IEA, 2024; IEA, 2024, Global Overview). Türkiye açısından bakıldığında, ülkemiz yüksek güneş potansiyeline sahip olmasına rağmen bu potansiyel henüz tam olarak değerlendirilememiştir (Dinçer, 2011; TİSEJ, 2019). Türkiyenin Güneş enerjisi potansiyeli haritası Görsel 1.'de verilmiştir.

Görsel 1. Türkiye'nin Fotovoltaik Güç Potansiyeli Haritası

2024 yılında Türkiye'de rüzgar ve güneşten elde edilen elektrik üretimi, yerli kömürden gelen üretimi geride bırakmış, güneş enerjisinin payı %7,5'e yükselmiştir (Dünya Enerji, 2025). Bu doğrultuda, Türkiye'nin enerji stratejileri hem arz güvenliğini sağlamak hem de karbon salınımını azaltmak amacıyla güneş enerjisinin yaygınlaştırılmasını hedeflemektedir (Eurasian Research, 2024). Deneylerin gerçekleştirildiği Elazığ ili, Doğu Anadolu Bölgesi'nde yer almasına rağmen güneş enerjisi açısından avantaja sahiptir. Örneğin, 1.036,8 kWp kapasiteli bir fotovoltaik santral ile yapılan performans analizinde, Ocak-Temmuz 2018 döneminde sistemin verimliliği ile PV*SOL simülasyon sonuçları arasındaki farkın düşük olduğu (yaklaşık %0,03) tespit edilmiştir (Özdemir & Çelik, 2025)

Güneş enerjisinden elektrik üretimi, güneş ışınımının doğrudan elektrik enerjisine dönüştürülmesi esasına dayanır. Bu dönüşüm, fotovoltaik (PV) hücreler aracılığıyla gerçekleşir; hücrelerde bulunan yarı iletken malzemeler (çoğunlukla silisyum), güneş ışığına maruz kaldığında fotoelektrik etki sayesinde elektronları serbest bırakarak bir elektrik akımı oluşturur (Kalogirou, 2014). Bu sistemlerde modül yapısı, eğim açısı, yönelme, sıcaklık, ışınım şiddeti ve kirlenme (toz, kuş pisliği vb.) gibi çevresel ve fiziksel faktörler verimi doğrudan

etkiler (Hassan ve ark., 2022). Özellikle yüzey kirliliği, gelen ışınımın panele ulaşmasını engelleyerek enerji üretiminde ciddi kayıplara neden olabilir; yapılan çalışmalar, uzun süre temizlenmeyen panellerde %25–40'a varan verim düşüşleri bildirmiştir (Saidan ve ark., 2020). Ayrıca panel sıcaklığının artması, yarı iletkenlerin iç direncini yükselterek çıkış gücünü azaltır; bu nedenle soğutma sistemleri, uygun eğim ve havalandırma tasarımı verim artışı açısından önemlidir (Sarver ve ark 2013). Dolayısıyla güneş enerjisinden maksimum elektrik üretimi için çevresel koşulların doğru analiz edilmesi, panel malzemesinin seçimi ve düzenli bakım uygulamaları hayati önem taşımaktadır. Son zamanlarda yapay zekanın neredeyse bütün alanlarda yaygın olarak kullanıldığı bilinmektedir. Güneş panellerinin optimizasyonu yapay zekanın etkili kullanımı sonucunda mümkün olmaktadır. Bu konuda literatürde birçok kıymetli çalışma mevcuttur bunlar aşağıda verilmiştir.

Karagözoğlu ve arkadaşları (2023), fotovoltaik (PV) sistemlerde yapay sinir ağı (YSA) tabanlı bir maksimum güç noktası izleme (MPPT) simülasyonu geliştirerek değişken çevre koşullarında sistemin tepkisini incelemiştir. Çalışmada ışınım ve sıcaklık giriş parametreleri olarak kullanılmış, Levenberg–Marquardt algoritmasıyla eğitilen ağın klasik MPPT yöntemlerine kıyasla daha hızlı yakınsama ve yaklaşık %98 verim sağladığı belirlenmiştir. Bulgular, YSA tabanlı yaklaşımın dalgalı ışınım ve sıcaklık koşullarında güç salınımlarını azaltarak izleme kararlılığını artırdığını göstermiştir.

Kapucu ve arkadaşları (2019), ise Ege Üniversitesi Güneş Enerjisi Enstitüsü verilerini kullanarak, topluluk (ensemble) öğrenmesi temelli bir arıza tespit modeli önermiştir. Muğla'daki konut tipi bir PV kurulumundan elde edilen elektriksel ve meteorolojik veriler üzerinde yapılan analizlerde, sistemin kısmi gölgelenme **ve** kısa devre gibi arızaları yüksek doğruluk oranlarıyla sınıflandırabildiği görülmüştür. Model, Python/Scikit-learn ortamında optimize edilerek tekil algoritmalara kıyasla daha yüksek genelleme başarımı sunmuştur.

Uğuz ve arkadaşları (2019), tarafından yürütülen bir diğer çalışmada, Türkiye'nin farklı coğrafi bölgelerinde PV sistemlerinden elde edilebilecek güç üretiminin makine öğrenmesi (ML) tabanlı yöntemlerle tahmini amaçlanmıştır. NASA meteorolojik girdileri ve RETScreen temelli parametreler kullanılarak çoklu regresyon, yapay sinir ağı ve diğer yöntemlerin karşılaştırıldığı araştırmada, ML modellerinin kısa ve orta vadeli güç tahminlerinde başarılı performans sergilediği ve PV sistem tasarımı için karar destek potansiyeli taşıdığı sonucuna varılmıştır.

Eryılmaz ve arkadaşları (2023), tarafından yapılan çalışmada, Dicle Üniversitesi kampüsündeki PV istasyonu verileri kullanılarak GD-RVFLN (Gürbüz Düzenlenmiş Rastgele Vektör Fonksiyonel Bağlantı Ağı) modeli geliştirilmiştir. Bu model, 10 dakikalık zaman aralıklarında kısa dönem PV güç tahmini yapabilmiş ve 11 farklı modelle kıyaslandığında daha yüksek doğruluk ve hızlı öğrenme kapasitesi göstermiştir. Sonuçlar, önerilen yöntemin şebeke entegrasyonu ve işletme planlaması için önemli bir araç olabileceğini ortaya koymuştur.

Savaş ve arkadaşları (2023), ise güneş enerji santrallerinde yapay zekâ destekli bakım-onarım sistemine odaklanmış; sensör verilerinin analitiği, arıza tespiti ve öngörücü bakım yaklaşımlarıyla kapasite kullanım oranının artırılabileceğini belirtmiştir. Çalışma, saha operasyonlarının dijitalleşmesi ve bakım süreçlerinin otomasyonu için bütüncül bir yapay zekâ çerçevesi önermektedir.

Bahaidarah ve çalışma arkadaşları (2013), sıcak iklim koşullarında fotovoltaik (PV) modüllerin arka yüzeyine entegre edilen su soğutma sistemlerinin performans üzerindeki etkisini deneysel olarak incelemiştir. Bulgular, su sirkülasyonunun panel yüzey sıcaklığını yaklaşık 20 °C oranında düşürdüğünü ve bu sayede sistem veriminin %10–15 arasında

iyileştiğini göstermektedir. Bu sonuç, özellikle yüksek sıcaklık bölgelerinde PV modül verimliliğini artırmak için etkin bir aktif soğutma stratejisinin uygulanabileceğini ortaya koymaktadır.

Kalogirou (2014), tarafından yapılan araştırmada, faz değişim malzemesi (PCM) kullanılarak gerçekleştirilen pasif soğutma yöntemlerinin enerji tüketimi olmadan modül sıcaklığını dengelemede etkili olduğu ifade edilmiştir. Bu yaklaşım, PV sistemlerinde uzun vadeli performans kararlılığı ve sürdürülebilir soğutma açısından çevre dostu bir çözüm olarak öne çıkmaktadır.

Seme ve arkadaşları (2019), tarafından yürütülen teknik-ekonomik karşılaştırma çalışmasında, tek ve çift eksenli güneş izleme sistemleri analiz edilmiştir. Çalışma bulguları, çift eksenli izleme sistemlerinin sabit eğimli panellere göre yıllık enerji üretimini yaklaşık %30**,** tek eksenli sistemlerin ise %15–25 oranında artırdığını ortaya koymuştur. Bununla birlikte, yazarlar bu tür sistemlerin yüksek yatırım maliyetlerine sahip olduğunu, dolayısıyla ekonomik uygulanabilirliğin sistem ölçeği ve yerel koşullara göre dikkatle değerlendirilmesi gerektiğini vurgulamıştır.

Bu çalışma Elazığ iklim koşullarında gerçekleşmiş olup yapılan deneylerde 2 adet polikristal panel kullanılmıştır. Yapılan deneyler 4 gün sürmüş panellerden biri bir saatlik aralıklarla temizlenmiş diğeri ise kirli bırakılmıştır. 2 panelden de eş zamanlı olarak akım, gerilim, güç, sıcaklık ve radyasyon ölçümleri alınmıştır. Bunların yanında dış sıcaklık, rüzgar hızı, nem oranı parametreleri kaydedilmiştir. Alınan verilerle panellerin enerji ekserji verimi hesaplanmış ve deney sonuçları karşılaştırılmıştır.

2. Materyal ve Metod

Deneysel çalışmalar Elazığ İli iklim şartlarında Fırat Üniversitesi Makine Mühendisliği bölümü çatısında kurulan deney düzeneğinde gerçekleştirilmiştir. Yapılan deneyler 4 gün sürmüştür ve deneyler 09:10- 16:00 saatleri arasında gerçekleştirilmiştir. Deneylerde 2 adet Polikristal PV Panel kullanılmıştır. Deney setinin görüntüsü Görsel 2-3.'de verilmiştir.

Görsel 2. Saatte Bir Temizlenen PV Panel

Elektriksel Güç	Solar Multimetre	±0.1 Watt

2.1 Hesaplama Prosedürü

2.1.1 Enerji Analizi

PV panelin enerji verimi panele gelen toplam güneş enerjisine kıyasla panelin ürettiği elektrik enerjisini ifade eder.PV Panel enerji verimi Denklem 1.' de verilmiştir.

P: Güç

A: Panel Yüzey Alanı

G: Solar Radyasyon

$$\eta_{en} = \frac{P}{A \cdot G} \tag{1}$$

2.1.2 EkserjiAnalizi

Fotovoltaik sistemde dış kaynaktan gelen tek ekserji akışı, panel yüzeyine ulaşan güneş ışınımının ekserjisidir. Bu giriş ekserjisinin büyüklüğü, ortam sıcaklığı, güneşin etkin sıcaklığı ve yüzeye ulaşan güneş radyasyonu değerlerine bağlı olarak değişmektedir. İlgili ekserji değeri, Denklem 2. kullanılarak hesaplanmıştır. (Petela,1964)

$$\dot{E}x_{sol,pv} = A_{PV}\, G\, [1 + \frac{1}{3} * \left(\frac{T_a}{T_{sun}}\right)^4 - \frac{4}{3}" * (\frac{T_a}{T_{sun}})] \quad (kWh) \tag{2}$$

Bu denklemde Ta ve Tsun sırasıyla ortalama çevre sıcaklığını ve güneşin etkin sıcaklığını göstermektedir. Güneş sıcaklığı hesaplamalarda 6000 K olarak kabul edilmiştir. Elektrik enerjisi, herhangi bir sistemde doğrudan ekserjiye eşdeğer olduğundan, PV panelde üretilen elektrik enerjisi de sistemin ekserji çıktısını temsil etmektedir. Dolayısıyla panelin maksimum elektriksel iş potansiyeli, çevre koşullarına bağlı olarak belirlenen ekserji değeriyle ifade edilmekte ve bu değer Denklem 3. kullanılarak hesaplanmaktadır.

$$\dot{E}x_{elek,PV} = V_{OC}^{*} * I_{SC}^{*} \quad (kWh) \tag{3}$$

Güneş enerjisinin elektrik enerjisine dönüşümü esnasında oluşan ekserji yıkımı Denklem 4 ile hesaplanmıştır.

$$\dot{E}x_{D,conv} = \dot{E}x_{soll} - \dot{E}x_{elec,PV} \tag{4}$$

Isı transferi ile oluşan ekserji yıkımı Denklem 5 ile hesaplanmıştır.

$$\dot{E}x_{D,therm} = \dot{Q} * \left(1 - \frac{T_{amb}}{T_{cell}}\right) \tag{5}$$

Bu denklemde Q, Tamb ve Tcell sırayla çevreye olan ısı kaybını, ortalama çevre sıcaklığını ve panel sıcaklığını ifade eder. Panel yüzeyinden çevreye olan ısı kaybı Denklem 6 ile hesaplanmıştır.

$$\dot{Q} = U * A_{PV} * (T_{cell} - T_{amb}) = (h_{conv} + h_{rad}) * A_{PV} * (T_{cell} - T_a) \tag{6}$$

Bu denklemde U toplam ısı transferi katsayını ifade eder ve U konveksiyon ve radyasyon katsayılarının toplamıyla elde edilir. Konveksiyon ısı transfer katsayısı denklem 7 ile hesaplanmıştır. (Bayrak ve diğerleri, 2017)

$$h_{conv} = 2.8 + 3 * V_W \quad (W/m^2\,°C) \tag{7}$$

Bu denklemde Vw saatlik ortalama rüzgar hızını ifade etmektedir.PV ve çevre arasında ışınım transfer katsayısı denklem 8 ile hesaplanmıştır.

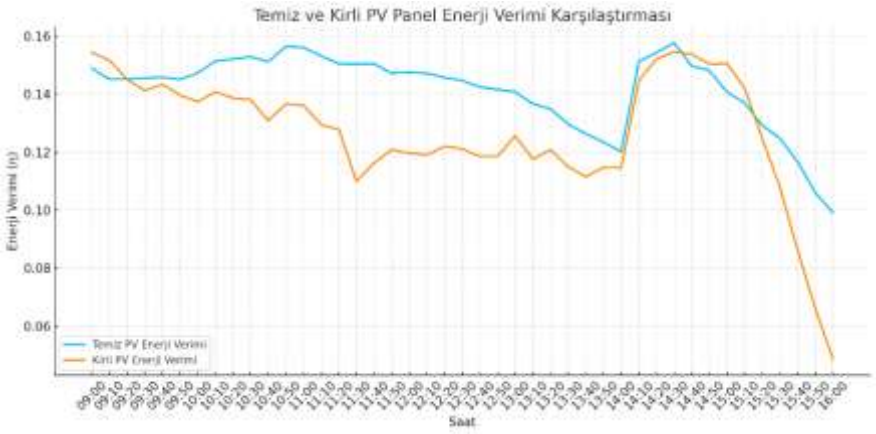
$$h_{rad} = \varepsilon * \sigma * (T_{sky} - T_{cell}) * (T_{sky}^{\,2} - T_{cell}^{\,2}) \qquad (W/m^2\,°C) \tag{8}$$

Burada ε ve σ sırayla emisyon ve Stefan- Boltzmann sabitini ifade eder. Bu denklemde kullanılan gökyüzü sıcaklığı Denklem 9 kullanılarak hesaplanmıştır.

$$T_{sky} = T_{amb} - 6 \quad (°C) \tag{9}$$

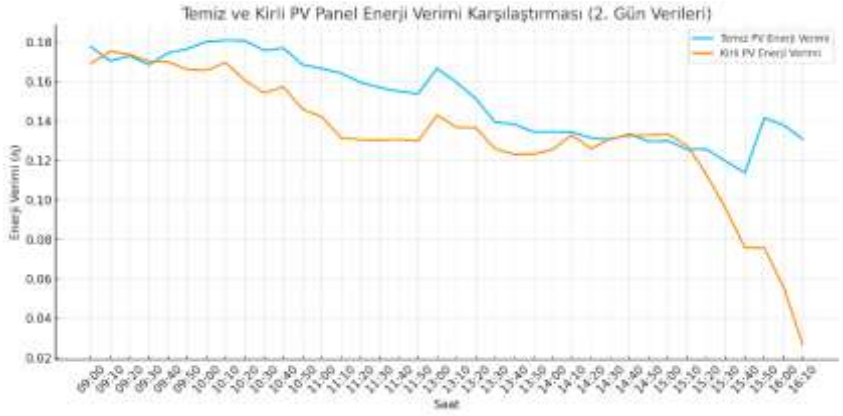
Pv panelden ekserji çıkış değeri Denklem 10 kullanılarak hesaplanmıştır.

$$\dot{E}x_{out,PV} = \dot{E}x_{soll} - \dot{E}x_{dest,conv} - \dot{E}x_{dest,elek} - \dot{E}x_{dest,therm} = P_{max}^{\,*} - \dot{E}x_{dest,therm} \tag{10}$$



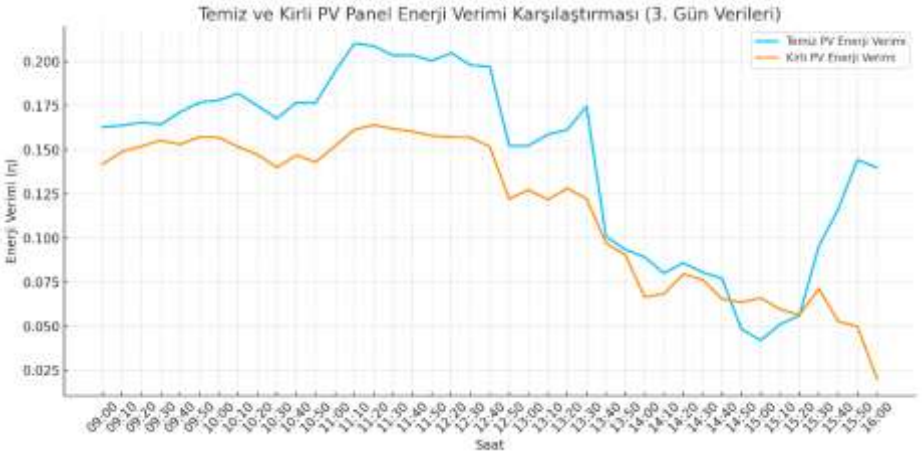
PV panelin ekserji verimi denklem 11 kullanılarak hesaplanmıştır.

$$\Psi_{PV} = \frac{Ex_{out,pv}}{Ex_{sol,pv}} = \frac{P_{max}^{\,*} - \dot{E}x_{D,therm}}{Ex_{sol,pv}} \tag{11}$$

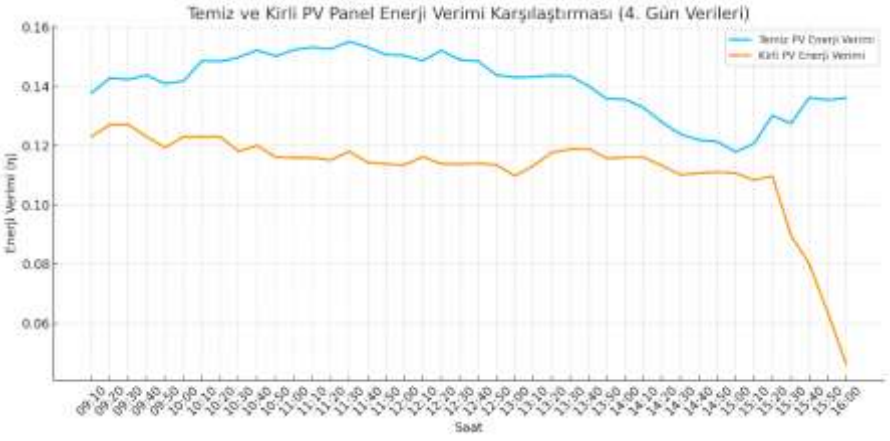


3. BULGULAR

Yapılan deneylerde temiz PV panel performansı ve kirli PV panel performansı karşılaştırılmış ve temiz PV panelin %17,3 daha verimli olduğu sonucuna ulaşılmıştır.



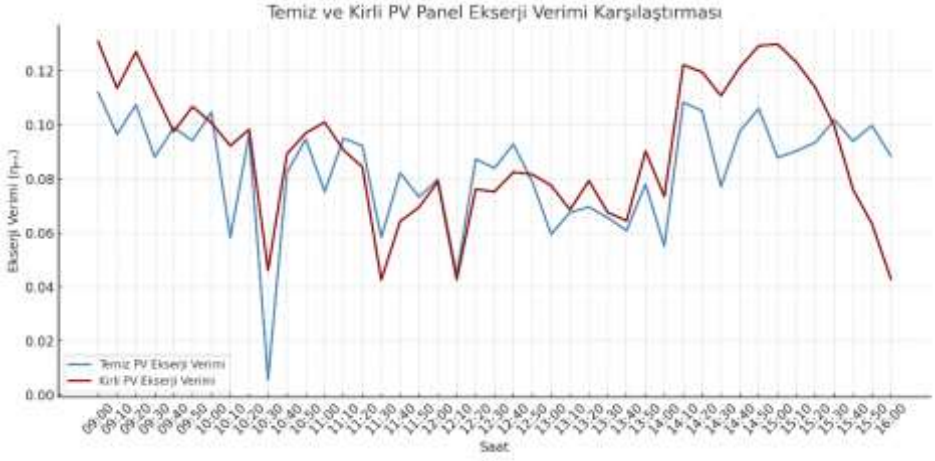
PV Panellerin deney yapılan tüm günler için enerji verimliliği karşılaştırma grafiği Görsel 6-9. arasında verilmiştir.



Görsel 6. 1. Gün PV Panel Enerji Verimliliği Karşılaştırma Grafiği

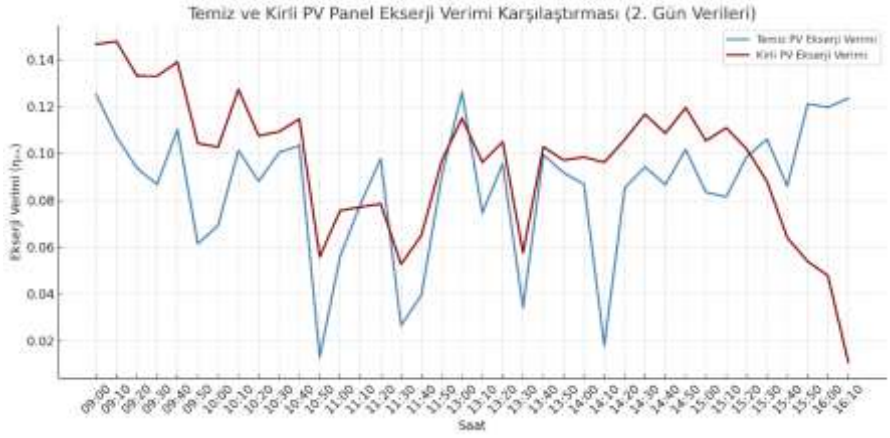
Görsel 7. 2. Gün PV Panel Enerji Verimliliği Karşılaştırma Grafiği

Görsel 8. 3. Gün PV Panel Enerji Verimliliği Karşılaştırma Grafiği



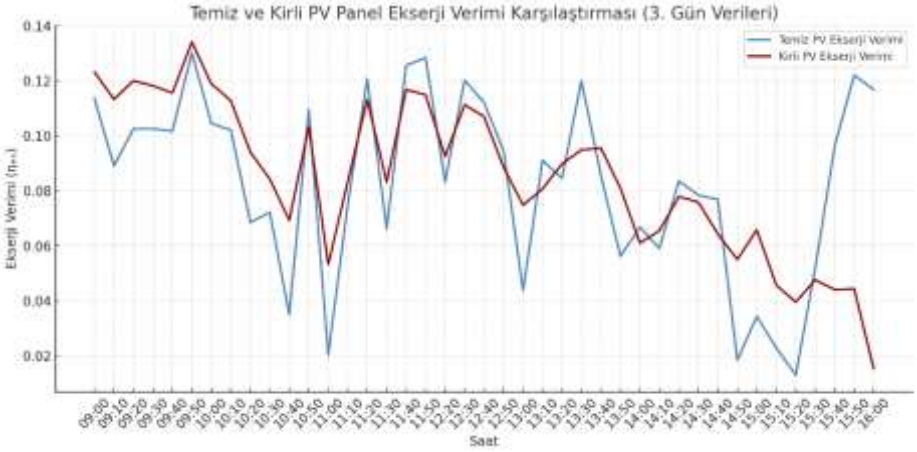
Görsel 9. 4. Gün PV Panel Enerji Verimliliği Karşılaştırma Grafiği

Grafiklerdeki mavi çizgi temiz PV panelin enerji verimliliğini, turuncu çizgi ise kirli (tozlu) PV panelin enerji verimliliğini göstermektedir. Tüm günler için ortak eğilim, kirli panelin verim değerlerinin temiz panele göre belirgin biçimde düşük olmasıdır. Bu fark, gün ilerledikçe ve panel yüzeyinde sıcaklık ve toz birikimi arttıkça daha da belirginleşmektedir. Toz birikimi, panel yüzeyine düşen güneş ışığının bir kısmının emilmeden yansımasına neden olarak absorbe

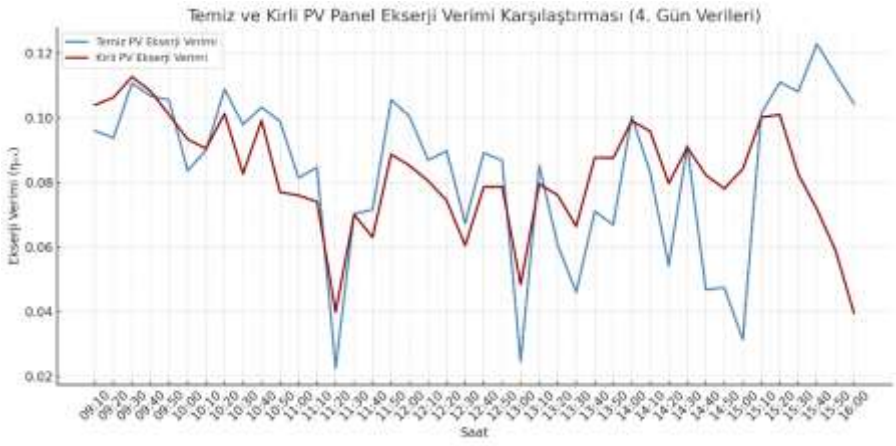


edilen radyasyon miktarını azaltır. Bu durum, özellikle öğle saatlerinde hücre sıcaklığı artışıyla birleştiğinde panelin dönüştürme verimini düşürmektedir.

Bu dört günlük gözlem sonucunda: Tozlanmanın artışıyla PV panel enerji verimi sürekli olarak azalmaktadır. Verim kaybı günlük ortalama %5–10 düzeyindedir. Dördüncü gün sonunda, kirli panelin enerji üretimi temiz panele göre yaklaşık %15-20 oranında daha düşüktür. Bu bulgular, periyodik temizlik veya kirlilik eşiğine dayalı bakım planlamasının PV sistem performansını korumak açısından zorunlu olduğunu göstermektedir.



Ekserji verimliği karşılaştırma grafikleri de Görsel 10-13. aralığında verilmiştir.



Görsel 10. 1. Gün PV Panel Ekserji Verimliliği Karşılaştırma Grafiği

Görsel 11. 2. Gün PV Panel Ekserji Verimliliği Karşılaştırma Grafiği

Görsel 12. 3. Gün PV Panel Ekserji Verimliliği Karşılaştırma Grafiği

Görsel 13. 4. Gün PV Panel Ekserji Verimliliği Karşılaştırma Grafiği

Tüm grafiklerde mavi çizgi temiz PV panelin ekserji verimini, bordo çizgi ise kirli PV panelin ekserji verimini göstermektedir. Dört gün boyunca her iki panelde de ekserji verimliliği %3–15 aralığında değişmiş; grafiklerdeki belirgin dalgalanmalar anlık ışınım, sıcaklık ve rüzgâr hızı değişimlerinden kaynaklanmıştır. Kirli panellerde, enerji verimliliği kadar olmasa da ekserji kayıpları gözlenmektedir; bu durum, tozun yüzey sıcaklığını artırarak hücre–çevre sıcaklık farkını büyütmesi ve dolayısıyla tersinmezlikleri artırmasıyla açıklanabilir.

Bu dört günlük gözlemlerden şu çıkarımlar yapılabilir: Ekserji verimi, enerji verimine göre daha düşük değerlerdedir çünkü sistemin termodinamik tersinmezlikleri hesaba katılmaktadır. Toz birikimi, yüzey sıcaklığını artırdığı için ekserji yıkımını da artırır. Günler ilerledikçe temiz ve kirli paneller arasındaki fark büyümekte, 4. gün sonunda kirli panelin ortalama ekserji verimi temiz panele göre yaklaşık %15–20 daha düşmektedir. Bu sonuç, PV sistemlerin sadece enerji değil, ekserji bazlı performans değerlendirmesinde de periyodik temizliğin ne kadar önemli olduğunu ortaya koymaktadır.

4. GENEL DEĞERLENDİRME VE SONUÇLAR

Dört günlük deneysel ölçümler sonucunda, temiz ve kirli PV panellerin ekserji verimleri arasında anlamlı farklar tespit edilmiştir. Ortalama olarak temiz panelin ekserji verimi %8–12 aralığında değişirken, kirli panelin verimi %6–9 seviyelerinde kalmıştır. Her iki panelde de gün ilerledikçe düşüş eğilimi gözlenmiş; bu durum, artan hücre sıcaklığının ve buna bağlı ekserji

yıkımlarının (tersinmezliklerin) etkisini göstermektedir. Kirli yüzeye sahip panellerde, ışınımın bir kısmı toz tabakası tarafından soğurulmadan yansıtıldığı için güneş enerjisinin iş potansiyeli (ekserjisi) azalmaktadır. Ayrıca, toz tabakasının oluşturduğu ısıl bariyer nedeniyle panel yüzey sıcaklığı artmakta, bu da çevre–hücre sıcaklık farkını büyüterek ekserji kayıplarını hızlandırmaktadır. Dördüncü gün sonunda kirli panelin ortalama ekserji veriminin temiz panele göre yaklaşık %25–30 oranında daha düşük olduğu saptanmıştır. Bu bulgu, fotovoltaik sistemlerin performans değerlendirmelerinde yalnızca enerji değil, ekserji analizinin de dikkate alınması gerektiğini vurgulamaktadır. .

5. TEŞEKKÜR

Bu çalışmadaki deneyler ‘Olumsuz Çevre Şartlarının Fotovoltaik Panel Verimi Üzerindeki Etkilerinin Görüntü İşleme Yöntemi Yardımıyla İncelenmesi’ isimli yüksek lisans çalışması kapsamında yapılmıştır. Yüksek lisans tezi FÜBAP MF.25.107 numaralı proje tarafından desteklenmektedir.

ABSTRACT

The rapid increase in urbanization in recent decades has resulted in a substantial worldwide rise in carbon emissions specifically inside metropolitan regions. Rajshahi, a city situated in Bangladesh, has garnered attention for its capacity to serve as a carbon sink. The objective of this study is to precisely assess and measure the carbon storage potential of several carbon sinks present in the city, including water bodies, vegetation, and bare soil. The research aims to estimate the spatial trend and quantify the current carbon storage capacity in each identified carbon sink within Rajshahi city. Additionally, it seeks to identify areas with high carbon sequestration potential, also referred to as carbon sequestration hotspots. This study employs Geographic Information Systems (GIS) and remote sensing techniques to conduct a thorough examination of the capacity for carbon sequestration in Rajshahi. Carbon absorption coefficient values derived from established global and regional were applied to each land cover type to quantify their respective carbon storage and sequestration capacities. The study revealed a notable surge in urban regions and a progressive decline in cool land coverings such as water bodies and vegetation. The urbanization rate experienced a nearly 10% growth from 1992 to 1997, while the extent of vegetative cover declined by almost 1 square kilometer. The results also indicate that bare land (53%) and vegetation (38%) constitute the dominant carbon sinks in Rajshahi City, contributing the highest amounts of above-ground biomass and carbon storage. Spatial analysis further reveals uneven distribution of carbon sinks across the city, with the northern and peripheral zones containing relatively higher biomass density than the central urban core. The study provides a baseline geospatial dataset for policymakers, urban planners, and environmental agencies to develop climate-responsive urban management strategies in rapidly urbanizing contexts.

Keywords: Carbon Sequestration Hotspots, Carbon Sinks, Carbon Stock, Geographic Information System (GIS), Remote Sensing, Land Use/Land Cover (LULC).

1. INTRODUCTION

Over the past few decades, there has been a significant increase in the worldwide urban population, with more than half of the world's people currently living in urban areas (Seto et al., 2012a). The rapid increase in urbanization has resulted in substantial alterations in land utilization, marked by widespread transformations of land into urban zones (Jiang et al., 2012). Efforts to lessen the effects of global environmental change frequently involve extensive plantation initiatives designed to decrease greenhouse gas emissions and improve carbon sequestration (Yang et al., 2020).The assessment of carbon sequestration in these plantations depends on comprehending how different management practices, disturbances, stand ages, and structures in different landscapes impact carbon sequestration rates (Cao et al., 2018). Prior research has conventionally depended on carbon storage information obtained from different tree species under consistent pedoclimatic circumstances (Trum et al., 2011) . Nevertheless, the accuracy of carbon storage calculations can be impeded by errors at the regional level caused by spatial variability (Yang et al., 2020b). A comprehensive comprehension of carbon conservation in several plantations is frequently constrained to evaluations of the carbon balance at a regional level.

Urban areas are frequently portrayed as hubs of ecological degradation, with their adverse effects extending from nearby ecosystems to the global level. Many factors that drive global change can be traced back to these highly populated areas (Strohbach & Haase, 2012). Urban areas are major contributors of greenhouse gases, especially carbon dioxide, which result from a range of activities carried out by city residents, including the use of fossil fuels, industrial manufacturing, high levels of traffic, heating, and cement production. In addition, the process of urbanization disturbs and alters soils and plants, which worsens emissions (Churkina, 2012). Urban areas are therefore involved in various worldwide transformations, such as the rise in carbon dioxide concentrations. Nevertheless, it is important to acknowledge that cities also play a role in providing crucial ecological services, like carbon sequestration. There is increasing concern about the function of urban settings in absorbing carbon and creating carbon sinks, which is being discussed in relation to accountability and attempts to reduce the impacts of climate change (Sohi, 2012).

The primary purpose of this study is to assess and quantify the capacity of the major carbon sinks (such as water body, vegetation and bare land) to sequester carbon dioxide from the atmosphere in the four major urbanized zones of Rajshahi City Corporation (RCC) area namely, City Centre, Eastern Fringe, Western Fringe and Northern Fringe over the past three decades (1992, 1997, 2002, 2007, 2012, 2017 & 2022), which has not been explored till the date following the micro-scale analysis. To fulfill the purpose this particular study (i) Estimated the spatial trend and quantified the current carbon storage capacity/carbon stock in each identified carbon sink within Rajshahi city and (ii) Identified carbon sequestration hotspots/ areas with high carbon sequestration potential in Rajshahi. This particular study has been conducted taking into consideration the hypothesis “There is a robust negative correlation among the rapid changes in LULC and the respective shrinkage of the major carbon sinks”.

2. MATERIALS AND METHODS

To achieve the mentioned objectives, the entire study is divided into three phases. In the first stage of the study preliminary literature about land use and land cover change, carbon sequestration, major carbon sinks, background of the Rajshahi city from the perspective of climatology has been reviewed to select a tentative research topic. Then the goal and objectives of the study has been formulated and study area has been selected based on the research topic. In the second stage comprehensive literature regarding the application of geographic

information systems (GIS) and remote sensing (RS) in land use/land cover (LULC) change detection through satellite image analysis has been reviewed to develop the concept. Secondary data (mainly satellite data) has been collected from the United States Geological Survey (USGS) to calculate the comparative fluctuation of land use/land cover (LULC).

Table 1: Details of the Required Satellite Images

Date Acquired (Year)	Scene ID	Sensor	Cloud Cover	Path/ Row	Spatial Resolution (m)
1992	LT05_L1TP_138043_19920205_201	TM	< 10%	138/43	30
1997	LT05_L1TP_138043_19970306_201

Source: USGS Earth Explorer, 2025.

In the last stage, analysis from landsat satellite images and in-depth ground truthing of satellite data has been focused. Based on the spatial and temporal data received from the image analysis, the carbon storage capacity/carbon stock in each identified carbon sink carbon sequestration hotspots/ areas with high carbon sequestration potential in Rajshahi has been identified. Based on the major findings, policy induced recommendations from both the study results and authors have been provided.

In order to evaluate the current carbon storage capacity of the Rajshahi city corporation area, this study takes into account the carbon storage factors (measured in kilograms of carbon per square meter) for vegetation cover, bare ground, and water bodies, as determined by Dorendorf in 2014. The carbon sequestration of Rajshahi city has been determined using Equation (1)

$$CS = \sum_{i=1}^{n} CSi \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (1)$$

In this study, CS represents the overall carbon storage of Rajshahi city. The variable i refers to the specific storage category, while n represents the total number of storage categories. In this particular study, n is equal to 3, which includes Vegetation Cover, Water Body, and Bare Land. CSi is determined by applying Equation (2)

$$CSi = \sum ASi \times Ei \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (2)$$

The equation represents the relationship between the total existent area of individual storage type (ASi) and the equivalency factor (Ei). By combining Equations (1) and (2), the calculation of CS may be determined using Equation (3)

$$CS = \sum_{i=1}^{n} (\sum ASi \times Ei) \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (3)$$

The equations were utilized to calculate the current carbon storage of Rajshahi city, and subsequently, a map illustrating the intensity of carbon storage and the locations with high carbon sequestration rates was generated.

Table 2: Coefficient of Carbon Absorption Factor

Carbon Sink	Coefficient of Absorption Factor (kg of CO_2 /sq. m)	References
Vegetation Cover	0.67	(Dorendorf, 2014; Ghosh et al., 2017; Nowak & Crane, 2002a)
Water Body	1.28	(Taylor et al., 2019)
Bare Land	0.83	(Ghosh et al., 2017)

Source: Author, 2025

3. RESULTS and DISCUSSION

3.1 Temporal Variation of Carbon Absorption

Across the study period, vegetation—which contributes the most to carbon absorption—has experienced a continuous and steep decline. In 1993, vegetation covered about 76.89% of the area and accounted for 74.32% of total carbon absorption. By 2023, vegetation area dropped to 18.33%, absorbing only 37.74% of total carbon. This pattern reflects increasing urban expansion, infrastructure development, and land conversion. Similar trends have been documented in rapidly urbanizing Asian cities, where vegetation loss is strongly associated with declining carbon sequestration and ecosystem quality (Seto et al., 2012b). Studies also show that the loss of tree cover results in disproportionate reductions in carbon uptake because vegetation—especially urban trees serve as the primary carbon sink in cities (Davies et al., 2011; Nowak & Crane, 2002b)

Bare land increased from 12.41% in 1993 to 21.05% in 2023. Interestingly, its share of carbon absorption rose from 14.86% to 53.69%. This rise does not indicate that bare land is becoming more efficient at absorbing carbon. Rather, it reflects the sharp decline in vegetation cover—the main carbon-absorbing class—combined with the relative increase in bare land area. In other words, bare land represents a larger portion of the remaining land, so its percentage share of total carbon absorption increases even though its actual ecological contribution remains low. Urban studies indicate that as vegetated land declines, other land classes—such as built-up or bare surfaces—appear to hold a greater share of ecological functioning simply due to area proportion, not ecological performance (Zhao et al., 2016). Bare land typically stores very little carbon and usually signals land degradation or transition toward construction activities.

Water bodies also show a gradual decrease from 5.86% to 2.18% over 30 years. Correspondingly, carbon absorption from water bodies fell from 10.82% to 8.57%. Shrinking water bodies are commonly linked with urban sprawl, encroachment, and sedimentation problems. Studies in Bangladesh and other South Asian cities show that the reduction of wetlands and water bodies contributes to ecosystem instability and reduced carbon sequestration capacity (Ahmed et al., 2013).Wetlands—although less effective than vegetation—still play a meaningful role in carbon cycling through sediment carbon storage and organic matter accumulation (Table 3).

Table 3: Temporal Variation of Carbon Absorption Capacity

Study Period	Carbon Sink	Area (sq m)	Area (%)	Carbon Absorption	Carbon Absorption (%)
	Water Body	2816100	5.86	3604608	10.82
1993	Vegetation	36950400	76.89	24756768	74.32
	Bare Land	5964300	12.41	4950369	14.86
	Water Body	3324600	6.92	4255488	13.03
1998	Vegetation	26388900	54.92	17680563	54.15
	Bare Land	12912300	26.87	10717209	32.82
	Water Body	2005200	4.17	2566656	9.37
2003	Vegetation	22325400	46.46	14958018	54.58

3.2 Zone-Specific Carbon Absorption

The table 4 illustrates the differences in carbon absorption capability among certain study zones, namely the City Center, Eastern Fringe, Northern Fringe, and Western Fringe. Each zone is distinguished by its specific land cover composition, which encompasses water bodies, vegetation, and bare land, and their individual roles in absorbing carbon over the study period. Within the City Center, which is marked by urbanization, vegetation covers a relatively lesser fraction of the land compared to bare land. However, it plays a significant role in absorbing carbon, closely followed by bare land. Aquatic ecosystems make a moderate contribution to carbon sequestration in this area. Transitioning to the Eastern Fringe, an area that is between urban and rural environments, the dominant features of the landscape are vegetation and bare land. These elements play a crucial role in absorbing carbon, making a substantial contribution to the process. Water bodies in this zone have a limited impact on carbon absorption. The

Northern Fringe displays a varied terrain with significant vegetation coverage and noteworthy contributions from both vegetation and bare land to carbon sequestration. The contribution of water bodies in this area to carbon absorption is quite insignificant when compared to other types of land cover. The Western Fringe, which combines urban and peri-urban elements, demonstrates a substantial contribution of bare land to carbon absorption, followed by vegetation. The water bodies in this area make a moderate contribution to carbon sequestration. The overall results demonstrate the diverse impacts of different land cover types on carbon sequestration in different regions. Vegetation regularly acts as a significant carbon sink in all areas, but bare ground shows significant potential for absorbing carbon, especially in the Eastern and Western Fringes. Water bodies, although found in all areas, make a relatively small contribution to carbon absorption as a whole.

Table 4: Zone-Specific Carbon Absorption Capacity

Study Zone	Carbon Sink	Area (sq m)	Area (%)	Carbon Absorption	Carbon Absorption (%)
City Center	Water Body	83940	0.65	107444	6.13
	Vegetation	1052867	8.19	705421	40.25
	Bare Land	1132251	8.81	939768	53.62
Eastern Fringe	Water Body	273519	2.07	350104	6.02
	Vegetation	3495871	26.43	2342234	40.25
	Bare Land	3766495	28.48	3126191	53.73
Northern Fringe	Water Body	61171	0.51	78298	1.89
	Vegetation	2570748	21.26	1722401	41.49
	Bare Land	2832291	23.43	2350802	56.63
Western Fringe	Water Body	595297	6.15	761980	22.45
	Vegetation	1502477	15.52	1006660	29.66
	Bare Land	1958433	20.24	1625499	47.89

3.3 **Carbon Absorption Capacity by Existing Carbon Sink**

The figure provides an evaluation of the carbon absorption potential in different carbon sink categories, specifically Water Body, Vegetation, and Bare Land. Each carbon sink category is assessed according to its ability to sequester carbon dioxide (CO2) in kilograms (kgCO2) and its proportionate contribution to the overall carbon absorption. Water bodies exhibit a moderate potential to absorb carbon, effectively sequestering 1,297,826 kgCO2, representing 9% of the overall carbon absorption. The most notable carbon sink is vegetation, which has a capacity of 5,776,716 kgCO2, accounting for 38% of the overall carbon absorption. The category of bare land demonstrates the greatest ability for carbon absorption, with a total absorption of 8,042,260 kgCO2, accounting for 53% of the overall carbon absorption.

Overall observations suggest that water bodies have a limited impact on carbon absorption, in contrast to vegetation and uncovered land which have a more significant influence. Vegetation,

due to its widespread presence and biological activities, is the main reservoir for carbon, highlighting the significance of conserving and improving wooded regions to promote carbon sequestration initiatives. Barren land, despite its absence of plant life, exhibits significant capacity for carbon absorption, possibly attributable to soil processes and land management techniques.

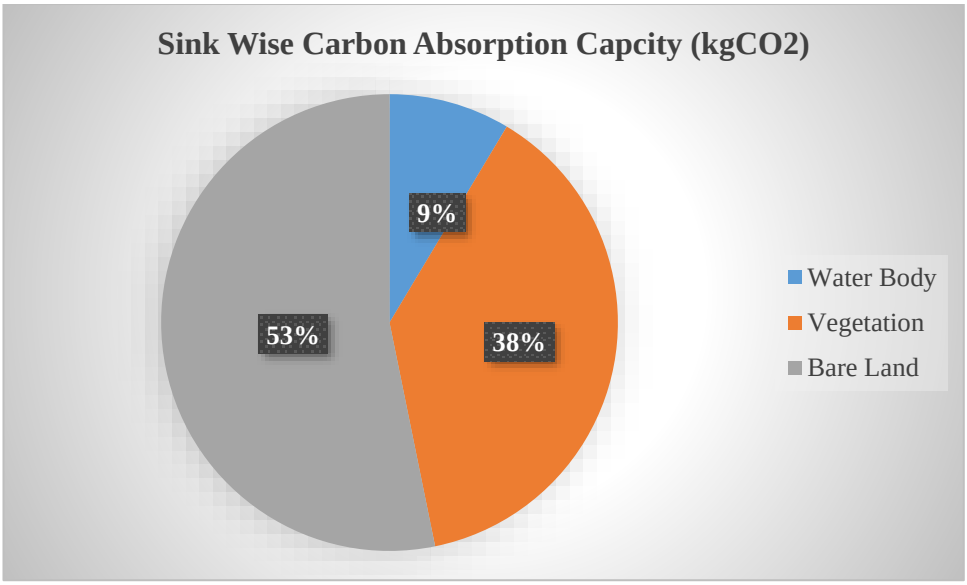

Figure 1: Percentage of Carbon Absorption by Current Carbon Sinks

Source: Prepared by Author, 2025.

The figure presents the carbon absorption capacity (measured in kgCO2/year) of four specific areas of a city: City Center, Eastern Fringe, Northern Fringe, and Western Fringe. The Eastern Fringe has the maximum absorption capacity, specifically 5,818,528.88 kgCO2/year, whereas the Northern Fringe has a little lower capacity of 4,151,501.529 kgCO2/year. By comparison, the City Center can absorb 1,752,632.192 kgCO2 per year, whereas the Western Fringe has a capacity to absorb 3,394,139.106 kgCO2 per year.

The findings indicate substantial disparities in the capacity for carbon absorption among various metropolitan areas, which are likely influenced by factors such as the density of vegetation, land utilization patterns, and environmental circumstances. The significant difference in the ability to absorb carbon highlights the need for focused interventions and urban planning methods to improve carbon sequestration in urban areas.

The variations in carbon absorption capabilities among metropolitan areas emphasize the intricate relationship between urbanization and environmental sustainability. It is essential to address these differences by implementing strategic planning and green infrastructure efforts in order to promote resilient and sustainable cities, reduce the impacts of climate change, and maintain ecological balance in urban environments.

Numerous studies corroborate the trends identified in the carbon absorption distribution throughout Rajshahi City, notably the diminishing influence of vegetation and the escalating prevalence of bare land within the urban carbon budget. Studies on the swiftly expanding cities of South Asia indicate that urban sprawl frequently results in considerable degradation of green cover, thereby markedly diminishing the carbon sequestration potential of urban ecosystems (Dewan & Yamaguchi, 2009). In Bangladesh, analogous trends have been observed in Dhaka, Khulna, and Rajshahi, where vegetated regions have gradually been supplanted by constructed

surfaces and barren land, leading to fragmented green spaces and diminished ecological functionality (Ahmed et al., 2013; Rahman & Hasan, 2024). These literatures collectively underscore that persistent land-cover alterations in Rajshahi are significantly diminishing natural carbon sinks, emphasizing the necessity for strategic urban greening and landscape restoration.

4. Conclusions and Policy Implication

The exhaustive examination of alterations in land cover and the capacity of carbon absorption during the period of investigation from 1992 to 2022 reveals many significant findings concerning urbanization patterns and the ecological viability within the city under consideration. The observed trends indicate a significant rise in metropolitan areas, resulting in the reduction of green coverings such as vegetation and water bodies. This trend highlights the swift rate of urban growth and its substantial influence on changes in land use. The high degree of urbanization, namely in the City Center and Eastern Fringe areas, presents difficulties for urban planning, environmental management, and the preservation of biodiversity. The decrease in plant cover and reduction in the capacity to absorb carbon highlight the pressing requirement for sustainable land use practices and activities aimed at restoring ecosystems. The results highlight the complex connection between urbanization and environmental sustainability, underlining the significance of well-planned actions and the creation of eco-friendly infrastructure to improve the capture of carbon dioxide and maintain a healthy ecological equilibrium in metropolitan areas. To tackle these difficulties, it is necessary to employ a

variety of disciplines, involve all relevant parties, and develop methods for long-term planning that promote cities that are resilient, enjoyable to live in, and environmentally sustainable.

The findings indicate that the city of Rajshahi requires immediate targeted policy modifications to enhance its carbon storage capacity. To compensate for the decline in vegetation over the years, urban greening initiatives must be prioritized, particularly regarding the planting of trees in public spaces, along streets, and within residential neighborhoods. By preserving existing green spaces and establishing new urban forests or pocket parks, one can enhance local microclimates and increase carbon sequestration. The city should implement more stringent land-use zoning regulations to prevent the conversion of vegetated and wetland areas into developed spaces. Creating ecological conservation zones, particularly adjacent to aquatic environments and peri-urban green belts, may safeguard vital ecosystem services. Policies for the restoration and protection of wetlands are crucial due to the diminishing number of water bodies, as wetlands significantly contribute to carbon cycling and possess flood resilience. Urban development projects may incorporate regulations for green infrastructure, such as rooftop gardens, vertical greenery, and permeable landscapes. This will assist in reducing the carbon emissions associated with rapid construction. Incorporating regular monitoring through geographic information systems and remote sensing is essential for tracking land cover changes, evaluating the effectiveness of implemented policies, and facilitating data-driven urban planning. By implementing these measures collaboratively, Rajshahi will transition to a more ecologically balanced urban environment capable of effectively addressing the impacts of climate change.

ABSTRACT

This study investigates the mechanisms of chemical burn-on formation on the surface of steel castings produced in sand molds and proposes the application of an anti-burn-on coating based on kaolinite ($Al_2Si_2O_5(OH)_4$, aluminum silicate). The physico-chemical properties of the developed coating are characterized, demonstrating its effectiveness in minimizing burn-on defects on cast surfaces. The application of this coating significantly improves the surface quality of steel castings and enhances the techno-economic efficiency of the foundry process.

Keywords: burn-on; steel castings; burn-on formation mechanism; anti-burn-on coating; foundry defect prevention.

Introduction

The formation of burn-on deposits during steel sand casting remains a significant challenge, adversely impacting the surface quality of castings. Burn-on refers to a tenacious layer where the casting metal surface fuses with molding sand, forming a crust that is difficult to remove and often necessitates additional finishing operations. This defect—categorized as a surface imperfection—arises from complex physical and chemical interactions between the molten metal (and its oxides) and the mold material. Removing burn-on requires extra labor and material, increasing production costs, and also creates environmental concerns due to the cleaning processes (e.g. abrasive blasting, grinding). During steel casting in sand molds, intense thermal exposure causes the molten metal to adhere firmly to sand grains, leading to a burn-on layer that mars the casting surface and must be mechanically cleaned. Addressing burn-on is vital in both mass production and custom casting, especially for complex geometries or components with strict surface requirements.

Chemical burnt on occurs in castings of alloys with a high melting point as a result of complex reactions between casting metal, its oxides and the mold material. Unlike mechanical burning, the sand grains in the burnt layer are bound mainly by the products of chemical reactions occurring at high temperatures, mainly silicates.

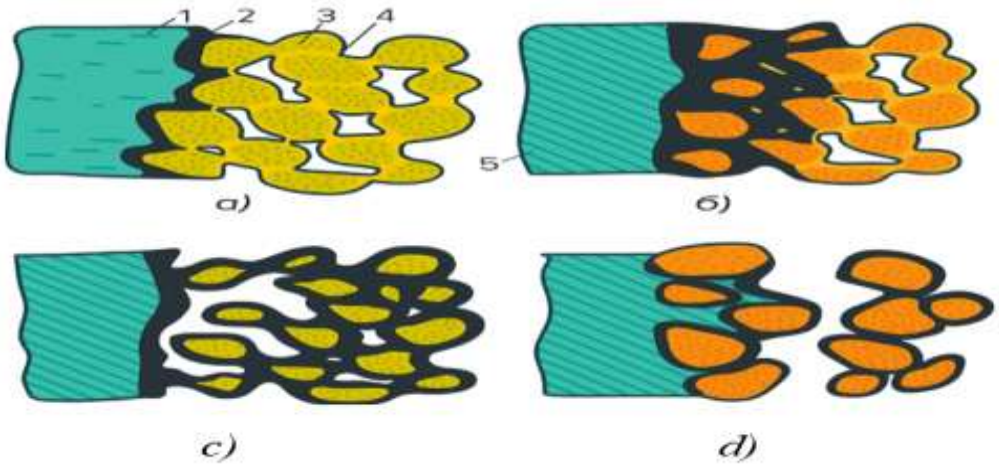
Oxides of alloy components enter the metal-mold interface in two ways: in small quantities - in the form of oxides dissolved in the melt and formed during smelting and filling of the mold, and mainly as a result of oxidation of the hot solidifying surface of the casting. A massive steel casting remains in a hot state longer, and therefore more oxides form on its surface.

It is believed that burn-on does not form in two cases: when the surface of the casting is not oxidized or is very strongly oxidized. Burn-on cannot form on an unoxidized metal surface, since only metal oxides interact with the silica of the mold; interaction of unoxidized metal with silica is unlikely.

For example, in small, rapidly cooling castings, where a thin oxide layer forms on the metal surface, it is sufficient to use a refractory dust or a thin layer of paint to prevent burning-on to prevent direct contact of the metal oxides with the mold silica. It is much more difficult to avoid burning-on on medium-weight castings, where oxides form on the casting surface in larger quantities than on small ones, but still insufficient to obtain an oxide layer of optimal thickness, ensuring the production of an easily removable burn-on.

On thick-walled castings obtained in liquid glass molds without the use of coatings, an easily removable burn-on crust is formed, since steel easily oxidizes and produces a large amount of oxides in the burn-on crust.

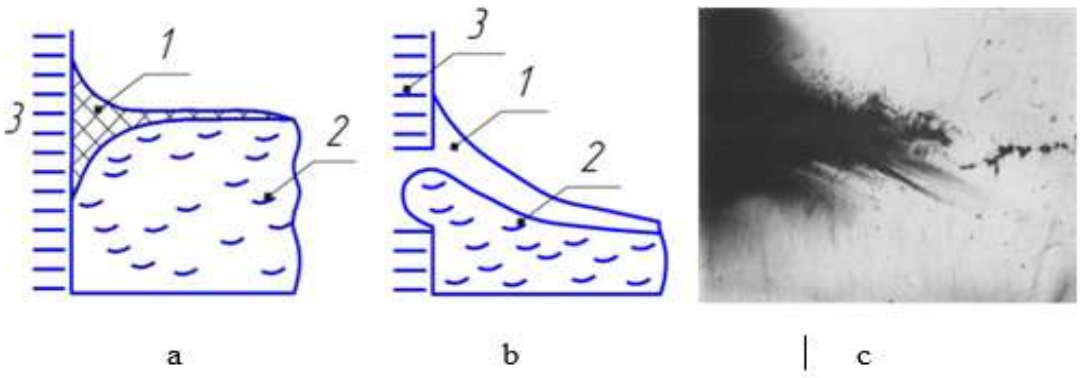
FeO formed on the surface of castings has a melting point of 1380° C, so it can remain in a liquid state for quite a long time on the surface of even a crystallized steel casting. Iron oxides wet quartz sand well and, under the action of capillary pressure, easily penetrate into the pores of the casting mold, reacting with silica: the formation of ferrosilicate from iron (II) oxide and silicon dioxide:



$$2\,FeO + SiO_2 \rightarrow 2\,FeO \cdot SiO_2$$

In alloys with a high manganese content, the formation of burn-on is also promoted by a similar reaction between manganese oxide and silica. As a result, **manganosilicate ($2MnO\ SiO_2$) is formed** - a typical component of slags in ferromanganese smelting and in foundry production.

$$2MnO + SiO_2 \rightarrow 2MnO \cdot SiO_2$$



The low-melting silicates fayalite formed as a result of these reactions ($2FeO \cdot SiO_2$) and tephroite **($2MnO \cdot SiO_2$)** after hardening cements sand grains into layers of burnt-on material.

The mechanism of burnt-on formation

Drawing 1. Formation of chemical burnt-on

The formation of chemical burn-on is represented as follows. After pouring the mold, the surface of the casting 1 is covered with a layer 2 of oxides and iron silicates (drawing 1, a: 3 - quartz grains, 4 - film of the fastener). The rate of oxidation of the steel at the first moment after solidification of the casting 5 (Fig. 1, b) in the presence of a large amount of free oxygen in the pores of the mold is high, the resulting oxide melt accumulates in the boundary surface, increasing the relative contact area of the casting and the mold. Some of the melt penetrates deep into the mold between the sand grains, forming and binding the burn-on crust with the casting (see Fig. 1, b). Subsequently, oxidation of the casting surface slows down sharply due to a decrease in the oxidizing capacity of the gases in the mold and a decrease in the temperature of the metal, the rate of formation of a new oxide melt on the boundary surface becomes less than the rate of its migration into the molding mixture, and a gap appears between the casting and the mold (see Fig. 1, c). In this case, the relative area of contact between the metal and the mold decreases see Fig. 1,d). Drawing 2 shows the formation of a burn-on pattern.

Drawing 2. Scheme of formation of burnt-on: 1-burnt-on, 2-liquid metal, 3-sand form ; a- initial stage; b – formation of burnt-on; c – natural appearance of the surface layer of the casting

Recently, the following main ways of preventing chemical burn-on have been considered: protecting the metal in the casting mold from oxidation; creating an oxide film of optimal thickness between the surface of the casting and the burn-on crust in order to obtain an easily separated burn-on; using coatings and molding materials with increased fire resistance and chemically inert to the metal and its oxides. Based on the research results, practical recommendations were developed to prevent burning on carbon steel castings

When producing castings with a wall thickness of up to 10-12 mm, it is more expedient to obtain a poorly developed burn-on stage *a* (see Fig. 1), for which it is necessary to add organic substances to the mixture that form reducing gases (bitumen, fuel oil, coal dust, etc.), slowing down the oxidation of the metal and, consequently, the onset of stage *b* in the structure of the burn-on (see Fig. 1). On castings with walls of 10-35 mm, due to the long time of exposure to high temperature, the process develops to the stage of a hard-to-remove burn-on (see Fig. 1 *b*). Organic additives are already ineffective here, but coatings based on marshalite, alumina, zircon, corundum, aluminum powder again allow obtaining a poorly developed burn-on. Castings with a wall thickness of over 35 mm are obtained with an easily detachable burn-on, since the processes pass to stage *c*. Additives to the mixture that create reducing gases that can delay the development of processes at stage *b* are harmful in this case. Clays, feldspars, slags, etc., that increase viscosity and reduce the rate of migration of the contact melt into the mold, are undesirable. When using sand-clay mixtures for castings with a wall thickness of up to 20-25 mm, clay and dust must be removed from the original sand; the molding mixture must not contain residues of liquid glass mixture, impurities of iron ores, feldspars and other easily sintered fluxes. Additive in a mixture of low-ash substances (fuel oil, bitumen solution) gives positive results. Small 0.2-2% additives to the molding mixture of Mg_2 CO_3, NaCl and other salts, as well as the replacement of clays with bentonites create conditions for obtaining; easily removable burnt-on. It is recommended to cover casting molds with walls of 25-50 mm with paints or pastes based on marshalite, zircon, corundum, etc. How at such thicknesses of castings, a difficult to separate stage occurs: burning *b*(see Fig. 1).

The outer spherical surfaces of castings with walls of 50-70 mm are obtained with easily separated burnt-on (see Fig. 1). Here the shrinkage of the metal and the strength of the mold in a hot state, which is facilitated by the gap, have an effect. The strength of the mold at high temperatures can be increased by adding liquid glass, iron ores and other fluxes to the initial mixture. It is recommended to cover the inner surfaces of such castings with pastes or facings based on zircon, corundum, chrome-magnesite and magnesite.

In forms made of sand-oil and sand-resin mixtures, castings with a wall thickness of up to 15-25 mm are obtained with a poorly developed burn-on. In this case, the sand must be cleaned of clays and other fluxes, and the fasteners must not leave a lot of ash after burning out. Thicker-walled castings should be made using highly refractory coatings of marshalite, zircon (for walls of 30-60 mm) and corundum, chromomagnesite, magnesite (for walls thicker than 60 mm).

When the critical pressure of the metal in the mold is exceeded, either finer-grained sands or special fine-grained highly refractory materials should be used in the form of coatings and facings on the molds. The nature of the atmosphere in the mold after pouring when using The effect of the listed highly refractory materials is less noticeable than when using quartz sand. With an increase in the oxidizing capacity of gases, the refractory resistance of the non-stick coating, especially based on marshalite and zircon, only slightly decreases. Measures to eliminate burning come down to selecting the type of coating depending on the wall thickness. For casting molds with a wall thickness of 20-25 mm, marshalite paints are sufficient. Casting

molds with walls of 25-50 mm require coating with paints or pastes based on alumina, zircon or corundum.

Use of non-stick paints. Radical measures to combat burning include applying silicate-based paint to the surface of the mold. and aluminum **kaolinite** $Al_2 Si_2 O_5 (OH)_4$, pastes and rubs. Kaolinite is a crystalline **clay mineral** that is **a hydrated aluminosilicate.** Aluminum silicate has high heat resistance, is **a refractory filler**, and can withstand temperatures above 1500 °C. It contributes to the smoothness of the casting surface. It is used as a base for water and alcohol suspensions in non-stick coatings applied to molds and rods in metal casting. It forms a dense **heat-protective screen** between the metal melt and the mold. It is chemically inert, does not interact with the metal, preventing **burning.** It is well distributed over the mold surface and creates a smooth protective layer.

As the temperature increases, kaolinite **dehydrates ,** turning into metakaolin, then into mullite and amorphous silica. This leads to **Formation of a dense, ceramic crust** resistant to thermal shock. The resulting layer **reduces the heat flow** from the molten metal to the mold. This **reduces the risk of thermal cracking** and damage to the mold. Kaolinite **does not react with iron, steel, cast iron and alloys ,** preventing the formation of chemical burn-on. The compacted kaolin layer **limits the penetration of metal into the pores of the mold** and protects against sand sintering. After contact with the metal, the kaolin layer **facilitates the removal of the casting ,** reducing the need for cleaning. Additional components for paints are also used, which are shown in Table 1.

Table 1. Components included in the non-stick mixture.

Component	Purpose
aluminum silicate **kaolinite** $Al_2 Si_2 O_5 (OH)_4$.	**aluminosilicate clay** or **kaolin clay .**
Water/alcohol	Dispersion medium (water/alcohol based)
Surfactants	Improves spreadability and wettability
Fine dispersed ceramics	Increases the strength of the coating
Sodium/potassium silicate	A binder that fixes the coating

Highly refractory powders applied to the surface in the form of paints or pastes isolate the grains of quartz sand from contact with the poured metal and prevent its penetration into the pores of the mold. This prevents chemical interaction of quartz with iron oxides and the formation of burn-on. An important criterion for the properties of non-burn-on materials is the degree of their wetting by liquid metal and its oxides.

To prevent burning, the grain base of the coatings is selected so that it is not wetted by the liquid metal and, if possible, its oxides. It must match the poured alloy and the mold material; basic oxides of the alloy cannot be combined with an acidic grain base of the coating and vice versa. It is unacceptable to use two fillers in the paint that can chemically interact with each other. The fire resistance of the paint filler must be higher than the temperature of the poured alloy. Therefore, many industries use paints made of highly refractory materials, despite their high cost, since the increased costs of preparing high-quality coatings are offset by improving

the marketable appearance of castings and reducing the costs of their cleaning. Figure 3 shows the condition of a steel casting before and after using a kaolin-based dye.

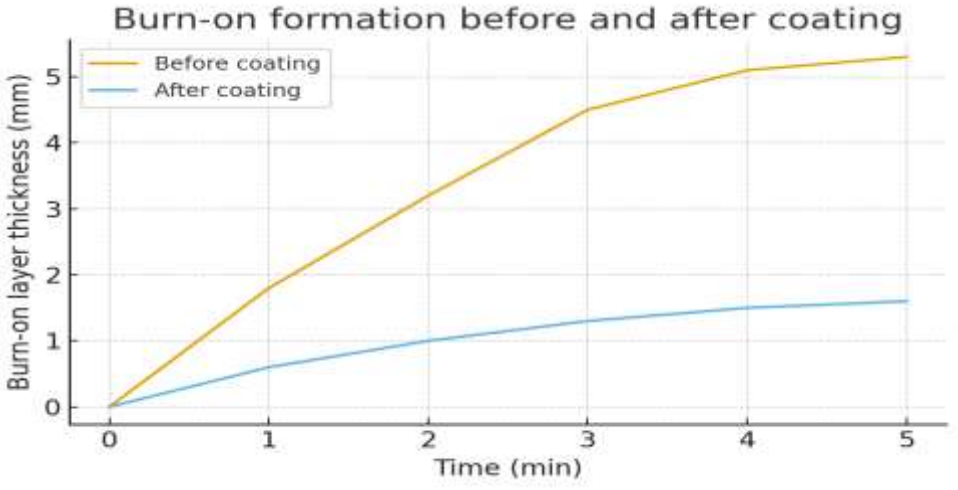


Figure 3. Casting surface before and after application of anti-stick mixture.

The following requirements are imposed on the binders: maximum retention of strength at high pouring temperatures (thermal resistance); thermoplasticity at drying and pouring temperatures; to prevent peeling and cracking of the coating; minimum gas formation.

Therefore, for obtaining castings with a high-quality surface, binding materials with high heat resistance (both organic and inorganic), which minimally interact with iron oxides, are very promising.

In the production of large and thick-walled castings, the surface of the molds is heated to 1000° and more. Therefore, it is necessary to add inorganic binders to the paints, which are distinguished by higher heat resistance than organic ones. These include liquid glass, sulfates, phosphates, etc. A distinctive feature of coatings with phosphate binders is high adhesion strength to the painted surface when pouring metal, low gas-forming capacity, high heat resistance and fire resistance, worsens the wetting of the coatings with metal and its oxides. Graph 1 shows the appearance of burnt food before and after applying a non-stick coating.

At present, there are no universal coatings for casting molds that would give the required effect on all types of casting. All known coatings show their positive effect only in a certain temperature range, with a given composition of the molding mixture and on a specific type of casting. Therefore, along with the paints produced, enterprises produce their own coatings of different compositions for certain types of casting, and they do not go beyond the boundaries

of this enterprise. The main disadvantage of this method is the complication of the technology. Table 2 shows the data after using non-stick paint.

Table: Comparison of casting conditions **before and after application** of aluminum silicate based non-stick paint

Parameter	Before applying paint	After applying paint
Surface type	Rough, with burnt marks	Smooth, clean
Presence of burnt-on residue	Often present (10–50% of area)	Virtually absent (0–5%)
Need for cleaning	High (grinding, sandblasting)	Minimal or none required
Casting defect rate	5-15%	Less than 1%
Labor costs for processing	Elevated	Reduced by 30-50%
Material consumption	Uncoated: up to 5% for cleaning	Coated: savings in the production cycle
Casting extraction speed	Delays due to sticking	Quick Extraction
Mold/core life	Reduced due to aggressive contact	Increased by a protective layer

Conclusion

This study examined the mechanism of chemical burn-on formation in disposable sand casting molds. Scientific investigations have demonstrated that burn-on is a dense, adherent layer formed on the surface of steel castings as a result of high-temperature chemical interaction between metal oxides (FeO, MnO) and silica (SiO_2) present in the molding sand. During casting, the surface of the steel undergoes oxidation, leading to the formation of liquid iron oxides (FeO), which exhibit high wettability with quartz sand. This phenomenon results in the penetration of oxides into the mold structure, cementing the sand grains and forming a persistent surface defect known as burn-on.Burn-on significantly deteriorates the surface quality, dimensional accuracy, and integrity of steel castings. Various methods, protective coatings, and additives are employed in foundry practice to minimize or eliminate this defect.

The article focuses on the application of an anti-stick coating based on aluminum silicate — kaolinite ($Al_2Si_2O_5(OH)_4$) — applied to the surface of disposable sand molds. Kaolinite has proven to be effective in reducing chemical burn-on, enhancing casting quality, lowering production costs, and forming a thermally stable and chemically inert barrier between the molten metal and the mold material.

Аннотация. В данной работе исследованы механизмы образования химического пригара на поверхности стальных отливок при формовании в песчаные формы и предложено противопригарное покрытие на основе каолинита ($Al_2Si_2O_5(OH)_4$, силиката алюминия). Охарактеризованы физико-химические свойства разработанного покрытия, показывающие его эффективность в минимизации образования пригара на отливках. Применение данного покрытия повышает качество поверхности стальных отливок и повышает технико-экономическую эффективность литейного производства,

ABSTRACT

In the context of a global extinction crisis occurring at an unprecedented rate, traditional conservation strategies focusing on single species are increasingly revealing fundamental limitations in addressing complex, systemic drivers of degradation. This research report, titled “Beyond Species,” conducts a comprehensive Systematic Literature Review (SLR) on the paradigm shift toward Integrated Landscape Management (ILM) and ecosystem-based approaches in biodiversity hotspots, with a specific focus on Vietnam and Southeast Asia. Based on a synthesis of hundreds of academic papers, technical reports, and field data from the 2015–2025 period, this study delves into five key pillars: the rationale for the paradigm shift, the technological revolution in monitoring, the effectiveness of community governance models, ecological financial mechanisms, and national policy frameworks. Findings indicate that while species-focused approaches remain foundational for urgent recovery goals, long-term sustainability requires managing “functional biodiversity” and ecological processes (such as gene flow and nutrient cycling) beyond the boundaries of isolated protected areas. In Vietnam, the Payment for Forest Environmental Services (PFES) mechanism has achieved significant financial success but faces major challenges regarding "additionality" and actual conservation effectiveness due to a lack of strong linkages with biodiversity indicators. Simultaneously, the explosion of advanced monitoring technologies such as environmental DNA (eDNA) and Artificial Intelligence (AI) is ushering in an era of biological data transparency, enabling the detection of cryptic species and automating big data analysis. However, barriers regarding technical capacity and a lack of standardized reference libraries are stifling this potential. The report concludes that to achieve the goals of the Kunming-Montreal Global Biodiversity Framework by 2030, Vietnam needs a structural transformation: from fragmented administrative management to integrated governance, institutionalizing the

role of community co-management, and applying digital technology to quantify the true value of "natural capital."

Keywords: Integrated Landscape Management (ILM), Biodiversity Hotspots, Environmental DNA (eDNA), Artificial Intelligence (AI), Payment for Ecosystem Services (PFES), Vietnam.

1. INTRODUCTION: THE URGENCY OF A NEW PARADIGM

1.1. The Anthropocene context and biodiversity crisis

We are living in the Anthropocene, a geological epoch where human activity has become the dominant force shaping the Earth's biological and geographical systems. One of the most tragic characteristics of this era is the catastrophic decline of global biodiversity, often referred to as the "Sixth Mass Extinction." Unlike previous extinction events caused by natural disasters, the current crisis is driven by a combination of factors, including land-use change, overexploitation of resources, climate change, pollution, and the invasion of alien species (Tobias et al., 2025).

For decades, the dominant conservation model was "Fortress Conservation," which focused on strictly zoning protected areas to separate nature from humans, often prioritizing the protection of charismatic megafauna, such as tigers, elephants, or rhinos. While this model has prevented the extinction of certain specific species, it has increasingly proven insufficient in dealing with systemic and transboundary threats. Focusing solely on lists of threatened species (like the IUCN Red List) while ignoring complex ecological interaction networks—known as "functional biodiversity"—is leading to "empty forests," where trees remain, but the animals performing ecological functions (such as seed dispersal, pollination) have vanished (Tilker et al., 2019).

The concept of "Beyond Species" emerges from this context. It does not deny the importance of species protection but proposes a scaling up of management: from individuals to populations, from species to ecosystem functions, and from isolated protected areas to integrated landscapes where humans and nature coexist (Tobias et al., 2025).

1.2. The Indo-Burma biodiversity hotspot and focus on Vietnam

This study focuses on Southeast Asia, particularly the Indo-Burma biodiversity hotspot, one of the biologically richest yet most severely threatened regions on the planet. Vietnam, located entirely within this hotspot, is a prime example of the tension between rapid economic development and natural resource conservation.

Vietnam ranks 16th in the world for biodiversity, with over 50,000 identified species, including thousands of endemic species found nowhere else. However, this richness is rapidly eroding. Recent reports indicate that 21% of mammals, 6.5% of birds, and 38% of freshwater fish species in Vietnam are threatened with extinction (WWF Vietnam, 2021). Habitat loss due to the conversion of forests to agricultural land (especially industrial crops like coffee, rubber, and acacia), combined with illegal hunting and wildlife trade, has pushed many species to the brink. The extinction of the Javan Rhinoceros in Vietnam in 2010 was a painful wake-up call regarding the failure of old conservation mechanisms against exploitation pressures (UNDP Viet Nam, 2018).

The Vietnamese government has demonstrated strong commitment through the enactment of the Law on Biodiversity (2008), the Law on Forestry (2017), and most recently, the National Biodiversity Strategy to 2030, Vision to 2050 (NBSAP) (Ministry of Natural Resources and Environment, 2022). However, a significant "implementation gap" exists between policy and practice, stemming from institutional barriers, a lack of sustainable financial resources, and limitations in scientific monitoring capacity (T. T. Pham et al., 2022).

1.3. Research objectives and questions

This report aims to synthesize and analyze the latest scientific evidence to provide a comprehensive view of integrated approaches in biological resource management. The goal is

not just to list problems but to identify transformative solutions capable of reversing biodiversity decline.

The core Research Questions (*RQs*) include:

RQ1: What strategies and theoretical frameworks are shaping the shift from single-species conservation to integrated ecosystem management in biodiversity hotspots?

RQ2: How is the Industry 4.0 technology revolution (eDNA, AI, Remote Sensing) changing the capacity for monitoring and managing biological resources?

RQ3: What are the specific challenges and barriers in implementing conservation policies in Vietnam, particularly institutional fragmentation and resource allocation?

RQ4: What role do local communities play in the integrated management model, and how do mechanisms like Co-management and Payment for Ecosystem Services (PES) truly deliver social and ecological effectiveness?

RQ5: What policy implications are necessary to realize the goals of NBSAP 2030 and the Global Biodiversity Framework?

2. METHODOLOGY AND THEORETICAL FRAMEWORK

2.1. Systematic Literature Review (SLR) process

This study applies the Systematic Literature Review (SLR) method based on the principles of the PRISMA statement (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) to ensure transparency, objectivity, and reproducibility. The SLR process allows for the synthesis of fragmented evidence from various fields—from molecular biology and computer science to environmental economics and political science—into a unified analytical framework.

Search and Selection Strategy:

Literature searches were conducted on reputable academic databases (Scopus, Web of Science, Google Scholar) and grey literature repositories of international organizations (IUCN, UNDP, WWF, FAO, World Bank, GIZ, Vietnam government organizations). Search keywords were built around key thematic clusters:

Management themes: "integrated landscape management", "ecosystem approach", "biological resource management", "nature-based solutions".

Technology themes: "environmental DNA", "eDNA", "artificial intelligence in conservation", "camera trapping", "remote sensing", "bioacoustics".

Social/Policy themes: "community-based management", "payment for ecosystem services", "PFES", "co-management", "biodiversity governance".

Geographic scope: "Vietnam", "Southeast Asia", "Indo-Burma hotspot", "tropical ecosystems".

Selection criteria included: *(1)* Documents published from 2015 to present (to ensure currency in technology and policy); *(2)* Documents written in English; *(3)* Studies with empirical data or specific policy analysis related to tropical or developing regions. Editorials without data, general textbooks, and studies prior to 2015 (except for original legal texts) were excluded.

2.2. Theoretical framework: From species to systems

This report is built upon the integration of three main theoretical frameworks:

1. Ecosystem approach: Adopted by the Convention on Biological Diversity (CBD), this is a strategy for the integrated management of land, water, and living resources that promotes conservation and sustainable use in an equitable way. This theory emphasizes that humans are an integral component of ecosystems, and management must consider impacts across multiple spatial and temporal scales (Triyanti et al., 2024).

2. Socio-Ecological Systems (SES): The SES framework views the interaction between biological factors (forests, species, water sources) and social factors (communities, markets, institutions) as a complex adaptive system. The sustainability of biological resources depends on the resilience of this entire system to external shocks such as climate change or market fluctuations (Dung et al., 2016; Dung et al., 2022; Mai & Kim, 2025).

3. Integrated Landscape Management (ILM): ILM is the practical application of the Ecosystem Approach in planning. It seeks to optimize diverse benefits (food, livelihoods, conservation) within the same landscape through coordination among multiple stakeholders. This framework helps resolve land-use conflicts—for example, between hydropower development and watershed protection—which are very common in Vietnam (Uetake et al., 2019).

3. "Beyond Species": Strategic shift in resource management

3.1. Limitations of species-focused conservation

While species-specific programs have achieved certain successes, they often face systemic limitations. First, protecting a single species does not guarantee safety for the entire ecosystem if foundational ecological processes are disrupted. For instance, protecting elephants without protecting their migration corridors leads to human-elephant conflict and genetic degradation due to population fragmentation (Tobias et al., 2025).

Second, species-focused strategies often overlook "non-charismatic" species that play critical ecological roles, such as fungi, insects, or soil microbes. Recent studies using hyperspectral remote sensing combined with soil eDNA have shown that microbial biodiversity correlates closely with vegetation health and forest resilience, yet this group is largely absent from traditional management plans (Skidmore et al., 2025).

The concept of "Beyond Species" proposes management based on ecosystem function. This means prioritizing the protection of "ecological networks"—such as pollination networks between plants and insects, or nutrient cycles maintained by scavengers (Tobias et al., 2025). Trophic pyramids and energy flow diagrams illustrate that ecosystem integrity depends on the diversity and abundance of organisms participating in these interactions, not just a checklist of present species.

3.2. Integrated Landscape Approach (ILM) in Southeast Asia

In Southeast Asia and Vietnam, ILM is gradually replacing sectoral management approaches. Instead of the Ministry of Agriculture managing crops, the Ministry of Natural Resources managing land, and Forest Rangers managing forests separately, ILM promotes interdisciplinary coordination across a shared landscape unit (e.g., river basin, coastal zone).

A prime example is initiatives in the Mekong Delta, where Nature-based Solutions (NbS) like mangrove restoration are integrated into planning for erosion control and climate change adaptation. This approach not only protects coastal biodiversity but also provides the critical ecosystem service of mitigating wave and storm impacts. However, ILM implementation faces significant difficulties due to administrative barriers. Land-use decisions are often made at the provincial level without inter-regional coordination, leading to the optimization of local

economic benefits (e.g., intensive shrimp farming) damaging the ecological function of the entire region (water pollution, mangrove loss) (Dang et al., 2021; Tun et al., 2025).

Furthermore, ILM requires private sector engagement. Large agricultural companies are beginning to realize that their supply chains depend on landscape health (water sources, soil fertility). Initiatives like "Production-Protection approaches" are being piloted, where companies commit to Zero Deforestation and support farmers in applying sustainable farming practices in buffer zones of protected areas (Denier et al., 2015).

4. THE TECHNOLOGICAL REVOLUTION IN BIODIVERSITY MONITORING

One of the most critical factors driving the "Beyond Species" approach is the emergence of advanced monitoring technologies. These tools help managers overcome the "taxonomic impediment" and collect data at unprecedented scale and precision.

4.1. Environmental DNA (eDNA): Seeing the invisible

Environmental DNA (eDNA) is considered a "game-changer" in biological monitoring. This technique allows for the detection of species presence via genetic material (skin cells, feces, mucus) left in the environment (water, soil, air) without direct observation or capture of animals (Leempoel et al., 2020).

Applications in Vietnam: In the Annamites (Truong Son range), one of the world's densest and most inaccessible forest regions, researchers have used eDNA collected from... terrestrial leeches (iDNA - invertebrate-derived DNA) to detect rare animals. Since leeches feed on the blood of various animals, analyzing DNA in their stomachs provides a comprehensive picture of the mammalian community in the area. This method has helped identify the presence of critically endangered and cryptic species like the Annamite striped rabbit and Saola, species that traditional camera trapping might miss or require immense effort to record (Drinkwater et al., 2021).

Comparison with camera trapping: Comparative research between soil eDNA and long-term camera trapping (9 years) shows that eDNA can detect all mammal species recorded by cameras, while also detecting many small mammals (rats, bats, insectivores) that cameras often miss. This proves eDNA is a powerful complementary tool, offering a more comprehensive view of biodiversity (Leempoel et al., 2020).

SuoiAI project: Recently, the "SuoiAI" project in Vietnam is pioneering the construction of a comprehensive dataset on aquatic invertebrates. By combining traditional sampling with machine learning image analysis, this project aims to automate the identification of bio-indicator species in streams, enabling rapid and large-scale assessment of water quality and ecosystem health. This is a prime example of using technology to monitor species groups often neglected ("Beyond Species" literally moving beyond large mammals) (Vo et al., 2025).

Challenges: However, widespread eDNA application in Vietnam faces a major barrier: the lack of reference libraries. To identify a species from an eDNA sample, a template gene sequence of that species must exist in the database for comparison. Given Vietnam's high biodiversity and many undescribed species, this library remains very incomplete (Leempoel et al., 2020). Additionally, hot and humid tropical conditions cause DNA to degrade quickly, requiring strict and costly sample preservation protocols.

4.2. Artificial Intelligence (AI) and monitoring automation

The explosion of data from camera traps, bioacoustics recorders, and satellites has created a new challenge: data overload. AI is solving this problem by automating processing and analysis.

Computer vision in camera trapping: Deep Learning models, particularly Convolutional Neural Networks (CNNs) like ResNet, YOLO, or MobileNet, are being trained to automatically recognize animal species in millions of camera trap images. Studies show these models can achieve over 90-99% accuracy in species classification, significantly reducing human time and effort (Song et al., 2025). In Vietnam, this technology is used not only for animals but is also being developed to identify precious timber species to control illegal logging.

Bioacoustic monitoring: AI is also applied to analyze forest audio recordings, helping detect calls of birds, gibbons, and even gunshots or chainsaws in real-time. This allows managers to react quickly to threats (Kerry et al., 2022).

Multi-source data integration: The modern trend is integrating AI with spatial data (GIS) and eDNA to create more accurate species distribution prediction models. For example, the eDITH (eDNA Integrating Transport and Hydrology) model combines hydrological data with eDNA to simulate the transport of genetic material in river basins, helping pinpoint exact locations of animal populations (Mas-Carrió et al., 2022).

4.3. Governance implications of technology

Technology is not just a technical tool but a governance tool. The transparency provided by eDNA and camera trap data can be used to evaluate the effectiveness of conservation interventions. For instance, quantitative camera trap data can prove whether forest patrol teams actually reduce hunting pressure, serving as a basis for results-based payment mechanisms (Microsoft and Planet, 2023).

5. PAYMENT FOR ECOSYSTEM SERVICES (PFES): ACHIEVEMENTS AND LIMITATIONS

Vietnam is a pioneer in Southeast Asia in legislating and implementing a national Payment for Forest Environmental Services (PFES) system through Decree 99/2010/ND-CP (Trædal & Vedeld, 2017). This is a crucial effort to shift from state budget-based management to sustainable market-based financial mechanisms.

5.1. Financial and social effectiveness

PFES has generated a massive and stable revenue stream for Vietnam's forestry sector. Revenue mainly comes from hydropower plants and clean water supply companies, entities that must pay forest owners to maintain water regulation and soil erosion control capabilities (Do et al., 2018).

Livelihood impact: In many localities, PFES money has become a significant income source for households contracted to protect forests, contributing from 16% to 74% of total household income in areas like Cat Tien National Park or Lam Dong (Pham et al., 2021). This has helped raise awareness about forest values and encouraged participation in patrol activities.

Social capital: Research indicates that PFES also contributes to strengthening community cohesion through joint patrol activities and village fund management (Roongtawanreongsri et al., 2023).

5.2. Limitations regarding biodiversity conservation effectiveness

Despite financial success, PFES in Vietnam faces major criticism regarding its actual effectiveness in biodiversity conservation ("Beyond Species").

Lack of additionality: A case study in Dak Lak province showed that after 8 years of PFES implementation, natural forest area continued to decline. The cause is that the payment level is too low (about 20-40 VND/kWh for hydropower) to compete with profits from converting forest land to high-value industrial crops like coffee, pepper, or durian (Do et al., 2018).

Distribution mechanism: The majority of PFES funds (about 90% in some cases) are paid to State Forest Management Boards, while only a small portion (about 10%) reaches communities and households directly protecting forests. This reduces people's motivation (Pham et al., 2021).

Misaligned objectives: Currently, PFES primarily pays based on *forest area* (vegetation cover) rather than *biodiversity quality*. A monoculture acacia forest (low biological value) can still receive environmental service payments equivalent to a species-rich natural forest, provided it meets coverage criteria. This does not incentivize the protection of animals or complex natural forest structures (Pham et al., 2021).

5.3. Towards PFES 2.0

For PFES to truly support biodiversity conservation, strong reform is needed: *Performance-based biodiversity payment:* Pilot models of additional payments for the presence of endangered species or habitat quality are needed, using data from camera traps and eDNA for verification (Microsoft and Planet, 2023). *Revenue diversification:* Expand PFES to other services such as carbon sequestration (C-PFES) and ecotourism to increase payment unit prices, creating sufficient economic incentive to prevent deforestation (Do et al., 2018).

6. Community-based governance and the role of citizens

The "Beyond Species" model cannot be separated from the human element. Local communities, especially ethnic minority groups living in and around protected areas, are the *de facto* managers of resources.

6.1. Community-BASED Forest Management (CBFM) model

Theory on CBFM posits that when communities are empowered with ownership and management of resources, they protect them more effectively than the state due to livelihood and cultural attachment.

Success at Xuan Nha: A pilot model at Xuan Nha Nature Reserve (Son La) demonstrated the effectiveness of combining traditional customary law with formal legal regulations to build village forest protection conventions. Success factors included clear objectives, stable rule systems, and strong support from local people (Phan & Nong, 2024).

General effectiveness: Literature reviews show that community-managed forests often have deforestation rates lower than or equivalent to strictly state-managed forests, but with lower costs and higher social benefits (Bayrak & Marafa, 2020; McElwee et al., 2022; Reyes et al., 2024).

6.2. Institutional and practical barriers

However, implementing CBFM in Vietnam faces many difficulties:

Lack of true ownership: In Vietnam's legal system, especially for Special-Use Forests (SUF), the community's role often stops at "contracted protection" rather than "co-management" with real decision-making power. Forest land allocated to communities is often poor, degraded, and of low economic value, reducing protection incentives (Agarwal et al., 2022).

Gender and social inequality: In many projects, the voices of women and marginalized groups are often drowned out by community elites (elite capture). Although women play a key role in collecting non-timber forest products and managing water, they are rarely involved in village forest management boards (Bayrak & Marafa, 2020; McElwee et al., 2022; Reyes et al., 2024).

Limitations in Marine Protected Areas (MPA): Although the 2017 Law on Fisheries recognized the concept of co-management in protecting aquatic resources, implementation in MPAs like Cu Lao Cham or Phu Quoc remains confused. Coordination mechanisms between MPA Management Boards (state) and fishing communities often lack legal binding and sustainable financial resources (Khuu et al., 2023; Pham et al., 2020; Quyet et al., 2023; Vo et al., 2020).

7. POLICY CHALLENGES AND IMPLEMENTATION GAPS IN VIETNAM

Vietnam has built a massive legal framework for conservation, but implementation effectiveness remains a big question mark.

Institutional fragmentation and conflict of interest: One of the biggest barriers is fragmentation in state management. Responsibility for biodiversity conservation is split between the Ministry of Natural Resources and Environment (MONRE) - responsible for biodiversity policy, and the Ministry of Agriculture and Rural Development (MARD) - responsible for managing the system of special-use forests and marine protected areas. Overlapping functions and lack of coordination between these two ministries often lead to confusion in direction and local implementation (Dung & Tuyet, 2025). Additionally, conflicts between economic development and conservation goals remain intense. Plans for hydropower, transport infrastructure, and tourism often encroach on ecologically sensitive areas. Environmental Impact Assessments (EIA) are often formalities and have not truly prevented projects harmful to biodiversity (WWF Vietnam, 2021).

"Empty forest" syndrome and law enforcement: Although Vietnam's forest cover has increased, forest quality and wildlife populations have declined. Rampant snaring ("snaring crisis") has turned many protected areas into "empty forests," where vegetation remains intact but large mammals and birds have been exterminated (Tilker et al., 2019). Law enforcement capacity remains weak, lacking personnel and equipment, while corruption has reduced the effectiveness of patrol and control work (Pham et al., 2022).

National strategy (NBSAP) and international commitments: The National Biodiversity Strategy to 2030 (NBSAP) sets ambitious goals such as expanding protected area coverage and restoring 20% of degraded ecosystems (Dung & Tuyet, 2025). To achieve this, Vietnam is considering recognizing "Other Effective Area-based Conservation Measures" (OECMs). OECMs present an opportunity to recognize informal conservation areas (such as sacred forests, community watershed forests, military zones) contributing to national conservation goals. However, there are currently no specific technical guidelines to identify and support OECMs (Do et al., 2024; Höffner et al., 2024).

A notable new policy proposal is the establishment of a "Natural Heritage Species" list alongside the endangered/rare species list. This effort aims to elevate the conservation status of endemic species with high cultural and ecological value, creating a stronger legal basis for prioritizing protection resources (Gray et al., 2025).

8. Discussion and implications: Towards the future

Integrating data into decision making: The Data Revolution needs to be translated into policy action. Data from eDNA and AI should not just reside in scientific papers but must be integrated into national biodiversity reporting systems. Building a centralized national database, standardizing eDNA sampling protocols, and sharing data between research and management agencies are urgent steps (Leempoel et al., 2020).

Restructuring conservation finance: The conservation finance model needs to shift from dependence on state budgets and international aid to blended finance mechanisms. Reforming PFES to pay for biodiversity outcomes, combined with carbon credit markets and green bonds, can generate breakthrough resources. However, equitable benefit-sharing mechanisms must be ensured so that local communities truly benefit and become active conservation partners (UNDP Viet Nam, 2018).

Substantive empowerment for communities: "Beyond Species" also means "Beyond Government." Conservation cannot succeed without the participation of civil society and communities. Co-management rights need to be institutionalized in the Law on Biodiversity and Law on Forestry, granting legal and financial power to community groups managing OECMs and buffer zones.

9. CONCLUSION AND RECOMMENDATIONS

This study confirms that the "Beyond Species" approach—integrating species management, ecosystem function, modern technology, and human communities—is the only path to secure a future for biodiversity hotspots like Vietnam. The shift from isolated conservation to integrated landscape management is happening but needs acceleration through institutional reforms and technology investment.

Based on the analysis, the report proposes the following recommendations:

Policy: Rapidly issue technical guidelines and legal frameworks for OECMs to expand conservation space beyond the formal special-use forest system. Promote substantive co-management mechanisms in National Parks and Marine Protected Areas.

Technology: Invest in building national DNA barcode reference libraries for Vietnamese flora and fauna to maximize the potential of eDNA technology. Apply AI and Digital Transformation in forest patrol and monitoring.

Finance: Reform PFES policy towards "multi-value," integrating payments for carbon sequestration and biodiversity conservation. Increase payment levels to ensure competitiveness with the opportunity costs of other land uses.

Governance: Enhance inter-ministerial coordination between MONRE and MARD through high-level coordination mechanisms or shared data integration. Improve law enforcement capacity to address snaring and illegal wildlife trade decisively.

Only by combining the power of technology, the wisdom of local communities, and the decisiveness of policy can we hope to reverse the extinction wave and preserve the priceless natural heritage for future generations.

List of Tables:

Table 1: Comparison of traditional and modern biodiversity monitoring methods

Feature	Traditional methods (Field surveys, manual camera trapping)	Modern methods (eDNA, AI, bioacoustics)
Target detection	Large mammals, easily observable birds. Hard to detect cryptic, small species.	All taxa (from microbes to large mammals), including cryptic, rare species (Leempoel et al., 2020).
Cost and time	Labor-intensive, long data processing time (manual image sorting).	High initial cost but decreases with scale. Fast processing via automation (Song et al., 2025).
Accuracy	Dependent on expert skill. Prone to misses.	High sensitivity, quantifiable. Dependent on reference libraries (Leempoel et al., 2020).
Environmental impact	Can be invasive (capture, disturbance).	Non-invasive (water/soil sampling), minimal impact on animals (Stephenson et al., 2022).
Applicability	Small scale, localized.	Large landscape scale, continuous real-time monitoring (T. Vo et al., 2025).

Table 2: Summary of barriers and solutions for biological resource management in Vietnam

Sector	Main barriers	Proposed solutions
Institutional	Fragmented management between MONRE and MARD; Functional overlap.	Inter-ministerial coordination mechanism; Unified national biodiversity data.
Financial	PFES does not pay for Biodiversity value; Low payment levels; Inequitable distribution.	PFES 2.0 (Carbon + Biodiversity integration); Green bonds; Community conservation funds.
Community	Lack of true land ownership; Low livelihood benefits; Gender inequality.	Institutionalize Co-management; Recognize community-managed OECMs; Empower women.
Technical	Lack of baseline data; "Empty forests" due to snaring; Weak monitoring capacity.	Apply eDNA/AI; Establish intelligent patrol systems (SMART); Strengthen law enforcement.

ABSTRACT

The field of engineering, a cornerstone of global innovation, remains a sector where gender inequality is widely experienced, despite housing a large number of talented female professionals. This study aims to comprehensively examine this issue, starting from the premise that achieving gender equality in the engineering profession is an ethical imperative and a critical strategic priority for the industry to realise its full potential. The study aims to provide a concrete and actionable roadmap for reversing inequality. In this paper, concrete indicators of gender inequality will be identified by comparing the representation rates of female engineers in employment, promotion, salary, and leadership positions from education to the highest levels of their careers with current data. In the second phase, structural, cultural, and psychological barriers (including social prejudices, a lack of role models, and difficulties with work-life balance) that hinder women's entry, retention, and advancement in this field will be analysed in depth. Finally, solution-oriented and actionable strategies will be developed in light of best practices and success stories from international literature. The paper's findings seek the source of inequality in engineering, not only in individual preferences but also in the barriers imposed by institutional and social structures. By clarifying existing inequality indicators, the potential negative impacts of the sector's lack of diversity on innovation and economic performance will be highlighted. Ultimately, this research lists actionable steps for educational institutions, the private sector, and policymakers to create fair and equal opportunities in the engineering profession. The study aims to trigger a comprehensive transformation in the engineering sector by encouraging the participation of female engineers and establishing inclusivity as a core value.

Keywords: Gender Equality in Engineering, Women Engineers, Diversity, Career Barriers

1. Introduction

The historical underrepresentation of women in STEM (Science, Technology, Engineering, and Mathematics) fields is a direct result of centuries-old cultural biases and systemic barriers. Due to social restrictions and institutional structures, women's contributions to these areas have been marginalised, which has limited the effective utilisation of potential human capital. Even pioneering figures like Marie Curie, who revolutionised radioactivity, and Ada Lovelace, who developed the first machine algorithm, often faced scepticism and limited recognition in their time (Gjersoe, 2018; Holman et al., 2018; Rubiano-Matulevich et al., 2019; Lee & Lee, 2025). While these successful individuals represent the exceptions of their time, ensuring gender diversity in STEM fields is a mandatory economic requirement in today's global economy to promote innovation, maximise productivity, and support sustainable economic growth. Diverse teams are better able to handle complicated challenges because they contribute a range of ideas and techniques, according to research (Jones et al., 2020).

The presence of women in the STEM fields, where innovation and adaptability are indispensable, brings in unique views that enhance collaboration. The presence of women in STEM fields also has a direct impact on the economy. A study conducted by the World Economic Forum indicated that if gender equality were realised in STEM fields, global GDP would be augmented by trillions of dollars, especially by reducing the labour shortage in the areas of high-demand technical professionals (Bell et al., 2011; Gómez-Zará et al., 2022). Taking care of this disparity is vital not only for the financial aspect but also for the social development and the prevention of negative technological externalities. Algorithms that are made with no diverse inputs, for instance, can cause market disruptions by unintentional bias reinforcement, such as unrecognised female faces in this case (Afreen et al., 2025; Ho et al., 2025). Thus, reaching gender diversity is not only an essential strategic economic necessity for equitable development, but it is also a pledge to capture human capital effectively and to redistribute that human capital through education, mentorship, and institutional reforms in a way that maximises social welfare. Yet the problem persists, and research into the barriers and the methods for promoting inclusivity has to be continuous. It is very important to understand the historical background, to shape the current debates and steer the future initiatives.

The paper aims to present the situation of women in STEM in terms of obstacles, progress, and possibilities. Even though significant policy changes, improved education, and positive social attitudes have occurred, the gender gap in these areas is still a major issue. This research tries to give a thorough insight into the core problems by looking at the different difficulties that women encounter, such as the institutional obstacles, the cultural biases, the psychological and personal factors, and so on (Galsanjigmed & Sekiguchi, 2023; Mashazi & Nkabinde-Thamae, 2025). The main purpose of writing this article is to point out the advancements in women's empowerment to join and do well in STEM (Science, Technology, Engineering, and Mathematics) careers. Through education reforms, mentorship programs, and international collaborations, gender disparities have been greatly reduced. Nevertheless, the article also highlights the unfair treatment that still exists, especially concerning the areas of leadership and access to the latest technological innovations. Furthermore, the paper outlines useful approaches to building an inclusive ecosystem.

The strategies include technology playing a role in connecting people, improving laws and regulations, and creating friendly places. In addition to the case studies and success stories that are presented, the study also includes examples of how both individuals and groups have worked together to change the environment for women in STEM positively (Alsaleh, 2024; Akanfe et al., 2025; Djatmiko et al., 2025). The aim of the paper is to motivate the different

parties—the researchers, the educators, the lawmakers, and the business leaders—to be more committed to gender parity in the future. It envisages a time when women will have the same chances as men to take part in and profit from the advancements in STEM, thus fostering global innovation and growth.

2. Literature Review

Due to social norms and gender prejudices, women have historically made important contributions to STEM disciplines but have often gone unrecognised. For instance, Ada Lovelace's work on Charles Babbage's Analytical Engine provided the groundwork for contemporary computing. Lovelace is sometimes considered to as the first computer programmer. Her understanding of algorithms extended beyond her period, demonstrating the ability of machines to carry out tasks other than mathematical computations (Zwolak, 2023). In a similar vein, Marie Curie was the first individual to receive two Nobel Prizes for her revolutionary work on radioactivity.

Rosalind Franklin, whose X-ray crystallography was crucial in understanding the double helix structure of DNA, is another prominent woman. Her achievements were overshadowed by those of her male coworkers, who received greater praise despite her crucial role (Franklin & Gosling, 1953; Crouse, 2007). NASA mathematician Katherine Johnson played a crucial role in determining the paths of space missions, including the Apollo 11 moon landing, but until recently, little was known about her. Rigid gender roles enforced by societal standards throughout these times frequently restricted women's access to professional and educational possibilities. Despite their propensity for science, many women were excluded from higher education or forced into administrative positions. Individuals who succeeded in making contributions to STEM were subjected to institutionalised prejudices, where their contributions were frequently disregarded or attributed to male colleagues (Loff, 2016; Jones et al., 2017). Instead of being discouraged by these difficulties, these pioneers cleared the path for later generations. Their tenacity emphasises the necessity of structural adjustments to acknowledge and encourage women's achievements in STEM fields while resolving prejudices that still exist today.

Technological developments and industrial revolutions have had a significant impact on the development of STEM professions, both creating new opportunities and redefining old ones. Mechanisation was brought about by the First Industrial Revolution, which greatly advanced industries like manufacturing and engineering. However, because cultural institutions restricted women to occupations outside of the industrial workforce, these improvements mainly excluded women (Khan et al., 2025)

With its emphasis on electricity and mass production, the Second Industrial Revolution started to make room for women in technical positions. For instance, women entered traditionally male-dominated engineering and manufacturing positions during World War II due to the demand for specialised labour. Although many of them returned to home responsibilities after the war, this was a turning point for women's involvement in STEM (Hirschman & Mogford, 2009; Wyrwich, 2019; Bikse et al., 2022). With the introduction of computing, information technology, and telecommunications, the 20th-century Digital Revolution drastically changed STEM professions. During this time, trailblazing women like Grace Hopper emerged, creating the first compiler and laying the groundwork for programming languages. The STEM environment has continued to be redefined by developments in biotechnology, nanotechnology, and artificial intelligence, opening doors in previously unthinkable disciplines (Kohnke & Zaugg, 2025; Song et al., 2025). Although women now have more opportunities thanks to technical advancements, cultural prejudice and structural restrictions still exist. Women are still

underrepresented in cutting-edge industries like artificial intelligence and quantum computing even today, underscoring the necessity of ongoing reform and campaigning to guarantee equal participation.

3. Gender Gaps Over Decades

Gender disparities in STEM continue despite advancements, which are a reflection of long-standing structural issues. The discrepancy in female involvement rates across STEM fields is seen in both historical and current data. For example, only 7% of American engineering graduates were female in the 1970s, compared to 58% in the life sciences (Charlesworth & Banaji, 2019). Although the number of women pursuing careers in biology and medicine had significantly increased by the 1990s, their representation in computer science and engineering remained below 20% (Verdín et al., 2018; Wang et al., 2023).

While there have been some improvements, recent data still shows gaps. Women accounted for 28% of the STEM workforce worldwide in 2020, with notable regional and discipline-specific differences. While women are nearly 50% more prevalent in the life sciences, they are still disproportionately underrepresented in computer science (around 25%) and engineering (less than 15%) (Meoli et al., 2024; EL-Deghaidy et al., 2025). Just 10% of top positions in STEM-related companies are held by women, demonstrating an even worse underrepresentation in leadership roles (George, 2024). There are a number of reasons why these gaps continue to exist. Girls are discouraged from pursuing STEM education due to societal biases, especially in mathematics and physics. Issues including gender pay disparities and a lack of mentorship opportunities play important roles in workplace environments that frequently lack the inclusion required to retain women (Helman et al., 2020; González-Gallego et al., 2025). Although they have shown potential, efforts to bridge these gaps—such as mentorship programs, diversity initiatives, and targeted scholarships—remain inadequate. In order to achieve gender parity in STEM, it is necessary to address underlying issues such as workplace practices, educational disparities, and cultural attitudes.

4. Obstacles that Women Encounter in STEM

The existing societal and cultural biases linked to women's roles in STEM have further led to the creation of gender stereotypes, which, in turn, adversely affect the entry of women into technical careers. Society has always been pretty clear from the start about the categories of careers that women are supposed to go to those characterised as nurturing or creative, while men are left with the choices of logical and technical fields. The survey conducted by Verdugo-Castro et al. (2023) points, among others, to such prevarications as the main reason that so few girls decide to pursue subjects with low popularity, such as mathematics and physics, especially in the countries of their origin. In addition, a global study encompassing 34 countries has admitted that girls living in places with a strong habit of gender stereotyping would have less ambitious plans concerning STEM jobs, even though their capabilities in these areas would be as good as or better than boys' (Ferreira et al., 2025).

The cultural reinforcement can sometimes be very delicate; for example, the parents' and teachers' unintentional actions could make girls refrain from entering technical careers, or the STEM fields could be presented as "male-dominated" ones. Moreover, the situation is made worse by the media. The women's presence in STEM fields is extremely limited, and mainly in the roles that are either supportive or secondary in the case of popular culture. The idea of "women non-belonging" in STEM is thus strengthened through these representations, which in turn corresponds to the development of women's still very low presence in technical occupations (Froehlich et al., 2022; Sikhosana et al., 2025). Cultural prejudices present extra challenges for women in STEM disciplines in the workplace, such as "double bind" scenarios

where they must strike a balance between conflicting expectations—being forceful enough to take the initiative but not so assertive that they are perceived as unlikable. These barriers not only hinder career advancement but also lead to higher turnover rates among women in technical fields (Ewim & Dosunmu, 2025). Initiatives to overcome these cultural barriers include mentorship programs and coding camps, which encourage young girls to explore STEM careers. Measures to legitimise the presence of women in technical professions are also crucial for dispelling stereotypes and fostering diversity (Martín-Peciña et al., 2025).

5. Barriers from Institutions

Women's advancement in STEM is still hampered by institutional impediments in academia and business. An uneven playing field is caused by structural problems such unequal compensation, few possibilities for career growth, and underrepresentation in leadership positions. According to a study by the American Association of University Women, women in STEM fields make about 20% less than men, even when they have the same credentials and occupations (Górska & Burlakova, 2025). In addition to depressing women, pay disparity indicates a lack of institutional commitment to gender equality.

Disparities in leadership are still another major problem. Despite making up nearly 50% of entry-level workers in several businesses, women hold less than 15% of leadership positions in STEM-related fields worldwide (Galsanjigmed & Sekiguchi, 2023). Biases in promotion procedures, a lack of mentorship opportunities, and the "glass ceiling" phenomenon that limits women's upward mobility are all factors contributing to this disparity. Other obstacles that women encounter in academia include fewer tenure-track jobs and restricted access to research funding. For instance, data indicate that female academics typically receive lower funds than their male counterparts, which restricts their capacity to carry out high-impact studies and obtain recognition (Correa et al., 2025). Additionally, women in STEM areas report greater rates of harassment at work, which raises turnover rates (Litzellachner et al., 2024).

To address these difficulties, institutional measures including fair hiring procedures, diversity training, and transparent pay audits are essential. Women can also overcome structural obstacles and advance in their careers by supporting leadership pipelines and mentorship programs (Corbett et al., 2024).

6. Psychological and Personal Obstacles

Women's experiences and retention in STEM professions are greatly impacted by psychological and personal obstacles such as impostor syndrome and a lack of role models. Women in STEM fields are disproportionately affected by impostor syndrome, which is characterised by feelings of inadequacy and self-doubt despite obvious accomplishments. According to studies, imposter syndrome has affected up to 70% of women in STEM at some time in their careers (Clark et al., 2021).

The information discussed above is often the consequence of working in male-dominated areas, which puts extra pressure on women to prove their worth. The situation gets even more complicated because there are very few visible role models in the STEM field. It is very difficult for lots of women to envision a successful career in technical fields when they cannot find mentors or leaders who have gone through similar situations. A particular research found that girls who have female role models in science and engineering are more inclined to choose STEM careers; however, that exposure is quite limited (González-Pérez et al., 2020; Mansour, 2025). Such mental issues also lead to diminished confidence when it comes to applying for high-stakes projects or taking up leadership positions. It has been found that women only apply for jobs if they meet 100% of the requirements, while men do so even with only 60%

(Fluchtmann et al., 2021). This reluctance on the part of women often leads to their not being considered for promotion opportunities. In order to get through these barriers, it is extremely important to set up support networks and provide women in STEM with mentorship opportunities. Some of the initiatives that are aimed at reducing the impact of impostor syndrome are leadership development, peer groups, and sponsorship programs. Moreover, the presence of women in the STEM fields can be enhanced through conferences, the media, and educational settings, which in turn will grow the self-esteem and encourage the upcoming generation of women to go for it and be the best in these fields (Lee et al., 2024).

7. Ongoing Projects and Efforts

The goal of initiatives to boost women's involvement in STEM education has been to remove obstacles that deter females from pursuing technical fields. Young women's curiosity and self-assurance have been greatly boosted by scholarships, focused programs, and neighbourhood projects. Girls are encouraged to pursue further education in STEM fields by scholarship schemes. Thousands of women around the world have benefited from programs like the L'Oréal-UNESCO For Women in Science Fellowship, which offer financial support and acknowledgement for their contributions to scientific research (Freedman et al., 2023). In a similar vein, regional awards like the Google Anita Borg Memorial Scholarship are designed to bridge the gender gap in technological areas by empowering women in computer science (George, 2024).

Programs for younger girls have just as much of an impact. Girls are introduced to programming, robotics, and business through groups like Girls Who Code and Technovation, which also offer mentorship and practical experience. By addressing the gender gap at a young age, these programs help dispel social preconceptions and develop fundamental skills (Torres-Ramos et al., 2021). As an illustration of the long-term benefits of early intervention, participants in these programs have gone on to win international coding competitions and land internships in prestigious software businesses. Additionally, attempts to include gender-sensitive teaching methods into STEM curricula have gained momentum (Nikghadam-Hojjati et al., 2025). To guarantee a nurturing environment for young students, teacher training initiatives that encourage inclusivity and eradicate gender prejudices are also being implemented globally. In order to ensure that young women see STEM as an accessible and fulfilling professional option, these educational changes must be able to provide them with tools, mentorship, and role models (Bustamante-Mora et al., 2025).

The topic has gained international attention thanks to global initiatives and legislation that support gender equality in STEM, which have also created platforms for cooperation and innovation. Progress has been fueled in large part by regional initiatives in poor nations and organisations like UN Women. Campaigns by UN Women, like Step It Up for Gender Equality in STEM, promote collaborations and legislative changes that support women's involvement in STEM. These efforts highlight the role of institutions and governments in establishing supportive frameworks, such as fair pay, anti-discrimination laws, and access to high-quality education (Lwamba et al., 2022).

Additionally, regional initiatives have made a substantial contribution. Through summer camps, scholarships, and mentoring by female scientists, the Vigyan Jyoti initiative in India encourages high school girls to pursue professions in STEM. Girls' enrollment in STEM programs at prestigious universities has significantly increased since the program's inception (Mehta et al., 2024). In a similar vein, the African Girls Can Code Initiative in Africa prepares young women for jobs in technology and engineering by providing them with digital and technical skills (Awuah et al., 2025).

In industrialised nations, policy frameworks have also been crucial. For example, the Gender Equality Strategy of the European Union uses funding, research grants, and public awareness initiatives to raise the number of women in STEM disciplines. In order to ensure inclusivity in ground-breaking studies, programs such as Horizon Europe offer special financing possibilities for female researchers (Irod et al., 2025). Problems like resource inequality and cultural prejudices still exist in spite of these initiatives. Achieving long-term impact requires bolstering international partnerships and guaranteeing ongoing funding for these projects. This chart highlights the collective efforts for gender equality in STEM by giving a summary of significant international initiatives and their quantifiable results (Işıkgöz et al., 2025).

8. Contributions and Success Stories

Pioneering women have made significant contributions to STEM throughout history, frequently going against social norms to produce ground-breaking discoveries. In addition to advancing scientific knowledge, their accomplishments have opened doors for upcoming generations of women working in technical domains. Ada Lovelace, one of the pioneers, is credited with being the first person to program a computer. The concept of algorithms was first introduced by her work on Charles Babbage's Analytical Engine, which showed that machines were capable of doing more than just basic calculations (Zwolak, 2023). Lovelace's vision established the groundwork for contemporary computers, an industry that still influences society today.

Two-time Nobel laureate Marie Curie transformed the study of radioactivity. In addition to advancing science, her discoveries of radium and polonium had a significant impact on medicine, resulting in the creation of radiation therapy for the treatment of cancer (Shanbhag et al., 2024). Despite working in a setting where men predominated, Curie's accomplishments made her a symbol of excellence and tenacity. Rosalind Franklin was instrumental in the discovery of DNA's structure in the middle of the 20th century. Although her efforts were overshadowed by those of her male peers, her X-ray crystallography study provided the crucial data required to identify the double-helix structure (Freedman et al., 2023). NASA mathematician Katherine Johnson played a crucial role in determining the Apollo missions' paths, guaranteeing the accomplishment of space exploration projects (Johnson, 2020).

These trailblazers serve as examples of the tenacity and intelligence of women in STEM, motivating continued efforts to honour and celebrate their accomplishments. Society may continue to combat prejudices and advance inclusivity in scientific fields by recognising their accomplishments (García-Silva et al., 2025).

Modern women in STEM are spearheading innovative initiatives that tackle some of the most important global issues. Their work demonstrates the revolutionary influence of female leadership in science and technology across a wide range of industries, from renewable energy to artificial intelligence. Renowned computer scientist and AI researcher Fei-Fei Li has led the way in the advancement of artificial intelligence. Her leadership at Stanford University's Human-Centred AI Institute and her work on computer vision provide a strong emphasis on ethical AI development, making sure that advances in technology benefit people (Etchemendy & Li, 2024).

Li's efforts have impacted accessibility, education, and healthcare uses of AI. Katharine Hayhoe is a prominent climate scientist and campaigner in the field of environmental research. Her outreach initiatives have assisted in bridging the knowledge gap between scientists and the general population, and her research on the effects of climate change has influenced international policy (Geiger et al., 2022). The groundbreaking gene-editing technique CRISPR-

Cas9 was co-developed by Dr Jennifer Doudna, another renowned inventor. This discovery has revolutionised genetics, allowing for more precise DNA changes and creating new opportunities in agriculture and health (Gostimskaya, 2022). Doudna has won a Nobel Prize and gained international prominence for her contributions to the advancement of biotechnology. These contemporary innovators inspire the next generation to seek careers in science and technology by demonstrating the potential of women in STEM to bring about significant change.

Conclusion

The various obstacles, advancements, and potential directions for attaining gender inclusion in STEM professions have all been discussed in this article. Women have historically made substantial contributions to STEM, but their presence and success have been constrained by widespread institutional, societal, and personal obstacles. Girls are discouraged from pursuing STEM occupations at a young age due to societal biases and gender stereotypes, and institutional obstacles such as unequal compensation, a lack of leadership chances, and insufficient mentorship further impede women's advancement. Another level of complication is added by personal issues like impostor syndrome and a lack of role models. However, a number of projects aiming at closing these disparities demonstrate improvement. Young women are now more emboldened to pursue STEM education thanks to educational innovations like coding programs and grants.

Mentorship programs and flexible work schedules are two examples of industry initiatives that have improved career advancement and retention. Women now have more access to technology and resources thanks to international initiatives like UN Women's campaigns and regional initiatives in underprivileged areas (Lwamba et al., 2022). Women now have more opportunities to lead and innovate in STEM domains, such as artificial intelligence, quantum computing, and green technology. The STEM ecosystem may become more inclusive by implementing proactive tactics, including legislation changes, community development initiatives, and institutional accountability, guaranteeing that women are not just participants but also leaders in influencing the future. We may imagine a route toward a diverse and equitable STEM landscape that benefits individuals, corporations, and societies equally by tackling systemic impediments and building on recent advancements. Beyond personal success, gender inclusion promotes advancement in society. It gives communities more power, motivates the next generation, and produces role models who dispel misconceptions. Women's achievements in STEM professions have already started to change cultural perceptions, inspiring young girls to pursue careers in traditionally male-dominated fields. It will take consistent work, cooperation, and dedication from all parties involved to achieve gender parity in STEM (Dickson & Alharthi, 2025). We can build inclusive ecosystems and remove structural barriers to ensure that chances in science and technology are not determined by a person's gender in the future.

This change will guarantee that STEM areas continue to develop, innovate, and address the urgent problems of our day in addition to creating a more equitable world. A vibrant, just, and creative global community is built on inclusivity, which is more than just a goal.

ÖZET

Bu çalışma, tarihi yapıların korunmasında dijital teknolojilerin rolünü mimarlık, iletişim ve pazarlama disiplinlerinin kesişiminde ele almaktadır. Günümüzde kültürel miras yapıları yalnızca fiziksel olarak korunmakla kalmamakta; aynı zamanda dijital ortamda belgelenmekte, temsil edilmekte ve sürdürülebilir turizm stratejilerinin merkezinde yeniden konumlandırılmaktadır. Mimarlık açısından çalışma, yapay zekâ destekli 3B tarama, fotogrametri ve BIM tabanlı belgeleme tekniklerinin tarihi yapıların özgün niteliklerini koruma süreçlerine katkısını tartışmaktadır. İletişim perspektifinde, dijital arşivler, artırılmış gerçeklik uygulamaları ve kültürel hikâye anlatımı yöntemlerinin mirasın görünürlüğünü ve toplumsal farkındalığı nasıl artırdığı incelenmektedir. İşletme ve marketing boyutunda ise, tarihi yapıların dijital temsilinin sürdürülebilir turizm markalaşmasına etkisi, destinasyon imajı ve ziyaretçi deneyimi açısından değerlendirilmektedir Sonuç olarak çalışma, dijital koruma teknolojilerinin yalnızca teknik bir süreç olmadığını; kültürel iletişim ve turizm ekonomisiyle bütünleşen çok katmanlı bir dönüşüm olduğunu ortaya koymaktadır.

Anahtar Kelimeler: Dijital Koruma, Kültürel Miras, Yapay Zekâ, AR/VR, Turizm Markalaşması

A NEW PARADIGM IN DIGITAL PRESERVATION OF HISTORIC STRUCTURES: AI-BASED DOCUMENTATION, CULTURAL COMMUNICATION, AND SUSTAINABLE TOURISM BRANDING

ABSTRACT

This study examines the role of digital technologies in the preservation of historic structures through the integrated perspectives of architecture, communication, and marketing. Today, cultural heritage buildings are not only physically conserved but also digitally documented, represented, and repositioned at the center of sustainable tourism strategies. Architecturally, the research discusses how AI-assisted 3D scanning, photogrammetry, and BIM-based documentation contribute to safeguarding the authenticity of historic structures. From a communication standpoint, it analyzes how digital archives, augmented reality applications, and cultural storytelling enhance the visibility and public understanding of heritage assets. In the marketing domain, the study evaluates how the digital representation of historic buildings shapes sustainable tourism branding, destination image, and visitor experience. The paper concludes that digital preservation technologies constitute not merely a technical process but a multilayered transformation intertwined with cultural communication and tourism economics.

Keywords: Digital Preservation, Cultural Heritage, Artificial Intelligence, AR/VR, Tourism Branding

Giriş

Dijital dönüşüm, kültürel miras alanlarında köklü bir paradigma değişimini beraberinde getirmiş; tarihi yapıların korunması, belgelenmesi ve aktarılması süreçleri geleneksel yöntemlerin ötesine geçerek yapay zekâ, 3B modelleme, dijital ikiz teknolojileri ve artırılmış gerçeklik (AR/VR) uygulamalarıyla yeniden tanımlanmıştır (Pocobelli et al., 2018). Tarihi yapıların korunması artık yalnızca fiziksel müdahalelerle sürdürülen bir mimari pratik olmaktan çıkmış; dijital kültürel iletişim, veri temelli belgeleme ve turizm odaklı markalaşma stratejilerini kapsayan çok disiplinli bir alana dönüşmüştür. Günümüzde UNESCO, ICOMOS ve uluslararası araştırma ağları; dijital koruma teknolojilerinin sürdürülebilir kültürel miras yönetiminde kritik bir rol üstlendiğini vurgulamaktadır (UNESCO, 2022). Dijital ikiz sistemleri, yapay zekâ destekli hasar tespit yazılımları, AR destekli deneyim alanları ve dijital arşivleme yöntemleri, hem mimari koruma süreçlerini güçlendirmekte hem de kültürel mirasın toplumsal görünürlüğünü artırarak turizm ekonomisine yeni değerler kazandırmaktadır. Bu çalışma, yapay zekâ destekli dijital belgelemenin teknik boyutlarını, kültürel iletişim stratejileriyle birleşen dijital hikâyeleştirme yöntemlerini ve bunların sürdürülebilir turizm markalaşmasına etkisini bütüncül bir çerçevede ele almaktadır.

1. Kavramsal Çerçeve

1.1. Dijital Kültürel Miras ve Yeni Koruma Yaklaşımı

Dijital kültürel miras, tarihi yapıların dijital araçlar üzerinden belgelenmesi, korunması ve erişilebilir hâle getirilmesini kapsayan yeni bir kavramsal yapıdır. Fotogrametri, lazer tarama, 3B rekonstrüksiyon, dijital arşivleme ve sanal mekân oluşturma gibi yöntemler kültürel mirasın hem fiziksel hem dijital ortamda sürdürülebilir şekilde yaşatılmasını mümkün kılmaktadır (Almeida & Ferreira, 2021).

Bu yaklaşım üç temel dönüşüm üretmektedir:

- **Teknik dönüşüm:** Yüksek doğruluklu 3B modeller, veri temelli hasar analizi, dijital ikiz üretimi.
- **Toplumsal dönüşüm:** Mirasın daha geniş kitlelerce erişilebilir ve anlaşılır hâle gelmesi.
- **Ekonomik dönüşüm:** Dijitalleştirilmiş mirasın yeni deneyim formatlarıyla turizm değerine dönüşmesi.

1.2. Yapay Zekâ Destekli Mimari Belgeleme

Yapay zekâ, kültürel miras belgeleme süreçlerinde yeniden yapılandırmayı hızlandıran ve doğruluk oranını artıran bir teknoloji olarak öne çıkmaktadır.

AI tabanlı uygulamalar:

- Yüzey bozulmalarını ve çatlakları otomatik sınıflandırır,
- Fotogrametrik verileri derin öğrenme ile işler,
- Eksik tarihi öğeleri tahmini modellerle tamamlar,
- Lazer tarama verilerinden saniyeler içinde 3B model çıkarır,
- Restorasyon için dijital karar destek sistemi sunar (Giusti & Calantropio, 2020).

Bu süreç, kültürel miras korumasında **hız, doğruluk ve maliyet avantajı** sağlayarak restorasyonun planlama aşamalarını kökten değiştirmektedir.

1.3. Dijital Kültürel İletişim ve Turizm Markalaşması

Tarihi yapılar yalnızca belgelenmekle kalmaz; dijital iletişim stratejileri sayesinde hikâye anlatımı yoluyla yeniden anlam kazanır. AR/VR deneyimleri, sanal müzeler, dijital turlar, mobil uygulamalar ve sosyal medya içerik stratejileri, kültürel mirası yeni kuşaklara aktarmada güçlü araçlar hâline gelmiştir (Pescarin, 2018).

Bu yaklaşım turizm alanında üç temel etki yaratır:

1. **Destinasyon Kimliği:** Dijital deneyim, tarihi yapıyı markasal bir değer unsuruna dönüştürür.

2. **Ziyaretçi Deneyimi:** Dijital rehberlik, interaktif hikâyeler ve sanal keşifler ziyaretçinin mekânla duygusal bağını artırır.

3. **Sürdürülebilirlik:** Fiziksel aşınma riskini azaltır, turizmin mekân üzerindeki baskısını düşürür.

Dijital temsil, tarihi yapıyı küresel görünürlüğe taşıyarak turizm markalaşmasını destekleyen stratejik bir araç hâline gelir (Yung & Chan, 2022).

2. Yöntem

Bu araştırma, nitel araştırma yöntemlerinden literatür taraması, kavramsal analiz ve disiplinler arası karşılaştırmalı inceleme tekniklerine dayanmaktadır.

Tarama sürecinde:

- Mimarlık: Dijital belgeleme ve yapay zekâ tabanlı koruma yöntemleri
- İletişim: Dijital kültür, AR/VR iletişimi, hikâyeleştirme stratejileri
- İşletme/Marketing: Turizm markalaşması, destinasyon imajı, dijital deneyim pazarlaması

alanlarında 2018–2024 yılları arasında yayımlanan uluslararası makaleler incelenmiştir.

Veriler Web of Science, Scopus, SpringerLink ve Google Scholar üzerinden toplanmış; bulgular konu başlıklarına göre tematik analizle sınıflandırılmıştır.

3. Bulgular

3.1. Yapay Zekâ Destekli Belgelemede Paradigma Değişimi

Araştırma bulguları, yapay zekâ tabanlı dijital belgeleme tekniklerinin kültürel miras koruma alanında devrim niteliğinde bir dönüşüm yarattığını göstermektedir. Geleneksel yöntemler; insan gözüne dayalı gözlem, manuel çizim, sınırlı hassasiyete sahip fotogrametik ölçümler veya uzun süren CAD tabanlı modelleme süreçleri gibi aşamalar içerirken, yapay zekâ destekli modeller hem zamansal hem ekonomik hem de teknik açıdan çok daha üstün performans sergilemektedir.

Derin öğrenme algoritmaları, fotogrametri ve lazer tarama çıktılarındaki milyonlarca veri noktasını saniyeler içerisinde işleyebilmekte; yüksek çözünürlüklü 3B dijital ikiz modeller üreterek yapıların özgün detaylarını birebir yansıtabilmektedir (Giusti & Calantropio, 2020). Bu sayede:

- **Hasar tespiti otomatikleşmiş**, çatlaklar, nem lekeleri, deformasyonlar ve malzeme kayıpları AI tarafından birkaç saniyede sınıflandırılabilir hâle gelmiştir.

- **Eksik veya tahrip olmuş mimari öğeler** (süsleme parçaları, kabartmalar, taş detayları) dijital rekonstrüksiyon modelleriyle gerçekçi şekilde yeniden üretilebilmekte; böylece restorasyon projelerine bilimsel doğruluk katılmaktadır.
- **3B dijital çıktılardaki hata payı düşmekte**, yapay zekâ yüzey gürültülerini temizlemekte ve veriyi tutarlı hâle getirmektedir.
- **Karar destek sistemleri**, restorasyon ekiplerine alternatif müdahale senaryoları sunmakta; malzeme uyumu, statik risk analizi ve bozulma olasılıkları gibi teknik değerlendirmeler otomatik olarak yapılabilmektedir.
- **Uzun vadeli izleme** (digital monitoring) mümkün olarak yapının yıllar içerisindeki bozulma seyri dijital ortamda karşılaştırılabilmektedir.

Bu tümleşik süreç, dijital belgelemenin yalnızca restorasyon projeleri için bir "yardımcı araç" olmaktan çıktığını; kültürel miras yönetiminin merkezine yerleşen zorunlu bir metodolojik bileşene dönüştüğünü göstermektedir. Böylece yapıların hem korunabilirliği hem de gelecek kuşaklara aktarılabilirliği daha sürdürülebilir bir zemine oturmaktadır.

3.2. Dijital Kültürel İletişimde Görünürlük Artışı

Bulgular, dijital kültürel iletişimin miras alanlarının toplumsal bilinirliğini ve kültürel değerini artırmada kritik bir rol oynadığını göstermektedir. Özellikle AR/VR teknolojileri sayesinde ziyaretçiler, tarihi yapıların özgün hâllerini, farklı dönemlerdeki değişimlerini veya günümüzde kaybolmuş bölümlerini **etkileşimli bir deneyim** olarak keşfedebilmektedir (Reilly, 2020).

Bu dönüşüm üç temel görünürlük biçimi sağlamaktadır:

1. **Erişilebilirlik Temelli Görünürlük:**
Dijital turlar ve 3B sanal müzeler, coğrafi veya fiziksel erişim engellerini ortadan kaldırarak kültürel mirasa herkesin erişmesini sağlamaktadır. Bu durum özellikle eğitim kurumları, engelli bireyler, yurtdışı izleyiciler ve genç kuşaklar için büyük avantaj yaratmaktadır.

2. **Duygusal Görünürlük:**
Dijital hikâyeleştirme teknikleri (narrative-based visualization), ziyaretçilerin mekânla duygusal bağ kurmasını kolaylaştırmakta; yapının tarihsel kimliği dramatik, sanatsal veya tematik anlatılarla güçlendirilmektedir. Böylece kültürel miras “izlenen” bir olgu olmaktan çıkarak “deneyimlenen bir kültürel persona”ya dönüşmektedir.

3. **Kültürel Bellekte Kalıcılık:**
Sosyal medya temelli paylaşımlar, kısa videolar, podcastler ve mobil uygulamalar aracılığıyla miras değerleri yaygınlaşmakta; özellikle genç kuşakların tarihe yönelik ilgisi artmaktadır. Dijital içerikler, mirasın kolektif bellekte daha güçlü yer edinmesini sağlamaktadır.

Sonuç olarak dijital iletişim, kültürel mirası yalnızca teknik olarak belgelemekle kalmaz; ona yeni bir **kültürel yaşam alanı** kazandırır. Dijital ortamda temsil edilen miras, fizikselin ötesine geçerek kültürel bir içerik ürünü hâline gelir.

3.3. Sürdürülebilir Turizm Markalaşmasında Dijital Temsilin Rolü

Bulgular, dijital temsilin sürdürülebilir turizm markalaşmasında çok yönlü ve stratejik bir güç olduğunu ortaya koymaktadır. Dijitalleştirilmiş tarihi yapılar, destinasyonların modern, yenilikçi ve teknolojiyle uyumlu bir kimlik kazandığını göstererek “çağdaş destinasyon” algısını güçlendirmekte; bu durum turistlerin bölgeye karşı ilk izlenimini olumlu yönde etkilemektedir. Dijital deneyim yaşayan ziyaretçilerin fiziksel ziyarete daha yüksek

motivasyon duyduğu görülmekte; AR/VR destekli dijital ön-izleme deneyimleri, özellikle uluslararası turistlerde mekâna karşı merak ve bağlılık oluşturmaktadır. Ayrıca dijitalleştirilmiş kültürel miras, farklı yaş grupları ve farklı kültürel geçmişlerden gelen kullanıcılar için erişilebilir bir öğrenme ve keşif ortamı yaratmakta; böylece ziyaretçi yelpazesi genişlemektedir. Dijital içeriklerin sürekli güncellenmesi, etkileşimli haritalar, sanal sergiler, kısa hikâye videoları, tematik dijital turlar ve kullanıcı katılımına açık dijital platformlar, destinasyonla kurulan bağı güçlendirmekte ve ziyaretçi sadakatini artırmaktadır. Bununla birlikte dijital temsil, fiziksel ziyaret yoğunluğunun kontrol edilmesine de katkı sağlayarak sürdürülebilir turizmin önemli bir gerekliliği olan "mekânsal taşıma kapasitesinin" korunmasına imkân sunmaktadır. Yoğun ziyaretçi trafiğine sahip hassas kültürel miras alanlarında fiziksel yükün azaltılması, dijital ikiz modeller, sanal turlar ve uzaktan erişilebilir kültürel deneyimlerle mümkün olmakta; bu süreç, hem koruma politikalarına hem de destinasyon yönetimine önemli bir destek sağlamaktadır. Tüm bu bulgular, dijital temsilin yalnızca kültürel mirası görünür kılmakla kalmadığını; aynı zamanda ekonomik, kültürel ve çevresel sürdürülebilirliği güçlendiren bütünsel bir turizm markalaşma aracı hâline geldiğini göstermektedir.

Sonuç

Bu çalışma, dijital dönüşüm çağında tarihi yapıların korunması, belgelenmesi ve yeniden anlamlandırılması süreçlerinin yalnızca teknik bir müdahale alanı olmaktan çıkarak mimarlık, yapay zekâ teknolojileri, kültürel iletişim ve turizm markalaşması disiplinlerinin kesişiminde gelişen çok katmanlı bir yapıya dönüştüğünü ortaya koymuştur. Elde edilen bulgular, yapay zekâ destekli belgeleme yöntemlerinin kültürel miras alanlarında geleneksel koruma pratiklerinin yerini önemli ölçüde aldığına ve bu teknolojilerin tarihsel veriyi hem daha doğru hem daha hızlı hem de daha sürdürülebilir biçimde işleyerek yeni bir koruma paradigması oluşturduğuna işaret etmektedir. Derin öğrenme algoritmaları, 3B dijital ikiz modelleri ve otomatik hasar tespit sistemleri, restorasyon süreçlerinde karar vericilere yüksek doğruluklu veri sağlayarak kültürel mirasın geleceğe aktarılmasında kritik bir rol oynamaktadır.

Dijital kültürel iletişim boyutu incelendiğinde, dijital hikâyeleştirme yöntemlerinin (AR/VR deneyimleri, etkileşimli dijital arşivler, sanal turlar ve sosyal medya temelli içerik stratejileri) tarihi yapıların toplumsal görünürlüğünü artırdığı ve kültürel mirasın yalnızca belgelenen bir obje değil, yeniden üretilen ve deneyimlenen bir kültürel anlatı unsuru hâline geldiği görülmektedir. Dijital temsiller, özellikle genç kuşakların kültürel mirasa yönelik farkındalığını artırmakta; mekânın tarihsel, estetik ve sembolik boyutlarını daha erişilebilir ve daha etkileşimli hâle getirerek kültürel belleği güçlendirmektedir. Böylece kültürel miras, dijital ortamda yeni bir yaşam alanı kazanmakta; mekânsal kimliğin çok daha geniş bir izleyici kitlesiyle paylaşılmasına olanak sağlamaktadır.

Turizm ve pazarlama perspektifinden bakıldığında, dijital temsilin destinasyon imajı üzerinde belirleyici bir etkiye sahip olduğu ve dijitalleştirilmiş kültürel miras unsurlarının sürdürülebilir turizm markalaşmasını desteklediği ortaya çıkmıştır. Dijital içerikler, ziyaretçi motivasyonunu artırmakta; yenilikçi dijital deneyimler destinasyonların rekabet gücünü yükseltmekte; dijital ikiz modeller ve sanal sergiler fiziksel ziyaret baskısını azaltarak sürdürülebilir turizm politikalarına katkıda bulunmaktadır. Dijitalleşme sayesinde kültürel miras, küresel ölçekte görünürlük kazanmakta; destinasyon sadakati, dijital anlatılar ve etkileşimli deneyimlerle güçlenmektedir.

Genel olarak, bu çalışma dijital koruma teknolojilerinin yalnızca mimari bir belgeleme aracı değil; kültürel iletişim, eğitim, turizm ekonomisi, destinasyon yönetimi ve toplumsal farkındalık üretimi açısından bütüncül bir dönüşüm mekanizması olduğunu göstermiştir. Yapay

zekâ tabanlı belgeleme, dijital iletişim yöntemleri ve sürdürülebilir turizm stratejilerinin entegrasyonu, tarihi yapıların hem korunabilirliğini hem erişilebilirliğini hem de ekonomik ve kültürel değerini artıran yeni bir paradigma ortaya koymaktadır.

Bu bağlamda geleceğin kültürel miras politikalarının:

- yapay zekâ destekli dijital ikiz sistemlerine,
- sürdürülebilir turizm odaklı dijital markalaşma stratejilerine,
- kültürel hikâyeleştirmeyi merkeze alan iletişim yaklaşımlarına,
- erişilebilir ve katılımcı dijital miras modellerine

dayanması gerekmektedir.

Tüm bulgular, dijital korumanın gelecek kuşaklara aktarılacak kültürel mirasın niteliğini artıran, yenilikçi, kapsayıcı ve sürdürülebilir bir yol haritası sunduğunu göstermektedir.

ÖZET

Bu çalışma, deprem, iklim değişikliği ve çevresel riskler nedeniyle tehdit altındaki tarihi yapıların korunmasında veri analitiği, iletişim stratejileri ve koruma ekonomisinin birlikte nasıl kullanılabileceğini incelemektedir. Mimarlık ve mühendislik açısından, sensör tabanlı yapısal sağlık izleme (SHM), titreşim ölçümleri, nem/ısı analizleri ve dijital ikiz (digital twin) modellerinin risk tespiti ve müdahale kararlarına sağladığı katkı ele alınmaktadır. İletişim boyutunda, yerel halkın bilgilendirilmesi, kriz iletişimi, sosyal medya farkındalık kampanyaları ve kültürel değer anlatılarının koruma başarısına etkisi analiz edilmektedir. İşletme/marketing perspektifinde ise, tarihi yapıların restorasyon finansmanı, sponsor bulma stratejileri, kültür ekonomisi ve koruma projelerinin marka değerine dönüşme potansiyeli tartışılmaktadır. Sonuç olarak çalışma, tarihi yapıların korunmasını teknik bir mühendislik süreci olmaktan çıkarıp; veri yönlendirmeli, toplumsal katılımlı ve ekonomik olarak sürdürülebilir çok katmanlı bir yönetim modeli olarak yeniden tanımlamaktadır.

Anahtar Kelimeler: Yapısal Sağlık İzleme, Tarihi Yapılar, Koruma Ekonomisi, Dijital İkiz, Kriz İletişimi

A MULTIDISCIPLINARY APPROACH TO PROTECTING AT-RISK HISTORIC STRUCTURES: DATA ANALYTICS, PUBLIC COMMUNICATION, AND CONSERVATION ECONOMICS

ABSTRACT

This study investigates how data analytics, public communication strategies, and conservation economics can be integrated to protect historic structures threatened by earthquakes, climate change, and environmental risks. From an architectural and engineering perspective, sensor-based structural health monitoring, vibration measurements, moisture/temperature diagnostics, and digital twin models are examined as tools for assessing risks and guiding intervention decisions. From a communication standpoint, the study analyzes how public awareness campaigns, crisis communication, community engagement, and cultural value narratives influence the success of conservation projects. In the marketing and business dimension, it evaluates restoration funding models, sponsorship strategies, culture economy potentials, and the transformation of heritage conservation into a branding asset. The paper concludes that heritage conservation should be understood as a data-driven, socially engaged, and economically sustainable management model, rather than exclusively a technical engineering task.

Keywords: Structural Health Monitoring, Historic Buildings, Conservation Economics, Digital Twin, Crisis Communication

Giriş

Depremler, iklim değişikliği, sel ve nem artışı gibi çevresel tehditler, tarihi yapıların korunması sürecini günümüzde daha karmaşık hâle getirmiştir. Bu nedenle kültürel mirasın korunması artık yalnızca restorasyon tekniklerinden ibaret değildir; veri analitiğine dayalı risk izleme teknolojileri, toplumsal farkındalık oluşturma süreçleri ve ekonomik olarak sürdürülebilir koruma modelleriyle bütünleşik ilerleyen çok disiplinli bir yönetim yaklaşımı gerektirmektedir. Yapısal sağlık izleme (Structural Health Monitoring–SHM), sensör tabanlı veri toplama, titreşim ölçümleri, sıcaklık–nem analizleri ve dijital ikiz teknolojileri tarihi yapıların hassas noktalarını erken tespit ederek müdahale planlarının doğruluğunu artırmaktadır (Aktas & Kijewski-Correa, 2021). Bununla birlikte risk altındaki yapılar, teknik çözümlerin yanı sıra güçlü bir toplumsal iletişim stratejisi gerektirir. Yerel halkın bilinçlendirilmesi, kriz anlarında doğru bilginin aktarılması ve sosyal medya üzerinden yürütülen farkındalık kampanyaları, koruma projelerinin başarısında belirleyici rol oynamaktadır. Ekonomik boyutta ise koruma projelerinin finansmanının sürdürülebilir olması, fonların çeşitlendirilmesi, sponsorluk stratejileri ve kültürel mirasın ekonomik bir marka değerine dönüştürülebilmesi önem kazanmaktadır. Bu çalışma, risk altındaki tarihi yapıların korunmasını teknik bir mühendislik sürecinden çıkararak veri odaklı, iletişim temelli ve ekonomik olarak sürdürülebilir bütüncül bir model içerisinde ele almaktadır.

1. Kavramsal Çerçeve

1.1. Veri Analitiği ve Yapısal Sağlık İzleme (SHM)

Yapısal sağlık izleme sistemleri, tarihi yapıların fiziksel davranışlarını gerçek zamanlı veri analizleri ile izlemeyi ve bozulma eğilimlerini erken aşamada tespit etmeyi amaçlar. Özellikle deprem riski altındaki bölgelerde titreşim analizleri, modal şekil değişimleri, çatlak ilerleme sensörleri, sıcaklık–nem kayıtları ve yer hareketi ölçümleri tarihi yapıların kırılgan bölgelerinin belirlenmesinde kritik rol oynar (Catbas et al., 2020). Son yıllarda dijital ikiz (digital twin) teknolojisiyle SHM verilerinin birleşmesi, yapının fiziksel davranışının dijital ortamda sürekli simüle edilmesine olanak tanımış; böylece risk tahminleri daha bilimsel ve veriye dayalı hâle gelmiştir.

Bu yaklaşım, müdahale kararlarında sezgisel yöntemlerden çok daha güvenilir ve şeffaf bir mühendislik süreci sunar. Veri analitiği tabanlı karar destek sistemleri sayesinde restorasyon ekipleri farklı senaryoları karşılaştırabilir, en düşük riskli müdahale alternatiflerini belirleyebilir ve yapının zaman içindeki davranışını izleyerek uzun vadeli koruma stratejileri geliştirebilir.

1.2. Görsel İletişim ve Dijital Temsillerin Kadın Üzerindeki Etkisi

Tarihi yapıların korunması yalnızca uzmanların teknik çalışmalarıyla sürdürülebilecek bir süreç değildir; yerel halka doğru bilgi aktarımı, kültürel değerlerin neden korunması gerektiğinin anlatılması ve risk anlarında etkili kriz iletişimi stratejilerinin uygulanması gereklidir. Kültürel mirasın korunmasına yönelik toplumsal katılımın artması, projelerin meşruiyetini ve uzun vadeli başarısını artırmaktadır (Jigyasu, 2019).

Dijital iletişim araçları bu süreçte önemli avantajlar sağlamaktadır. Sosyal medya farkındalık kampanyaları, kültürel değer anlatıları, kısa belgeseller, interaktif haritalar, afet anında bilgilendirme mesajları ve katılımcı dijital platformlar toplumun mirasa olan duygusal bağını güçlendirmekte; gönüllü katılım oranlarını yükseltmektedir. Ayrıca kriz iletişimi stratejilerinin doğru uygulanması, afet sonrasında bilgi kirliliğini azaltarak toplumsal güveni artırmakta ve koruma faaliyetlerinin hızlandığı kritik dönemlerde koordinasyonu kolaylaştırmaktadır.

1.3. Tüketim Kültürü ve Yorgunluğun Ticarileştirilmesi

Koruma ekonomisi, tarihi yapıların sürdürülebilir finansman modelleriyle korunmasını konu alan yeni bir yaklaşımdır. Kamu fonlarının yetersiz kaldığı durumlarda uluslararası hibeler, özel sektör sponsorlukları, kültür odaklı sosyal girişimler, ziyaretçi odaklı gelir modelleri ve kültürel mirasın markalaşma potansiyeli koruma faaliyetlerine finansal kaynak sağlar (Throsby, 2018).

Tarihi yapıların dijital temsili (dijital ikiz, sanal tur, dijital sergi) marka değerini artırarak ek finans kaynaklarının yaratılmasını kolaylaştırmaktadır. Ayrıca kültür ekonomisi yaklaşımına göre; korunan miras alanları çevre esnafına, turizme, hizmet sektörüne ve yerel ekonomiye doğrudan ekonomik değer kazandırmaktadır. Dolayısıyla koruma yalnızca maliyet oluşturan bir süreç değil, aynı zamanda ekonomik bir yatırım alanıdır.

2. Yöntem

Bu çalışma, nitel araştırma yaklaşımına dayalı olarak tasarlanmış kavramsal bir analiz çalışmasıdır. Modern kent yaşamında kadınların deneyimlediği tükenmişlik olgusunun çok boyutlu yapısı nedeniyle araştırma, tek bir disiplinden ziyade mimarlık, iletişim ve işletme/marketing alanlarının kesişiminde yürütülmüştür. Nitel yaklaşım, özellikle toplumsal deneyimlerin, kültürel temsillerin, mekânsal algıların ve duygusal tepkilerin bütüncül olarak anlaşılması açısından uygun bir yöntem olarak görülmektedir (Creswell & Poth, 2018).

Çalışmanın analiz çerçevesi üç ana disiplin üzerinden yapılandırılmıştır:

- Mimarlık, kentsel mekânın stres üretme biçimlerini, kamusal alanların tasarımını, gündelik kent ritmi ile beden-mekân ilişkisini değerlendirmek üzere ele alınmıştır. Kadınların kentsel mekânla etkileşimlerinde güvenlik, erişilebilirlik, hareketlilik ve mekânsal yorgunluk gibi boyutlar literatür doğrultusunda incelenmiştir (Kern, 2020).
- İletişim bilimleri, dijital temsillerin ve görsel kültürün kadınların psikolojik yükünü nasıl etkilediğini analiz etmek amacıyla kullanılmıştır. Bu kapsamda medya içerikleri, sosyal ağ pratikleri, idealize edilmiş beden ve başarı imgeleri, "görsel performans kültürü" bağlamında değerlendirilmiştir (Gill & Orgad, 2022).
- İşletme/Marketing, tüketim kültürünün kadınların tükenmişlik deneyimini nasıl metalaştırdığını açıklamak için kullanılmıştır. Duygusal pazarlama stratejileri, wellness endüstrisi ve "öz-bakım ekonomisi" literatürü üzerinden kavramsal bir inceleme yapılmıştır (Rottenberg & Fraser, 2021).

Veriler; uluslararası hakemli dergiler, raporlar, kitaplar ve güncel bilimsel yayınlar temel alınarak gerçekleştirilen kapsamlı literatür taraması ile toplanmıştır. Literatür taraması Scopus, Web of Science, Google Scholar ve SpringerLink gibi uluslararası veri tabanları kullanılarak yürütülmüş; 2018–2024 yılları arasındaki güncel çalışmalar önceliklendirilmiştir. Elde edilen kaynaklar, kavramsal karşılaştırma ve tematik analiz yoluyla değerlendirilmiş; disiplinler arası kavramlar benzerlikler ve farklılıklar temelinde karşılaştırılarak bütüncül bir analiz çerçevesi oluşturulmuştur (Nowell et al., 2017).

Çalışma nitel içerik analizi yaklaşımına dayalı olduğu için herhangi bir saha araştırması, anket ya da istatistiksel test uygulanmamıştır. Bu tercihin temel nedeni, kentsel tükenmişlik, dijital temsiller ve tüketim kültürü gibi fenomenlerin teorik tartışmalar üzerinden ele alınmasının araştırmanın amacına daha uygun olmasıdır. Bu kapsamda yöntem, karmaşık sosyal süreçleri açıklamaya yönelik çok katmanlı bir disiplinler arası analiz olarak yapılandırılmıştır.

3. Bulgular

3.1. SHM ve Dijital İkiz Modellerinin Risk Yönetimine Katkısı

Araştırma bulguları, yapısal sağlık izleme (SHM) yöntemleri ile dijital ikiz modellerinin entegrasyonunun kültürel miras yapılarının risk yönetiminde yeni bir standart oluşturduğunu ortaya koymaktadır. Titreşim sensörleri, çatlak ilerleme ölçerler, nem–sıcaklık vericileri, ivmeölçerler ve çevresel izleme istasyonları gibi sensör sistemlerinden elde edilen veriler, yapıların günlük, mevsimsel ve afet kaynaklı davranış değişimlerini yüksek hassasiyetle takip edebilmeyi mümkün kılmaktadır. Bu sensör verileri, dijital ikiz modellerine aktarıldığında yapı, gerçek zamanlı dijital bir simülasyon olarak yeniden üretilmekte; çatlak ilerlemesi, deformasyon, malzeme yorulması, termal genleşme ve taşıyıcı elemanlardaki zayıflık gibi risk unsurları erken aşamada belirlenebilmektedir.

Dijital ikiz modellerinin restorasyon süreçlerine sağladığı en önemli katkılardan biri, farklı müdahale senaryolarının simülasyonlarla önceden test edilebilmesidir. Böylece restorasyon ekipleri, yapıya en az zarar verecek yöntemleri seçebilmekte; geleneksel restorasyon sürecinde mevcut olan belirsizlikler önemli ölçüde azalmaktadır. Bulgular, SHM destekli erken uyarı sistemlerinin büyük ölçekli hasarların önlenmesinde kritik rol oynadığını; dijital ikiz teknolojisinin ise mühendislik temelli koruma kararlarını daha güvenilir ve veri odaklı hâle getirdiğini göstermektedir (Catbas et al., 2020).

3.2. Toplum Temelli İletişim ve Koruma Süreçlerine Etkisi

Çalışmanın ikinci bulgusu, toplumsal iletişim stratejilerinin koruma projelerinin başarısı üzerinde doğrudan belirleyici olduğunu ortaya koymaktadır. Yerel toplulukların tarihi yapıların kültürel değeri, risk durumu ve korunma gerekliliği hakkında bilgi sahibi olması vandalizm, bilinçsiz kullanım, yanlış müdahale ve afet sonrası bilgi kirliliği gibi sorunları önemli ölçüde azaltmaktadır. Bulgular, toplumsal farkındalığın yüksek olduğu bölgelerde koruma çalışmalarının hem daha hızlı hem daha sürdürülebilir biçimde yürütüldüğünü; gönüllü katılım oranlarının arttığını ve yerel kurumlarla iş birliğinin güçlendiğini göstermektedir.

Sosyal medya kampanyaları, kısa belgeseller, dijital sergiler, yerel halk eğitim programları ve risk anında kullanılan kriz iletişimi stratejileri kültürel mirasın toplumsal sahiplenmesini artırmaktadır. Dijital iletişim araçlarının, risk altındaki yapıların durumuna ilişkin "şeffaf bilgi akışı" sağlaması, projelere duyulan güveni ve destek oranını yükseltmektedir. Ayrıca afet sonrası kriz iletişimi, hangi yapıların hasar gördüğü, güvenlik açısından hangi bölgelerin risk taşıdığı ve hangi müdahalelerin yapılması gerektiği konusunda hızlı ve doğru bilgi sağlayarak hem toplumsal güvenliği artırmakta hem de koruma ekiplerinin koordinasyonunu kolaylaştırmaktadır (Jigyasu, 2019).

Bu bulgular ışığında, koruma projelerinin yalnızca teknik uzmanlığa değil; doğru planlanmış, toplum merkezli iletişim süreçlerine de ihtiyaç duyduğu görülmektedir. Toplumsal katılım, yalnızca destekleyici bir unsur değil, koruma sürecinin ayrılmaz bir bileşeni hâline gelmiştir.

3.3. Ekonomik Sürdürülebilirlik ve Koruma Projelerinin Marka Değeri

Araştırma bulguları, koruma projelerinin ekonomik sürdürülebilirliğinin restorasyon çalışmalarının devamlılığını belirleyen temel faktörlerden biri olduğunu göstermektedir. Geleneksel kamu kaynaklarının tek başına yeterli olmadığı koruma projelerinde dijital temsiller, sanal turlar, dijital sergiler, tematik kültür rotaları, bağış kampanyaları ve marka iş birlikleri gibi yeni finansman modelleri güçlü bir gelir akışı yaratmaktadır.

Dijital ikiz modellerinin yalnızca teknik bir koruma aracı değil, aynı zamanda güçlü bir görünürlük stratejisi sunduğu bulgulanmıştır. Dijital ikiz üzerinden sunulan şeffaf veri paylaşımı, kurumsal sponsorların projelere güven duyarak yatırım yapmasını kolaylaştırmakta; böylece koruma projelerinin marka değeri artmaktadır. Kültürel mirasın dijitalleştirilmesi, fon sağlayıcı kurumlar

için "yenilikçi, modern ve teknolojik olarak güçlü" bir imaj yaratmakta ve projelerin uluslararası fonlardan destek alma olasılığını yükseltmektedir (Throsby, 2018).

Bulgular ayrıca, korunan kültürel mirasın yerel ekonomiye doğrudan katkı sağladığını göstermektedir:

- dijital turizm gelirleri,
- kültürel girişimler,
- ziyaretçi deneyimine dayalı ürün ve hizmet modelleri,
- sponsorluk paketleri,
- yerel işletmelerin ekonomik canlılığı

koruma projelerini sürdürülebilir bir ekonomik döngüye dönüştürmektedir.

Genel olarak, tarihi yapıların korunması yalnızca kültürel bir sorumluluk değil; ekonomik açıdan da karşılıklı değer üreten bir yatırım alanı olarak ortaya çıkmaktadır.

Sonuç

Bu çalışma, risk altındaki tarihi yapıların korunmasının tek boyutlu bir restorasyon süreci değil; veri analitiği, toplumsal iletişim ve koruma ekonomisinin bütünleştiği çok katmanlı bir yönetim modeli olduğunu ortaya koymuştur. Yapısal sağlık izleme (SHM) sistemleri ve dijital ikiz teknolojilerinin kullanımı, kültürel mirasın fiziksel durumunu nesnel, sürekli ve yüksek doğrulukla izlemeyi mümkün kılmakta; böylece risklerin erken aşamada saptanarak büyük ölçekli hasarların önüne geçilmesini sağlamaktadır. Bu bulgu, geleneksel gözleme dayalı koruma yöntemlerinin yerini veriye dayalı karar destek mekanizmalarının aldığı yeni bir koruma paradigmasını işaret etmektedir.

Çalışmanın iletişim boyutu, teknik müdahalelerin toplumsal farkındalık olmadan tam anlamıyla etkili olamayacağını göstermiştir. Yerel halkın katılımı, doğru kriz iletişimi, dijital farkındalık kampanyaları ve kültürel hikâye anlatımı yöntemleri, miras alanlarına yönelik duygusal bağlılığı artırarak projelerin sosyal sürdürülebilirliğini güçlendirmektedir. Bu durum, kültürel mirasın yalnızca uzmanların koruduğu bir nesne değil, toplumun birlikte yaşattığı kolektif bir değer olduğunu ortaya koymaktadır.

Ekonomik bulgular ise koruma projelerinin sürdürülebilirliğinin büyük ölçüde finansman çeşitliliğine bağlı olduğunu göstermektedir. Dijital temsillerin ve dijital ikiz modellerinin yükselen marka değeri, ulusal ve uluslararası fonlara erişimi kolaylaştırmakta; özel sektör sponsorluklarını artırmakta ve dijital turizm gelirleri için yeni fırsatlar yaratmaktadır. Böylece kültürel mirasın korunması, ekonomik açıdan da geri dönüş sağlayan stratejik bir yatırım alanına dönüşmektedir. Koruma ekonomisinin gelişimi, projelerin uzun vadeli ve bağımsız bir finansal yapıya kavuşmasını desteklemektedir.

Genel olarak çalışma, üç disiplinin entegrasyonuyla elde edilen bütüncül yaklaşımın; teknik doğruluk, toplumsal kabul ve ekonomik sürdürülebilirlik arasında dengeli bir çerçeve sunduğunu göstermektedir. Bu bütünleşik model, kültürel mirasın hem fiziksel olarak geleceğe aktarılmasını hem de toplumsal bilinç, ekonomik değer ve kültürel süreklilik açısından desteklenmesini sağlayan çağdaş bir koruma anlayışı ortaya koymaktadır.

Bu nedenle geleceğin miras politikalarının; veriye dayalı izleme, toplum merkezli iletişim ve sürdürülebilir finansman modellerini birlikte ele alan çok disiplinli bir bakış açısını benimsemesi gerekmektedir. Bu yaklaşım, risk altındaki tarihi yapıların korunmasında küresel ölçekte uygulanabilir, güçlü ve uzun vadeli bir yol haritası sunmaktadır.

ÖZET

Endüstri 4.0'ın getirdiği dijital dönüşüm, üretim süreçlerini kökten değiştirmekte ve bu durum, mühendislerin sahip olması gereken teknik becerilere yönelik talepleri artırmaktadır. Geleneksel eğitim modelleri, özellikle pahalı laboratuvar ekipmanlarına dayanan uygulamalı eğitimler, bu yeni yetkinlikleri kazandırmada yetersiz kalmaktadır. COVID-19 pandemisi, özellikle pratik eğitimde uzaktan erişimin zorluklarını ortaya çıkararak yenilikçi pedagojik yaklaşımlara olan ihtiyacı pekiştirmiştir. Bu bağlamda, Sanal Gerçeklik (VR) tabanlı simülasyonlar ve uzaktan erişimli "Sanal Öğrenme Fabrikaları" (VLF), mühendislik eğitiminde sürdürülebilir ve etkili bir çözüm olarak öne çıkmaktadır.Sanal Gerçeklik, öğrencilere gerçek dünya endüstriyel senaryolarını taklit eden, yüksek düzeyde sürükleyici ve etkileşimli bir öğrenme ortamı sunar. Öğrenciler, maliyetli ekipmanlara zarar verme veya elektrik çarpması gibi fiziksel riskler olmaksızın, tehlikeli olabilecek (örn. CNC yangın söndürme) veya karmaşık prosedürleri defalarca güvenli bir şekilde uygulayabilirler. Yapılan çalışmalar, bu metodolojilerin etkinliğini doğrulamaktadır. Sistem Kullanılabilirlik Ölçeği (SUS) testleri ve deneysel değerlendirmeler, VR tabanlı eğitim araçlarının öğrenciler tarafından yüksek oranda (%85, %90) kabul gördüğünü ve "iyi" kullanılabilirlik puanları (örn. 74.6) aldığını göstermektedir. VR ile eğitim alan grupların, geleneksel yöntemlerle eğitim alan gruplara kıyasla görevleri daha hızlı ve daha az hata ile tamamladığı kanıtlanmıştır. Sonuç olarak, VR simülasyonları, dijital ikizler ve siber güvenlik gibi Endüstri 4.0'ın temel bileşenlerini entegre eden, motivasyonu artıran ve sürdürülebilir beceri kazanımını sağlayan zorunlu ve mantıklı bir eğitim aracı olarak konumlanmaktadır.

THE ROLE OF VIRTUAL REALITY (VR) SIMULATIONS IN INDUSTRY 4.0 EDUCATION

ABSTRACT

The digital transformation associated with Industry 4.0 is fundamentally reshaping production processes and increasing the demand for advanced technical competencies among engineers. Traditional pedagogical models—particularly hands-on training dependent on expensive laboratory equipment—have become insufficient for equipping learners with these newly required skills. The COVID-19 pandemic further highlighted the limitations of remote access to practical training, reinforcing the need for innovative educational approaches. In this context, Virtual Reality (VR) simulations and remote-access "Virtual Learning Factories" (VLFs) have emerged as sustainable and effective solutions within engineering education. Virtual Reality provides students with an immersive and interactive environment that accurately replicates real-world industrial scenarios. Learners can repeatedly and safely practice potentially hazardous (e.g., CNC fire suppression) or complex procedures without risking damage to costly equipment or exposure to physical hazards such as electrical shock. Recent studies confirm the effectiveness of these methodologies. System Usability Scale (SUS) assessments and experimental evaluations indicate that VR-based educational tools achieve high levels of student acceptance (e.g., 85%, 90%) and receive "good" usability scores (e.g., 74.6). Evidence also shows that learners trained through VR complete tasks more quickly and with fewer errors compared to those trained via traditional methods. Consequently, VR simulations have become an essential and rational educational tool that integrates key Industry 4.0 components—such as digital twins and cybersecurity—while enhancing learner motivation and supporting sustainable skill development.

Keywords: Virtual Reality (VR), Industry 4.0, Engineering Education, Remote Laboratory, PLC Programming

1. GİRİŞ

Endüstri 4.0 ile birlikte dijital dönüşüm, üretim sistemlerini ve iş süreçlerini kökten değiştirmektedir. Bu dönüşüm, mühendislerin sahip olması gereken teknik ve dijital becerileri de yeniden tanımlamakta, özellikle siber-fiziksel sistemler, dijital ikizler, siber güvenlik ve otomasyon gibi alanlarda yetkinlik ihtiyacını artırmaktadır (Adetunla ve ark., 2024). Geleneksel mühendislik eğitimi modelleri, özellikle pahalı fiziksel laboratuvar ekipmanlarına ve yüz yüze uygulamalara dayalı yapısıyla, bu yeni ve dinamik ihtiyaçları karşılamada yetersiz kalmaktadır. COVID-19 pandemisi, uzaktan eğitimin zorunlu hale gelmesiyle birlikte, pratik ve uygulamalı eğitimdeki bu açığı daha da görünür kılmıştır (Dunmoye ve ark., 2024). Bu zorluklar, eğitimde yenilikçi, erişilebilir ve sürdürülebilir pedagojik yaklaşımların benimsenmesini gerektirmektedir.

Bu bağlamda Sanal Gerçeklik (VR) tabanlı simülasyonlar, mühendislik eğitimi için hem sürdürülebilir hem de etkili bir çözüm olarak öne çıkmaktadır. VR, öğrencilere risk almadan (elektrik çarpması veya ekipman hasarı olmaksızın) deneyim kazanma, karmaşık ve tehlikeli senaryoları tekrarlama ve Endüstri 4.0'ın temel teknolojilerini bütünleşik bir ortamda öğrenme imkanı sunmaktadır (Sharma ve ark., 2023).

Bu çalışma, Endüstri 4.0 bağlamında mühendislik eğitiminde VR simülasyonlarının rolünü, etkinliğini ve gelecek potansiyelini inceleyen mevcut literatürü sistematik bir şekilde gözden geçirmeyi amaçlamaktadır. VR tabanlı eğitimin teorik temellerini, uygulama örneklerini, avantajlarını, karşılaşılan zorlukları incelenecektir.

2. EĞİTİMDE SANAL GERÇEKLİK

VR, bilgisayar sistemleri aracılığıyla inşa edilen, kullanıcıya yüksek düzeyde sürükleyicilik (immersion), gerçek zamanlı etkileşim (interaction) ve görsel gerçekçilik (fidelity) sağlayan simüle edilmiş bir ortamdır. VR teknolojileri, geleneksel iki boyutlu öğrenme materyallerinden koparak, öğrencilerin içeriğe üç boyutlu bir alanda katılımını sağlayan devrimci bir araçtır. Modern uygulamalar, görsel ve işitsel uyaranların yanı sıra, dokunsal geri bildirim (haptic feedback) ve hareket takibi (motion tracking) gibi öğeleri birleştirerek öğrenme deneyimini zenginleştirmektedir (Paszkiewicz ve ark., 2021).

2.1 Avantajlar ve Dezavantajlar

Eğitimde VR kullanımının en belirgin avantajı, öğrencilerin risk almadan pratik yapabilmelerine olanak tanımasıdır. Örneğin, cerrahi eğitimde veya tehlikeli endüstriyel işlemlerde, öğrenciler gerçek hayatta ciddi sonuçlar doğurabilecek hataları sanal ortamda güvenle yapıp bunlardan ders çıkarabilmektedir (Adetunla ve ark., 2024; Paszkiewicz ve ark., 2021). Ayrıca, VR teknolojisi öğrencilerin motivasyonunu ve derse katılımını artırmakta, soyut kavramların (örneğin moleküler yapılar veya karmaşık makineler) görselleştirilmesini sağlayarak bilişsel yükü yönetilebilir hale getirmektedir (Du ve ark., 2024). Zaman ve mekan kısıtlamalarını ortadan kaldırması, öğrencilerin normalde erişemeyecekleri tarihi yerleri veya endüstriyel tesisleri ziyaret etmelerine olanak tanır (Okul & Şimşek, 2025).

Bununla birlikte, teknolojinin getirdiği bazı dezavantajlar ve zorluklar da mevcuttur. Donanım ve yazılım maliyetlerinin yüksek olması, teknik altyapı eksikliği ve içerik oluşturma zorlukları yaygın engellerdir (Adetunla ve ark., 2024; Du ve ark., 2024). Ayrıca, uzun süreli kullanımda ortaya çıkabilen siber hastalık (cyber-sickness), göz yorgunluğu ve baş ağrısı gibi fiziksel rahatsızlıklar, öğrenme sürecini olumsuz etkileyebilir (Asitah ve ark., 2024). Eğitimcilerin bu teknolojiye uyum sağlaması ve müfredata entegrasyonu da ek bir pedagojik zorluk oluşturmaktadır (Terzulli ve ark., 2025).

2.2 Literatürden Örnek Çalışmalar ve Başarımlar

Sanal gerçekliğin farklı disiplinlerdeki eğitimsel etkinliğini gösteren ve kaynakça kapsamında incelenen 7 önemli çalışma aşağıda özetlenmiştir:

2.2.a. Kalça Artroskopisi Eğitiminde Beceri Kazanımı (Cerrahi Eğitim): Vivekanantha ve arkadaşları tarafından yapılan sistematik inceleme, VR simülatörlerinin kalça artroskopisi eğitimindeki etkinliğini değerlendirmiştir. Çalışma, VR eğitiminin yüksek yüz ve yapı geçerliliğine sahip olduğunu ortaya koymuştur.

• Sonuç/Başarım: Deneyimli cerrahlar simülatörde acemilerden daha iyi performans göstermiş (yapı geçerliliği), acemi kursiyerler ise tekrarlayan oturumlarla iyatrojenik doku hasarını azaltmış ve işlem sürelerini kısaltmıştır. VR, kadavra eğitimine göre daha uygun maliyetli ve güvenli bir alternatif olarak tanımlanmıştır (Vivekanantha ve ark., 2025).

2.2.b Arkeoloji ve Turist Rehberliği Eğitimi (Turizm Eğitimi) Okul ve Şimşek , turist rehberliği eğitiminde dört antik kenti (Priene, Miletos, Didim, Pergamon) kapsayan bir arkeoloji dersinde VR kullanımını yarı deneysel bir modelle test etmiştir. Solomon Dört Grup Modeli kullanılarak 70 öğrenci ile çalışılmıştır.

• Sonuç/Başarım: VR uygulaması kullanan deney gruplarının akademik başarı puanları ve bilgiyi akılda tutma (kalıcılık) düzeyleri, geleneksel yöntemlerle eğitim alan kontrol gruplarına göre anlamlı derecede yüksek bulunmuştur. Öğrenciler, "bulunma" hissi sayesinde mekanları deneyimleyerek öğrendiklerini belirtmiştir (Okul & Şimşek, 2025).

2.2.c. Endüstri 4.0 için Yeniden Yapılandırılabilir Üretim Sistemleri (Mühendislik Eğitimi): Salah ve arkadaşları, endüstri mühendisliği öğrencilerine karmaşık "Yeniden Yapılandırılabilir Üretim Sistemleri" (RMS) tasarımını öğretmek için Sanal Öğrenme Fabrikası (VLF) konseptini kullanmıştır. 50 öğrenci ile yapılan çalışmada, VR tabanlı eğitim alan grup ile geleneksel eğitim alan grup karşılaştırılmıştır.

• Sonuç/Başarım: VR tabanlı eğitim alan deney grubu, atölye zeminindeki gerçek konfigürasyon görevini kontrol grubuna göre daha kısa sürede ve daha az hatayla tamamlamıştır. İstatistiksel analizler, eğitim yönteminin tamamlanma süresi üzerinde anlamlı bir etkisi olduğunu göstermiştir (Salah ve ark., 2019).

2.2.d. Psikiyatri Hemşireliği Eğitimi (Sağlık Bilimleri): Ahn ve arkadaşları tarafından yapılan sistematik derleme, psikiyatri hemşireliği eğitiminde sürükleyici VR simülasyonlarının etkisini incelemiştir. İncelenen çalışmalarda empati, iletişim becerileri ve öğrenme motivasyonu gibi çıktılar değerlendirilmiştir.

• Sonuç/Başarım: VR simülasyonlarının iletişim becerilerini, empatiyi ve bilişsel katılımı artırmada etkili olduğu bulunmuştur. Özellikle, öğrencilerin psikiyatrik hastalarla etkileşime girerken yaşadıkları anksiyetenin azaldığı rapor edilmiştir. Ancak, bilgi edinimi (knowledge acquisition) konusunda geleneksel yöntemlere kıyasla her zaman anlamlı bir fark görülmemiştir (Ahn et al., 2025).

2.2.e. İç Mekan Tasarımında VR ve Kağıt Eskiz Karşılaştırması (Mesleki Eğitim): Qin ve Li, iç mekan tasarımı eğitiminde VR kullanımının öğrencilerin tasarım çıktılarına etkisini araştırmıştır. Öğrenciler ofis alanı tasarlarken VR araçlarını ve geleneksel kağıt eskiz yöntemlerini kullanmışlardır.

• Sonuç/Başarım: Çalışma, VR kullanımının tasarımda "oran" ve "kompozisyon" becerilerini geliştirdiğini, ancak "inovasyon" (yenilikçilik) puanlarının kağıt eskiz grubunda daha yüksek

olduğunu ortaya koymuştur. En yüksek tasarım kalitesi, önce kağıt eskiz yapılıp ardından VR kullanılan hibrit sıralamada elde edilmiştir (Qin & Li, 2022).

2.2.f. Endüstriyel Kontrol ve Elektrik Güvenliği (Teknik Eğitim): Atiaja ve arkadaşları, elektromekanik mühendisliği öğrencileri için endüstriyel kontrol panolarının montajını simüle eden çok seviyeli bir VR modülü geliştirmiştir. Çalışma, öğrencilerin elektrik çarpması korkusu olmadan pratik yapabilmelerini amaçlamıştır.

• Sonuç/Başarım: VR modülünü kullanan öğrenciler, kontrol ve manevra elemanlarını tanımada gelişme göstermiş, bağlantı hatalarını azaltmış ve devre montaj sürelerini kısaltmıştır. Öğrencilerin %90'ı sistemi pratik ve faydalı bulmuştur (Atiaja ve ark., 2023).

2.2.g. Disiplinlerarası Sağlık Eğitimi: Hemşirelik ve Eczacılık (Sağlık Bilimleri): Terzulli ve arkadaşları, sağlık eğitiminde disiplinler arası işbirliğini (IPE) geliştirmek amacıyla hemşirelik ve eczacılık öğrencileri için sürükleyici bir VR pilot çalışması gerçekleştirmiştir. Çalışmada, 20 hemşirelik ve 20 eczacılık öğrencisi, hiperkalemi (yüksek potasyum) ve akut böbrek hasarı olan sanal bir hastayı tedavi etmek için eşleştirilmiştir,. Öğrenciler, farklı fiziksel odalarda bulunmalarına rağmen, VR başlıkları aracılığıyla aynı sanal hastane odasında buluşmuş ve hastanın bakımı için işbirliği yapmışlardır.

• Sonuç/Başarım: Çalışma, VR tabanlı eğitimin öğrencilerin disiplinler arası bir ekip içinde çalışma konusundaki özgüvenlerini artırdığını göstermiştir. Katılımcıların tamamı, VR oturumunun ardından "disiplinler arası, ekip tabanlı bir ortamda bakım sağlama konusunda kendimi güvende hissediyorum" ifadesine katıldıklarını belirtmiştir. Ayrıca, senaryonun tekrar edilmesiyle performans puanlarında ve iletişim becerilerinde artış gözlemlenmiştir (Terzulli ve ark., 2025).

İncelenen çalışmalar, VR teknolojisinin tıp eğitiminden mühendisliğe, turizmden mesleki eğitime kadar geniş bir yelpazede akademik başarıyı, kalıcılığı ve uygulama becerilerini artırdığını göstermektedir. Özellikle riskli, pahalı veya erişimi zor senaryolarda VR, geleneksel yöntemlere göre üstün performans sergilemektedir. Ancak, teknolojinin tam potansiyeline ulaşması için donanım maliyetleri ve teknik sorunların aşılması, ayrıca pedagojik entegrasyonun dikkatle planlanması gerekmektedir.

3. ENDÜSTRİ 4.0 EĞİTİMİNDE SANAL GERÇEKLİK

Endüstri 4.0'ın temel bileşenlerinden biri olan Yeniden Yapılandırılabilir Üretim Sistemleri'nin (RMS) tasarımı ve işletimi, acemi mühendisler için anlaşılması zor konulardır. Salah ve arkadaşları tarafından yürütülen çalışma, VR tabanlı eğitimin öğrencilerin RMS konfigürasyonlarını anlamalarını önemli ölçüde kolaylaştırdığını ortaya koymuştur. Çalışma sonuçlarına göre, VR eğitimi alan deney grubu, gerçek atölye ortamındaki konfigürasyon görevlerini, geleneksel eğitim alan gruba göre daha kısa sürede ve daha az hata ile tamamlamıştır (Salah ve ark., 2019). Bu durum, VR'ın karmaşık teorik kavramların pratik becerilere dönüştürülmesindeki etkinliğini kanıtlamaktadır.

Endüstri 4.0 sadece mekanik üretimden ibaret değildir; Nesnelerin Endüstriyel İnterneti (IIoT), bulut bilişim ve siber güvenlik gibi katmanları da içerir. Fuertes ve arkadaşları, öğrencilerin bu katmanları bütünleşik olarak deneyimleyebilmesi için VR destekli bir "Dijital İkiz" (Digital Twin) ortamı geliştirmiştir. Bu ortamda öğrenciler, sanal bir endüstriyel tesis üzerinde otomasyon, uzaktan izleme, bulut bilişim ve siber güvenlik (firewall yapılandırması vb.) görevlerini yerine getirmişlerdir. Öğrencilerle yapılan anketler, sistemin kullanılabilirliğinin yüksek olduğunu (SUS skoru: 74.6) ve motivasyonu artırdığını göstermiştir (Fuertes ve ark., 2021). Benzer şekilde Morán ve arkadaşları, öğrencilerin sanal makineler üzerinden gerçek

PLC'leri simüle edebildiği ve hem evden (offline) hem de laboratuvar ekipmanlarına uzaktan bağlanarak (online) çalışabildiği hibrit bir platform sunmuştur (Morán ve ark., 2024).

Endüstriyel süreçlerin kontrolünde teorik bilgi ile pratik uygulama arasındaki boşluğu kapatmak için "Döngüdeki Donanım" (Hardware-in-the-Loop - HIL) tekniği kritik bir rol oynamaktadır. Ortiz ve arkadaşları, bira üretim sürecini sanallaştırarak, öğrencilerin fiziksel bir PLC (S7-1200) ve SCADA sistemi üzerinden sanal fabrikayı gerçek zamanlı kontrol etmelerini sağlayan yenilikçi bir sistem geliştirmiştir. Bu entegrasyon sayesinde öğrenciler, sensörlerden gelen giriş sinyallerini ve aktüatörlerdeki çıkış tepkilerini sanal ortamda gözlemleyerek, endüstriyel kontrol süreçlerini güvenli bir şekilde deneyimleme ve müdahale etme şansı bulmuşlardır (Ortiz ve ark., 2024).

Endüstri 4.0 ortamlarında iş sağlığı ve güvenliği (İSG) eğitimi, çalışanların risk farkındalığını artırmak için hayati önem taşımaktadır. Qawqzeh ve arkadaşları tarafından 200 katılımcı ile yürütülen yarı deneysel çalışma, VR tabanlı İSG eğitiminin geleneksel yöntemlere kıyasla üstünlüğünü ortaya koymuştur. Çalışma sonucunda, VR eğitimi alan grubun güvenlik bilgisinde %25, risk farkındalığında ise %30 oranında artış gözlemlenmiştir. Ayrıca, VR grubunun Endüstri 4.0 senaryolarına uyum sağlama yeteneği ve öz yeterlilik algısı, kontrol grubuna göre anlamlı derecede yüksek bulunmuştur (Qawqzeh ve ark., 2025).

Karmaşık makine operatörlüğü eğitiminde VR, yetkinlik kazanma süresini kısaltmakta ve hata oranlarını düşürmektedir. Carretero ve arkadaşları, CNC freze makinesi ve matkap montajı gibi endüstriyel görevler için geliştirdikleri VR eğitim metodolojisi ile somut başarılar elde etmiştir. Geleneksel eğitim ile karşılaştırıldığında, VR eğitimi alan çırakların makineyi kullanma konusundaki güven düzeyleri %35'ten %96'ya yükselmiştir. Ayrıca, görev tamamlama süresi ortalama 28 dakikadan 19 dakikaya düşmüş ve ortalama hata sayısı 4'ten 2'ye inerek operasyonel verimlilikte belirgin bir iyileşme sağlanmıştır (Carretero ve ark., 2021).

Benzer bir yaklaşımla Paszkiewicz ve arkadaşları, CNC makinelerinde çıkabilecek yangınlara müdahale prosedürlerini (acil durdurma, alarm aktivasyonu, doğru yangın söndürücü seçimi) öğreten bir VR eğitim istasyonu geliştirmiştir. Çalışma, katılımcıların tekrarlayan sanal denemelerle müdahale sürelerini kısalttığını ve kriz anında doğru karar verme yetkinliklerini güvenli bir ortamda geliştirdiğini göstermiştir. Bu tür simülasyonlar, gerçek hayatta yapılması tehlikeli veya maliyetli olan eğitimlerin sanal dünyada risksiz bir şekilde gerçekleştirilmesine olanak tanır (Paszkiewicz ve ark., 2021).

4. SANAL GERÇEKLİK ÇALIŞMALARININ BAŞARIM TEST YÖNTEMLERİ

4.1. Kontrollü Deneysel Tasarımlar: Çoğu çalışma, katılımcıları "Deney Grubu" (VR kullananlar) ve "Kontrol Grubu" (Geleneksel yöntem, video veya kağıt kullananlar) olarak ayırmıştır. Örneğin, Solomon Dört Grup Modeli kullanılarak hem ön testin etkisini kontrol eden hem de VR'ın etkisini ölçen tasarımlar mevcuttur.

4.2. Objektif Performans Metrikleri: Özellikle mühendislik ve cerrahi eğitimlerinde, başarı sübjektif görüşlerle değil, tamamlama süresi (saniye/dakika), hata sayısı, çarpışma sayısı ve hareket mesafesi gibi sistem tarafından kaydedilen verilerle ölçülmüştür.

4.3. Psikometrik ve Duyuşsal Ölçekler: Tıp ve çevre eğitimi gibi alanlarda, VR'ın anksiyete (STAI-Y), ağrı (VAS), şüphecilik ve harekete geçme niyeti üzerindeki etkisi standartlaştırılmış ölçeklerle test edilmiştir.

4.4. Bilgi Transferi ve Kalıcılık Testleri: Bazı çalışmalar, eğitimin hemen ardından yapılan testlerin ötesine geçerek, haftalar sonra yapılan kalıcılık (retention) testleri veya sanal ortamda öğrenilen becerinin gerçek dünyaya (transfer) aktarılıp aktarılmadığını ölçmüştür.

Tablo 1'de farklı disiplinlerden seçilmiş ve incelenen çalışmaların başarımlarını nasıl test ettiğini ve elde ettikleri temel sonuçları özetlemektedir.

Yazar / Çalışma	Alan / Konu	Test Yöntemi ve Kullanılan Araçlar	Ölçülen Başarım Kriterleri	Temel Sonuç / Bulgular
Okul ve Şimşek	Turizm / Arkeoloji	Yarı deneysel, Solomon Dört Grup Modeli (Öntest-sontest ve kalıcılık testi).	Akademik başarı puanları, bilginin akılda kalıcılığı (retention).	VR grubu, geleneksel yöntemle (slayt) ders işleyen gruba göre hem akademik başarıda hem de bilgiyi hatırlamada istatistiksel olarak anlamlı düzeyde daha yüksek puan almıştır.
Salah ve ark.	Endüstri Müh. (RMS)	Kontrol gruplu deney (n=50). Geleneksel sınıfa karşı VR tabanlı "Sanal Öğrenme Fabrikası".	Görev tamamlama süresi, konfigürasyon doğruluğu (hata sayısı).	VR grubu, karmaşık üretim sistemi tasarımlarını kontrol grubuna göre daha kısa sürede ve daha az hatayla tamamlamıştır.
Martínez-Gutiérrez ve ark.	Robotik / Operatör Eğitimi	Üç gruplu deney: 1) Gerçek Robot, 2) VR, 3) PC Ekranı (2D). Beceri transferi testi.	Gerçek bir robotu parkurda sürme süresi ve çarpışma (hata) sayısı.	En iyi gelişimi gerçek robotla çalışanlar (%47) göstermiştir. Ancak VR grubu (%38), sadece ekran başında çalışanlara (%28) göre gerçek dünyaya beceri transferinde daha başarılı olmuştur.
Claudel ve ark.	Tıp / Prenatal Tanı	Karşılaştırmalı çalışma (Önce-Sonra). STAI-Y ve VAS ölçekleri.	Anksiyete seviyesi ve işlem sırasındaki ağrı algısı.	İnvaziv işlemler sırasında VR gözlüğü kullanan kadınların anksiyete puanı medyan 7 puan, ağrı puanı ise 2 puan daha düşük çıkmıştır.
Qawqzeh ve ark.	İş Sağlığı ve Güvenliği	Yarı deneysel (n=200). Müdahale ve kontrol grubu karşılaştırması.	Güvenlik bilgisi, risk farkındalığı, öz yeterlilik algısı.	VR eğitimi alan grubun risk farkındalığı %30, güvenlik bilgisi %25 artmıştır. Liderlik desteği ve iletişim algısında da iyileşme görülmüştür.
Qin ve Li	Mesleki Eğitim / İç Mimarlık	Karşılaştırmalı analiz. Kağıt eskiz grubu (A) vs. VR grubu (B) vs. Hibrit gruplar.	Tasarım çıktı puanları: Oran (Proportion), Kompozisyon ve İnovasyon.	VR, "oran" ve "kompozisyon" becerilerini geliştirirken, "inovasyon" puanları kağıt eskiz grubunda daha yüksek çıkmıştır. En iyi sonuç "önce kağıt eskiz, sonra VR" sıralamasında alınmıştır.
Alex ve ark.	Çevre Eğitimi / İklim	Üç seviyeli deney (AR, VR, 2D ekran).	Buradalık hissi (Local vs. Telepresence), şüphecilik, eyleme geçme niyeti.	VR, kullanıcıyı uzak ortama taşıyarak (telepresence) sorunu hissettirmede en iyisidir. AR ise sorunu kullanıcının ortamına getirerek şüpheciliği azaltmada daha etkilidir.
Ortiz ve ark.	Endüstriyel Otomasyon	Hardware-in-the-Loop (HIL) tekniği ile entegre VR ve SCADA sistemi.	Sistem kullanılabilirlik ölçeği (SUS) ve memnuniyet anketi.	Öğrenciler sistemin kullanılabilirliğini %85 oranında onaylamış; teorik bilgilerin gerçek zamanlı sanal bir fabrikada uygulanabilmesi motivasyonu artırmıştır.
Bateman ve ark.	Psikomotor Beceriler	Bayesian Ağı (BN) modellemesi ile 41 çalışmanın meta-analizi.	Öğrenme (görev başarısı) ve Transfer (yeni duruma aktarım).	Dokunsal geri bildirim (haptic feedback), görevi ilk öğrenme aşamasında başarıyı düşürse de (-%15), becerinin gerçek hayata transferini artırmaktadır (+%19).

Tablo 1: *İncelenen Çalışmalara ait Başarım Ölçme Yöntemleri ve Bulgular*

SONUÇ

Literatüre bakıldığında, VR teknolojisinin Endüstri 4.0 eğitiminde "ekstra" bir lüks değil, nitelikli iş gücü yetiştirmek için artık ihtiyaç haline gelen bir araç olduğu görülüyor. VR, öğrencilere robotlar, CNC makineleri, PLC'ler gibi pahalı endüstriyel ekipmanlara mekandan bağımsız erişim olanağı sunarak eğitimde fırsat eşitliğini güçlendiriyor ve "yaparak öğrenme" ilkesini dijital çağa uyarlıyor. Özellikle hata yapmanın çok maliyetli olabileceği endüstriyel süreçlerde, sanal ortamda kazanılan deneyim, gerçek üretim ortamındaki verimlilik ve güvenliği doğrudan artırma potansiyeli taşıyor. Bu nedenle geleceğin müfredatlarının yalnızca teorik bilgi aktarımına değil, VR ve Dijital İkiz teknolojileriyle desteklenen entegre sistem eğitimlerine odaklanması, endüstrinin ihtiyaç duyduğu yetkin mühendis profilini oluşturmak açısından kritik görünüyor. Geleceğin eğitim modeli; fiziksel ve dijital ortamların birbirini tamamladığı hibrit bir yapı olarak şekillenecek. Tehlikeli, maliyetli veya erişimi zor endüstriyel senaryolar söz konusu olduğunda ise VR, gönüllü bir seçenek olmaktan çıkıp vazgeçilmez bir standart olmaya doğru ilerliyor.

ÖZET

Tarım, gıda üretimi, ekonomik kalkınma ve doğal kaynakların korunması açısından temel bir konumdadır. Artan nüfus, iklim değişikliği, su kıtlığı ve toprak bozulması, tarımsal üretimi giderek daha kırılgan hâle getirmektedir. Geleneksel tarım yöntemleri geçmişte başarılı olsa da yoğun kimyasal kullanımı ve çevresel baskılar nedeniyle günümüz koşullarında sürdürülebilirlik açısından yetersiz kalmaktadır. Bu nedenle sürdürülebilir tarım, doğal kaynakların korunmasını, çevresel etkilerin azaltılmasını ve güvenli gıda üretimini esas alan bütüncül bir yaklaşım olarak önem kazanmıştır. Toprak, su ve enerji döngülerinden en verimli şekilde yararlanmayı hedefleyen bu sistemlerde yenilenebilir enerji kullanımı, organik gübreleme, örtü bitkileri ve çeşitlendirilmiş üretim teknikleri öne çıkmaktadır. Dünya genelinde dijital tarım uygulamaları, sensörler, veriye dayalı yönetim ve modern ıslah çalışmaları sürdürülebilir üretimi desteklemektedir. Ancak üreticilerin bilgi eksikliği, yüksek yatırım maliyetleri ve yeniliklere karşı isteksizlik gibi sınırlamalar, bu uygulamaların yaygınlaşmasını güçleştirmektedir. İklim değişikliğinin yol açtığı sıcaklık artışları, kuraklık, sel, zararlı ve hastalık baskısı sürdürülebilir uygulamaların gerekliliğini daha da artırmaktadır. Toprak sağlığını koruyan, su verimliliğini yükselten ve karbon tutulumunu destekleyen yöntemler tarım sistemlerini iklim risklerine karşı daha dayanıklı hâle getirmektedir. Sonuç olarak sürdürülebilir tarım; çevresel koruma, ekonomik dayanıklılık ve toplumsal refahı birlikte ele alan bir yaklaşım olup, geleceğe yönelik tarım politikalarının merkezinde yer alması gereken stratejik bir dönüşümü ifade etmektedir.

Anahtar Kelimeler: Sürdürülebilir tarım, Ekolojik denge, Yenilik ve yayılım süreçleri, Tarımsal sürdürülebilirlik politikaları

SUSTAINABLE AGRICULTURAL SYSTEMS IN ENVIRONMENTAL, ECONOMIC, AND SOCIAL DIMENSIONS

ABSTRACT

Agriculture occupies a central role in food production, economic development, and the preservation of natural resources. Rising population, climate change, water scarcity, and soil degradation are increasingly making agricultural production more vulnerable. Although traditional farming practices were effective in the past, their reliance on intensive chemical inputs and the associated environmental pressures render them insufficient for sustainability under current conditions. Consequently, sustainable agriculture has gained importance as a holistic approach that prioritizes the conservation of natural resources, the reduction of environmental impacts, and the production of safe food. These systems aim to optimize soil, water, and energy cycles, with practices such as renewable energy utilization, organic fertilization, cover cropping, and diversified production techniques being central. Globally, digital farming applications, sensors, data-driven management, and modern breeding programs are supporting sustainable production. However, limitations such as farmers' lack of knowledge, high investment costs, and reluctance to adopt innovations hinder the widespread implementation of these practices. Climate change–induced temperature increases, droughts, floods, and pest and disease pressures further emphasize the necessity of sustainable approaches. Methods that maintain soil health, enhance water efficiency, and promote carbon sequestration increase the resilience of agricultural systems to climate risks. In conclusion, sustainable agriculture represents a strategic transformation that integrates environmental protection, economic resilience, and societal well-being, and should occupy a central place in future agricultural policies.

Keywords: Sustainable agriculture, Ecological balance, Innovation and adoption processes, Agricultural sustainability policies

GİRİŞ

Tarım, gıda üretimini sağlayarak ve ekonomik kalkınmaya katkıda bulunarak insan yaşamının sürdürülmesinde temel bir rol oynamaktadır. Tüketicilerin güvenli gıdaya ulaşması, gıdaların raf ömrünü uzatmak amacıyla işlenmeleri, ekolojik dengenin ve tarımsal kaynakların korunması vb. gelişmeler tarımı önemli bir sektör haline getirmiştir. Dünyada nüfusun hızlı bir şekilde artması çevresel sorunları da beraberinde getirmektedir (Yılmaz ve Yücel, 2017). Son yıllarda iklim değişikliği, kaynak kıtlığı ve artan gıda talebi tarım sektörünün karşı karşıya kaldığı en önemli zorlukların başında gelmektedir. Bu talebin karşılanmasında yoğun girdili konvansiyonel (geleneksel) tarımsal uygulamalar önem kazanmıştır (Eryılmaz ve Kılıç,2018). Geleneksel tarım teknikleri geçmişte başarılı olsa da genellikle sürdürülemez çevresel etkilere, aşırı kimyasal girdiye ve verimsiz kaynak kullanımına neden olmaktadır. Ayrıca hızlı nüfus artışı ve iklim değişikliklerinin yaşandığı bir çağda ürün yönetimi ve kaynak bulmada zorluk yaşanmaktadır (Wang ve Li, 2025).

Sürdürülebilirlik kavramı, çevresel kaynakların sınırlı olduğu dünyada ekonomik büyüme ve kalkınmanın geleceğini güvence altına almak amacıyla ortaya çıkmıştır. Sürdürülebilir tarım, doğaya zarar vermeyen teknolojilerin kullanıldığı, uzun vadede verimi artırmayı amaçlayan, doğal kaynakların korunmasını sağlayan tarımsal üretim yöntemlerinin bütünüdür (Yılmaz ve Yücel, 2017). Sürdürülebilir tarımın dünyada önem kazanmasıyla birlikte çevreyi ve insan sağlığını korumayı hedefleyen bu sistemlerin yaygınlaştırılması giderek daha kritik bir hâl almıştır. En yaygın sürdürülebilir tarım sistemlerinden biri olan iyi tarım uygulamaları, her geçen gün daha fazla önem kazanmakta; yapılan işlemlerin kayıt altına alınmasını esas alan kontrollü bir tarımsal faaliyet olarak öne çıkmaktadır. İyi tarım uygulamalarında kullanılan zirai ilaç ve gübrenin miktarı, uygulama zamanı, uygulayıcının ismi, ürünün tür ve çeşidi gibi kayıtlar tutularak izlenebilirlik ve sürdürülebilirlik yerine getirilmiş olur (Eryılmaz ve Kılıç, 2018).

Sürdürülebilir tarım kavramı, tarımsal verimliliği en üst düzeye çıkarırken ekonomik istikrarı korumaya; aynı zamanda sınırlı doğal kaynak kullanımını ve zararlı çevresel etkileri en aza indirmeye dayanır. Tarımsal sürdürülebilirlik, herkes için sonsuza dek izlenmesi gereken toplumsal bir hedeftir ve genel ilkeler tarafından yönlendirilmelidir (Gerber, 1992).

Sürdürülebilir tarım sistemleri, mevcut toprak besin ve su döngülerinden, enerji akışlarından, faydalı toprak organizmalarından ve doğal zararlı kontrol mekanizmalarından maksimum düzeyde yararlanacak şekilde tasarlanır. Mevcut döngü ve akışlardan yararlanılarak çevresel zararlar önlenebilir ya da en aza indirilebilir. Bu sistemler ayrıca besleyici ve insan sağlığına zarar verebilecek maddelerle kontamine olmamış gıda üretmeyi hedefler. Sürdürülebilir tarım sistemlerinin bir diğer önemli boyutu ise yenilenebilir enerji kaynaklarının entegrasyonudur. Sürdürülebilir bir sistem biyolojik, jeotermal, hidroelektrik, güneş veya rüzgâr gibi yenilenebilir enerji kaynaklarını kullanır. Yeraltı suyunun yenilenme hızından fazla kullanılması gibi geri dönüştürülebilir kaynakların aşırı kullanımı rezervleri tüketir ve sürdürülemez. Dünyaya ulaşan güneş radyasyonu doğadaki en temel yenilenebilir enerji kaynağıdır. Biyosistemi, okyanusu ve atmosfer akımlarını güçlendirir ve küresel iklimi etkiler (Omer, 2008). Yenilenebilir enerji kaynakları, özellikle kırsal alanlarda tarımsal üretimin sürdürülebilirliğini destekler; fosil yakıtlara olan bağımlılığı azaltarak çevresel etkileri en aza indirir. Böylece sürdürülebilir tarımın çevresel, ekonomik ve sosyal hedeflerine ulaşmasına katkıda bulunur.

Bilgi eksikliği, uygulamaların benimsenmesinde önemli bir engel oluşturmaktadır. Sürdürülebilir bir uygulamanın varlığına ilişkin bilgi eksikliği, uygulamanın maliyet ve faydalarına dair belirsizlikler ve uygulamanın nasıl gerçekleştirileceğine dair yetersiz bilgi, benimsemenin önünde önemli engeller yaratabilir. Bu sorunlar, üreticilerin sürdürülebilir

uygulamaları benimsemelerini teşvik eden tarımsal yayım programlarının geliştirilmesi açısından kritik sonuçlar doğurur. Bilgi eksikliklerini azaltmak, uygulamaların benimsenmesi ve sürdürülebilir tarım sistemlerinin geliştirilmesi önünde önemli bir engel oluştukları için öncelikli bir araştırma alanıdır (Reganold ve ark. 2011).

Günümüzde artan nüfus, iklim değişikliği ve doğal kaynakların azalması, tarımsal üretimde sürdürülebilirliği zorunlu hale getirmiştir. Bu bağlamda, sürdürülebilir tarımsal gelişmelerin hem yerel hem de küresel ölçekte değerlendirilmesi büyük önem taşımaktadır. Bu makalenin amacı, Türkiye ve dünyada sürdürülebilir tarımsal gelişmelerin tarihsel sürecini, mevcut uygulamalarını ve gelecek projeksiyonlarını analiz ederek; çevresel, ekonomik ve sosyal boyutlarda sürdürülebilirliğin tarımsal kalkınmaya etkilerini ortaya koymaktır.

1. Sürdürülebilir Tarım Kavramı

Sürdürülebilir tarım, ekonomik, çevresel ve sosyal hedefleri bütünleştirerek tarımsal üretimin uzun vadede devamlılığını sağlamayı amaçlayan bir yaklaşımdır (Hansen, 1996). Bu yaklaşım, tarımsal sistemlerin üretkenliğini korurken çevresel kaynakların ve toplumsal refahın sürdürülebilir biçimde kullanılmasına odaklanır (Ikerd, 1990). Sürdürülebilir uygulamalar, hem çevresel ve sosyal faydalar sağlamak hem de üreticilerin maliyetlerini düşürerek ekonomik getirilerini artırmak amacıyla geliştirilir. Uygulamaların maliyet-fayda dengesi farklılık gösterdiğinden, üreticilerin kararları ve yayım faaliyetlerinin etkinliği doğrudan etkilenir (Pannell, 2008). Bilgi eksiklikleri, uygulamanın varlığı, maliyeti, faydası ve uygulama yöntemleri hakkında karar alıcıların sahip olduğu sınırlı bilgiler, benimsenmenin önünde önemli bir engel oluşturmaktadır. Sürdürülebilir uygulamaların benimsenmesi iki sosyal süreçle açıklanabilir: yenilik ve iş birliği. Ekonomik faydaların maliyetleri aşan uygulamalarda yenilik ön plana çıkarken, sosyal faydaların kolektif çabayla sağlandığı uygulamalarda iş birliği temel rol oynar (Rogers, 2003; Ostrom, 1990). Yüksek öncelikli yenilik uygulamaları, bireysel faydalar nedeniyle daha kolay benimsenirken, yüksek öncelikli iş birliği uygulamaları kolektif hareket gerektirir. Öğrenme stratejileri ve sosyal ağlar, bilgi eksikliklerinin oluşumunu etkiler ve düşük fayda-yüksek maliyet uygulamalarda bilgi boşlukları daha yaygındır.

2. Türkiye ve Dünyada Yaşanan Gelişmeler

Dünyada tarım alanlarının azalması ve su kaynaklarının giderek daha fazla tehdit altına girmesi, küresel gıda güvenliği açısından ciddi bir sorun teşkil etmektedir. Özellikle iklim değişikliği, toprak erozyonu, su kıtlığı ve hava kirliliği gibi faktörler, tarımın verimli bir şekilde sürdürülebilmesi önünde büyük engeller oluşturmaktadır. Bu durumda, tarım politikalarının yeniden şekillendirilmesi, sürdürülebilir tarım tekniklerinin uygulanması ve verimli toprakların korunması, oldukça kritik bir hale gelmiştir. Brezilya ve İsrail gibi ülkeler, tarım verimliliğini artırmak için toprak ıslahı konusunda önemli adımlar atarken, Türkiye ve Çin gibi bazı ülkeler ise sınırlı tarım alanlarını başka kullanım alanlarına dönüştürme yoluna gitmişlerdir. Bu da bir yandan verimli toprakların kaybı, diğer yandan da üretim kapasitesinin azalması anlamına gelmektedir. Bu sorunun çözülmesi için daha etkili ve sürdürülebilir tarım yöntemlerinin benimsenmesi şarttır. Tarım sektöründe sürdürülebilirliğin sağlanabilmesi, büyük ölçüde teknolojik yeniliklerin ve modern üretim tekniklerinin etkin biçimde uygulanmasına bağlıdır. Bu kapsamda dijital tarım uygulamaları, su kaynaklarının rasyonel yönetimi ve toprak verimliliğini artırmaya yönelik ıslah çalışmaları, üretim süreçlerinin verimliliğini yükseltmekte ve kaynak kullanımını optimize etmektedir. Söz konusu gelişmeler, küresel ölçekte gıda güvenliğinin korunması açısından stratejik bir önem taşımaktadır (Turhan, 2005).

Tarımsal üretim süreçlerinde aşırı kimyasal girdi kullanımının ürün kalitesi ve çevre üzerindeki olumsuz etkilerini en aza indirmek ve çevresel sürdürülebilirliği sağlamak amacıyla, özellikle

gelişmiş ülkeler başta olmak üzere birçok ülkede sürdürülebilir tarım sistemlerinin uygulanması ve desteklenmesi teşvik edilmektedir. Finlandiya'da tarımsal faaliyetlerde su kaynaklarının neden olduğu çevresel kirliliğinin azaltılmasına, Almanya, İsviçre, Hollanda ve Fransa gibi ülkelerde ise tarıma elverişliliği düşük alanların üretim sürecine dâhil edilmesine yönelik politikalar kapsamında mali destek programları yürütülmektedir. Geleneksel tarım uygulamalarının karşı karşıya olduğu verimlilik, kaynak kullanımı ve çevresel sürdürülebilirlik sorunlarının aşılabilmesi amacıyla, büyük veri analitiği ve makine öğrenimi gibi yenilikçi teknolojiler geliştirilmiştir. Tarım alanlarının yoğun ve verimli kullanımında dünya liderlerinden biri konumunda bulunan Çin, söz konusu teknolojileri kapsamlı biçimde benimsemiş ve geliştirmiştir. Toprak sağlığı, hava koşulları ve nem düzeylerinin gerçek zamanlı izlenebilmesi için insansız hava araçları (dronlar), yapay zekâ algoritmaları ve nesnelerin interneti (IoT) tabanlı sistemler etkin biçimde kullanılmaktadır. Bu teknolojik yaklaşımlar, tarımsal üretim verimliliğinin artırılmasına ve karar verme süreçlerinin daha bilimsel temellere dayandırılmasına önemli katkılar sağlamaktadır (Wang ve Li, 2025).

Doğal kaynakların korunması ile çevresel zararları en aza indirgeyen, topraktaki karbon miktarını artıran, toprak erozyonunu azaltan, gıda kalitesini artırarak insan sağlığının ve gıda güvenliğinin üst seviyede tutulmasını sağlayan iyi tarım uygulamaları Türkiye' de ilk kez 2007 yılında başlamış olup üretici sayısı ve üretim alanı bakımından 2013 yılından itibaren önemli oranda artış yaşanmıştır (Kayişoğlu ve Türksoy, 2023).

Çizelge 1: 2007-2021 İyi Tarım Göstergeleri

Yıl	İl Sayısı	Üretici Sayısı	Üretim Alanı (Ha)	Üretim Miktarı (Ton)
2007	18	651	5.361	6.000
2021	63	10.265	389.485	6.162.544

3. Sürdürülebilir Tarım Sistemleri ve Temel Hedefler

Sürdürülebilir tarım sistemleri, mevcut toprak besin ve su döngülerinden, enerji akışlarından, faydalı toprak organizmalarından ve doğal zararlı kontrol mekanizmalarından maksimum düzeyde yararlanacak şekilde tasarlanır. Böylece çevresel zararlar önlenebilir veya en aza indirilebilir (Lichtfouse ve ark., 2009). Sistemler aynı zamanda besleyici ve insan sağlığına zarar vermeyecek şekilde güvenli gıda üretmeyi hedefler. Temel hedefler arasında; daha kârlı çiftlik gelirleri sağlamak, çevresel korumayı teşvik etmek ve çiftçi aileleri ile kırsal toplulukların yaşam kalitesini artırmak bulunur. Bu hedefler doğrultusunda toprak kalitesinin korunması ve iyileştirilmesi, tükenebilir kaynaklara bağımlılığın azaltılması ve çevresel risklerin minimize edilmesi büyük önem taşır. Ekolojik açıdan, sürdürülebilir tarım yoğun üretime rağmen çevre kalitesini korumayı hedefler. Yoğun hayvancılık ve sentetik gübre kullanımı, sera gazı emisyonlarına katkıda bulunur ve su ile toprak kalitesine zarar verir. Bunun aksine, sürdürülebilir uygulamalar, toprak ve su yönetimi, örtü bitkileri, ürün ve peyzaj çeşitliliği, agroforestry ve organik gübreleme gibi yöntemlerle çevresel riskleri azaltır. Ayrıca, sürdürülebilir enerji kullanımı; biyokütle, güneş, rüzgâr ve hidroelektrik gibi yenilenebilir enerji kaynaklarıyla fosil yakıtlara bağımlılığı azaltarak çevresel etkileri en aza indirir (Omer, 2008).

4. Geleneksel Tarım ve Bilgi Eksikliği

Geleneksel tarım uygulamaları, özellikle gelişmekte olan ve az gelişmiş bölgelerde hâlâ yaygın olup, çoğunlukla yüksek maliyet, sınırlı eğitim düzeyi ve pazarlama kanallarının kısıtlılığı gibi faktörlerden etkilenmektedir. Bu durum, çiftçilerin yeni tarımsal teknolojileri ve sürdürülebilir uygulamaları benimseme isteksizliğine yol açmaktadır. Üreticilerin bilgi eksikliği, sürdürülebilir tarım uygulamalarının verimli bir şekilde yayılmasının önünde önemli bir engel oluşturmaktadır; örneğin, uygulamaların maliyeti, faydaları ve doğru yöntemleri hakkında yeterli bilgiye sahip olmamaları, benimsemeyi geciktirmektedir (Pannell, 2008). Aynı zamanda, geleneksel tarım yöntemleri, iklim değişikliği, kuraklık, zararlılar ve doğal afetler gibi mevcut çevresel risklere karşı direnç geliştirmede sınırlı kalabilmektedir. Bu nedenle, üreticilerin bilgi ve eğitim düzeyinin artırılması, sosyal ağların güçlendirilmesi ve doğru yayım stratejilerinin uygulanması, sürdürülebilir tarımın etkin bir şekilde benimsenmesini ve uzun vadeli verimliliğin sağlanmasını mümkün kılmaktadır (Rogers, 2003; Ostrom, 1990).

5. İklim Değişikliği ve Sürdürülebilir Tarım

İklim değişikliği, küresel tarımın karşı karşıya olduğu en ciddi zorluklardan biri olarak ön plana çıkmaktadır. Artan sıcaklıklar, düzensiz yağış dağılımları, kuraklık, sel ve ekstrem hava olayları, tarımsal üretim üzerinde doğrudan ve dolaylı etkiler yaratmaktadır. Bu durum, çölleşme tehdidini artırmakta ve bazı bölgelerde tarımsal üretimi sürdürülemez hâle getirmektedir. Tuzluluk, böcek ve hastalık istilaları ile su kaynaklarının azalması hem bitkisel hem de hayvansal üretimi olumsuz etkilemektedir. Mevcut tarım alanlarının verimliliği, bu çevresel baskılar nedeniyle azalmakta, gıda güvenliği ve ekonomik sürdürülebilirlik üzerinde ciddi riskler oluşmaktadır. Küresel nüfusun 2050 yılına kadar 9,7 milyara ulaşması öngörülürken, bu etkiler tarım dışı kalacak alanların artması ve kaynakların daha verimli yönetilmesi ihtiyacını doğurmaktadır. Geleneksel tarım sistemleri, iklim değişikliğine uyum sağlama kapasitesi sınırlı olduğundan, sürdürülebilir tarım uygulamalarının önemi daha da belirginleşmektedir. Sürdürülebilir tarım, doğal kaynakların yönetimi ve korunmasını ön plana çıkararak iklim değişikliğinin olumsuz etkilerini azaltmayı hedefler (FAO). Toprak ve su döngülerinden, enerji akışlarından ve biyolojik çeşitlilikten maksimum yararlanmak hem verimliliği artırmak hem de çevresel zararları en aza indirmek açısından kritik öneme sahiptir. Örtü bitkileri, ürün ve peyzaj çeşitliliği, agroforestry, minimum toprak işleme ve organik gübreleme gibi uygulamalar, tarımsal sistemleri iklim stresine karşı daha dirençli hâle getirir. Bu yöntemler, aynı zamanda sera gazı emisyonlarının azaltılmasına, karbon bağlanmasına ve toprak sağlığının korunmasına katkı sağlar. İklim değişikliği ile mücadelede yenilikçi teknolojiler ve dijital tarım uygulamaları da önemli bir rol üstlenmektedir. Akıllı sulama sistemleri, hassas gübreleme ve yapay zekâ tabanlı üretim planlaması, tarımda kaynak kullanımını optimize ederek verimliliği artırmakta ve çevresel riskleri azaltmaktadır. Benzer şekilde, iklim dostu tarım uygulamaları, sera gazı emisyonlarını azaltan ve çiftçilerin iklim değişikliğine uyumunu kolaylaştıran stratejiler sunmaktadır. Bu yaklaşımlar hem ekonomik hem de ekolojik sürdürülebilirliği bir arada sağlayarak uzun vadeli üretkenliği güvence altına alır. Sürdürülebilir tarımın iklim değişikliği ile ilişkisi aynı zamanda sosyo-ekonomik boyutu da kapsamaktadır. Çiftçilerin eğitim düzeyi, bilgi eksikliği ve sınırlı erişim imkânları, yeniliklerin benimsenmesini sınırlandırmakta ve iklim risklerine karşı kırılganlığı artırmaktadır. Bu nedenle, bilgi ağlarının güçlendirilmesi, eğitim programlarının uygulanması ve topluluk temelli iş birliği mekanizmalarının desteklenmesi, iklim değişikliğine karşı daha dirençli ve sürdürülebilir tarım sistemlerinin oluşturulmasını mümkün kılmaktadır (Rogers, 2003; Ostrom, 1990).

6. Sürdürülebilir Tarım Yenilikleri ve Benimsenme Süreci

Sürdürülebilir tarım yenilikleri, iklim değişikliği, zararlılar, kuraklık, doğal afetler ve gıda güvensizliği gibi tarımın karşı karşıya olduğu zorlukların üstesinden gelmede önemli araçlar olarak kabul edilmektedir. Ancak bu yeniliklerin benimsenme düzeyi sınırlıdır ve benimsenmenin belirleyicileri üzerine daha fazla araştırmaya ihtiyaç duyulmaktadır. Bu durum, akademisyenlerin politika yapıcılara sürdürülebilir tarım yeniliklerinin benimsenmesini güçlendirecek daha net ve uygulanabilir mesajlar iletebilmesi için yeni çalışmaların gerekliliğini ortaya koymaktadır. Farklı kavramsal modeller; agroforestry sistemleri, gübre ağaç sistemleri, koruyucu tarım, organik tarım ve yeşil pestisitler gibi yeniliklerin benimsenmesini etkileyen faktörleri incelemektedir. Rogers tarafından geliştirilen "yeniliklerin yayılımı teorisi" (Diffusion of Innovations, DOI), yenilikçi teknolojilerin yayılımı ve benimsenmesinin; teknolojinin uyumluluğu ve karmaşıklığı, potansiyel kullanıcının özellikleri, kişinin teknolojiye ilişkin algısı ve bilgisi ile grup, kitle ve bireysel iletişim kanalları tarafından belirlendiğini öne sürmektedir. Tarımsal ürünlerde sürdürülebilir uygulamaların benimsenmesini etkileyen iki temel sosyal süreç bulunmaktadır. Bunlardan en bilineni, Rogers (2003) tarafından ortaya atılan ve tarımsal karar verme üzerine yüzlerce çalışmada uygulanan "yeniliğin yayılımı" modelidir (Prokopy ve ark., 2008). Bu hedeflere ulaşmak amacıyla birçok tarımsal ürün ve bölgede, üreticilerin sürdürülebilir uygulamaları benimsemesini teşvik eden yerel programlar ve ortaklıklar geliştirilmiştir (Warner, 2007a, b). Sürdürülebilir tarım, ekonomik, çevresel ve sosyal hedefleri birleştirmeyi amaçlayan bir yaklaşım olarak uzun bir geçmişe sahiptir (Hansen, 1996). Bu yaklaşım, tarımsal sistemlerin üretkenliğini ve faydasını uzun vadede sürdürebilmesini sağlayacak şekilde tasarlanmıştır (Ikerd, 1990). Sürdürülebilir uygulamaların benimsenmesi iki sosyal süreçle açıklanabilir: yenilik ve iş birliği. Ekonomik faydaların maliyetlerden fazla olduğu uygulamalarda yenilik, sosyal faydaların kolektif çabayla sağlandığı uygulamalarda ise iş birliği ön plana çıkar (Rogers, 2003; Ostrom, 1990). Sürdürülebilir yenilikler, çevresel ve sosyal fayda üretirken ekonomik değer sağlayan ürünler, hizmetler, teknolojiler, süreçler ve yönetim tekniklerini kapsar. Sürdürülebilir tarım yenilikleri; çiftçi düzeyinde yeşil gübre, kompost, koruyucu toprak işleme ve baklagil ekim nöbeti gibi uygulamaları; çiftlik dışı düzeyde ise kısa tedarik zincirleri ve kooperatiflerin benimsenmesini içerir. Ayrıca dijital tarım teknolojileri ve yapay zekâ çözümleri, su, gübre ve herbisit kullanımını optimize ederek değişen iklim koşullarına uyum sağlamayı desteklemektedir.

7. Yeni Araştırma Yönelimleri ve Teknolojik Uygulamalar

Ekolojik yoğunlaştırma, genetik ve sosyo-ekonomik yoğunlaştırma ile iklim dostu tarım gibi yeni araştırma yönelimleri, tarımsal verimliliği artırmayı ve çevresel etkileri azaltmayı hedeflemektedir. Bu yaklaşımlar, agroekoloji ve bütüncül sistem düşüncesi ile birleşerek, bitkiler, hayvanlar, insanlar ve çevre arasındaki karşılıklı bağımlılığı güçlendirmekte, gıda güvenliğini ve biyolojik çeşitliliği desteklemektedir. Sürdürülebilir tarımın, yalnızca bireysel üretim süreçlerini değil, aynı zamanda toplumsal yapıları, teknolojik yenilikleri ve politika mekanizmalarını da kapsayan kapsamlı bir sistem olduğu görülmektedir.

Sonuç

Sürdürülebilir tarımın etkin bir şekilde uygulanması, ekonomik, çevresel ve sosyal boyutların bir arada değerlendirilmesini gerektirmektedir. Ancak bu süreç, üreticilerin bilgi eksikliği, yüksek yatırım maliyetleri, yeniliğe isteksizlik, toplumsal farkındalık eksikliği ve karmaşık/yetersiz yasal çerçeveler gibi çok boyutlu sınırlamalarla karşı karşıyadır. Bu engeller, sürdürülebilir tarım uygulamalarının yaygınlaştırılmasını ve benimsenmesini güçleştirmektedir. Söz konusu sınırlamaların ekonomik, sosyal ve yönetsel boyutları, tarımın geleceğine yönelik stratejilerin yalnızca tek bir düzeyde değil, sektörler arası ve paydaşlar arası

iş birliğine dayalı olarak geliştirilmesini zorunlu kılmaktadır. Sürdürülebilir tarım, doğal kaynakların korunması, çevresel etkilerin azaltılması ve kırsal toplulukların yaşam kalitesinin iyileştirilmesi gibi hedefleri bütüncül bir şekilde ele alırken, teknolojik yeniliklerin ve dijital tarım çözümlerinin doğru uygulanmasıyla ekonomik sürdürülebilirliği de desteklemektedir. Günümüzde artan nüfus, iklim değişikliği ve doğal kaynakların azalması, tarımsal üretimde sürdürülebilirliği zorunlu hale getirmiştir. Bu bağlamda, sürdürülebilir tarımsal gelişmelerin hem yerel hem de küresel ölçekte değerlendirilmesi büyük önem taşımaktadır. Bu makalede sürdürülebilir tarım kavramını ve sistemlerini ele alarak; temel hedefleri, geleneksel tarımdaki bilgi eksikliklerini, iklim değişikliğiyle ilişkisini, yeniliklerin benimsenme sürecini, yeni araştırma yönelimlerini ve teknolojik uygulamaları incelenmiştir. Bu çalışma, mevcut tarımsal süreçler ve uygulamalara dair kapsamlı bir bakış sunmakta ve sürdürülebilir tarımın yayılımı ile etkinliğinin artırılması için odaklanılması gereken alanları ortaya koymaktadır. Özellikle bilgi ağlarının güçlendirilmesi, eğitim ve yayım programlarının geliştirilmesi, iklim değişikliği ve çevresel risklerin yönetilmesi ile yenilikçi teknolojilerin benimsenmesi, gelecekteki araştırmalar ve politika önerileri için kritik öneme sahiptir.

ÖZET

Kuraklık, dünyada önemli çevre sorunlarından biridir. Bir mevsim ile birkaç yıl aralığı kapsayabilen, mevsim ortalamasından düşük yağış dönemleri ya da yağışın olmaması sonucu kuraklık ortaya çıkmaktadır. Bir bölgenin iklim koşulları temel alınarak, ilgili bölgede beklenen yağış miktarının düşmesi meteorolojik kuraklığı; belirli bir zaman aralığında, meralar ve üretimi yapılan belirli bir tarımsal ürün için gerekli olan toprak suyu ve toprak nemi olmaması tarımsal kuraklığı; yer altı ve yüzey suyu kaynaklarındaki azalma hidrolojik kuraklığı göstermektedir. Bu üç temel kuraklık türü ile doğrudan ya da dolaylı olarak ilişkili kuraklık türleri de bulunmaktadır. Bu kapsamda, hızlı bir şekilde başlayarak etkisi haftalarca sürebilen birçok sektörü olumsuz etkileyebilen kuraklık ani kuraklığı; ekosistemi etkileyen hem doğal hem de insan kaynaklı döngülere yol açan periyodik su kıtlığı ekolojik kuraklığı; su arzı ve talebine bağlı olarak endüstriyel hizmet ve ticari mal bulunabilirliğinin azalması sosyo-ekonomik kuraklığı temsil etmektedir. Kuraklık, doğal ve yapay nedenlerle meydana gelmektedir. Kuraklığın doğal nedenleri hava koşullarında değişkenlik, hava sirkülasyonu, okyanus sıcaklığında dalgalanmalar ve toprak neminin azalması olarak sıralanabilir. Kuraklığın yapay nedenleri ise tarımsal faaliyetlerin bilinçli yapılmaması, nehirler üzerine inşa edilen barajların kentleşme ve arazi değişikliklerine yol açabilmesi, ormanların yok olması ve madencilik faaliyetleri olarak sıralanabilir. Kuraklığın toprak ve su kaynaklarında bozulmalara bağlı olarak kaynaklarda tükenme, tarımsal üretim verimliliğinde düşme, biyolojik çeşitliliğin olumsuz etkilenmesi, kuraklık sonucu ormanların kuruması ve orman yangınları gibi etkileri bulunmaktadır. Dolayısıyla kuraklığın türleri, nedenleri ve etkilerine ilişkin bileşenler, kuraklıkla mücadele tedbirlerinin planlanması açısından önemlidir.

Anahtar Kelimeler: Çevre sorunu, Kuraklık, Kuraklık bileşenleri

TYPES OF DROUGHT, CAUSES AND EFFECTS

ABSTRACT

Drought is one of the major environmental problems in the world. It occurs as a result of periods of below-average rainfall or no rainfall at all, which can last from one season to several years. Based on a region's climatic conditions, a decrease in the expected amount of rainfall in that region indicates meteorological drought; the absence of soil water and soil moisture necessary for pastures and the production of specific agricultural products within a certain time frame indicates agricultural drought; and a decrease in groundwater and surface water resources indicates hydrological drought. There are also types of drought that are directly or indirectly related to these three basic types of drought. In this context, drought that begins rapidly and can last for weeks, negatively affecting many sectors, represents sudden drought; periodic water scarcity that causes both natural and human-induced cycles affecting the ecosystem represents ecological drought; and the decrease in the availability of industrial services and commercial goods depending on water supply and demand represents socio-economic drought. Drought occurs due to both natural and artificial causes. The natural causes of drought include variability in weather conditions, air circulation, fluctuations in ocean temperatures, and a decrease in soil moisture. The artificial causes of drought include the lack of awareness in agricultural activities, the construction of dams on rivers leading to urbanisation and land changes, deforestation, and mining activities. The effects of drought include depletion of resources due to degradation of soil and water resources, decline in agricultural production efficiency, negative impact on biological diversity, drying of forests as a result of drought, and forest fires. Therefore, the components related to the types, causes, and effects of drought are important for planning measures to address drought.

Keywords: Environmental problem, Drought, Drought components

1. Giriş

Dünya iklimlerinde meydana gelen kuraklık çevresel, ekonomik ve toplumsal etkileri olan bir doğal afet olarak kabul edilmektedir (Naumann vd., 2018; Van Loon, 2015). Kuraklığın başlangıcını tespit edebilmek, genel olarak zor olabilir. Kasırga, hortum ve deprem gibi ani gelişen birçok doğal afetin aksine, kuraklığın kademeli ve sinsi bir şekilde gelişebildiği rapor edilmiştir (Cravens vd., 2021; Wu vd., 2018a). Kuraklık, su döngüsünde aşırılık durumu ve diğer bağımlı sistemlerin zorladığı bir süreç olarak görülebilir (Wilhite vd., 2007). Dolayısıyla kuraklık, su döngüsünün herhangi bir noktasında, su talebi ve su arzı arasında dengesizliğe yol açan herhangi bir bağlantıda ortaya çıkabilir. Tarım ve enerji üretiminin su temini aşamasında aksamalar olması kuraklıkla ilişkili olup, kuraklık ekosistemler için önemli tehditlerden biridir. Tarımsal, endüstriyel ve yaşamsal alanlarda ihtiyaçlar su ile karşılanamadığında, olumsuz etkiler ortaya çıkabilir. Kuraklığın getirdiği olumsuzlukları en aza indirmek için su kaynaklarının planlanması ve yönetimi önem arz etmektedir. Su kaynaklarının tahsisi ve düzenlenmesi ile ilişkili olan kuraklık, su talebi ve su arzı bakımından değerlendirilebilir. Su temin sisteminde yüzey akışı, toprak nemi ve rezervuar suyu depolanması ile bitkilerin büyüme süreci su talep sisteminde bulunmaktadır. Su temini kapsamında, buzul ve yağış gibi su kaynaklarının zaman ve mekânsal ölçekte değiştiği bildirilmiştir. Geleneksel olarak bu durumların bir mevsim ya da daha fazla mevsim süresince kademeli gerçekleşmesi, kuraklık koşullarının yavaş şekilde başlaması ile karakterize edilmiştir (Jing vd., 2012; Fung vd., 2020; Mishra ve Singh, 2010). Kuraklığın olası etkilerinin yönetiminde ve buna uyum sağlamada, küresel ve bölgesel değerlendirmeler yapılması gerekmektedir. Bu derlemenin amacı, kuraklıkla mücadele tedbirlerinin iyi planlanması için kuraklığın türleri, nedenleri ve etkilerine ilişkin bileşenleri sunmaktır.

2. Kuraklık Türleri

Kuraklık genel olarak yağış, yer altı suyu, toprak suyu ve akarsu akışının dahil olduğu su eksikliği olarak tanımlanmıştır. Hidrolojik döngü değişkenleriyle ilişkili olan kuraklığın türleri bulunmaktadır. Bu türler Şekil 1'de sunulduğu üzere, temelde su eksikliğinin belirli değişkenlerine göre meteorolojik kuraklık, tarımsal kuraklık, hidrolojik kuraklık olarak sıralanabilir (Mishra ve Singh, 2010; NDMC, 2025). Bu temel kuraklık türleri ile ilişkili ani kuraklık, ekolojik kuraklık ve sosyo-ekonomik kuraklık türleri de bulunmaktadır (Mishra ve Singh, 2010).

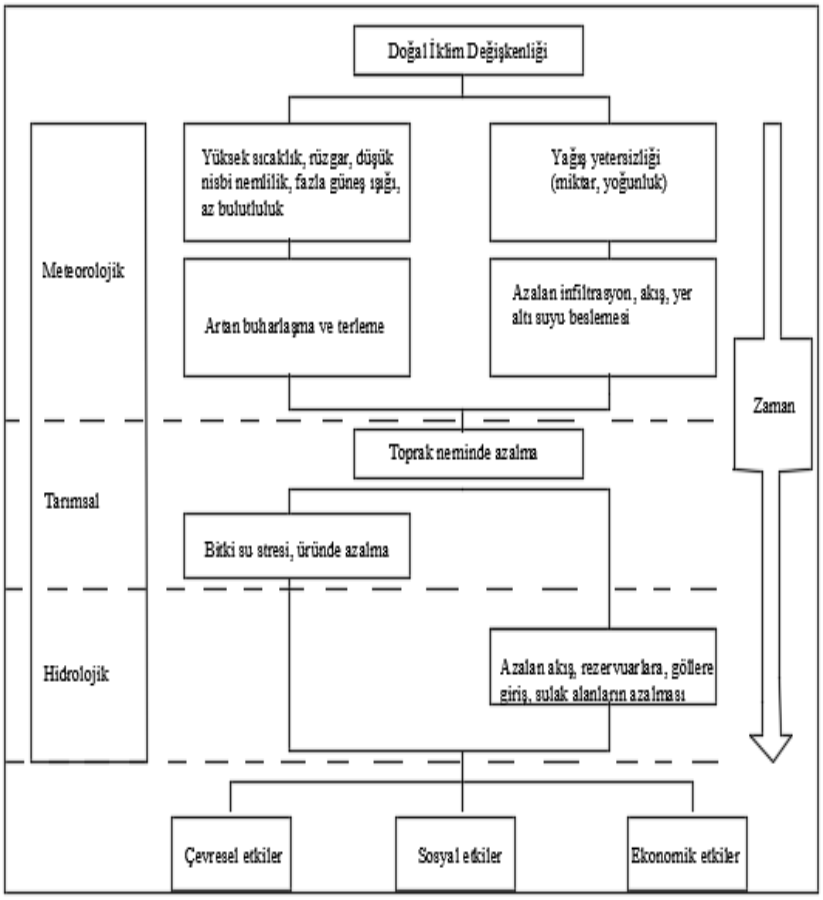
2.1. Meteorolojik Kuraklık

Meteorolojik kuraklık, ardışık dönemlerde yağış azaldığında meydana gelmektedir. Bu kuraklık süresinin fazla olması, kanal akışı ve yer altı suyu rezervlerinde azalmayla hidrolojik kuraklığa neden olabilir. Toprakta mahsullere ulaşan su miktarı, tarımsal faaliyeti olumsuz etkileyecek ölçüde azaldığında tarımsal üretimde azalmaya yol açan tarımsal kuraklığı oluşturacaktır. Kuraklık yağış, sıcaklık, rüzgâr hızı ve güneşlenme süresi gibi faktörlerden etkilenmektedir. Bu faktörlere, antropojenik etkiler de eklendiğinde kuraklığın süreci belirsizlikleri beraberinde getirmektedir (West vd., 2019; Chang vd., 2024).

2.2. Tarımsal Kuraklık

Tarımsal kuraklık, toprak nem açığı ve yağış eksikliğinin yanı sıra hava sıcaklığı ve buharlaşma artışının sonucu olan toprak nem açığı olarak bildirilmiştir. Bu kuraklığın tarımsal faaliyet sonucu elde edilen ürünler üzerindeki etkisi mevsimlere göre değişkenlik göstererek, ürünlerin farklı büyüme adımlarıyla ilişkilendirilmiştir (Mishra ve Singh, 2010; Yu vd., 2018; Wu vd., 2018b).

2.3. Hidrolojik Kuraklık



Meteorolojik kuraklığın genel olarak hidrolojik kuraklığın kaynağı olduğu rapor edilmiştir. Atmosferik süreçlerde meydana gelen anormal durumlar veya antropojenik etkiler nedeniyle yüzey suyu, yeraltı suyu veya rezervuar seviyelerinin uzun vadeli ortalamaların altına düşmesi sonucu hidrolojik kuraklık meydana gelmektedir. Bu kuraklık, tarımsal, evsel ve endüstriyel sistemlerde su arzını tehdit edebilir. Bu nedenle hidrolojik kuraklığın gelişim süreci, kuraklık risk yönetimi ve su kaynakları yönetimi için önem arz etmektedir (Wang vd., 2016; Zhang vd., 2022).

2.4. Ani Kuraklık

Ani kuraklık, yağışın hızla azalmasının neden olduğu buharlaşmadaki artış ve toprak nemliliğinin ani kuruması olarak bildirilmiştir (Koster vd., 2019; Osman vd., 2022). Yağışın ani düşüşü genel olarak normal olmayan derecede yüksek sıcaklık ya da sıcak hava dalgası, güneş radyasyonu, rüzgâr ve düşük nem seviyesini beraberinde getirmektedir (Lowman vd., 2023).

2.5. Ekolojik Kuraklık

Ekolojik kuraklık ekosistemleri dayanıklılık eşiğinin ötesine, savunmasız duruma getiren, ekosistem hizmetlerini etkileyen su mevcudiyetinde epizodik bir açıklık olarak bildirilmiştir (Crausbay vd., 2017). Ekolojik hassasiyetli bölgelerde, büyüme hızı ve hidrolojik süreçleri değiştirmek gibi çeşitli değişiklikler nedeniyle nem ve termal koşullar bitki örtüsü sağlığını etkilemektedir (Vose vd., 2016; Clark vd., 2016).

Şekil 1. Kuraklık türleri

2.6. Sosyo-Ekonomik Kuraklık

Su kaynaklarının su talebini karşılayamadığı durumlarda ortaya çıkan kuraklık türüdür (Zhao vd., 2019). Dolayısıyla, su arzı ve talebiyle ilişkilendirilmektedir.

3. Kuraklık Nedenleri

Atmosfer sistemindeki nem, dünya okyanuslarından kıtalara taşınmaktadır. Bu nemin bir kısmı yeraltı su katmanları, göller ve buzullara hapsolmakta ve nemin geri kalan kısmı ise bitki, nehir ve toprak aracılığıyla akmaktadır. Dolayısıyla kuraklık, genel olarak nem akışındaki sapmalar nedeniyle oluşmaktadır (Ault, 2020). Kuraklığın doğrudan nedenini belirlemek karmaşık olup, genel olarak yağış olmaması veya yağış seviyesinin ortalamanın altında olması durumunda meydana geldiği bilinmektedir. Ayrıca su kaynaklarının kötü yönetimi, ormansızlaşma, arazi kullanımı ve madencilik faaliyetleri gibi antropojenik etkilerin kuraklığın sıklığı ve şiddetini kolayca arttırabileceği bilinmektedir (Ayugi vd., 2020; Abara vd., 2020).

Hava koşulları değişkenliği, hava sirkülasyonu, toprak neminde azalma, okyanus sıcaklığında dalgalanma gibi faktörler, doğal faktörler kaynaklı kuraklıktır. Dünyada bazı bölgelerde, iklim değişikliğine bağlı olarak sıcaklık artışı ve buharlaşma artışı, yaşam koşullarını zor duruma getirmektedir. Buna ilaveten, bazı bölgelerde de yağışın azalması kuraklık riskini arttırmaktadır (Ndayiragije ve Li, 2022).

Su döngüsünün mekânsal düzeni ve sürecini baraj inşaatı, çok havzalı su transferi, tarımsal su yönlendirme ve yapay yağmur gibi insan faaliyetleri, bölgesel buharlaşma taşınım sürecini dönüştürebilir ve su dengesini değiştirebilir. Bu faaliyetlerin su miktarı ve kalitesinin zamansal ve mekânsal süreçlerini değiştirdiği bildirilmiştir. Su talebi sisteminde hidrolik düzenleme kapasitesi, tarımsal yapı, endüstriyel yapı, nüfus gelişimi gibi durumlar, su döngüsü sisteminde su talebini değiştirebilir (Jing vd., 2012).

4. Kuraklık Etkileri

İklim değişikliği etkilerinin çok yönlü olması göz önünde bulundurulduğunda kuraklığın süre, yoğunluk ve alansal yayılım bakımından hem bölgesel değişiklik hem de yerel değişiklik gösterdiği rapor edilmiştir (Loukas vd., 2008). Su temini, yağış ve sıcaklığa duyarlıdır. İklim değişikliğine bağlı olarak topraktaki değişim ve bitki örtüsü, buharlaşma oranını değiştirebilir. Bu değişiklik nedeniyle, su döngüsünde değişimlerin sonucu olarak hidrotermal dengenin bozulacağı beklenmektedir. Kuraklık yüzey sularında azalma, akış hızlarında değişme ve artan şekilde çok yıllık ve çok yıllık olmayan alanların kısmen ya da tamamen kuruması şeklinde kendini göstermektedir. Dolayısıyla balıklar, algler, bitkiler ve mikroorganizmaların dahil olduğu tatlı su ekosistemlerinin taksonomik ve işlevsel biyoçeşitliliğinde azalmalara yol açarak ekolojik süreçleri ve insanlara sağladığı avantajları değiştirmektedir. Kuraklık sıklığı, sıcaklık artışı ile ilişkilendirilerek su kaynağı sisteminin kararlılığını azaltmaktadır. İklim değişikliğinin enerji süreci ve dinamik alanı değiştirerek sıcaklık, yağış ve rüzgâr faktörünü değiştirdiği bildirilmiştir. Buna ilaveten, hava olaylarının aşırılığı arttıkça toprak nemi, yer altı suyu, yüzey suyu ve diğer su kaynaklarının yapısının değişebileceği rapor edilmiştir (Jing vd., 2012; Stubbington vd., 2024).

5. Sonuç

Gelecekte olası kuraklıklara uyum sağlamak ve yönetmek için kuraklığın türleri, nedenleri ve etkilerine ilişkin bileşenlerin, yeni bilgi ve tekniklerin uygulanması açısından değerlendirilmesi gerekmektedir. Kuraklığın nasıl geliştiği anlaşıldığında, kuraklık etkileri azaltılarak gıda güvenliği ve sürdürülebilir bölgesel kalkınma sağlanabilir. Böylece, küresel ve belirli bir alandaki kuraklık davranışının anlaşılmasında ilerleme kaydedilmesi kaçınılmaz olacaktır.

Doğa ve insan arasında geri beslemeleri kapsayan bileşik süreçlerle karakterize edilen çok boyutlu ve ölçekli bir olgu olarak kuraklığın anlaşılması, su kaynakları sistemlerinin yönetimi ve planlanması için avantajlı olacak yeni bakış açıları sağlayacaktır. Doğal akış rejimlerini destekleyen ve habitatlarda çeşitlendirme yapan doğal süreçlere teşvik eden yönetim stratejileri, işlevsel olarak ekosistemlerde biyoçeşitliliği desteklemek için hayati önem taşımaktadır. Kuraklığa ilişkin durumları iyi yönetebilmek için hem küresel hem de bölgesel iş birlikleri yapılması önerilmektedir.

ÖZET

Bu çalışmada dijital tarımın çiftçi davranışları ve tarımsal politikalar üzerindeki etkileri incelenmiştir. Öncelikle dünyada ve Türkiye'de dijital tarımın gelişimi ele alınmış, kullanılan teknolojiler ve uygulama örnekleri kısaca değerlendirilmiştir. Çalışmanın bulguları, dijital tarımın çiftçilerin üretim kararlarını daha bilinçli ve planlı hâle getirdiğini göstermektedir. Ayrıca verimlilik, kaynak kullanımı ve risk yönetimi gibi konularda olumlu etkiler sağladığı görülmüştür. Türkiye'de dijital tarım uygulamaları giderek artmakla birlikte, altyapı ve dijital okuryazarlık gibi bazı sınırlamalar sürecin hızını etkileyebilmektedir. Araştırma ayrıca, dijitalleşmenin tarımsal politikaların veri temelli ve daha hedef odaklı olmasına katkı sağladığını ortaya koymaktadır. Genel olarak çalışma, dijital tarımın hem üreticiler hem de tarım politikaları için önemli bir dönüştürücü güç olduğunu göstermektedir.

IMPACT OF DIGITAL FARMING ON FARMER BEHAVIOR AND AGRICULTURAL POLICIES

ABSTRACT

This study examines the impact of digital agriculture on farmer behavior and agricultural policies. First, the development of digital agriculture globally and in Turkey is examined, and the technologies and application examples used are briefly evaluated. The study's findings indicate that digital agriculture enables farmers to make more informed and planned production decisions. It has also been shown to have positive impacts on productivity, resource utilization, and risk management. While digital agriculture applications are steadily increasing in Turkey, some limitations, such as infrastructure and digital literacy, can slow the pace of the process. The study also reveals that digitalization contributes to agricultural policies being data-driven and more targeted. Overall, the study demonstrates that digital agriculture is a significant transformative force for both producers and agricultural policies.

Keywords: Technology, development, reaction, impact, behavior, digital agriculture

GİRİŞ

Dijital tarım, sensörler, modüller ve dronlar gibi teknolojik aletlerle ekim yapılacak tarlaya özel havadan ve sudan aldığı verileri analiz ederek ekim ve hasat zamanlarını tarımsal süreci, hava durumunu, maliyeti ve erken uyarı sistemi hakkında genel bilgileri çiftçiye sunan bir sistemdir. Dünya genelinde tarımsal üretim; iklim değişikliği, nüfus artışı, girdi maliyetlerindeki yükselme ve iş gücündeki azalma gibi önemli baskılarla karşı karşıyadır. Bu nedenle, tarım sektöründe dijital teknolojilerin kullanımı hızla artmakta ve Tarım 4.0 olarak adlandırılan yeni bir paradigma ortaya çıkmaktadır. Dijital tarım; sensör teknolojileri, uydu görüntüleri, dronler, nesnelerin interneti (IoT), büyük veri analitiği, yapay zeka ve robotik sistemlerin tarımsal üretim süreçlerine entegre edilmesini kapsamaktadır. Dijital tarım gıda sektörünü önemli ölçüde geliştirme potansiyeline sahip olup geleceğin en önemli faktörlerinden biri haline gelmektedir. ileri teknolojiyi insanların kontrolünde çok yönlü bir sistem haline getirmeyi amaçlamaktadır. Dijital tarımın sağladığı dijitalleşme tarımın daha ekonomik ve devamlı olması için önemli bir etken iken aynı zamanda gıda güvenliği ve çevre için de çok önemlidir. Bilimsel araştırmalar, dijital tarım teknolojilerinin başarılı olabilmesi için çiftçilerin bu teknolojileri benimsemesi gerektiğini, bunun da eğitim ve bilinçlendirme programlarıyla desteklenmesi gerektiğini göstermektedir. Tarım sektörü insanlık tarihinin en önemli geçim kaynağı olmuş ve zaman ilerledikçe yenilikler ve değişiklikler yaşanmıştır. Türkiye tarım ekonomisi anlamında dünyada önemli bir yere sahiptir ayrıca sahip olduğu tarımsal alan, genç nüfus yoğunluğu ve Avrupa Asya gibi pazarlara yakınlığından dolayı büyük bir potansiyele sahiptir. Teknolojik gelişmelerden ve dijital tarımdan yararlanılırsa sahip olunan bu tarım potansiyelinden en üst seviyede yararlanabilecektir. Türkiye gibi gelişmekte olan ülkeler nüfusun belli bir kısmının tarım sektöründe çalışması, teknolojik yetersizlik tarım üretiminin büyük ölçüde doğal şartlara bağlı olması ayrıca organizasyon eksikliği gibi konuların çözüme kavuşması için altyapı ve teknolojiye yatırım yapılması gerekmektedir. Bu çalışmanın amacı, teknolojinin gelişmesiyle beraber tarım politikalarının ve çiftçilerin bu yenilik ve gelişmeler üzerindeki tepkileri ve davranışlarını gözlemlemektir. Araştırma, Türkiye tarımının dönüşüm potansiyeli ve politika yapıcılar için stratejik çıkarımlar sunması açısından önem taşımaktadır.

1.GELENEKSEL TARIMDAN DİJİTAL TARIMA

Tarım sektörü geleneksel yöntemlerden tarım teknolojilerine doğru bir kayma yaşamaktadır. Geleneksel tarımda büyük çoğunlukla insan gücünden yararlanılırken dijital tarımda sensörler, dronlar, modüller gibi sistemlerden yararlanılmaktadır. Dijital tarımda kullanılan modern teknoloji daha verimli ve daha sürdürülebilir bir üretim süreci sunmaktadır. Aşağıdaki tabloda, bu iki tarım türünün temel farklılıkları karşılaştırmalı olarak ele alınmaktadır.

Sanayi Devrimi ile Tarım 1.0 dönemini başlanmıştır. 1950'lerde yaşanan Yeşil Devrim, seri üretim teknikleri ve traktör kullanımının yaygınlaşmasıyla verimliliği artırırken; 1990'lardan itibaren bilgisayar ve otomasyon sistemleriyle hassas tarım uygulamaları devreye girmiştir. Günümüzde ise Tarım 4.0 olarak adlandırılan dijital tarım dönemi, bilgi ve teknolojilerinin, yapay zeka, büyük veri ve nesnelerin interneti gibi yenilikçi sistemlerle birleşerek tarımı daha verimli, sürdürülebilir ve akıllı hâle getirmesini sağlamaktadır.

Tablo 1. Geleneksel Tarım ve Dijital Tarım Arasındaki Farklar

ÖZELLİKLER	GELENEKSEL TARIM	DİJİTAL TARIM
İş Gücü ve İhtiyacı	Yoğun iş gücü gerektirir.	Geliştirilen robotik cihazlar ve dronlar sayesinde daha az iş gücü ile yapılır.
Üretim Süreci ve Verim	Ürün elde etme süreci uzundur ve bunun sonucu olarak üretim miktarı da düşüktür.	Daha kısa sürede ürün yetiştirilebilmektedir. Buna bağlı üretim oranı yüksektir.
Hastalık ve Zararlar	Bitki hastalık ve zararları geç tespit edilmektedir bunun sonucunda geç müdahale edilmektedir.	Bitki hastalıkları daha erken tespit edilmektedir.
Tahmin ve Analiz	Arazi durumu, ürün ve verim hakkında tahmin yürütülmektedir.	Büyük oranda hassasiyet ve doğrulukla sonuca varılmaktadır.
Sulama Bağımlılığı	Çiftçiler, sulama için tüp kuyulara sahip oldukları için muson yağmurlarına bağımlı değillerdir.	Akıllı sulama sistemleri ile su tasarrufu sağlanır.
Girdi Kullanımı ve Verimlilik	Aşırı girdi kullanımı vardır ve düşük verimliliğe sahiptir.	Modern tarımda girdiler daha düşüktür.
Üretim Süresi ve Bilimsellik	Bu teknikler çok zaman alır ve üretim azdır.	Zamandan tasarruf sağlanır ve bilime dayalı üretim yapılır
Uygulama Tarihi	Geleneksel tarım uygulamaları, geçmişi çok eskilere dayanan ve artık uygulanmayan uygulamalardır.	Modern tarım tamamen sermaye yoğunluğuna dayalıdır.
Gübre Kullanımı	Gübre olarak inek gübresi ve diğer doğal gübre türleri kullanılır.	Pestisitler ve kimyasal gübreler kullanılmaktadır.
Tohum Kullanımı	Kullanılan geleneksel tohumlar vardır.	Modern tarımda genetik olarak geliştirilmiş tohumlar tercih edilebilir.

(Çilesiz ve Karaköy, 2022).

1.1 Dijital Tarım Teknolojileri ve Uygulama Alanları: Dijital tarım, tarımsal üretimde ölçülebilirliği, izlenebilirliği ve verimliliği artıran teknolojilerin geniş bir yelpazesini içermektedir. Bu teknolojiler arasında:

Hassas Tarım Uygulamaları: Sensörler, uydular ve dronlar ile bitki sağlığı, besin durumu ve toprak nemi gibi özellikleri izlenerek su, ilaç ve gübre kullanımı optimize edilmektedir. Ayrıca hassas tarım ilaç kullanımını azaltmayı, hayvanların potansiyelinden en üst düzeyde faydalanmayı ve hastalıkları erken teşhis etmeyi sağlamaktadır. Geleneksel sağım sistemleri veri depolayamazken, tasarlanan sistem sağım sırasında ölçülen verileri mikrodenetleyici ile Raspberry Pi'a kablosuz aktarılmaktadır. Veriler MySQL veri tabanında saklanır ve Android cihazlardan erişilmektedir. Süt miktarı ve sıcaklığı anlık izlenebilir, tarihe göre filtrelenerek analiz edilebilmektedir. Toplanan bilgiler PDF olarak raporlanabilir; böylece sağım süreci takip edilerek hayvan sağlığı ve verimliliğine yönelik veri temelli kararlar alınabilmektedir.

IoT Tabanlı Sistemler: Tarla ve sera ortamında sıcaklık, nem, EC, pH ve ışık gibi parametreler gerçek zamanlı ölçülerek otomatik kontrol sağlanmaktadır. IoT (Nesnelerin İnterneti) tabanlı sistemler, sensörler ve internet bağlantısı aracılığıyla verilerin toplanmasını, iletilmesini ve analiz edilmesini mümkün kılmaktadır. Bu sistemler, toprak nemi, sıcaklık, ışık, pH, hava durumu ve bitki sağlığı gibi parametreleri izleyerek veri odaklı karar alınmasını sağlamaktadır. IoT çözümleri sulama, gübreleme ve ilaçlama süreçlerini otomatikleştirerek kaynak kullanımını optimize emektedir. Ayrıca hayvan sağlığı takibi, sera koşullarının kontrolü ve ürün

izlenebilirliği gibi uygulamaları da desteklemektedir. Böylece üretim verimliliği artarken maliyetler düşer ve çevresel etkiler azalır (Akpınar, 2025).

Yapay Zeka ve Büyük Veri Analitiği: Büyük veri, tarımda üretim tahmini, hastalık riski analizi ve doğru uygulama zamanlarını belirler. Bu teknoloji, doğal dil işleme, görüntü tanıma ve öngörücü analizler gibi birçok alanda (Russell ve Norvig, 1995) tercih edilip kullanılabilmektedir. Yapay zeka ve Nesnelerin İnterneti, verileri kullanarak ürün kalitesini artırır, süreçleri optimize ederek maliyet ve israfı azaltmaktadır. Endüstri 5.0 ile tarım, uzaktan algılama, yapay zeka ve bulut bilişimle dönüşmektedir. Büyük Veri Analitiği, hava, toprak, sulama, uydu ve pazar verilerini işleyerek verim tahmini, risk analizi ve kaynak optimizasyonu sağlamaktadır. Böylece çiftçiler daha hızlı, doğru ve sürdürülebilir kararlar alabilmektedir (Akpınar 2025; Çakmakçı ve Çakmakçı, 2023; Dertli ve Dertli, 2023).

Robotik Sistemler ve Otomasyon: Otonom traktörler, robotik hasat makineleri ve otomatik sulama sistemleri iş gücü verimliliğini artırmaktadır. Dijital tarımda robotik sistemler ve otomasyon, ekim, sulama, gübreleme, ilaçlama, hasat ve paketleme gibi tekrarlayan işleri insan müdahalesi olmadan yürütülmektedir. Bu teknolojiler iş gücü maliyetlerini düşürür, üretimde hassasiyeti artırır ve kaynak kullanımını optimize eder. RPA, işletmelerin verimliliğini artırırken, hata oranlarını düşürerek maliyet avantajı sağlama konusunda da büyük etkiler yaratabilmektedir. Özellikle finans, insan kaynakları ve müşteri hizmetleri gibi alanlarda yaygın olarak kullanıldığı (Aguirre ve Rodriguez, 2017) göz önüne alındığında çok kapsamlı bir perspektif çizmektedir. RPA yazılımları, büyük veri ve yapay zeka ile birleştirildiğinde, süreçlerin daha akıllı hale gelmesine olanak tanımaktadır (Akpınar, 2025).

Dijital Pazarlama ve Blok Zincir: Ürün izlenebilirliği, kalite sertifikasyonu ve aracısız satış mekanizmaları dijital tarım ile güçlenmektedir. Dijital pazarlama, çiftçilerin ürünlerini online platformlar ve sosyal medya üzerinden doğrudan tüketici veya perakendeciye sunmasını sağlayarak pazar erişimini artırmaktadır. Blok zincir teknolojisi, tedarik zincirinde veri doğruluğunu garanti eder, ürünlerin menşei, işlenme ve dağıtım süreçlerini kaydederek gıda güvenliği ve izlenebilirlik sağlayarak sahtecilik ve hatalı bilgilerin önüne geçmektedir. Ayrıca blok zincir, ödeme ve sözleşme süreçlerini otomatikleştirerek çiftçilerin gelirlerini güvence altına alır ve veri temelli üretim kararlarını desteklemektedir (Çakıroğlu, 2023).

2.TEKNOLOJİ ADAPTASYONU VE DİJİTAL OKURYAZARLIK

Tarımsal alanda başlıca zorluklar arasında kırsal alanda altyapı eksikliği, dijital okuryazarlık düzeyinin düşük olması ve yüksek maliyetler bulunmaktadır. Dijital tarıma adım atmak için ilk olarak dijital altyapının oluşturulması gerekmektedir. İşletmeye uygun bir dijital altyapı planı oluşturulmalı ve çalışanlara da gerekli olan dijital teknoloji eğitimi verilmesi yeni teknolojilerin anlaşılmasına ve kullanılmasına katkı sağlayacaktır. Örneğin, Pakistan'da yapılan bir çalışmada dijital eğitimler, enerji verimli tarım uygulamalarının benimsenmesini ve çiftçilerin refahını arttırmıştır. Benzer şekilde, Kenya'da küçük ölçekli çiftçiler yapay zeka destekli araçlar sayesinde üretkenliklerini artırmış, ancak alt yapı ve dijital okur yazarlık eksiklikleri benimsemeyi sınırlamıştır. Bu nedenle, eğitim, uygun alt yapı ve devlet destekleri, dijital tarımın yaygınlaşması ve sürdürülebilir şekilde uygulanması için kritik önemdedir. Ayrıca, AB ve diğer ülkelerdeki dijital tarım politikaları, çiftçilerin teknolojiyi daha etkin kullanabilmesi ve tarımda sürdürülebilirliğin sağlanması açısından örnek teşkil etmektedir. Dijital tarım sadece üretim de verimliliği artırmakla kalmaz, aynı zamanda çevresel kaynakların korunmasına ve ekonomik sürdürülebilirliğe de katkı sağlar. Karar verici konumdaki üreticilerin yaş ortalaması 50-55 yaş civarındadır. Yaş ile eğitim durumu açısından teknoloji kullanımın düşük olması, teknolojik yeniliğin ezberleri bozması ya da teknolojik dönüşümlerden kaçınılması tarım sektöründe dijitalleşmenin önündeki en önemli engel olarak

görülmektedir. Tarım alanın da kullanılan teknolojik ekipman ve yazılım teknolojilerinin birbiri ile uyumu ekipmanların birlikte çalışabilirliği için çok önemlidir. Modern teknolojilerin, geleneksel teknolojilere göre daha maliyetli olması çiftçilerin bu teknolojiden yararlanmasının önüne geçmektedir. Tarımsal dijitalleşme iklim değişikleri ile mücadelede önemli bir faktördür. Tarım sektörünün dijitalleşmesi için öncelikle karşılaştığı zorlukların ortadan kaldırılması gerekmektedir. Zorlukların aşılması için devlet ve özel sektör ortaklaşa çalışarak, kırsal alanlarda altyapının geliştirilmesi, dijital okuryazarlık düzeyinin yükseltilmesi, dijital teknolojilerin maliyetinin düşürülmesi gerekmektedir. Aşağıdaki tabloda zorluklar, zorlukların detayları ve çözüm stratejileri önerilmiştir (Akpınar, 2025; Göl ve Tarhan 2024; Tutar ve ark. 2025).

Zorluklar	Zorlukların Detayları	Çözüm Stratejileri
Dijital Altyapı Eksikliği	Kırsal alanda teknolojik ve internet altyapı yetersizliği. ve enerji altyapısı sorunları teknolojinin yaygınlaşmasını sınırlamaktadır	Devlet ve özel sektör dayanışması ile kırsal alanlara altyapı desteği.
Dijital Okuryazarlık Düzeyinin Düşüklüğü	Çiftçilerin teknolojiye karşı uyum sağlama güçlüğü, yaş ve eğitime bağlı olarak teknolojiden kaçınma.	Çiftçiler için dijital becerilerinin artırmaya yönelik eğitim programlarının düzenlenmesi.
Yüksek Maliyetler	Dijital teknolojilerin yüksek maliyeti çiftçilerin erişimini engelliyor.	Çiftçilerin erişimi için ölçeklenebilir ve uygun maliyetli çözümlerin geliştirilmesi.
Veri Güvenliği ve Gizliliği	Büyük miktarda verinin toplanması ve işlenmesi Hassas tarım verilerinin korunması.	Güçlü şifreleme yöntemleri, güncel güvenlik protokollerine uyulması ve siber tehditlere karşı önlemler alınması.
Teknik Uyum ve Standardizasyon	Farklı teknolojik ekipmanların birlikte çalışabilirliği, teknik problemlere karşı çiftçilerin yetersiz kalması.	Tarım teknolojilerinde standardizasyonun teşvik edilmesi. Çiftçilerin sorunlara karşı destek alabilecekleri sistemlerin oluşturulması.
Kültürel ve Sosyal Engeller	Yaşlı çiftçilerin teknolojiye adaptasyonunda zorluklar. Dijital dönüşümün benimsenmesinde direnç.	Dijital dönüşümün faydalarını gösteren örnekler, pozitif algı yapmak için kampanyalar.
İklim Değişikliği ile Mücadele	İklim değişikliğine karşı tarım sektörünün direncini artırmak için dijitalleşmenin zorlukları.	Dijitalleşmenin iklim değişikliğiyle mücadelede nasıl kullanılacağını araştıran politikaların desteklenmesi

(Göl ve Tarhan, 2023).

2.1. Risk Yönetimi ve Sigorta Davranışı: Dijital veriler, hastalık, kuraklık ve don gibi riskleri erken tespit ederek çiftçilerin sigorta talebi ve risk yönetimini geliştirir. Tarım, doğal ve ekonomik risklerden en çok etkilenen sektördür; gelişmiş ülkeler tarım sigortası ve risk yönetim programları ile verim ve gelir kayıplarını çiftçiden sigorta sistemlerine transfer etmektedir. Tarımsal üretimde dolu, don, yangın, kuraklık, fırtına ve sel başlıca risklerdir (Tesbi, 2000). Çiftçiler yağmurlama, sisleme, örtü ve rüzgâr pervaneleri gibi önlemler alır; ekonomik zararlar ise ürün sigortası ile ilgili kuruluşlara transfer edilmektedir. Tarım sigortası, üretimin sürekliliği ve çiftçi gelirlerinin istikrarı için gerekli bir risk yönetimi aracıdır; kapsam ve yöntemi, ürünlerin doğal risklere duyarlılığı, risk sıklığı, hasar miktarı ve tarımın ekonomik önemi dikkate alınarak belirlenir (Çetin, 2003; Akçaöz ve ark., 2006).

3.2. Pazarlama Davranışları ve Dijital Platform Kullanımı: Dijital pazar uygulamaları, çiftçilerin ürünlerini avantajlı satmasını sağlayarak pazarda güç kazandırmaktadır. Dijital

okuryazarlık; dijital araçları kullanma, bilgiye erişme, değerlendirme, üretme ve paylaşma becerilerini kapsamaktadır (Bawden, 2008; Rainie ve ark., 2012).

3.3. Dijital Tarımın Tarımsal Politikalar Üzerindeki Etkileri: Dijitalleşme tarım politikalarını dönüştürmekte, verimlilik ve çiftçi refahını artırırken maliyetleri düşürmektedir. Türkiye'de yüksek maliyetler, altyapı ve personel yetersizlikleri ile dışa bağımlılık gelişimi sınırlamaktadır. Tarımsal örgütlenme, destekler, yerli Ar-Ge ve bağımlılığı azaltacak politikalar bu sorunları çözerek dijital tarımı sürdürülebilir üretim ve kırsal kalkınmada stratejik kılmaktadır (Yılmazer ve Tunalıoğlu, 2024).

3.4. Veri Temelli Politika Geliştirme: Dijital tarım verileri, tarım politikalarının hızlı, doğru ve yerelleştirilmiş şekilde oluşturulmasını sağlamaktadır. Değişken oranlı uygulama ve verim izleme sistemleri, tarla içi farklılıkları yönetmeyi kolaylaştırmaktadır. Yapay zeka, makine öğrenmesi ve IoT uygulamaları karar destek sistemlerini güçlendirmektedir. Değişken oranlı uygulama ve verim izleme sistemleri, Yapay zeka, makine öğrenmesi ve IoT uygulamalarının birlikte kullanımı çiftçilerin doğru zamanda doğru müdahale yapmasını sağlamaktadır. Dijital görüntü işleme teknikleri, ürün kalitesinin takibi ve zararlı hastalıkların erken teşhisi ile tarımsal sürdürülebilirliği desteklemektedir. Sensörler, uydu görüntüleri, dron ve iklim verileri analiz edilerek riskler öngörülür, üretim planlaması optimize edilir ve destekleme modelleri hedef odaklı hâle gelir. Böylece veri temelli politikalar, iklim uyumu ve gıda güvenliğini destekleyerek daha dirençli bir tarım sistemi oluşturmaktadır (Kılavuz ve Erdem, 2019; Severoğlu, 2025).

3.5. Destekleme Politikalarının Dijitalleşmesi: Veri tabanlı destekler, performans ve çevresel katkı odaklı teşvikler ile karbon ayak izi bazlı destekler dijital tarımda önem kazanmaktadır. Türkiye'de Kırsal Kalkınma Yatırımlarının Desteklenmesi Programı (KKYDP) ve AB destekli Tarım ve Kırsal Kalkınma Programı (IPARD), çiftçiler ve tarımsal küçük ve orta ölçekli işletmeler (KOBİ) için finansman sağlamaktadır. KKYDP, Türkiye'de ulusal kaynaklarla yürütülen kırsal kalkınma amaçlı tarımsal destekleri kapsamaktadır. Türkiye, Avrupa Birliği ve dünya genelinde tarım ve kırsal kalkınma desteklerinin etkinliğini artırmak için izleme ve değerlendirme çalışmalarına önem verilmektedir. Dünya Bankası, Avrupa Komisyonu ve OXFAM gibi kurumlar, son 20-30 yıldır proje kılavuzlarının hazırlanmasında çok yönlü metodoloji ve yaklaşımların geliştirilmesini desteklemektedir. Sübvansiyonlu krediler de dijital tarım yatırımlarına erişimi kolaylaştırmaktadır (Ataseven ve ark., 2020; Çobanoğlu ve ark. 2017).

3.6. İzlenebilirlik ve Gıda Güvenliği Politikaları: Blok zincir ve dijital kayıt sistemleri, ürünlerin izlenebilirliğini artırarak gıda güvenliğini desteklemektedir. Karar Destek Sistemleri (KDS), toplanan verilerin analiz edilerek kullanıcıya anlamlı bilgi sunulmasını sağlamaktadır. Bu sistem, tarımsal verileri işleyerek çiftçilere sulama zamanlaması, gübre kullanımı ve hastalık yönetimi gibi konularda önerilerde bulunabilecek bir yapıya sahiptir. Sürdürülebilir tarım, doğal kaynakları koruyarak, çevreyi kirletmemekte ve biyolojik çeşitliliği sürdürmektedir. Böylece kimyasal girdilerin azaltılması ve çevre dostu teknolojilerle uzun vadeli sağlıklı ve güvenilir gıda üretimini sağlamaktadır.

3.7. Çevresel Sürdürülebilirlik ve İklim Politikaları: Dijital tarım, su tasarrufu, gübre ve karbon emisyonlarının azaltılmasıyla ulusal iklim stratejilerine katkı sağlamaktadır. 2050'de artacak nüfus ve FAO'ya göre %60 artırılması gereken tarımsal üretim, hızlı bir dönüşümü zorunlu kılmaktadır. İklim-Akıllı Tarım, üretkenliği artırırken iklim uyumunu ve karbon tutumunu güçlendirmektedir. İklim değişikliği, tarımsal üretimi ve gıda güvenliğini ciddi şekilde tehdit etmektedir. Zararlı organizmaların artması ve çevresel koşulların değişmesi, gıda

arzını riske atmaktadır. Bu nedenle ülkeler, doğal kaynakları koruyan ve çevreye zarar vermeyen sürdürülebilir tarım uygulamalarına yönelmek zorundadır (Karaman, 2024).

SONUÇ

Bu çalışmada dijital tarımın dünyada ve Türkiye'deki genel durumu incelenmiş, ardından bu teknolojilerin çiftçi davranışları ile tarımsal politikalar üzerindeki etkileri değerlendirilmiştir. Bulgular, dijitalleşmenin küresel ölçekte tarımın dönüşümünde belirleyici bir rol oynadığını göstermektedir. Dünya genelinde sensör teknolojileri, uydu verileri, yapay zeka destekli tahmin modelleri ve otomasyon sistemlerinin tarımsal üretimde yaygınlaştığı görülmektedir. Buna bağlı olarak verim artışı, su tasarrufu ve risk yönetimi gibi alanlarda önemli kazanımlar sağlandığı görülmüştür. Türkiye'de ise dijital tarım uygulamalarının giderek yaygınlaşmasına rağmen, altyapı farklılıkları, çiftçilerin dijital okuryazarlık düzeyi ve yatırım maliyetleri gibi nedenlerle gelişmiş ülkelerle karşılaştırıldığında daha sınırlı bir yayılım olduğu anlaşılmaktadır. Son yıllarda yapılan kamu yatırımları, dijital destek programları ve özel sektör girişimleri bu alanda ilerlemeyi hızlandırsa da Türkiye'nin potansiyelini tam olarak kullanabilmesi için daha kapsayıcı ve sürekli destek mekanizmalarına ihtiyaç duyulduğu ortaya çıkmıştır. Araştırma sonuçlarına göre dijital tarım, çiftçilerin üretim kararlarını önemli ölçüde etkilemekte; daha bilinçli, veriye dayalı ve planlı bir üretim anlayışı gelişmesine katkı sağlamaktadır. Dijital araçları aktif kullanan çiftçilerin verimlilik, maliyet yönetimi ve sürdürülebilir üretim konusunda daha başarılı olduğu görülmüştür. Bu durum, dijitalleşmenin sadece bireysel üreticiyi değil, tarımsal politikaları da yeniden şekillendirdiğini göstermektedir. Politikaların veri temelli yapılara doğru ilerlemesi, destekleme modellerinde farklılaşmaya ve daha hedef odaklı stratejilere ihtiyaç duyulmasına yol açmaktadır. Genel olarak değerlendirildiğinde hem dünya genelinde hem de Türkiye'de dijital tarım, tarım sektörünün geleceğini belirleyen stratejik bir unsur hâline gelmiştir. Türkiye'nin bu dönüşümden maksimum faydayı sağlayabilmesi için altyapının güçlendirilmesi, çiftçilerin dijital becerilerinin artırılması ve tüm üreticilerin eşit şekilde bu teknolojilere erişebilmesini sağlayacak politikaların geliştirilmesi kritik öneme sahiptir. Dijital tarımın doğru şekilde yaygınlaştırılması hem çiftçilerin üretim davranışlarını iyileştirecek hem de ülkenin sürdürülebilir tarım hedeflerine ulaşmasını destekleyecektir. Dijital tarım teknolojileri, çiftçi davranışlarında köklü değişimlere neden olmakta ve tarımsal politikaların yeniden şekillendirilmesini zorunlu kılmaktadır. Teknolojiye dayalı karar alma, kaynak kullanımında verimlilik, risk yönetimi ve pazar entegrasyonu gibi açılardan çiftçilere önemli avantajlar sağlamaktadır. Bu çerçevede politika yapıcılar için öneriler şu şekildedir; çiftçilere yönelik sürekli eğitim ve yayım modelleri geliştirilmelidir. Dijital tarımda dijital okuryazarlık programları, çiftçilerin modern tarım teknolojilerini ve veri tabanlı uygulamaları etkin bir şekilde kullanabilmelerini amaçlar. Bu programlar, sensörler, IoT cihazları, yapay zeka uygulamaları ve tarımsal yazılımların nasıl çalıştığını öğretir. Ayrıca, veri analizi, dijital pazarlama ve çevrimiçi platformlar üzerinden bilgiye erişim konularında çiftçilerin becerilerini geliştirilmesine katkı sağlamaktadır. Dijital okuryazarlık, tarımda teknolojinin benimsenmesini hızlandırır, üretim verimliliğini artırır ve sürdürülebilir tarım uygulamalarının uygulanmasına katkı sağlar. Programlar aynı zamanda çiftçilerin karar alma süreçlerini destekleyerek riskleri azaltmakta ve kaynak kullanımını optimize etmektedir.

Altyapı Yatırımları: Kırsal bölgelerde geniş bant internet erişimi ve enerji altyapısı güçlendirilmelidir. Dijital tarımda altyapı yatırımları, teknolojik uygulamaların etkin bir şekilde kullanılabilmesi için gerekli fiziksel ve dijital temeli oluşturmayı hedefler. Bu yatırımlar; yüksek hızlı internet erişimi, sensör ve IoT cihazlarının kurulumu, veri depolama ve işleme sistemleri, akıllı sulama ve gübreleme sistemleri gibi modern tarım altyapılarını kapsamaktadır. Ayrıca, enerji kaynakları, bulut bilişim ve veri güvenliği çözümleri de

altyapının önemli bileşenlerindendir. Fiziki ve Sosyal Altyapı Yatırımları (KÖYDES, KIRDES), bilişim teknolojileri kullanımının yaygınlaştırılması, tarımsal verilerin gerçek zamanlı toplanmasını ve analiz edilmesini sağlar, karar alma süreçlerini hızlandırır ve üretim verimliliğini artırır. Altyapı yatırımları, dijital tarım teknolojilerinin sürdürülebilir bir şekilde uygulanmasına ve yaygınlaştırılmasına temel oluşturmaktadır (Özcan ve ark., 2020; T.C. Tarım ve Orman Bakanlığı, Tarım Reformu Genel Müdürlüğü, 2024).

Dijital Destekleme Mekanizmaları: Dijital ekipmanlara özel teşvikler, kredi ve hibe mekanizmaları oluşturulmalıdır. Dijital tarımda dijital destekleme mekanizmaları, çiftçilerin teknolojiyi benimsemesini teşvik eden ve verimliliği artırmayı amaçlayan finansal ve teknik araçları kapsamaktadır. Bu mekanizmalar arasında hibe programları, sübvansiyonlu krediler, devlet ve özel sektör destekli danışmanlık hizmetleri ile eğitim ve sertifikasyon programları yer alımaktadır. Tarım ve Orman Bakanlığı, akıllı tarım projelerine yönelik çeşitli hibe ve teşvik programları sunmaktadır. Özellikle Ar-Ge Destek Programı aracılığıyla, tarım sektöründe teknolojik yeniliklerin geliştirilmesi ve uygulanması teşvik edilmektedir. Bu program, özel sektörün Ar-Ge kültürünü ve kapasitesini artırmayı, yeni tür, çeşit, teknoloji ve ürünlerin geliştirilmesini amaçlamaktadır. Ayrıca, KOSGEB'in Ar-Ge ve İnovasyon Destek Programı, tarımsal teknolojiler geliştiren firmalara finansal destek sağlamaktadır. Örneğin, Görsentam firması bu program sayesinde, yapay zeka destekli tarım çözümleri geliştirerek ürün verimini artırmıştır. Ayrıca, tarımsal veri platformları ve yazılım çözümleri aracılığıyla üreticilere veriye dayalı karar alma imkânı sunulur. Bu destekler, dijital teknolojilerin sahada uygulanmasını kolaylaştırırken, üretim maliyetlerini düşürür ve sürdürülebilirliği artırmaktadır (Göl ve Tarhan 2023).

Ulusal Tarımsal Veri Platformu: Üretim verileri tek bir ulusal sistemde toplanmalı, analiz edilmeli ve politika yapıcıların kullanımına açılmalıdır. Dijital tarımda Ulusal Tarımsal Veri Platformu, tüm tarımsal üretim süreçlerinden toplanan verilerin merkezi bir sistemde birleştirilmesini sağlayan bir yapıdır. Bu platform, çiftçilere, KOBİ'lere ve politika yapıcılara veri temelli karar alma olanağı sunar; ürün izleme, toprak ve su yönetimi, iklim verileri, hastalık ve zararlı takibi gibi alanlarda rehberlik eder. Ayrıca, farklı veri kaynaklarının entegrasyonu sayesinde tarımsal üretimde verimliliğin artırılmasına ve kaynakların daha etkin kullanılmasına katkı sağlamaktadır (Pakdemirli ve ark., 2021).

Yerelleştirilmiş Dijital Çözümler: Bölgesel iklim ve toprak koşullarına uygun, çiftçi odaklı dijital uygulamalar geliştirilmelidir. Dijital tarımda yerelleştirilmiş dijital çözümler, bölgesel iklim, toprak yapısı, su kaynakları ve üretim koşullarına göre uyarlanmış teknolojik uygulamaları ifade etmektedir. Bu çözümler, çiftçilere kendi coğrafi ve ekolojik koşullarına uygun bilgi, araç ve öneriler sunarak verimliliği artırmayı hedeflemektedir. Örneğin, yerel bitki türleri için hassas sulama sistemleri, pest ve hastalık uyarı uygulamaları veya bölgesel gübreleme planları bu kapsama girmektedir. Ayrıca yerelleştirilmiş dijital çözümler, tarımsal üretimde riskleri azaltır, kaynak kullanımını optimize eder ve sürdürülebilirliği desteklemektedir (Çakmakçı ve Çakmakçı, 2021).

Yasal Çerçeve ve Veri Güvenliği: Tarımsal veri sahipliği, paylaşım standartları ve gizlilik hükümleri net şekilde düzenlenmelidir. Dijital tarımda yasal çerçeve, veri güvenliği ve mevzuatlar; verilerin toplanması, işlenmesi ve paylaşılmasında çiftçi verilerinin korunması, siber saldırılara karşı güvenliğin sağlanması ve izinsiz kullanımın önlenmesini kapsamaktadır. Bilgilerin güvenli bir şekilde yönetilmesi ve çiftçilerin dijital dönüşüm sürecinde karşılaşabileceği zorlukların minimize edilmesi için gereklidir (T.C. Tarım ve Orman Bakanlığı, 2025).

ABSTRACT

Global climate change is markedly increasing the severity of thermal stress in dairy cattle due to rising ambient temperatures and relative humidity levels. Thermal stress arises when the balance between metabolic heat production and environmental heat load is disrupted, resulting in a wide range of physiological consequences such as decreased feed intake, reductions in milk yield and composition, impaired reproductive performance, and elevated stress levels. This situation not only exacerbates production losses but also negatively affects animal welfare, creating multidimensional challenges for the sustainability of dairy farming. In recent years, the development of precision livestock farming technologies has made it possible to monitor environmental, physiological, and behavioral parameters of cattle in real time through environmental sensor systems, wearable biometric monitoring devices, and thermal imaging techniques. These technologies allow high-resolution, continuous monitoring of indicators such as body surface temperature, respiration rate, activity patterns, rumen function, heart rate, feeding behavior, and environmental heat load. When this sensor-based data flow is integrated with machine learning algorithms and decision support systems, it enables the early detection of heat stress, the objective classification of welfare status, and the development of adaptive management strategies that minimize production losses. This study addresses the thermal stress pressure imposed by climate change on dairy cattle, explains the scientific basis of the associated physiological responses, and provides a comprehensive evaluation of the application capacity and sustainability relevance of advanced sensor-based technologies used to monitor environmental, physiological, and behavioral parameters.

Keywords: Climate change; dairy cattle; thermal stress; digital sensor technologies; precision livestock farming; environmental monitoring.

I. INTRODUCTION

Although the Earth's climate has undergone natural fluctuations throughout human history, the warming trend observed in recent decades has begun to exert pronounced impacts on agricultural and livestock production systems. Global mean temperatures have risen by approximately 0.5-0.8°C since the 1860s, and projections indicate that this increase may reach 2°C by the end of the century if current trajectories persist (Kadıoğlu and Dokumacı, 2005; Özen, 2008). Within the context of dairy cattle production, increasing ambient temperatures and greater environmental variability substantially intensify heat stress, which in turn leads to reductions in milk yield, alterations in milk composition, impaired reproductive performance, and broader welfare challenges. Consequently, precision livestock farming (PLF) strategies and digital sensor-based monitoring technologies have become essential tools for safeguarding animal well-being and mitigating productivity losses. These technologies enable continuous assessment of physiological and environmental indicators, thereby supporting more resilient, adaptive, and sustainable management practices in modern dairy farming.

Between 1970 and 2023, the global cattle population increased from 1.08 billion to 1.58 billion head, representing an overall rise of approximately 46%; however, a clear deceleration in this upward trend has been evident particularly after 2010 (FAO, 2024). The trajectory observed in Türkiye closely mirrors this global pattern. According to TUIK (2024), the national cattle population-characterized by steady growth during the 1961-1980 period-declined to 10.76 million head in the 1990-2000 interval. Yet, following the implementation of targeted support schemes, genetic improvement initiatives, and modernization efforts across livestock production systems, cattle numbers began to recover after 2010, ultimately reaching a historical peak of 17.96 million head in 2020. Despite this temporary recovery, the decline to 16.42 million head after 2020 reflects the growing pressure exerted on livestock production by the intensifying impacts of climate change, consistent with global developments. Increasing temperatures, prolonged drought events, and fluctuations in feed crop production have emerged as major constraints limiting sustainable growth in livestock systems both worldwide and in Türkiye. Trends in global milk production exhibit a comparable pattern. Worldwide milk output rose from 391.9 million tons in 1970 to 968.2 million tons in 2023, marking roughly a 2.5-fold increase. Particularly after 2010, the widespread adoption of data-driven herd management tools, sensor-based monitoring technologies, automated milking systems, and digital surveillance platforms played a decisive role in accelerating production growth; consequently, between 2010 and 2023, global milk production expanded by 33% (FAO, 2024). Türkiye shows a similar tendency: national milk production increased from 7.3 million tons in 1970 to 21.4 million tons in 2023, nearly a threefold rise (TUIK, 2024).

Rojas Downing et al. (2017) emphasize that global demand for products of animal origin is projected to intensify in the coming decades. If current consumption trends continue, producers will need to increase output by approximately seventy percent over the next fifty years. Meeting this rising demand requires a stronger livestock production capacity and an agricultural infrastructure capable of supporting sustainable food supply systems. Long term sustainability in livestock production depends on the adoption of management practices that support resilience to heat stress, the preservation of high performing genetic resources, and the integration of automation and digital technologies into routine farm operations. Smart farming innovations highlighted by Alipio and Villena (2023) contribute significantly to this transformation, offering high accuracy and operational efficiency in the monitoring of animal health. Wearable smart devices and biosensors that rely on minimally invasive designs allow early identification of diseases and continuous monitoring of physiological and behavioral indicators. These technologies enhance the responsiveness of farm management and provide

objective real time assessments of herd well-being. Their expanding use reflects a broader shift toward data oriented and technology supported livestock production systems.

This study investigates the mechanisms of thermal stress observed in dairy cattle under the increasingly severe impacts of climate change within an integrated framework, and evaluates the innovative opportunities offered by advanced sensor technologies and digital monitoring systems for the early detection and effective management of this stress.

II. MECHANISMS OF THERMAL STRESS IN DAIRY CATTLE

Thermal stress arises when the metabolic heat produced by dairy cattle exceeds their capacity to dissipate heat to the surrounding environment, leading to an elevation in body temperature beyond the normal physiological range. Bernabucci et al. (2010) describe this condition as the cumulative external heat load acting on the animal and emphasize that thermal stress functions as a major environmental factor that challenges the ability of the organism to maintain homeothermic balance. The Temperature Humidity Index, commonly referred to as THI, represents one of the most widely used indicators for assessing thermal load. Hahn et al. (2009) highlight the essential role of THI in distinguishing among normal, moderate, severe and emergency levels of stress. Such classifications provide a foundational framework for identifying early responses to heat in field conditions and for guiding the development of appropriate management strategies. Thermal stress influences a wide range of physiological functions in dairy cattle, including feed intake, body temperature regulation, milk production, reproductive performance and behavioral responses (Cook et al., 2007; Tucker et al., 2008; Rhoads et al., 2009). Cows exposed to heat stress typically show reductions in feed intake and rumination activity (Grant and Miner, 2015), along with disruptions in energy metabolism, impaired lactation physiology and declines in fertility (Thatcher et al., 2010; Roth, 2020). Garner et al. (2017) report that thermal load exerts an even stronger suppressive effect on lactation during estrus periods. These findings indicate that heat stress contributes not only to short term productivity losses but also to longer term challenges related to reproductive efficiency.

At the physiological level, disruption of thermal balance triggers increases in respiration rate, elevations in body temperature, acceleration in heart rate and greater evaporative heat loss through sweating (Aloia et al., 2024). Becker et al. (2020) report that heat stress in Holstein cows reduces concentrate intake by five percent, forage intake by twenty two percent and the energy available for milk synthesis by thirty to fifty percent. These outcomes indicate that greater thermal load substantially limits overall productive capacity through decreased feed intake and reduced efficiency of energy utilization. Thermal stress also produces marked alterations in both the quantity and composition of milk. Chen et al. (2024) show that reduced dry matter intake under heat stress directly diminishes milk yield and negatively affects milk composition. Kadzere et al. (2002) identify an optimal temperature range of five to twenty five degrees Celsius for lactating cows, and Michael et al. (2022) note that temperatures exceeding this range, especially under high humidity, can cause reductions in milk yield of ten to forty percent. These findings demonstrate the close interaction among environmental temperature, energy metabolism and rumen function, and reveal that even modest changes in the thermal environment can generate significant consequences for milk production.

Behavioral responses under thermal stress closely parallel the physiological indicators observed in dairy cattle. Polsky and von Keyserlingk (2017) report that cows exposed to heat stress show reduced feed intake, increased water consumption, altered patterns of lying and standing and greater use of shaded areas. These behavioral adjustments reflect attempts by the animal to reduce excessive heat load. Silanikove (2000) emphasizes that effective management

of heat stress begins with integrated monitoring of both behavioral and physiological responses. Identification of thermal thresholds that are critical for animal welfare enhances understanding of cattle sensitivity to heat stress. Yan et al. (2021) demonstrate that changes in body temperature and respiration rate provide important signals under varying environmental conditions, while Heinicke et al. (2019) show that individual activity responses serve as valuable indicators for early detection of accumulated thermal load. Armstrong (1994) offers a functional framework for interpreting the Temperature Humidity Index by classifying values below 71 as the comfort zone, values from 72 to 79 as mild stress, values from 80 to 90 as moderate stress and values above 90 as severe stress. Zimbelman et al. (2009) reveal that reductions in milk yield can begin even when the Temperature Humidity Index reaches 65, indicating that high producing dairy cows may experience performance losses at considerably lower thresholds. Taken together, these findings show that the Temperature Humidity Index functions not only as an indicator of environmental conditions but also as a critical decision parameter for the early identification of production losses and for the continuous assessment of animal welfare.

When these findings are considered collectively, it becomes evident that thermal stress disrupts physiological, metabolic and behavioral processes in dairy cattle at the same time, leading to substantial impairments in both welfare and productive performance. As a result, the integration of precision livestock technologies is regarded as a strategic necessity in modern dairy production rather than a mere innovation, since timely, highly sensitive and objective monitoring of these multilayered stress responses is essential for effective management.

III. DIGITAL TRANSFORMATION IN DAIRY CATTLE PRODUCTION AND APPLICATIONS OF PRECISION LIVESTOCK FARMING

Rising environmental temperatures associated with global warming place substantial pressure on the ability of farm animals to maintain homeothermal balance, and this challenge increasingly amplifies the negative effects of heat stress on physiological, behavioral and metabolic functions. The decline in productive performance, disruption of metabolic stability and reduction in welfare caused by heat stress have positioned this phenomenon as a major limiting factor in modern dairy farming. Early identification and effective management of thermal stress hold critical importance, both for reducing biological losses and for supporting the economic sustainability of dairy operations. Continued increases in temperature driven by climate change compel dairy farms to adopt more innovative and data-oriented management strategies. In this context, digitalization offers comprehensive solutions for mitigating the impacts of heat stress through real time monitoring and predictive analytics. These approaches enable more accurate detection of stress conditions and support proactive decision making aimed at safeguarding herd health and productivity (Neculai Valeanu et al., 2024).

In modern dairy herds, the need for precise data collection is becoming increasingly important for improving productivity and enhancing the accuracy of management decisions. Liu et al. (2023) emphasize that sensor-based monitoring technologies have gained critical relevance, as animal behavior is closely linked to overall health status. Advances in the Internet of Things, artificial intelligence and computer vision have enabled integrated analysis of data obtained from image, sound and motion sensors, resulting in substantial improvements in both the accuracy and continuity of herd management. Among the physiological responses associated with thermal stress, respiration rate stands out due to its sensitivity to environmental variation and its rapid adjustment capacity, making it a reliable indicator for early detection. Hoffmann et al. (2020) report that modern sensor technologies can monitor essential parameters such as respiration rate, body temperature, heart rate and activity level with high accuracy, thereby

supporting the development of data driven early warning systems. Findings from a climate-controlled experiment conducted by Zhou et al. (2022) show that once ambient temperature rises above 28 degrees Celsius, evaporative heat loss accounts for 70 to 80 percent of total heat dissipation and heat exchange associated with respiration increases by 34 percent within the temperature range of 16 to 32 degrees Celsius. These results strongly confirm the role of respiration rate as a key physiological marker for the early identification of thermal stress.

The multidimensional nature of heat stress involves not only fluctuations in environmental conditions but also dynamic variations in individual physiological and behavioral responses. This complexity demonstrates the limitations of traditional herd management approaches under modern production conditions and highlights the growing importance of Precision Livestock Farming. Precision Livestock Farming represents an integrated system based on information and communication technologies that enable real time collection, analysis and interpretation of extensive data related to animal and environment interactions (Banhazi et al., 2012; Tekin et al., 2021). The opportunities created by digitalization have become a strategic necessity for contemporary dairy operations, particularly in response to increasing expectations for sustainability, productivity and improved animal welfare (Liu et al., 2023; Jiang et al., 2023).

Wearable sensor technologies constitute a central component of Precision Livestock Farming and enable continuous and detailed monitoring of behaviors such as rumination, grazing, feeding and activity levels. Reiter et al. (2018) and Gehlot et al. (2022) report that accelerometer-based sensors provide high accuracy in predicting various diseases by identifying early shifts in behavioral patterns. Dzermeikaite et al. (2023) also indicate that sensor-based systems contribute significantly to reducing stress, improving welfare and preventing related economic losses. In cattle, ear tags, pedometers, rumen boluses and collar mounted sensors offer practical advantages due to their relatively large surface areas for attachment and represent economical tools capable of delivering continuous data at the individual animal level (Halachmi et al., 2019; Lamanna et al., 2025).

Multisensor systems based on the Internet of Things that enable simultaneous evaluation of environmental and behavioral indicators represent an essential component of Precision Livestock Farming. Pons et al. (2017) and Leliveld et al. (2024) demonstrate that variables related to barn microclimate, including temperature, humidity, carbon dioxide concentration, wind speed, water consumption and bedding characteristics, can be monitored at high resolution along with behaviors such as lying, standing, feeding and rumination. This integrated approach markedly enhances early warning capacity and supports rapid detection of stress related changes. By providing timely and effective intervention opportunities against environmental stressors, the approach has become a core element of the digital transformation occurring in modern dairy farming. Noninvasive sensor technologies developed for continuous and accurate monitoring of health status in dairy cattle allow measurement of physiological and behavioral parameters without any physical intervention to the animal and form the foundation of contemporary monitoring systems, as illustrated in Figure 1. The integration of Internet of Things architectures with cloud computing, edge computing and machine learning algorithms enables continuous assessment of data streams and supports the automation of decision-making processes in herd management (Tangorra et al., 2024; Aloia et al., 2024).

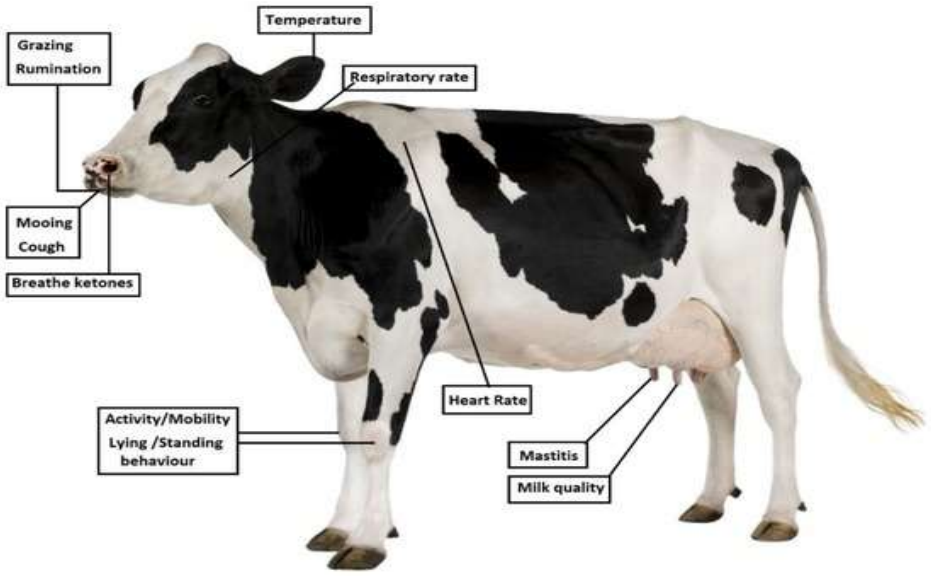

Figure 1. Core Components of Noninvasive Sensor Technologies Used for Monitoring Health in Dairy Cattle (Awasthi et al., 2016).

Machine learning provides substantial advantages for the analysis of multidimensional data sets obtained from sensors. Jensen et al. (2016) combined a dynamic linear model with a Naive Bayes classifier for early detection of mastitis and achieved a sensitivity of 80 percent and a specificity of 81 percent, representing a clear improvement compared with conventional monitoring methods. Pacheco et al. (2020) show that neural network models offer much higher accuracy, reaching 83 to 84 percent, for predicting heat stress compared with traditional indices such as the Temperature Humidity Index. In behavior-based estrus detection, a fuzzy logic model developed by Memmedova and Keskin (2011) achieved an accuracy of 98 percent, demonstrating the strong potential of this approach. Michie et al. (2020) note that direct measurement of feed intake is not always practical, yet accelerometer-based collars can estimate feeding time and provide a reliable indirect indicator of welfare related changes.

When all of these findings are considered together, digital transformation fundamentally reshapes the management paradigm of dairy farming systems. Sensor technologies based on the Internet of Things, together with artificial intelligence and machine learning applications, enable decisions related to animal welfare, health status and productive performance to be made more rapidly, more accurately and with greater predictability. Early identification of heat stress, automatic detection of changes in behavioral patterns and the implementation of data driven management models significantly reduce both biological losses and economic risks. The increasing adoption of Precision Livestock Farming practices is becoming a cornerstone of future dairy operations that aim to be sustainable, efficient and oriented toward high levels of animal welfare.

IV. RESEARCH FINDINGS AND DISCUSSION

This study demonstrates that climate change accelerates the onset of thermal stress in dairy cattle and that this condition produces multifaceted negative effects on animal health, welfare and productive performance. In the literature, Bernabucci et al. (2010) and Hahn et al. (2009) report that thermal load disrupts metabolic balance and restricts the physiological capacity of cattle, while Zimbelman et al. (2009) indicate that modern high yielding herds may experience productivity losses even at a Temperature Humidity Index of 65. These findings show that

climatic sensitivity is higher than previously assumed and that traditional management practices are insufficient under these emerging environmental conditions.

The effects of heat stress on feed intake, milk yield and reproductive performance have been confirmed by numerous studies. The reductions in feed intake ranging from 5 to 22 percent reported by Becker et al. (2020) and the productivity losses demonstrated by Chen et al. (2024) reveal that thermal load has critical economic implications for dairy production systems. Behavioral changes, including increased water consumption, greater use of shaded areas and irregularities in lying and standing times, have been documented by Polsky and von Keyserlingk (2017), who emphasize the importance of these responses as indicators for welfare assessment. Within this context, digital sensor technologies and Precision Livestock Farming applications play a strategic role in the management of thermal stress. Multisensor systems based on the Internet of Things enhance early warning capacity by monitoring environmental variables such as temperature, humidity, carbon dioxide concentration and bedding conditions together with behavioral indicators (Pons et al., 2017; Leliveld et al., 2024). Machine learning models have also shown superior accuracy compared with classical methods, particularly in the early prediction of heat stress and disease conditions (Jensen et al., 2016; Pacheco et al., 2020).

V. CONCLUSION

In conclusion, sustainable dairy farming increasingly requires data driven monitoring, rapid diagnosis and adaptive management strategies. Although digital sensor systems alone cannot fully address the challenges posed by thermal stress, their integration with appropriate housing design, ventilation, cooling and feeding management yields highly effective outcomes. Future research should focus on hybrid monitoring systems that combine multiple sensor data streams and on sensitivity analyses for different breeds and production models under changing climatic conditions.

ABSTRACT

Grain is a central strategic commodity within Türkiye's agricultural production system, serving as a key input for food security, livestock nutrition and agro industrial processing. However, climate related yield fluctuations, increasing input costs, regional variability in grain based cropping patterns and structural inefficiencies throughout the agricultural marketing chain create volatility in grain markets and weaken producer income stability. United Nations projections estimating a global population of 8.1 billion by 2025 further highlight the urgency of strengthening food supply security at national and global levels. Despite this need, major inefficiencies persist across the global agri food supply chain. In 2022, approximately 1.05 billion tons of food, equal to 19 percent of global production, was lost or wasted, while 783 million individuals faced undernutrition. This imbalance exposes significant vulnerabilities in post-harvest and distribution stages. Nearly 13 percent of losses occur during the post-harvest period, especially in cereals where inadequate storage engineering, improper handling, suboptimal transport conditions and insufficient moisture and aeration control accelerate deterioration caused by microbial activity and storage pests. Within this context, the licensed warehousing system acts as an essential post-harvest management mechanism by providing controlled storage environments, reducing losses, lowering supply pressure during harvest peaks, supporting quality standardization and improving agricultural supply chain governance. Türkiye currently hosts 475 warehouse enterprises, including 260 licensed facilities. Licensed storage capacity has reached 13.95 million tons, while total planned capacity stands at 26.48 million tons. Cereals, legumes and oilseeds record the highest utilization levels, with Konya leading at 16 percent, followed by Diyarbakır and Mardin. Between 2018 and 2024, Electronic Product Certificate (ELÜS) transactions increased twenty fourfold, indicating rapid system expansion. Licensed warehousing therefore functions not only as storage infrastructure but also as a strategic institutional component that strengthens agricultural economic resilience and reduces external dependency.

Keywords: Grain, storage, licensed warehousing, food security, Electronic Product Certificate (ELUS), global and regional market comparison

I. INTRODUCTION

Cereals have played a critical role since the dawn of civilization, serving as a fundamental food component both for direct human consumption and as an essential input in animal feed used for livestock production. Şanlıer (2013) states that approximately 55-65% of the daily global energy requirement and about 66% of the daily protein intake are met by cereal-based products, underscoring the fact that cereals constitute an indispensable strategic product group for global food security. Beyond being the primary source of energy and nutrients for human diets, cereals also provide crucial inputs for various economic sectors, including livestock production, food processing industries, and biofuel manufacturing. Therefore, the sustainability of cereal production, its support through efficient storage systems, and the delivery of cereals to consumers within stable market structures are fundamental components of national food supply security policies.

In recent years, climate change has increasingly influenced all stages of the agricultural production chain, exerting significant pressure on the continuity of cereal production. Rising temperatures, shifts in precipitation patterns, and the increasing frequency of extreme weather events have led to yield losses, declines in product quality, and fluctuations in overall output. Climate projections for Türkiye indicate that these changes will cause notable decreases particularly in barley, wheat, and maize production. Indeed, modeling studies suggest that yield increases in wheat will nearly stagnate by the 2030s, while maize production is expected to decline by approximately 10% by 2050 (Voyvoda et al., 2017). All these findings demonstrate that climate change–induced production fluctuations necessitate a re-evaluation not only of the agricultural production process itself but also of storage infrastructure planning, capacity expansion, and stock management strategies. In this context, addressing the impacts of climate change on cereal production and storage systems through a holistic approach is of critical importance for both national food security and agricultural sustainability.

According to United Nations projections, the world population is expected to reach approximately 8.1 billion people by 2025. This demographic increase further underscores the growing importance of global food security (UN, 2025). However, the fact that 1.05 billion tons of food were wasted worldwide in 2022, which corresponds to about 19 percent of the total amount of food produced, demonstrates the fragility of global food systems (UNEP, 2024). When this situation is considered together with the continued struggle of 783 million people facing inadequate nutrition in the same year, it becomes increasingly clear that food losses and food waste represent a critical challenge to global sustainability (FAO, 2023).

The rapid increase in population both worldwide and in Türkiye, the changes in per capita consumption patterns, and the contraction of agricultural production areas due to environmental, socioeconomic and political factors lead to periodic fluctuations in cereal supply. These fluctuations do not arise solely from the production stage. The high levels of losses occurring in the period after harvest also place considerable pressure on supply. FAO (2023) reports that global post-harvest cereal losses range between 10 and 15 percent, and that these rates can rise to as high as 20 percent in developing countries. Similarly, Philips and Throne (2010) state that losses occurring during storage reach approximately 10 to 20 percent of total production and that these losses mainly result from insufficient preparation before harvest, inadequate storage infrastructure and damage caused by insects and other pests. The study conducted by Bala (2016) also shows that annual cereal loss throughout the chain from harvest to consumption ranges from 10 to 25 percent and emphasizes that reducing these losses depends on proper threshing, cleaning, drying and storage under suitable conditions. When these findings are evaluated together, it becomes evident that cereal supply security is

associated not only with production volume but also with effective post-harvest management and storage practices that minimize loss rates. These findings demonstrate that reducing losses throughout the production and storage chain is of great importance for ensuring the sustainable security of food supply.

Due to these characteristics, cereals are regarded as a strategic group of agricultural products, and not only the volume of production but also the ability to store the harvested crop in a safe and high-quality manner is considered a decisive factor for national food supply security. In this context, licensed warehouses make a significant contribution by enabling products to be preserved under conditions that comply with established standards, thereby reducing losses caused by spoilage, decay and damage from harmful organisms.

Among the primary reasons for the development of the licensed warehousing system in Türkiye are the provision of reliable storage facilities for producers, the prevention of sudden and unbalanced entry of surplus supply into the market during harvest periods, the preservation of product quality in accordance with standards and the support of price stability in the market. In addition, the facilitation of access to finance through product certificates stands out as a factor that further strengthens the economic and structural necessity of the system (TEBGE, 2024). In this regard, enhancing the functionality and capacity of the licensed warehousing system emerges as one of the key areas of improvement within national food security policies in order to ensure the sustainability of cereal production and the supply chain in the face of climate change, population growth and structural market conditions.

II. CEREAL PRODUCTION TRENDS IN THE WORLD AND IN TÜRKIYE

Global cereal production has generally shown an upward trend in recent years. However, significant differences emerge between years due to variability in climatic conditions, production costs, contractions in cultivated areas and fluctuations in the supply and demand structure. According to WASDE data, global cereal production increased by 5.9 percent over the past decade, rising from 2190 million tons to 2320 million tons (Table 1). This increase is considered to be the result of technological developments in agricultural productivity and the expansion of production capacity. Within the cereal group, maize and wheat constitute the largest share of global production. Approximately 87.5 percent of total cereal production worldwide consists of these two products, with maize accounting for about 53 percent and wheat for about 34 percent. This situation reflects the high level of demand for these products both in human nutrition and in the feed and industrial sectors. Barley, although having a more limited production volume, continues to be an important component of livestock production and the beer and malt industry with its 6 percent share.

Table 1. Change in World Cereal Production by Years (Million Tons) (WASDE, 2025)

Product/ Years	2016/17	2017/18	2018/19	2019/20	2020/21	2021/22	2022/23	2023/24	2024/25
Wheat	757	761	732	760	773	780	803	794	799
Maize	1136	1094	1133	1133	1139	1224	1167	1233	1233
Barley	148	143	140	159	160	146	153	144	143
Rice	493	495	499	499	509	515	517	524	540
Other	149	143	139	143	159	146	147	140	145
Total (Rice except)	2190	2141	2144	2195	2231	2296	2270	2311	2320

Cereal production in Türkiye has demonstrated a sustained upward trajectory, registering an 11% increase between 2016 and 2025, from 34.3 million tons to 38.2 million tons (IGC, 2025). A disaggregated assessment of crop composition indicates that maize and wheat jointly constitute approximately 75.9% of the national cereal output. Within this structure, maize represents the predominant component with a share of roughly 54.4%, whereas wheat accounts for 21.5% (Table 2). This compositional profile evidences the centrality of maize and wheat in Türkiye's cereal production system and reinforces their strategic significance for sectoral resource allocation, yield optimization strategies, and long-term agricultural planning.

Table 2. Annual Variation in Cereal Production in Türkiye (Million Tons) (IGC, 2025)

Product/ Years	2016/17	2017/18	2018/19	2019/20	2020/21	2021/22	2022/23	2023/24	2024/25
Wheat	20,6	21,5	20	19	19,5	17,6	19,7	22	20,8
Maize	6,4	5,9	5,7	6	6,5	6,7	8,5	9	8,2
Barley	6,7	7,1	7	7,6	8,3	5,7	8,5	9,2	8,2
Rice	0,50	0,52	0,61	0,61	0,59	0,54	0,60	0,54	0,58
Other	0,6	0,7	0,7	0,7	0,8	0,8	1	1,1	1
Total (Rice except)	34,3	35,2	33,4	33,3	35,1	30,8	37,7	41,3	38,2

In Türkiye, the production trajectories of major cereal commodities have exhibited periodic fluctuations over the past decade, reflecting the interaction between agro-ecological variability and production system characteristics. Wheat output demonstrates interannual instability, with yield gains in climatically favorable seasons and measurable contractions during years affected by temperature and precipitation anomalies. Barley production shows even higher climate sensitivity, experiencing pronounced declines during drought episodes, thereby underscoring the crop's dependence on intra-seasonal rainfall distribution and its limited resilience under water-deficit conditions (TUIK, 2024). Conversely, maize production has followed a consistent upward trend, largely driven by its concentration in regions equipped with modern, pressurized irrigation technologies. Enhancements in irrigation infrastructure and water management efficiency have contributed significantly to yield stabilization and productivity gains, aligning maize production with intensive, input-responsive agricultural systems.

From a demographic perspective, the global population is estimated to have reached 8.23 billion in 2025, while Türkiye, with a population of 87.7 million, accounts for approximately one percent of the world's population (UN, 2025; TUIK, 2024). In the same year, Türkiye's cereal production corresponds to roughly 1.6% of global cereal output. Worldwide per capita cereal production stands at 281.7 kilograms annually, whereas this figure reaches 435.5 kilograms in Türkiye. The fact that Türkiye's per capita production level is approximately 55% higher than the global average indicates that the country contributes to global cereal production at a proportionally greater rate than its share of the world population. This situation underscores Türkiye's strong agricultural production potential at both regional and global scales.

III. STRUCTURAL ANALYSIS OF THE CEREAL MARKET IN TÜRKİYE

According to TEBGE (2024) data, an examination of barley statistics for the 2018-2023 period reveals notable shifts influencing both the production structure and the external trade balance

of the sector. Although barley yield increased by only 5% over this five-year interval, the harvested area and total output expanded by 22%, indicating that production growth was primarily driven by area expansion rather than productivity gains. During the same period, consumption rose by 28%, reflecting a substantial increase in feed demand and demonstrating that barley has become an increasingly critical input for the livestock sector (Table 3).

Table 3. Fundamental Indicators of Barley Production in Türkiye (TEBGE, 2024)

Years	Area	Yield	Production	Consumption	Feed Use	Stock Change	Imports	Exports	Self-Sufficiency
2018/19	26.119	268	7.000	6.951	85,7	-145	522	295	94,7
2019/20	28.691	265	7.600	7.536	86,0	552	978	35	94,8
2020/21	30.972	268	8.300	8.035	86,0	458	790	99	97,1
2021/22	31.691	181	5.750	8.095	85,8	94	2.989	205	66,8
2022/23	31.995	281	8.500	8.873	86,3	1.120	2.264	261	90,0

*Area, production: thousand da, Yield: kg/da, consumption, stock change, imports, exports: thousand tons, Self-Sufficiency: %

Barley production in Türkiye exhibits a regionally concentrated structure, with the Central Anatolia Region holding a strategically dominant position due to its substantial contribution to national output. Data from 2023 indicate that Konya ranks first with a production share of 15.1%, followed by Ankara with 8.5%. Kayseri and Şanlıurfa each account for 4.2% of total production, demonstrating that barley cultivation is geographically clustered and shows a pronounced regional concentration pattern (Figure 1). Developments in barley prices further complement this geographically concentrated production structure, revealing a distinct upward trajectory over time. The persistent increase in barley prices across years highlights the continuous escalation of agricultural commodity prices at both the farm and market-institutional levels. Examination of Figure 1 shows that all three-price series remained at relatively low and closely aligned levels during the 2021/22 marketing year, whereas in 2022/23 prices nearly doubled compared to the previous year. This upward trend continued into the 2023/24 period, indicating a transition toward a sustained high-price regime in the barley market, driven by cost structures and shifts in supply-demand dynamics.

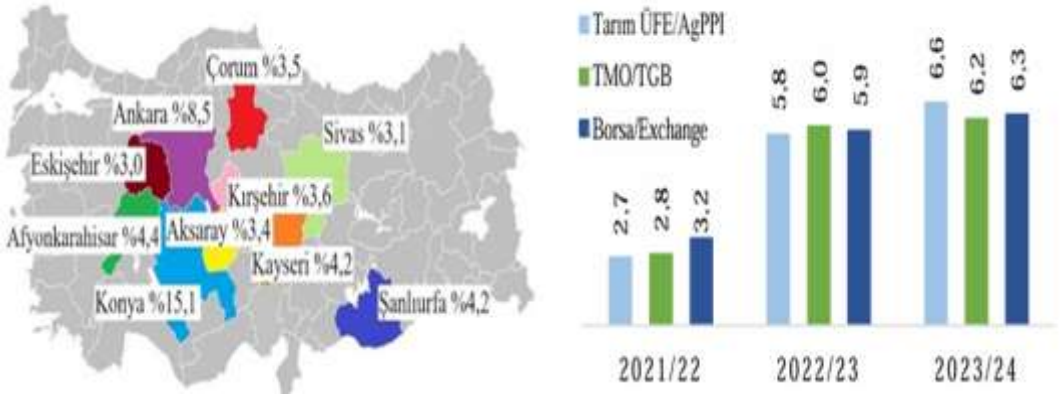

Figure 1. Distribution of Provincial Contributions to Barley Production and Trends in Barley Prices (TL/kg) (TEBGE, 2024)

Wheat is a strategic agricultural commodity in Türkiye and worldwide due to its status as a fundamental food source, its central role as a primary input for several agro industrial sectors such as flour and bakery production, and its function as a complementary feed ingredient in

livestock systems. Within this context, the fact that Türkiye produced approximately 22 million tons of wheat in the period from 2023 to 2024 is of critical importance for national food supply security (IGC, 2025). An examination of the geographical distribution of production shows that Konya accounts for 10.2 percent of national output, followed by Şanlıurfa with 7.8 percent and Ankara with 5 percent. This distribution demonstrates that wheat cultivation in Türkiye is concentrated in specific provinces (Figure 2). Although the self-sufficiency ratio reached 96 percent in the years 2022 and 2023, which may be viewed as a positive development, the decline in per capita wheat consumption to 178.6 kilograms indicates changes in demographic dynamics and dietary preferences. During the same period, imports increased by 89 percent, yields increased by 9 percent, consumption increased by 3 percent and exports increased by 2 percent. These changes suggest that both domestic and external demand for wheat have strengthened, thereby increasing the economic significance of the crop. However, the 1 percent decline in production and the 9 percent contraction in sown area point to a structural reduction that may create risks for long term supply security when the strategic nature of wheat is taken into account (Table 4). In addition, wheat prices have continued to rise across years. The simultaneous increase in the Agricultural Producer Price Index, the Turkish Grain Board procurement prices and the prices recorded in commodity exchanges indicates growing cost pressures throughout the agricultural sector. As shown in Figure 2, prices offered by the Turkish Grain Board were at the lowest level, while exchange prices were at the highest level in the period from 2021 to 2022. In the period from 2022 to 2023, all price indicators recorded an increase ranging from approximately two times to three times the level of the previous year. The continuation of high values for all indicators in the period from 2023 to 2024 indicates the establishment of a persistent high price structure in the wheat market, driven by production costs, supply and demand conditions and broader market forces.

Table 4. Fundamental Indicators of Wheat Production in Türkiye (TEBGE, 2024)

Years	Area	Yield	Production	Consumption	Feed Use	Stock Change	Imports	Exports	Self-Sufficiency
2018/19	72.993	274	20.000	18.805	2.212	-1.311	6.468	7.873	100,5
2019/20	68.463	278	19.000	20.070	2.267	1.148	10.793	7.531	89,5
2020/21	69.222	296	20.500	18.934	2.339	1.093	8.238	7.584	102,3
2021/22	67.447	262	17.650	19.115	2.145	-808,6	9.525	7.898	87,3
2022/23	66.287	298	19.750	19.373	2.453	3.380	12.208	8.028	96,0

*Area, production: thousand da, Yield: kg/da, consumption, stock change, imports, exports: thousand tons, Self-Sufficiency: %

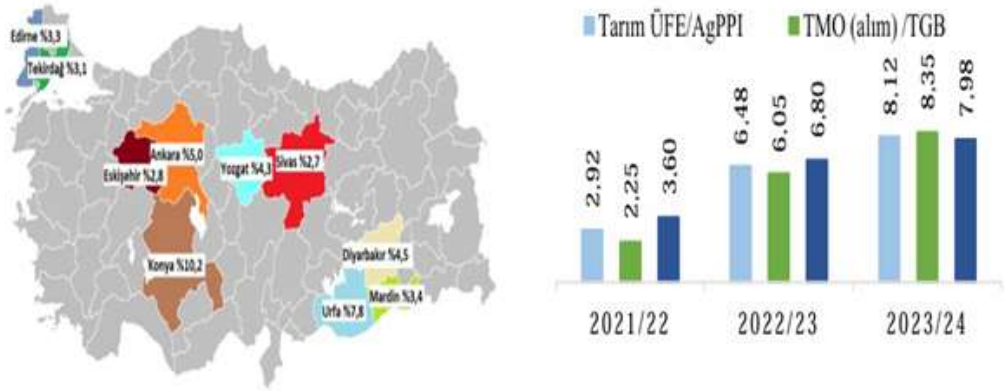

Figure 2. Distribution of Provincial Contributions to Wheat Production and Wheat Price Levels (TL per kg) (TEBGE, 2024)

Türkiye's maize production reached a record level of 9 million tons in the 2023 to 2024 period, underscoring the strategic importance of the country's expanding agricultural production capacity for national food supply security. The 54 percent increase in sown area and the 49 percent rise in total output strengthened Türkiye's maize production potential, while the improvement in the self-sufficiency ratio to 85.8 percent in 2022 to 2023 indicates that a larger share of domestic demand has been met through national production. In contrast, the 27 percent decline in imports and the 16 percent reduction in consumption suggest that market balances shifted in favor of domestic supply. At the same time, the 3 percent decrease in yield highlights the continuing influence of climatic and structural factors on production performance (Table 5). The concentration of production in Konya with 22.7 percent, Şanlıurfa with 11.8 percent and Adana with 11.1 percent demonstrates the critical role of specific agricultural basins in shaping Türkiye's national maize supply and emphasizes the strategic importance of regional production capacity. Moreover, when production and pricing indicators are evaluated together, it becomes evident that both regional production concentration and increasing cost pressures have contributed to the formation of a persistent high price structure in the maize market (Figure 3).

Table 5. Fundamental Indicators of Maize Production in Türkiye (TEBGE, 2024)

Years	Area	Yield	Production	Consumption	Feed Use	Stock Change	Imports	Exports	Self-Sufficiency
2018/19	5.919	963	5.700	7.866	6.451	-151	3.682	1.496	70,3
2019/20	6.388	939	6.000	7.706	6.376	114	2.720	720	75,5
2020/21	6.916	940	6.500	7.430	5.990	-327	1.814	1.017	84,9
2021/22	7.582	890	6.750	8.552	7.100	286	3.561	1.270	76,6
2022/23	9.119	932	8.500	6.611	8.019	-259	2.697	1.591	85,8

*Area, production: thousand da, Yield: kg/da, consumption, stock change, imports, exports: thousand tons, Self-Sufficiency: %

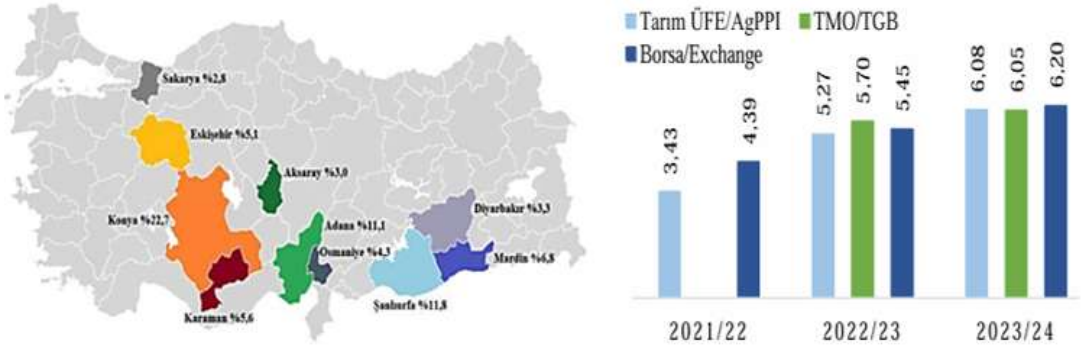

Figure 3. Distribution of Provincial Contributions to Maize Production and Maize Price Levels (TL per kg) (TEBGE, 2024)

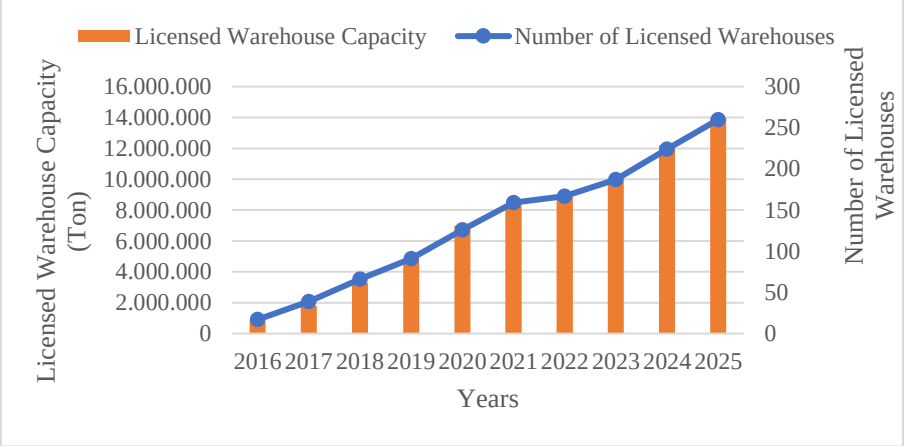
In conclusion, the increase in production of these strategically important crops enhances the effective functioning of the licensed warehousing system. The ability to store the growing production volume in accordance with quality standards, to mitigate market volatility and to facilitate producers' access to finance through electronic warehouse receipts (ELUS) further strengthens the critical role of licensed warehouses. Therefore, both production growth and national supply security objectives make the reinforcement of the licensed warehousing

infrastructure indispensable for agricultural market stability and sustainable resource management.



IV. HISTORICAL DEVELOPMENT OF STORAGE SYSTEMS AND LICENSED WAREHOUSING IN TÜRKIYE

In earlier societies, a variety of storage structures such as stone granaries, wooden chambers and rock carved warehouses were constructed to ensure the long term and secure preservation of cereals. A striking example of this practice can be observed in Karaman Taşkale, where two hundred and fifty-one rock granaries carved into a cliff approximately forty meters high during the Roman period have survived to the present day. These structures point to the deep and longstanding history of grain storage in Anatolia. During the Ottoman period, storage infrastructure became progressively more institutionalized. The Derince silo constructed in the year 1897 and the Haydarpaşa silos built between the years 1904 and 1907 by foreign companies represent early examples of grain storage facilities in the modern sense. In Türkiye, the construction of silos began in the second half of the nineteenth century with wooden structures, followed by a transition to brick and concrete silos, and after the year 1950 steel silos became increasingly widespread. This sequence of developments reflects the historical evolution of storage technology (Yıldırım, 2019).

The licensed warehousing system, which represents the institutional form of modern storage practices, was introduced in Türkiye in the year 2010 with the establishment of the first facility created through the partnership of the Turkish Grain Board and the Union of Chambers and Commodity Exchanges of Türkiye (Anonymous, 2025a). The first licensed warehouses were established in Polatlı, Lüleburgaz and Ahi Boz, enabling the storage of oilseeds, cereals and pulses. Licensed warehousing is a system in which agricultural products are stored securely, traceably and with quality control in facilities that meet predetermined technical standards and are subject to regular public oversight. Within this system, an Electronic Warehouse Receipt known as ELUS can be issued for products stored in licensed warehouses. The classification and quality analyses of stored products are conducted in authorized grading laboratories, and the trading of these products can be carried out through national and international commodity exchanges that specialize in agricultural products.

According to recent data, as of September there are 475 warehouse enterprises in Türkiye that hold establishment permits, and 260 of these have obtained operating licenses. The current capacity of licensed warehouses has reached 13.954.999 tons, while the total projected capacity of these enterprises stands at 26.481.009 tons (Anonymous, 2025b). Changes in the number of licensed warehouses and total storage capacity in Türkiye during the period 2016-2025 are presented in Figure 4 (Anonymous, 2025b).

These figures show that storage capacity dedicated to preserving agricultural products through modern warehousing infrastructure has increased rapidly, while also supporting market stability and the effective use of financial instruments in the agricultural sector. Furthermore, 98.6% of establishment capacity is allocated to cereals, pulses and oilseeds, indicating that the licensed warehousing system is heavily concentrated on these fundamental agricultural products. The remaining capacity is allocated to the storage of cotton, dried apricot, hazelnut, dried grape, olive, pistachio, olive oil and dairy products. When all product groups are evaluated together, the conversion rate of establishment capacity into licensed capacity is 52.7% (Table 6).

Şekil 4. Changes in the Number and Capacity of Licensed Warehouses in Türkiye During the Period 2016-2025 (Anonymous, 2025b)

Table 6. Total Establishment Capacity and Total Licensed Capacity by Product Groups (Anonymous, 2025b)

Product Group	Total İnstalled Capacity	Total Licensed Capacity
Cereals, Pulses and Oilseeds	25.823.980	13.753.470
Cotton	346.000	46.500
Dried Apricots/Grapes, Hazelnuts	203.529	133.529
Olives	63.500	13.500
Pistachios	19.000	4.000
Olive Oil	14.000	**-**
Dairy Products	11.000	4.000
Total	**26.481.009**	**13.954.999**

The data reveal that licensed warehousing capacity in Türkiye exhibits a pronounced concentration across provinces. Konya ranks first, accounting for 16% of the total establishment capacity, indicating that it occupies a central position within the country's storage infrastructure. Diyarbakır follows with a share of 8.7%, while Mardin ranks third with 6.3%. This distribution demonstrates that the Central Anatolia and Southeastern Anatolia regions hold strategic significance within the licensed warehousing system. The fact that licensed warehousing permits have been issued in 53 provinces nationwide indicates that the system has a broad geographical spread, although capacity remains concentrated in a limited number of key provinces. This pattern is likely associated with regional factors such as production structure, investment intensity and the effectiveness of licensing processes (Table 7).

Table 7. Distribution of Total Establishment Capacity and Licensed Warehouse Capacity by Provinces with the Highest Capacities in Türkiye (Anonymous, 2025b)

Provinces	Total İnstalled Capacity	Total Licensed Capacity
1. Konya	4.242.150	2.460.000
2. Diyarbakır	2.330.150	991.630
3. Mardin	1.691.190	739.190
4. Adana	1.607.480	985.030
5. Şanlıurfa	1.329.729	731.779
6. Yozgat	1.288.530	869.575
7. Aksaray	963.850	600.550
8. Tekirdağ	918.120	378.120
9. Eskişehir	803.320	366.320
10. Gaziantep	705.250	418.665

V. THE ELECTRONIC WAREHOUSE RECEIPT (ELUS) MARKET IN THE CEREAL SECTOR

During the period from 2018 to 2024, the transaction volume in licensed warehouses increased by a factor of 24, while the transaction value grew by a factor of 2.6. The sharp rise in transaction volume indicates that the use of the licensed warehousing system has expanded considerably and that the level of adoption among market participants has increased. On the other hand, the more moderate growth in transaction value suggests that the expansion in economic value generation has followed a limited and gradual trajectory. This pattern reveals that although the system has expanded rapidly in quantitative terms, its development in terms of value has remained more measured (Figure 5).

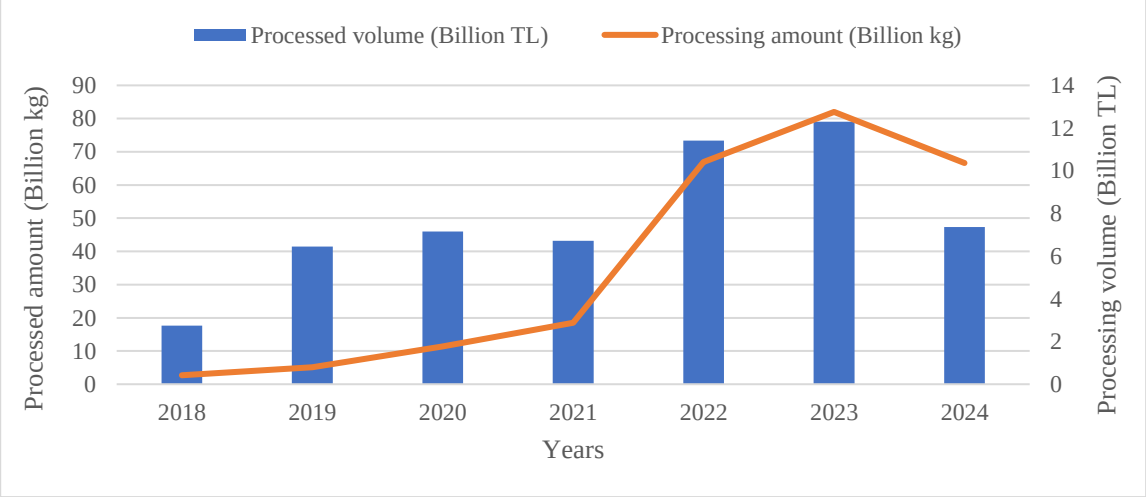


Figure 5. Changes in Transaction Volume and Transaction Value in Licensed Warehouses Between 2018 and 2024 (Anonymous, 2025c)

As of the year 2024, the distribution of transaction value in the Electronic Warehouse Receipt (ELUS) market by product is 54% for wheat, 33% for maize, 7% for barley, 2% for sunflower seed and 1% for other products. In the same year, when transaction volume by product is

examined, wheat ranks first with a total of 3,726,146,165 kilograms, followed by maize with 2,861,419,364 kilograms and barley with 641,655,835 kilograms (Figure 6). These figures indicate a pronounced concentration in both transaction value and transaction volume in the ELUS market, demonstrating that staple agricultural commodities, particularly cereals, continue to dominate market activity.

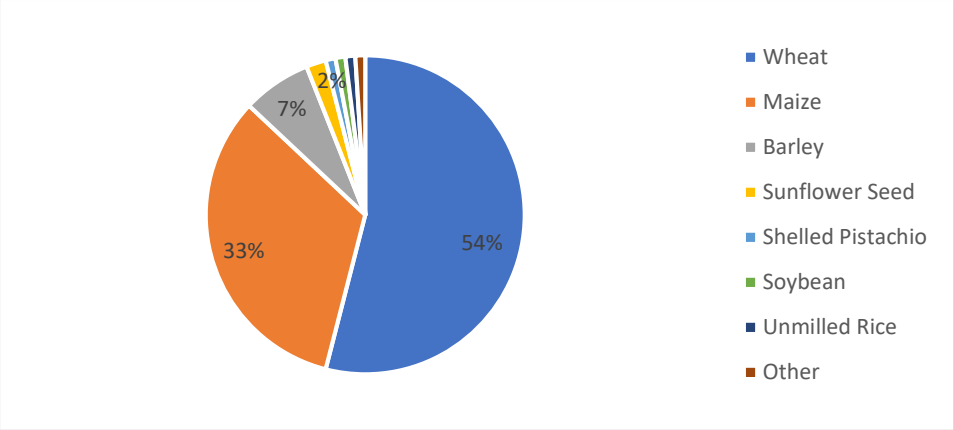

Figure 6. Transaction Value in the ELUS Market by Product in 2024 (Anonymous, 2025d)

VI. CONCLUSION

Cereal production is gaining increasing importance worldwide due to population growth and shifts in consumption patterns. Türkiye's agricultural production capacity holds a strategic position in terms of food security. In this context, modern storage infrastructure and the licensed warehousing system play a vital role in preserving production volumes and reducing post-harvest losses. In recent years, the licensed warehousing system in Türkiye has undergone rapid expansion, contributing significantly to the protection of product quality, the stabilization of prices and the safeguarding of producer incomes through increases in storage capacity. The system also functions as an effective instrument for strategic stockholding, market regulation, loss reduction and transparent trade. Accordingly, licensed warehousing supports Türkiye in maintaining its agricultural production potential and reducing external dependence. As a key component of sustainable agricultural policies, the system is expected to become even stronger in the coming years through further capacity expansion, more balanced regional distribution and the deepening of the Electronic Warehouse Receipt (ELUS) market. Overall, licensed warehousing is not merely an infrastructure development tool but a strategic mechanism positioned at the core of agricultural economics, food security and sustainable production policies. The continued expansion of the system will make substantial contributions to safeguarding Türkiye's agricultural production capacity and reducing reliance on external supply sources.

REGULATION, SAFETY AND CERTIFICATION ISSUES IN AUTONOMOUS FLIGHTS

Birsen AÇIKEL

Eskisehir Technical University, Vocational School of Information Technologies, Departments of Electronics and Automation, Eskisehir, Turkey

ORCID: 0000-0002-6067-5697

Email: birsena@eskisehir.edu.tr

ABSTRACT

Autonomous flight operations, encompassing unmanned and optionally piloted aircraft, offer a new paradigm in today's aviation in terms of operational efficiency, cost optimization, and the reduction of human error. However, this technological transformation, when integrated with existing airspace structures and regulations, brings with it serious regulatory, safety assurance and certification problems. The ability of autonomous systems to make decisions independently of human factors redefines the traditional understanding of "pilot responsibility"; this situation raises new debates at both legal and ethical levels. This study analyses current regulatory efforts undertaken by ICAO, EASA, and the FAA, examining international frameworks developed for the safe and standardized implementation of autonomous flight. Within the scope of the study, regulatory documents, accident and incident data, as well as certification procedures were evaluated; existing bottlenecks in technology validation, human audit, artificial intelligence transparency, and ethical responsibility were identified. The findings demonstrate the critical importance of cybersecurity, software validation, data reliability, and oversight mechanisms for the integration of autonomous systems into the airspace. As a result, in the face of the rapid development of artificial intelligence-based systems, existing aviation legislation needs to be restructured, and certification processes need to be adapted in a dynamic, transparent and ethical manner. This study proposes an integrated regulatory approach at the international level for the safe expansion of autonomous flights.

Keywords: Autonomous flight, certification, regulation, air safety, EASA, FAA, ICAO, AI in aviation

1. Introduction

The gradual merging of autonomous and semi-autonomous systems with the entire ecosystem is one of the most significant changes in technology that has taken place in the aviation sector. The transition of aircraft operations to be fully automated includes drones, UAVs, RPAS, and OPAs, which are all expected to result in better capacity, less operating cost, and reduced human errors among others. By making AI and advanced automation the key factors of decision-making for flight operations, the roles of the pilots and the systems are redefined in terms of the responsibility and accountability.

Nonetheless, the integration of autonomous systems to the current airport infrastructures creates tricky, partial, and hazardous circumstances. The classical takeoff configurations, which were originally based on human-controlled aircraft, are now facing the problem of introducing the systems that are capable of making autonomous decisions. Besides, the absence of unified international regulations for the automation systems adds to the difficulties in the certification, airport integration, and simplification processes.

This paper looks into the current global situation of the market, points out the safety assurance and certification trends, and gives an integrated renewable proposal for the safe rollout of autonomous flight. The focus is primarily on the very first stages of the deployment of autonomous systems, the technological development of that, and the safety management by ICAO, EASA, and the FAA.

2. Literature Review

2.1. Autonomous Flight Technologies

The future of aerial transport will undoubtedly rely upon the combination of advanced automation, AI-based decision-making, detect-and-avoid (DAA) systems, redundant avionics, secure command-and-control (C2), etc. The key features that will define the next-generation Unmanned Aircraft Systems (UAS), Remotely Piloted Aircraft Systems (RPAS), and Urban Air Mobility (UAM) are the very same sensing technologies, meanwhile, ICAO (2020), alongside FAA’s UAS Integration Office (2023), claim that the maturity of the autonomous systems is heavily dependent on the DAA algorithms' reliability, fail-operational redundant flight control architectures, and resilient data links that can sustain integrity under cyber threats.

Research is pointing out the potential of autonomous flying machines to operate in various fields. Some companies, namely Reliable Robotics and Xwing, have developed and tested to an extent an autonomous cargo airliner that is able to perform gate-to-gate automated taxi, takeoff, cruise, and landing (FAA, 2023). It has been found that the use of autonomous flight systems leads to significant improvement in logistics operations, access to the locations where the aircraft's pilot-less design is the only solution, and reduced costs related to the crew (one-third of the total operations cost can be reduced in the case of continuous operation in the 24/7 mode) (Clothier et al., 2019). In the context of public safety and disaster response, autonomous systems are already proving their worth by taking up the role of humans in the dangerous zones where, on the one hand, the human presence would have to be minimized and, on the other hand, the search-and-rescue, wildfire monitoring, and damage assessment missions would be supported (NASA, 2022).

One of the key areas where high-level autonomy is a must is represented by the Urban Air Mobility (UAM) platforms, which are the main application of such technology. EASA (2021) foresees that the UAM operations will be scaled to a much greater extent than just for a limited number of piloted flights, and this will be chiefly due to the airspace complexity and lack of

trained pilots. Airbus (2023) and another study by Boeing/Insitu reveal that autonomy of the aircraft will be the major factor that makes it possible for not just air taxis but also cargo drones to transport and even interact with digital traffic control systems (U-space/UTM) and cooperate with other airspace users across the world even in dense urban areas.

NASA's Aeronautics Research Mission Directorate has conducted studies that confirm and stress that the autonomy would be the key capability for the future air transport and traffic systems. Moreover, the very same document—NASA's Autonomy Strategy for Aeronautics (2022)—declared that futuristic urban air mobility comprising air taxis (AAM), UAM, high-altitude operations, and even robots handling cargo at a distance cannot be realized without an advanced system of onboard autonomy, continuous AI monitoring of the system, and an adaptive flight-deck automation. In like manner, the major players in the market like Airbus and Boeing have also pointed out in their technology roadmaps that autonomy is the main factor concerning the reduction of the operational burden, the enhancement of safety, and allowing airplanes to make contextually aware decisions instantly (Airbus, 2023; Boeing, 2022).

2.2. Regulatory Context

The rapid development of self-flying aircraft has not only boosted but also hastened regulatory measures around the world and mainly the International Civil Aviation Organization, the European Union Aviation Safety Agency, and the Federal Aviation Administration. Each authority has made a lot of progress in policy-making to cope with the issues relating to integration, safety in airspace, and certification routes, but the existing systems can still not support operations that are completely autonomous, particularly those which require making choices through AI.

The International Civil Aviation Organization (ICAO) laid out the basic regulatory framework for Remotely Piloted Aircraft Systems (RPAS) and eventually, unmanned aircraft. The ICAO Manual on Remotely Piloted Aircraft Systems (Doc 10019) contains worldwide directives regarding RPAS licensing, the performance of detect-and-avoid systems, command-and-control (C2) requirements, and international operations (ICAO, 2020). Moreover, ICAO Annexes 6, 2, and 10 have been amended, together with the publications, bearing in mind the necessities of communication, surveillance, and operations to unmanned aircraft.

ICAO published the RPAS Concept of Operations (ConOps) and the UAS Toolkit, which are the basis for cross-border operations and standardized safety assessment methodologies. Nevertheless, ICAO acknowledges that current SARPs (Standards and Recommended Practices) do not cater for high autonomy levels, in which human command is substituted by onboard decision making (ICAO, 2021).

The European Union Aviation Safety Agency (EASA) has put in place one of the most thorough supervisory frameworks for autonomous and highly automated aircraft systems. The U-space Regulation (Regulation (EU) 2021/664) sets out a unified framework for the use of UAVs in low-level airspace through the application of digital traffic management services, such as network identification, geofencing, and dynamic reconfiguration of airspace.

EASA has also made a passing of certification standards:

- SC Light-UAS for advanced unmanned aircraft
- SC-VTOL for eVTOL and air taxi vehicles, including autonomous and optionally piloted aircraft (EASA, 2019)

- AI Roadmap for Aviation (2023) indicating requirements for reliable AI, human supervision, algorithm transparency, and safety assurance

EASA asserts that the certification of AI-based automation under the current prescriptive frameworks like CS-23/CS-27 is impossible without the introduction of new performance-based methodologies (EASA, 2023). They also point out that the traditional DO-178C software requirements are not suitable for machine learning systems.

On the other hand, the U.S. Federal Aviation Administration (FAA) takes a more gradual route. The FAA's regulation known as Part 107 is in charge of small UAS operations while Part 135 exemptions have allowed autonomous cargo operations by companies like Zipline, Wing, Xwing, and Reliable Robotics (FAA, 2023).

The FAA made it possible to use new certification frameworks:

- UAS Type Certification under Part 21
- Reusable Safety Cases for Autonomous Flight
- MOSAIC Rulemaking (Modernization of Special Airworthiness Certification) for future autonomy in light aircraft
- Advice on detect-and-avoid and command-and-control performance according to RTCA DO-365 and DO-377

The FAA, however, concedes that there are substantial regulatory gaps for completely autonomous aircraft, particularly in the areas of human-out-of-the-loop decision-making, AI validation, and remote pilot responsibility (FAA, 2022).

Several unresolved issues, which are present across the ICAO, EASA, and FAA frameworks, include:

- Heterogeneous definitions for autonomy levels
- No consensus on the method for certifying avionics based on machine learning
- Diverse approaches to airspace integration (U-space, UTM, NAS Integration)
- Liability and accountability for AI personified decisions not structured clearly
- Safety models for continuous-learning algorithms are still insufficient

Evidently, the authorities have made enormous regulatory progress but they still admit that the existing aviation law which was originally intended for manned aircraft needs to be completely reformed to allow for higher autonomy levels.

2.3. Safety and Human Factors

Reduced pilot workload is usually mentioned as one of the main advantages of autonomous flight systems, but the literature mentions that the new safety risks for the planes are also considerable which come from the increased use of automation. Cross-sectional studies examining the functioning of a highly automated cockpit demonstrated that the over-reliance on automation could cause "automation complacency" to manifest, and that would result in the effective monitoring performance being lowered and the pilot's reaction to the system failure being accordingly delayed (Parasuraman & Manzey, 2010; FAA, 2022). Research results from the accident and incident investigations, including Air France 447 and Asiana 214, show the diminishing of the situational awareness and the misunderstanding of the automation modes being among the causes that could lead to catastrophic endings (NTSB, 2014; BEA, 2012).

The use of artificial intelligence in deciding matters comes with the extra risk of the non-transparency of the machine-learning models which is usually called the "black-box problem." In the AI Roadmap 2.0 by EASA (2023), it is stated that the absence of transparency in algorithms is a great barrier to certification, safety guarantee, and post-event accountability. The issue is critical in detect-and-avoid systems, adaptive flight control algorithms, and autonomous navigation as the real-time decision processes have to be explainable and traceable for safety supervision.

Another critical safety issue is posed by cybersecurity vulnerabilities. With the extensive utilization of data links, cloud communication services, and remote command systems, autonomous aircraft become susceptible to different types of threats like GPS spoofing, data link jamming, malware injections, and unauthorized access to flight control systems. Both ICAO (2020) and RTCA DO-326A assert that the cybersecurity framework should encompass the entire aircraft life cycle, from design to operation, more so in the case of autonomous systems which need continuous connectivity.

These new risks have led to the human control concept of "meaningful human control" (MHC) to be of great importance in discussions about safety governance related to autonomy. The concept, which was initially expressed mainly in the literature of human-machine interaction (Santoni de Sio & Van den Hoven, 2018), has now reached the discussions of rights in the aviation sector and asserts that humans must always have the ability to watch, intervene and be finally responsible for the important decisions made by the autonomous systems. EASA and ICAO emphasize that the development of autonomy should only serve to increase human power over the machines, and it should never be a straight replacement of the latter, especially in complex or non-nominal conditions.

To summarize, the existing literature agrees on the view that although autonomy can make regular operations safer, different kinds of risks come up from non-transparent AI behavior, cyber security issues, reduction in human situational awareness, and the lessening of the human operator's role. All these concerns demand the application of new verification, validation, and certification methods that are not limited to traditional aviation safety practices but rather encompass them.

3. Methodology

The regulatory, safety, and certification issues concerning the operations of unmanned aerial vehicles are the focus of this study which uses a qualitative document analysis approach. Document analysis is seen as a solid qualitative research method for doing a systematic review and interpretation of policies, regulations, technical standards, and accidents reports (Bowen, 2009). The application of this technique leads to the detection of patterns, regulatory voids, and the rise of topics that reveal the present governance of autonomous flight.

3.1 Data Sources

The main data set is made up of five document groups:

The regulatory documents issued by the ICAO, EASA, and the FAA—namely, ICAO Doc 10019, EASA's AI Roadmap 2.0, and FAA UAS Integration policies—were inspected in order to evaluate the existing regulatory methods, certification necessities, and safety benchmarks for autonomous systems (ICAO, 2020; EASA, 2023; FAA, 2023).

Reports of accident investigations taking place with the help of automation, remote piloting, or autonomy-related factors were analyzed. These consist of significant inquiries like Air France 447 (BEA, 2012), Asiana Airlines 214 (NTSB, 2014), and incidents that are drone-related and

have been recorded in the FAA's UAS accident database and EASA occurrence reports (EASA, 2022).

Evaluated were the documents articulating the certification frameworks for the autonomous and unmanned aircraft—like EASA's SC-VTOL, SC-Light UAS, and RTCA DO-365/DO-377 for detect-and-avoid and C2 links—so as to uncover the existing technological validation and verification limitations (RTCA, 2020; EASA, 2019).

A thorough examination of peer-reviewed articles related to AI interpretability, independent system safety, computer security, and human control that is important to society was conducted so as to fuse ethical and technological viewpoints. Main references are Parasuraman & Manzey (2010), Santoni de Sio & van den Hoven (2018), and various researches in the field of airplane autonomy (Johnson & Patel, 2021; Clothier et al., 2019).

A careful evaluation of comparative studies that focused on the differences among national aviation authorities like ICAO, EASA, and the FAA, was done with the intention of finding inconsistencies, policy bottlenecks, and the challenges of international harmonization (Kopardekar & Prevot, 2020; Thipphavong et al., 2018).

3.2 Analytical Procedure

A thematic coding method was employed in the analysis of the collected documents, following the qualitative research traditions established by Braun and Clarke's (2006) thematic analysis framework. Each document got codes assigned to it that were based on the repeating patterns and the relevant terminology and regulatory language of autonomous flight.

The coding process brought to light five main analytical themes:

- Regulation Gaps: Global regulatory frameworks characterized by inconsistencies, lack of definitions, and incomplete provisions concerning autonomy.
- Safety Assurance Issues: Verification of AI systems, validation of detect-and-avoid algorithms, and cybersecurity vulnerabilities management are the main issues.
- Certification Challenges: The present certification standards (e.g., DO-178C) applied to machine-learning–based avionics prove to be insufficient.
- Ethical and Legal Concerns: Issues related to liability attribution, accountability of AI decisions, and human supervision requirements.
- Technological Bottlenecks: Communication latency, data reliability, redundancy architecture limitations, and explainable AI constraints are among the main factors that restrict progress.

3.3 Reliability, Validity, and Triangulation

In order to enhance the methodological rigor of the study, the use of triangulation was applied by integrating:

- Regulatory documents
- Accident investigation findings
- Certification standards
- Peer-reviewed scientific literature

The credibility and reliability of the findings are thus reinforced by this mixed-document triangulation approach which is in line with the best practices prescribed by Patton (2015) and Bowen (2009).

4. Findings

4.1 Regulatory Challenges

The planetary transition from pilot-centric aviation to machine-based decision-making necessitates a thorough overhaul of the current aviation regulations. The present regulatory regimes—mainly based on the premise of a human pilot-in-command—do not encompass the required provisions for governing the complete autonomy of operations. The ICAO's RPAS Panel and the ICAO Legal Committee (ICAO, 2021) have pointed out that global civil aviation law is still based on the assumption of human accountability, human situational awareness, and human-led decision-making. The use of autonomous aircraft confronts these assumptions at all instances.

The issue of different definitions for autonomy levels is one of the most usually mentioned problems regarding regulations. Although EASA in its AI Roadmap 2.0 (2023) mentions "automation levels," and NASA places autonomy in its Autonomy Levels for UAM/AAM (NASA, 2022), ICAO has not yet recognized or created the same range of terms for levels of autonomy in the airspace as civil aviations have in automobiles using the SAE J3016 standard. Such a situation causes the issuance of varied certifications and different operational approvals in various states (Clothier & Newman, 2020).

Legal scholars point out that the prevailing liability regimes—based on either pilot-in-command or operator supervision—are not capable of dealing with situations where an aircraft's decision-making process is fully machine-based (Finck & Pallas, 2020). The judiciary and the regulatory bodies in the aviation sector are without any precedents for the following questions:

- who bears the responsibility—the producer,
- the airline,
- the application creator,
- or the party developing the AI system.

The EASA Artificial Intelligence Concept Paper observes that the traditional liability regime in case of defective products as well might not be able to cope when the systems are making context-dependent, nondeterministic decisions (EASA, 2021). The ICAO's Legal Committee echoes the same by stating that the current regulations cannot yet deal with AI machines that might change through uninterrupted learning (ICAO, 2021).

The approaches to airspace integration differ greatly from one jurisdiction to another:

Europe (EASA): The U-space framework (Regulation (EU) 2021/664) offers a digital ecosystem of air traffic management, featuring automated deconfliction.

United States (FAA): The FAA adopts a gradual approach leading to full integration into the NAS, based on safety cases instead of complete digital automation throughout the airspace (FAA, 2023).

Japan: Changes in the Civil Aeronautics Act (2022) allow for Level 4 autonomous flights, but only with strict government approval.

Singapore: The Civil Aviation Authority of Singapore (CAAS) has established a national testbed for the use of unmanned air vehicles (UAVs) in urban areas.

The great variations among these regions have the consequences of making it harder to do cross-border and certification recognition agreements. Researchers predict that if there is no harmonization, the regulatory isolation of the autonomous aircraft operators may result in their inability to scale up globally (Kopardekar & Prevot, 2020; Thipphavong et al., 2018).

Presently, ICAO SARPs (Standards and Recommended Practices) do not cover the situation in which humans are minimally or totally absent from the operations. The ICAO Doc 10019 however that provides guidance for RPAS, states that a remote pilot is still responsible for all aspects of the flight. As a result, operations that are completely automated where decisions are made without human intervention are not included in the current regulatory framework (ICAO, 2020).

EASA on its part has made it clear that it is a gap in regulation: its AI Roadmap 2.0 indicates that “no certification framework can ever be valid for an AI system taking safety-critical decisions without human supervision” (EASA, 2023). FAA findings are in line with this point of view, highlighting that the absence of a human controller during the real-time flow of the operation will pose a verification and validation problem that cannot be solved through existing DO-178C or Part 21 certification routes (FAA, 2022).

ICAO has laid down the basis for RPAS regulations, yet none of its present-day regulatory texts—Annex 2 (Rules of the Air), Annex 6 (Operations), and Annex 10 (Communication and Navigation)—are capable of covering the operational requirements, performance standards, or safety justification for:

- unmanned aerial vehicles,
- artificial intelligence decisions at flight-deck during the flight,
- automatic detect-and-avoid systems,
- or non-deterministic navigation with dynamic behavior.

The ICAO Future of Aviation Working Paper (2022) clearly states that the totally autonomous aircrafts “do not fit in the present classifications of aircraft operations” and hence the need for a new global regulatory framework.

4.2 Safety Assurance Issues

Autonomous operations not only bring a radical new set of risks to safety, but also the traditional aviation safety methodologies will not be able to handle these issues completely. One of the most critical issues is the failure of detect-and-avoid (DAA). The research of MIT Lincoln Laboratory and NASA revealed that due to situations such as occluded sensors, poor GPS performance, or very dynamic traffic scenarios, existing DAA algorithms might not work (Kopardekar et al., 2016; Kochenderfer & Chryssanthacopoulos, 2011). In fact even the systems like RTCA DO-365-compliant DAA technologies that are certified, still show performance limitations in the cases of dense urban environments and during rapid airspace conflict geometries (RTCA, 2020).

The use of AI in decision-making is another significant challenge that comes with opacity and it can be considered as the main source of such a problem. When sizing up the situation with EASA's AI Roadmap (2023), it is clear that the lack of transparency in the AI decision-making process has hindered the regulators' efforts to check if the AI decisions are explainable, predictable, and repeatable—these are the main requirements for the aviation certification. On

the other hand, recent investigations point out that AI's unexplainable behavior has been a contributing risk factor in several incidents linked to automation (Johnson & Patel, 2021).

The lack of security in cybersecurity adds to the worries about security issues even more. The full automation of aircraft keeps on exchanging data all the time through command-and-control (C2) links, GNSS signals, and cloud-based air traffic management systems like U-space or UTM and gets really exposed to the threats like GPS spoofing, jamming, man-in-the-middle attacks, and unauthorized access to the autopilot or navigation systems. The International Civil Aviation Organization (ICAO) report in 2020 and the European Union Aviation Safety Agency (EASA) guidelines on cybersecurity from 2021 have marked unmanned and autonomous systems as high-risk targets because of their heavy reliance on wireless communication. In fact, the incidents in 2019 where drones were reportedly spoofed in the Black Sea and the Middle East are just some of the real-world cases showing the operational impact of such attacks on navigation (Humphreys, 2013; C4ADS, 2019).

Significant risks are also posed by data integrity and sensor reliability problems. The operation of autonomous planes is based on the combined data coming from different sources like GNSS, IMUs, LIDAR, radar, ADS-B, and vision systems. The study conducted by NASA Armstrong Flight Research Center found that even a slight time-drift in data, loss of sensor packets, or unsynchronized sensor fusion could bring about flight-critical errors in the AI models used for decision-making (NASA, 2022). A similar problem is also being faced at the FAA UAS test areas, and one of the major causes in this case is the environmental conditions such as fog, rain, and electromagnetic interference that result in reduced sensor reliability (FAA, 2023).

The most difficult safety problem seems to be unpredictable system behavior in non-nominal or edge-case scenarios. Traditional avionics are deterministic while AI-enabled systems can respond unpredictably when encountering rare or out-of-distribution events. Research has shown that reinforcement learning-based flight controllers may demonstrate unsafe or unstable reactions when encountering unforeseen stimuli not present in their training datasets (Berquand et al., 2021). This unpredictability presents certification hurdles since regulators are required to show that the system will behave safely in all operational scenarios, a condition that is presently at odds with the variability of machine learning.

In light of these new risks, the top aviation authorities and safety researchers arrive at the same conclusion that classic safety assessment methods FMEA, Fault Hazard Assessment (FHA), and Bow-Tie analysis are not enough for the non-deterministic AI-driven systems (EASA, 2021; ICAO, 2022). However, safety barriers comprising of assurance cases, continuous monitoring frameworks, real-time risk assessment, and explainable AI (XAI) techniques are the only ones that can guarantee safety during the entire lifecycle of the system.

4.3 Certification Limitations

Certification authorities face considerable difficulties in the approval of autonomous and AI-based aviation systems, mainly due to the restrictions of current regulatory frameworks and the use of conventional software assurance techniques. Standardized testing and validation procedures for AI-driven systems are one of the most significant gaps that have been communicated widely. The traditional airworthiness software certification process is controlled by the DO-178C, DO-254, and DO-330 standards, which treat software as deterministic and rule-based. On the other hand, the behavior of machine-learning systems is non-deterministic and they cannot be validated through the same structural coverage and formal verification techniques (RTCA/EUROCAE, 2011; EASA, 2021). Thus, it cannot be assured that the

systems would behave predictably in all the operating conditions, which is a prerequisite declared by the airworthiness regulations themselves.

A major hurdle to overcome is the problem of verification of machine learning models and in particular those for anomaly detection, adaptive flight control, vision-based navigation and detect-and-avoid systems. Because machine-learning models are constantly updating their internal parameters according to the training data, they cannot be validated or certified through the traditional methods of traceability. A joint study conducted by MITRE and FAA (2022) explicitly states the case that ML models are not able to comply with the DO-178C requirement for complete requirements-based verification, thus making them incompatible with the existing certification pathways unless new assurance frameworks are put in place.

Moreover, the autonomous systems will need continuous software assurance, which is different from the static certification model that is employed for conventional avionics. The AI systems, for example, may require retraining or updating from time to time in order to keep up with the changes in their operational environment, thus maintaining their performance. According to NASA (2022) and EASA (2023), continuous-learning or periodically updated algorithms are indeed violating the "frozen software baseline" assumption of DO-178C. Consequently, this forms a regulatory paradox, since the updated ML models would in principle necessitate a new certification cycle after each training iteration.

The lack of metrics for certification based on performance being the major constraint for the autonomous behavior is another constraint. The FAA and EASA agree that prescriptive rule-based certification which is based on deterministic logic cannot assess the probabilistic, adaptive, and context-dependent behavior of autonomous systems (FAA, 2023; EASA, 2023). Researchers propose developing new performance-based methods, assurance cases (Bowen et al., 2020), operational safety envelopes, and scenario-based testing structures that would allow testing similar to those being developed in automobile autonomy (UNECE WP.29).

One of the major obstacles still facing the industry is the validation of autonomous detect-and-avoid (DAA) capabilities. While RTCA DO-365 fixed minimum measurements for DAA systems, these measurements were designed for Part 91/Part 107 drone flights rather than for self-flying drones in controlled airspace or at the same height as commercial aviation (RTCA, 2020). NASA Ames study reveals that DAA algorithms have in the future struggle in high-density traffic, complex geometries, multi-threat conflict scenarios, and degraded sensor environments (Kopardekar et al., 2016).

Regulatory actions like EASA's SC-VTOL (2019), SC-Light-UAS, and the FAA's Type Certification for drones under Part 21 are significant moves in the early phase of certifying autonomous systems. However, the two agencies point out that these special conditions only apply to low-mass, limited-scope operations, and thus do not yet offer a certification route for large, fully autonomous passenger aircraft (EASA, 2019; FAA, 2022).

In general, certification organizations encounter a fundamental problem: the certification concept employed for conventional avionics—grounded on determinism, traceability, and static requirements—cannot be transferred to the case of machine-learning-based autonomy. Therefore, new certification frameworks need to be created that will accept and support probabilistic behavior, AI interpretability, continuous updates, and scenario-based testing.

4.4 Ethical and Legal Dimensions

One of the most difficult and unresolved issues in the governance of aviation today is the ethical and legal questions which are still surrounding the use of autonomous aircraft. The gradual

takeover by AI-based systems of tasks that human pilots usually do raises doubts about who is responsible, who should be accountable, who should provide a clear view, and who has the right to decide among others. In particular, the situation under which a plane is completely flown by machines and humans may not be in control at any time, entails the raising of ethical issues that are outside the scope of existing aviation regulations to handle (ICAO, 2021).

The paramount legal question is actually the one who is to blame in case an autonomous aircraft inflicts harm. In the present scenario of ICAO Annexes and national aviation laws, the "pilot-in-command" (PIC) is the one who holds legal responsibility for all safety-critical decisions taken. Nevertheless, this legal framework disintegrates when the decision-making process is conducted by AI systems installed on the aircraft rather than by a human pilot. According to legal experts, the present liability structures—anchored in negligence, operator supervision, and human mistake—are totally inadequate for AI-sourced choices, particularly those derived from stochastic machine-learning models (Finck & Pallas, 2020; Vladeck, 2014).

EASA (2021) ascertains that during autonomous operations, responsibility might be assigned to different parties:

- the aircraft's manufacturer,
- AI algorithm developers,
- system integrators,
- operators or remote supervisors,
- data service providers located on the ground,
- or all these parties together.

The lack of definite international standards is a major source of concern regarding the disparate interpretations of liability that may occur in different jurisdictions.

A major issue from an ethical standpoint is to guarantee that AI-related decisions will have all the necessary attributes of being transparent, fair, and accountable. AI models employed in various domains of navigation, collision avoidance, and emergency response are often still "black-box" systems from which even the developers cannot infer the internal reasoning. EASA's AI Roadmap 2.0 (2023) underlines a point that "lack of explainability" is the major factor that impedes safety assurance, certification, and post-incident investigation. Likewise, the European Commission's trustworthy AI guidelines issued in 2019 also ask for algorithm transparency as a prerequisite for accountability.

Research indicates that non-transparent AI systems can yield:

- decision-making biased against certain groups in the allocation of emergency services (Danks & London, 2017),
- behavior of the system being unpredictable in the case of rare situations happening ("edge cases"),
- and difficulties with the acceptance of the system by the regulating authorities.

These issues are present to a much greater extent in aviation since safety-critical decision-making has to be totally transparent not only to regulators but also to the airline companies and investigators.

One more major ethical issue is that of deciding the right amount of human intervention. Scholars advocate for the concept of "meaningful human control" (MHC) as a must-have, a

term that was first created in the domain of robotics ethics (Santoni de Sio & van den Hoven, 2018) but is now commonly used in discussions on aviation autonomy. ICAO and EASA are the first regulatory bodies to consider MHC concepts in their viewpoints and to accept that humans must have the final say even when AI systems perform actions that are completely autonomous.

But, the question of "meaningful" control is still very vague. The issues in the debates are:

- Should humans be “in-the-loop”, “on-the-loop”, or totally out of the day-to-day command?
- How fast should humans be able to react for their control to be considered meaningful?
- Can a remote supervisor who has many planes under his command be aware of the situation well enough?

According to NASA studies on the supervision of control, people who are in charge of autonomous aircraft have their ability to perceive the situation correctly reduced and their reaction time lengthened, particularly, if they are monitoring more than one system (Johnson et al., 2021). Such results prompt the question whether it is right to depend on supervision from afar so much that it becomes the only model.

Unmanned airplanes are also raising issues regarding international jurisdiction. The existing International Civil Aviation Organization (ICAO) regulations assume the following presumptions:

- one state of registry,
- a pilot-in-command (PIC) with legal power,
- and a single chain of accountability.

However, the case of fully automated operations—particularly when relying on cloud-based navigation, remote data services, and cross-border digital communication—implies a multi-jurisdictional scenario of shared responsibility. For instance:

- The plane might be registered in Country A,
- The business which operates the plane might be in Country B,
- The data processing centre might be in Country C,
- And the plane might be flying over Countries D and E.

According to the ICAO’s Legal Committee (2021), there is no international agreement at present to identify the responsible party in case of AI-related decision-making spanning across various jurisdictions. The issues of illegal access to data or malfunctioning of cloud-based AI particularly reveal these legal uncertainties.

The change in the definition of the “pilot-in-command” is especially significant for optionally piloted or entirely automated aircraft. Regulations of both FAA and EASA still insist on the appointment of a human commanding pilot for each flight, even when AI controls the flight-critical operations. Notwithstanding, scholarly articles advocate that the duties of the PIC—such as keeping the situation under control, making decisions and reacting fast—cannot be completely entrusted to a distant human supervisor (Barnhart et al., 2021).

This implies a very serious legal dilemma:

- Will an AI system be regarded as a “co-pilot” or an “operator”?

- In case an AI opts for a course of action on its own, will the PIC still be held accountable?
- Is it necessary to come up with new legal frameworks, for instance "System-in-Command" (SIC)?

In its 2022 report on the Future of Air Mobility, ICAO presents the scenario where autonomy comes with a need for the sharing of the PIC concept between humans and AI, thus leading to a complete overhaul of the aviation law with the hybrid model—a radical shift from the traditional legal standards in aviation.

5. Discussion

The evidence points to the necessity for a new regulatory mindset that tolerates independence. The fast development of AI is testing the limits of current aviation legislation. The law makers of the coming days must set forth:

AI transparency requirements (machines that explain and do not hide their decisions)

Dynamic certification models that integrate regular oversight and updating after certification

Cyber-resilient systems with multiple shields of security

Communication paths that are backup so command can be assured

Using the performance-based method instead of prescribing rules

Besides, the human control that has significance should still be the main factor for safety even when the degree of freedom is high.

A globally accepted regulatory framework will be of paramount importance in the avoidance of the fragmented approaches that are not only hindering but also making the global operations difficult.

6. Conclusion and Recommendations

The future of aviation will be determined by autonomous flight operations, as they will not only boost up efficiency but also minimize human mistakes. Still, if there are no strong regulatory, safety, and certification frameworks in place, the risks involved in the implementation of autonomy might overtake the advantages.

The key recommendations are:

- Work out a set of globally harmonized autonomy regulations with the help of synchronized collaboration among ICAO, EASA, and FAA.
- Create certification frameworks for AI that are specific to the technology with clear testing, validation, and explainability requirements.
- Incorporate cybersecurity requirements in all phases of aircraft certification and operation.
- Install ongoing safety monitoring systems for AI-based capabilities.
- Revise legal liability frameworks for autonomous decision-making.
- Encourage the application of ethical governance principles that guarantee the results of fairness, accountability, and transparency.

An integrated international regulatory mechanism is a prerequisite to offset the deployment of autonomous flights with safety and scalability.

E posta: ahmetesiyok@beykent.edu.tr

ÖZET

Stereolitografi (SLA), hızlı prototipleme teknolojileri arasında yüksek çözünürlükte parça üretimi, mükemmel yüzey kalitesi ve geniş malzeme yelpazesi ile öne çıkan bir yöntemdir. Ancak, bu teknolojinin endüstriyel ve ofis tabanlı kullanımının hızla yaygınlaşması, önemli iş sağlığı ve güvenliği (İSG) risklerini de beraberinde getirmiştir. Bu bildirinin temel amacı, SLA teknolojisinin çalışma prensibi kısaca açıklandıktan sonra, prosesin her adımında ortaya çıkan riskleri sistematik olarak sınıflandırmak ve bu risklere yönelik alınabilecek önlemleri bir literatür taraması ışığında tartışmaktır. Yapılan incelemeler; risklerin başlıca kimyasal, fiziksel ve ergonomik kategorilerde toplandığını göstermiştir. Kimyasal riskler, kürlenmemiş fotopolimer reçinelerin içerdiği kimyasalların neden olduğu cilt tahrişleri, alerjik reaksiyonlar ve solunum yolu irritasyonları şeklindedir. Ayrıca, temizleme aşamasında yaygın olarak kullanılan izopropil alkol (IPA) gibi yanıcı çözücüler, hem yangın riski oluşturmakta hem de solunum sistemine zararlı buharlar yaymaktadır. Proses sırasında ortama salınan uçucu organik bileşikler (UOB'ler) ve ultra ince partiküller de hava kalitesi üzerinde olumsuz bir etki yapabilmektedir. Fiziksel riskler arasında ise ultraviyole (UV) ışınımına bağlı göz hasarları, elektrik çarpması ve mekanik yaralanmalar sayılabilir. Bu riskleri azaltmak için, hiyerarşik bir kontrol yaklaşımı önerilmektedir. En etkin yöntem, tehlikenin kaynağında kontrolünü sağlayan mühendislik kontrolleridir. Bunların başında yazıcıyı kapalı bir kabin içine alarak egzoz sistemi ile buhar ve partikülleri ortamdan uzaklaştırmak gelir. İdari kontroller kapsamında operatörlere kapsamlı eğitim, güvenli çalışma talimatları ve acil durum prosedürlerinin sağlanması kritiktir. Son olarak; kimyasallara dayanıklı nitril eldivenler, koruyucu gözlük ve uygun havalandırmanın olmadığı durumlarda solunum koruyucular gibi kişisel koruyucu donanım (KKD) kullanımı şarttır. Sonuç olarak, SLA teknolojisinden sağlıklı ve güvenli bir şekilde faydalanabilmek için, SLA'nın beraberinde getirdiği ve bu çalışmada anılan risk faktörlerini tanımak ve uygun İSG uygulamalarını hayata geçirmek; gelecekte oluşabilecek iş kazası ve meslek hastalıklarının önlenmesine ciddi katkı sunacaktır.

Anahtar Kelimeler: İş Sağlığı ve Güvenliği, Stereolitografi, Hızlı Prototipleme, Eklemeli İmalat.

OCCUPATIONAL HEALTH AND SAFETY IN RAPID PROTOTYPING PROCESSES USING THE STEREOLITHOGRAPHY (SLA) METHOD

ABSTRACT

Stereolithography (SLA) stands out among rapid prototyping technologies for its high-resolution part production, excellent surface quality, and wide range of materials. However, the rapid expansion of this technology in industrial and office-based use has also brought significant occupational health and safety (OHS) risks. The main objective of this report is to briefly explain the operating principle of SLA, systematically classify the risks in each step of the process, and discuss possible measures to address these risks based on a literature review. Analysis has shown that risks fall primarily into chemical, physical, and ergonomic categories. Chemical risks include skin irritation, allergic reactions, and respiratory irritation caused by chemicals contained in uncured photopolymer resins. Furthermore, flammable solvents such as isopropyl alcohol (IPA), commonly used in the cleaning phase, pose a fire risk and emit vapors harmful to the respiratory system. Volatile organic compounds (VOCs) and ultrafine particles released into the environment during the process can also negatively impact air quality. Physical risks include eye damage from ultraviolet (UV) radiation, electric shock, and mechanical injuries. A hierarchical control approach is recommended to reduce these risks. The most effective method is engineering controls that control the hazard at its source. Chief among these is enclosing the printer in a closed cabinet and removing vapors and particles with an exhaust system. Providing comprehensive training, safe work instructions, and emergency procedures for operators is critical within administrative controls. Finally, the use of personal protective equipment (PPE), such as chemical-resistant nitrile gloves, safety goggles and respiratory protection (in the absence of proper ventilation) is essential. In conclusion, to utilize SLA technology healthily and safely, recognizing the risk factors associated with SLA and the ones mentioned in this study and implementing appropriate OHS practices will significantly contribute to the prevention of future occupational accidents and occupational diseases.

Keywords: Occupational Health and Safety, Stereolithography, Rapid Prototyping, Additive Manufacturing.

1. INTRODUCTION

In todays digitalized production processes, additive manufacturing technologies have become an indispensable tool in many industries, particularly aerospace, automotive, medical, jewelry, and dentistry, thanks to the design freedom they offer compared to traditional production methods, the ability to produce complex geometries, and rapid prototyping capabilities (Gibson, Rosen, & Stucker, 2015). Stereolithography (SLA), the historical pioneer and one of the most widely used types of these technologies, was patented by Chuck Hull in 1986 and is based on the principle of layer-by-layer solidification of a liquid photopolymer resin pool with a laser (Hull, 1986). SLA, thanks to its high surface quality, excellent detail resolution, and a wide range of resin products with controllable mechanical properties, has a wide range of applications, ranging from precision prototyping to the manufacture of personalized products such as medical implants and hearing aids (Huang, Qin & Wang, 2020). However, the proliferation of this technology across businesses of all sizes, including office environments, has raised significant occupational health and safety (OHS) concerns. Although the places where SLA printers used are traditionally considered as low-risk places, they can still expose operators to chemical, physical, and ergonomic hazards. Uncured photopolymer resins, in particular, can cause irritation and allergic reactions upon skin contact due to the acrylate-based monomers they contain, and respiratory irritation and systemic effects upon inhalation of their vapors (Zontek, O'Brien, Jankovic, & Hollenbeck, 2017). Furthermore, flammable solvents (e.g., isopropyl alcohol) commonly used in post-printing processes pose a fire risk. Additionally, volatile organic compounds (VOCs) and ultrafine particles released into the environment during the process negatively impact indoor air quality (Stephens, Azimi, El Orch, & Ramos, 2013; Afshar-Mohajer, Wu, Ladun, Rajon, & Huang, 2015).

Therefore, the main objective of this report is to present the basic operating principle of SLA technology, then analyze the OHS risks that can be systematically identified at all stages of the process (e.g., resin preparation, printing, cleaning, final curing) based on a literature review, and comprehensively present the measures that can be taken against these risks in accordance with the hierarchical control principle (elimination, substitution, engineering controls, administrative controls, and Personal Protective Equipment - PPE). This study aims to emphasize that effective and sustainable utilization of SLA technology is only possible with an approach that prioritizes human health and safety.

2. THE WORKING PRINCIPLE OF THE STEREOLITHOGRAPHY (SLA) METHOD

Stereolithography (SLA) is a photopolymerization process that combines the fundamental principle of additive manufacturing—building a 3D object layer by layer from computer-aided design (CAD) data—with the principles of photochemistry (Gibson, Rosen, & Stucker, 2015). This method relies on the selective solidification of a liquid photopolymer resin with a light source of a specific wavelength (usually a 355 nm laser or 405 nm LED). The basic components and operating cycle of the SLA system are detailed below.

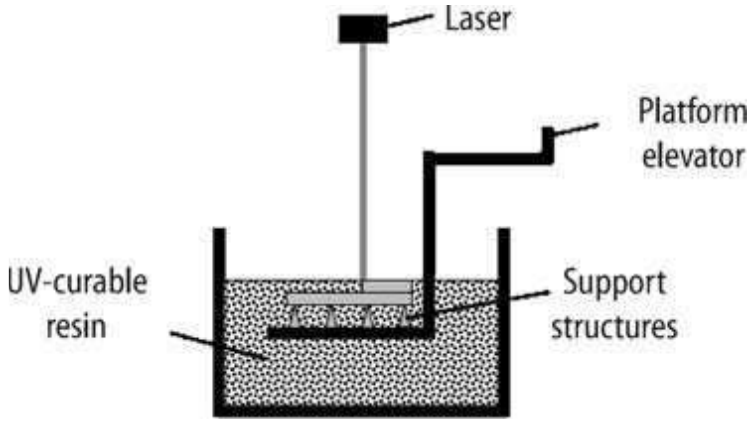

Figure 2.1. How the SLA System Works (Raja, V. & Fernandes, K. J., 2007).

2.1. Basic Components of the SLA System

Resin Chamber (Vat): This is the chamber containing the photopolymer resin. Especially in the "Bottom-Up" configuration, the chamber bottom consists of a transparent silicone-based film (usually FEP - Fluoroethylene Propylene or PDMS - Polydimethylsiloxane) that transmits UV light and allows the solidified resin to be easily separated (Chartrain, Williams, & Whittington, 2018). This film transmits the laser or projector light to the resin while also preventing the layers from adhering to the chamber bottom. Similarly, in the top-down configuration, the resin is contained within this chamber.

Build Platform: In top-down configuration, it is the plate on which the part is built, capable of moving in the vertical direction. In the initial position, the platform is located one layer thick (usually 25-100 microns) below the chamber surface. The resin is deposited on the platform in a thin film. The platform gradually moves downward along the Z-axis at the end of each layer, creating space for the next layer.

UV Light Source and Scanning System: There are two basic configurations:

- **Laser-Based SLA (Vat Polymerization):** In this system, a high-power UV laser (e.g., a 355 nm Solid State Laser) is controlled by a system of two mirrors called "galvanometers" that move along the X and Y axes. The galvanometers precisely scan the laser spot across the resin surface, drawing the cross-sectional contour of each layer.
- **Digital Light Processing (DLP):** This method utilizes a UV LED light source and a Digital Micromirror Device (DMD). A DMD consists of thousands of microscopic mirrors, each corresponding to a pixel. This device processes a cross-sectional image of each layer by simultaneously exposing (curing) the entire layer as an "image," rather than using a laser's point-by-point scanning technique (Huang, Qin & Wang, 2020). This generally makes DLP faster than laser-based SLA.

Control Software: Takes a CAD model (STL or 3MF file) and divides it into horizontal sections (layers). For each layer, the software generates the laser scan path (hatching and border strategies) or the digital mask for the DLP projector. It also controls platform movement, exposure times, and other machine parameters.

2.2. How the SLA Process Works

The SLA process can be broadly described as pre-processing (preparing the CAD model, preparing the printer and resin for printing), printing (layering and exposure, separation,

repeating the process for each layer), and post-processing (cleaning, final curing). These steps of the SLA process are explained below.

1. **Model Preparation and Slicing:** The CAD model is prepared and sliced in SLA software, adding support structures. Support structures are critical for supporting the overhangs and connecting the part to the platform.
2. **Layer Creation and Exposure:** The platform is lowered one layer below the chamber surface, allowing a thin layer of liquid resin to be deposited on the platform. The UV light source is activated. In a laser-based system, the laser is directed by galvanometers and scans the cross-sectional shape of the layer. The exposed resin undergoes a polymerization reaction, solidifying and chemically bonding to the platform or the previous layer. In a DLP system, the image of the entire layer is simultaneously projected onto the resin layer, ensuring simultaneous solidification.
3. **Repeat Cycle:** The platform is repositioned for the next layer (i.e., lowered one layer thickness into the uncured resin), and the resin on the surface fills the vacated area using a recoater or gravity. The blade scrapes the surface smoothly to ensure a smooth surface and removes any bubbles on the resin surface. Steps 2 and 3 are repeated until the entire part is created.
4. **Post-Processing:** Once printing is complete, the platform is removed from the resin chamber and the excess resin is allowed to drain. The part is then washed in an organic solvent (usually isopropyl alcohol - IPA) to remove any remaining uncured resin. Support structures are mechanically removed (usually by hand), and finally, the part is "post-cured," usually in a UV oven, to improve the part's mechanical properties and chemical stability. This post-curing process ensures that any monomers not fully reacted during printing fully polymerize and the part achieves the desired rigidity.

This detailed process allows us to understand why SLA is suitable for delicate and complex parts, but also poses OHS risks due to chemical use and mechanical processes.

3. HEALTH AND SAFETY RISKS IN SLA PROCEDURES

3.1. Chemical Risks

Chemical exposure is the most dominant and well-documented risk factor in SLA procedures. This includes photopolymer resins, solvents used for cleaning, and the volatile organic compounds that may be released into the environment during their use.

Photopolymer Resins: SLA resins contain acrylate and methacrylate based monomers and oligomers that solidify by cross-linking with UV light. In their uncured state, these substances can cause skin irritation, contact dermatitis, and allergic reactions (Huang, Qin & Wang, 2020). Inhalation of resin vapors can cause health problems such as headache, dizziness, nausea, and respiratory irritation (Zontek et al., 2017).

Cleaning Solvents: Isopropyl alcohol (IPA), commonly used for cleaning parts, is highly flammable, and its vapors can irritate the respiratory tract, cause headaches, and nausea (Afshar-Mohajer, Wu, Ladun, Rajon, & Huang, 2015). Prolonged or high-dose exposure can affect the central nervous system.

Volatile Organic Compound (VOC) Emissions: VOCs are released into the environment during the printing and cleaning processes. Stephens et al. (2013) found that VOC concentrations emitted from SLA printers are generally higher than those from fused deposition modeling (FDM) printers and can exceed office air quality standards. These emissions have also been linked to the formation of particulate matter (Kim et al. 2015).

3.2. Physical Risks

UV Radiation: UV light sources (lasers or high-power UV LEDs) from SLA printers can cause retinal damage if exposed directly to the eye. While most modern devices have enclosed housings and UV-blocking covers, this risk may occur during maintenance or intervention. The same exposure risk may also exist for UV ovens which are used for final curing.

Fire and Explosion Risk: The presence of flammable liquids (resin, IPA) poses a fire risk due to electrical faults, overheating, or sparks from static electricity. IPA vapor, in particular, is heavier than air and can accumulate in enclosed spaces, creating an explosive atmosphere.

Electric Shock: Printers with high voltage components (UV light source, heaters) present a risk of electric shock in the event of improper use or grounding fault.

Mechanical Risks: The moving platform and other mechanical parts may pose a risk of compression, especially during maintenance.

3.3. Ergonomic and Other Risks

Manipulation and Repetitive Tasks: Finishing operations such as removal of support structures, sanding, and cleaning may require repetitive hand movements and working in awkward positions, which may cause to musculoskeletal disorders (European Agency for Safety and Health at Work [EU-OSHA], 2019).

Waste Management: Used resin, deteriorated solvents, and contaminated cleaning materials can be classified as hazardous waste. Failure to properly dispose of these wastes can lead to environmental pollution and, indirectly, health risks.

In addition to those given above, a summary table from the literature expressing the risks arising in the SLA system along with the process stages is presented in Table 3.1. below.

Table 3.1. Hazards and Potential Impacts by SLA Process Stages

Process Step	Major Hazards	Potential Health/Safety Impacts	References
Resin Filling/Transporting	Liquid resin contact, spillage	Skin irritation, allergies, risk of slipping	Zontek et al. (2017)
Printing	Resin vapors (VOCs), UV radiation, electricity	Respiratory problems, eye damage, electric shock	Stephens et al. (2013)
Cleaning (with IPA)	Solvent vapors, flammability, contact	Respiratory irritation, narcotic effect, fire/explosion	Afshar-Mohajer et al. (2015)
Support Removal/Sanding	Mechanical stress, particle formation	Musculoskeletal disorders, respiratory tract irritation	EU-OSHA (2019)
Final Curing	UV radiation, residual vapor from the resin	Eye damage, respiratory irritation	Afshar-Mohajer et al. (2015)

4. RESULTS

The results include the precautions and safe working conditions. A hierarchical control approach (elimination, substitution, engineering controls, administrative controls, and Personal Protective Equipment - PPE) should be adopted to manage risks (National Institute for Occupational Safety and Health [NIOSH], 2022). Thus safe & healthy working conditions will be ensured.

4.1. Engineering Controls

Local Exhaust Ventilation: SLA printers should be housed in an enclosed cabinet, and this cabinet should be equipped with a local exhaust ventilation system that removes contaminated air to the outside environment or a filter system. This is the most effective way to control chemical exposure (Zontek et al., 2017).

Closed System Design: The printer should preferably have a sealed and automatic design that protects the operator from UV radiation and resin vapors.

Room Ventilation: Good general ventilation should be ensured in the room where the SLA procedure is performed.

4.2. Administrative Controls

Training and Awareness: All operators must be trained on the material safety data sheets of the chemicals used, the safe use of equipment, and emergency procedures (OSHA, 2012).

Marking and Labeling: All hazardous chemicals and equipment must be appropriately marked and hazardous areas must be designated.

Safe Working Procedures: Written procedures should be established for resin filling, cleaning, and maintenance operations. Marked areas where eating/drinking are prohibited should be established.

Emergency Plan: The steps to be followed in case of chemical spill, fire or injury should be determined and personnel should be trained on this subject.

Health Surveillance: Regular health screenings can be beneficial, especially for respiratory and skin problems.

4.3. Personal Protective Equipment (PPE)

The use of PPE should be used as a last line of defense after the other measures listed above have been implemented.

Gloves: Chemical-resistant nitrile gloves should be used; latex gloves should not be preferred as they do not provide sufficient protection.

Safety Glasses: Safety glasses are used to protect eyes against the liquid splashes and even vapor exposure.

Lab Coat: Should be used to protect the body and clothing from chemicals.

Respiratory Protection: In cases where ventilation is inadequate or especially in high-risk operations (IPA pouring, cabin cleaning), organic vapor filter masks (above FFP2/N95) should be used (NIOSH, 2022).

5. CONCLUSION

SLA technology, with the advantages it offers, will continue to play an indispensable role in production processes. However, for this technology to be used sustainably and safely, it is

essential to acknowledge and proactively manage the associated OHS risks. Literature review indicates that these risks are particularly concentrated around chemical exposure and fire. In this context, the following recommendations can be offered:

- SLA processes should be located in controlled laboratory or workshop environments rather than office environments.
- SLA printers should not be operated without local exhaust ventilation.
- Operator training and awareness should be central to safety culture.
- Manufacturers should be encouraged to develop "environmentally friendly" resins with lower toxicity and to design safer, fully enclosed systems.
- Studies should be initiated in our country (Turkiye) to develop OHS regulations and guidance documents specific to additive manufacturing technologies.

Only in this way, the health and safety of employees can be effectively protected while maximizing the innovative potential brought by SLA technology.

ÖZET

Küresel nüfus artışı, kentleşme ve iklim değişikliğinin geleneksel tarım üzerindeki baskıları, kapalı ve dikey bitkisel üretim sistemleri gibi yenilikçi yaklaşımları gıda güvenliği ve sürdürülebilirlik için kritik hale getirmiştir. Bu sistemler alan, su ve toprak kullanımında yüksek verimlilik sunsa da, özellikle yapay aydınlatma ve iklimlendirmeden kaynaklanan yüksek enerji tüketimi, ekonomik fizibiliteyi ve çevresel sürdürülebilirliği olumsuz etkilemektedir. Bu derleme makalesi, KVBÜS'lerde ışık ve enerji yönetiminin optimizasyonunda yapay zekâ tabanlı stratejilerin rolünü teknik ve analitik bir yaklaşımla incelemektedir. Makale, fotosentez ve bitki morfolojisi üzerindeki spektral etkileşimlerden enerji verimli LED teknolojilerinin dinamik kontrolüne ve HVAC sistemlerinin akıllı yönetimine kadar YZ'nin dönüştürücü potansiyelini ele almaktadır. Makine öğrenimi, derin öğrenme ve pekiştirmeli öğrenme gibi YZ algoritmaları, bitki büyümesini maksimize ederken enerji tüketimini ve operasyonel maliyetleri minimize eden adaptif ve özerk kontrol stratejilerinin geliştirilmesine olanak tanımaktadır. Spektral optimizasyon, dinamik ışık rejimleri, tahmine dayalı iklim kontrolü ve bitki fizyolojisi tahminleri gibi YZ uygulamaları, KVBÜS'ün verimliliğini, mahsul kalitesini ve sürdürülebilirliğini artırmaktadır. Ancak, yüksek başlangıç maliyetleri, veri yönetimi zorlukları, uzman personel eksikliği ve etik kaygılar gibi önemli engeller bulunmaktadır. Gelecekteki araştırmaların yenilenebilir enerji entegrasyonu, daha kapsamlı veri altyapıları, ileri düzey algoritmalar ve modüler sistem tasarımları aracılığıyla bu zorlukların üstesinden gelerek YZ tabanlı KVBÜS çözümlerinin etkinliğini ve erişilebilirliğini artıracağı vurgulanmaktadır. YZ'nin KVBÜS'leri daha verimli, ekonomik ve sürdürülebilir hale getirerek tarımın geleceğinde devrim yaratma potansiyeli olduğu sonucuna varılmıştır.

Anahtar Kelimeler: Kapalı Bitkisel Üretim, Dikey Tarım, Yapay Zekâ, Işık Yönetimi, Enerji Optimizasyonu, Makine Öğrenimi, Pekiştirmeli Öğrenme, Sürdürülebilir Tarım, Kontrollü Çevre Tarımı, Akıllı Tarım.

LIGHT AND ENERGY MANAGEMENT IN CONTROLLED/ VERTICAL PLANT PRODUCTION: ARTIFICIAL INTELLIGENCE–BASED OPTIMIZATION STRATEGIES

ABSTRACT

Global population growth, urbanization, and climate change, along with pressures on traditional agriculture, have made innovative approaches such as closed and vertical crop production systems critical for food security and sustainability. While these systems offer high efficiency in land, water, and soil use, high energy consumption, particularly from artificial lighting and air conditioning, negatively impacts economic feasibility and environmental sustainability. This review article examines the role of AI-based strategies in optimizing light and energy management in CVBÜSs from a technical and analytical perspective. The article explores the transformative potential of AI, from spectral interactions on photosynthesis and plant morphology to the dynamic control of energy-efficient LED technologies and the intelligent management of HVAC systems. AI algorithms such as machine learning, deep learning, and reinforcement learning enable the development of adaptive and autonomous control strategies that maximize plant growth while minimizing energy consumption and operational costs. AI applications such as spectral optimization, dynamic light regimes, predictive climate control, and plant physiology predictions are improving the efficiency, crop quality, and sustainability of CVBUS. However, significant obstacles remain, including high initial costs, data management challenges, a lack of specialized personnel, and ethical concerns. It is emphasized that future research will overcome these challenges through renewable energy integration, more comprehensive data infrastructures, advanced algorithms, and modular system designs, thereby increasing the effectiveness and accessibility of AI-based CVBUS solutions. It is concluded that AI has the potential to revolutionize the future of agriculture by making CVBUS more efficient, economical, and sustainable.

Keywords: Indoor Crop Production, Vertical Farming, Artificial Intelligence, Light Management, Energy Optimization, Machine Learning, Reinforcement Learning, Sustainable Agriculture, Controlled Environment Agriculture, Smart Agriculture.

1. Giriş

Dünya nüfusunun hızla artması, kentleşme ve iklim değişikliğinin getirdiği çevresel zorluklar, geleneksel tarım yöntemlerinin sürdürülebilirliğini tehdit etmektedir. Bu bağlamda, kapalı ve dikey bitkisel üretim sistemleri gibi yenilikçi yaklaşımlar, gıda güvenliği ve sürdürülebilirlik açısından önemli bir potansiyel sunmaktadır. Bu sistemler, dar alanlarda yüksek verim sağlarken, su ve toprak kullanımını minimize ederek kaynak verimliliğini artırmaktadır (Ojo & Zahid, 2022). Ancak, kapalı ve dikey bitkisel üretim sistemlerinin yaygınlaşmasının önündeki en büyük engellerden biri, özellikle aydınlatma ve iklimlendirme sistemlerinden kaynaklanan yüksek enerji tüketimidir. Aydınlatma, bir dikey çiftlikteki enerji tüketiminin %65 ila %85'ini oluştururken, ısıtma, havalandırma ve iklimlendirme sistemleri %10 ila %20'sini oluşturur (Arcasi et al., 2023).

Bu yüksek enerji maliyetleri, kapalı ve dikey bitkisel üretim sistemlerinin ekonomik fizibilitesini ve çevresel sürdürülebilirliğini olumsuz etkilemektedir. Bu nedenle, bu sistemlerde ışık ve enerji yönetiminin optimize edilmesi, hem operasyonel maliyetleri düşürmek hem de çevresel ayak izini azaltmak için kritik öneme sahiptir (Aborujilah, 2025). Geleneksel yöntemlerle yapılan ışık ve enerji yönetimi, bitkinin farklı büyüme evrelerine ve çevresel koşullara dinamik olarak adapte olma yeteneğinden yoksundur. Bu durum, optimal olmayan büyüme koşullarına, enerji israfına ve düşük verimliliğe yol açabilmektedir (Kaiser et al., 2024).

Son yıllarda, yapay zekâ tabanlı teknolojiler, kapalı ve dikey bitkisel üretim sistemlerinde ışık ve enerji yönetimini optimize etme konusunda çığır açan fırsatlar sunmaktadır (Martin, 2024; Payili, 2025). Makine öğrenimi ve derin öğrenme algoritmaları, bitki büyüme verileri, çevresel sensör verileri ve enerji tüketim modellerini analiz ederek, bitki türüne ve gelişim evresine özel, dinamik ışık spektrumları ve yoğunlukları ile enerji verimli iklimlendirme stratejileri geliştirebilir. YZ tabanlı sistemler, enerji kullanımını optimize ederek, mevcut YZ dışı teknolojilere kıyasla enerji tüketiminde önemli azalmalar sağlayabilmektedir (Decardi-Nelson & You, 2024). Örneğin, yapay zeka tabanlı kontrol çerçeveleri, derin pekiştirmeli öğrenme tekniklerini kullanarak seralarda enerji verimli kontrol sağlayabilmektedir. Bu entegre yaklaşımlar, yalnızca kaynak kullanımını iyileştirmekle kalmaz, aynı zamanda mahsul verimini ve kalitesini artırarak sistemlerin genel sürdürülebilirliğini ve karlılığını yükseltir (Hoseinzadeh & Garcia, 2024).

Bu derleme makalesi, kapalı ve dikey bitkisel üretim sistemlerinde ışık ve enerji yönetiminin yapay zekâ tabanlı optimizasyon stratejilerini kapsamlı bir şekilde incelemeyi amaçlamaktadır. Makale, bu sistemlerin temel prensiplerini, ışık ve enerji yönetimindeki mevcut zorlukları, yapay zekânın bu zorlukları aşmada nasıl kullanılabileceğini ve gelecekteki potansiyel uygulamalarını teknik ve analitik bir yaklaşımla değerlendirecektir. Her paragrafta teknik bir açıklama, bilimsel veya fizyolojik bir mekanizmanın analizi, açık bir neden-sonuç ilişkisi ve gerektiğinde literatür tarzında kavramsal genişletmelerle konuyu derinlemesine ele alacaktır.

2. Kapalı/Dikey Bitkisel Üretim Sistemlerinin Temelleri

Kapalı ve dikey bitkisel üretim sistemleri, bitki yetiştiriciliğinde kontrollü bir ortam sağlayarak çevresel koşulları optimize etmeyi hedefleyen modern tarım yaklaşımlarıdır. Bu sistemler, topraksız tarım yöntemlerini (hidroponik, aeroponik, akuaponik gibi) dikey olarak istiflenmiş katmanlarda birleştirerek birim alandan elde edilen verimi maksimize eder (Malabadi et al., 2024; Sowmya et al., 2024). Temel prensip, ışık, sıcaklık, nem, karbondioksit konsantrasyonu ve besin çözeltisi gibi tüm büyüme faktörlerinin insan kontrolünde veya otomatik sistemler aracılığıyla hassas bir şekilde düzenlenmesidir (Stutte et al., 2023). Bu sayede, bitkiler dış iklim

koşullarından tamamen bağımsız olarak yıl boyunca optimum koşullarda yetiştirilebilir (Chatterjee et al., 2020, p. 6).

2.1. Tanım ve Kapsam

Kontrollü Çevre Tarımı, bitki büyümesini optimize etmek için çevresel koşulların yönetildiği tüm kapalı yapıları kapsayan geniş bir terimdir. Bu terim, gelişmiş seraları, büyüme odalarını ve özellikle yapay aydınlatmalı bitki fabrikalarını veya dikey çiftlikleri içerir (Dietze et al., 2024). Dikey tarım ise, ürünlerin dikey olarak istiflenmiş katmanlarda, kontrollü iç mekan koşullarında, genellikle yapay ışık ve topraksız yöntemler kullanılarak yetiştirildiği bir CEA türüdür. Bu yaklaşım, temel olarak güneş ışığı gibi doğal etkileşimleri dışarıda bırakarak yüksek düzeyde hassasiyet ve kontrol sunar (Stanghellini & Katzin, 2024).

2.2. Avantajlar

Kapalı ve dikey bitkisel üretim sistemleri, geleneksel tarıma kıyasla bir dizi önemli avantaj sunmaktadır:

Alan Verimliliği: Bitkilerin dikey katmanlarda yetiştirilmesi sayesinde, birim alandan elde edilen ürün miktarı önemli ölçüde artar. Bu durum, özellikle kentsel alanlarda sınırlı tarım arazisi sorununa çözüm sunar.

Kaynak Verimliliği: Topraksız yetiştirme yöntemleri ve kapalı sistemlerdeki su geri dönüşümü sayesinde, geleneksel tarıma kıyasla %70 ila %95'e kadar daha az su tüketilir. Benzer şekilde, besin maddeleri de daha verimli kullanılır (Malabadi et al., 2024).

Yıl Boyunca Üretim ve Yüksek Verim: Dış iklim koşullarından bağımsızlık, yıl boyunca tutarlı ve yüksek kalitede ürün elde edilmesini sağlar. Bitki türüne göre mevsimsel kısıtlamalar ortadan kalkar.

Pestisit ve Herbisit Kullanımının Azalması: Kapalı ve steril ortamlar, zararlı ve hastalıkların sisteme girişini sınırlar, böylece pestisit ve herbisit kullanımını büyük ölçüde azaltır veya tamamen ortadan kaldırır. Bu durum, daha sağlıklı ve güvenli gıda üretimine olanak tanır.

Kentsel Gıda Güvenliği ve Tedarik Zinciri Kısaltma: Üretim tesislerinin tüketime yakın kurulabilmesi, taşıma maliyetlerini ve karbon ayak izini azaltır. Ayrıca, taze ürünlerin daha hızlı bir şekilde tüketicilere ulaşmasını sağlar (Lubna et al., 2022).

İklim Değişikliğine Karşı Direnç: Aşırı hava olayları (kuraklık, sel, don vb.) ve mevsimsel değişikliklerden etkilenmeme, gıda üretiminde istikrar ve güvenilirlik sağlar.

2.3. Zorluklar

Avantajlarına rağmen, kapalı ve dikey bitkisel üretim sistemleri önemli zorluklarla karşı karşıyadır:

Yüksek Başlangıç ve İşletme Maliyetleri: Özellikle arazi alımı, tesis kurulumu, ileri teknoloji ekipmanları ve nitelikli işgücü gereksinimi yüksek başlangıç maliyetlerine yol açar.

Yüksek Enerji Tüketimi: Yapay aydınlatma ve iklimlendirme sistemleri, bu sistemlerin en büyük enerji tüketicileridir ve yüksek işletme maliyetlerine neden olur. Bu durum, geleneksel tarıma göre 100 kata kadar daha fazla enerji gerektirebilir (Gurung et al., 2024, p. 109).

Teknolojik Bağımlılık ve Bakım: Sistemler, sensörler, YZ ve robotik gibi sofistike teknolojilere bağımlıdır ve bu da karmaşık bakım ve işletme süreçlerini beraberinde getirir (Akintuyi, 2024, p. 120).

Uzman Personel İhtiyacı: Bu ileri teknoloji sistemlerin kurulumu, yönetimi ve optimizasyonu için ziraat, mühendislik ve yazılım alanlarında uzmanlaşmış personele ihtiyaç duyulmaktadır. Nitelikli personel eksikliği, yaygınlaşmanın önünde bir engel teşkil edebilir (Aborujilah, 2025).

Sınırlı Mahsul Çeşitliliği ve Ölçeklenebilirlik: Mevcut dikey çiftlikler genellikle yapraklı yeşillikler ve bazı meyveler gibi belirli ürünler üzerinde yoğunlaşmaktadır. Daha geniş bir mahsul yelpazesini ekonomik olarak üretmek ve büyük ölçekte üretim yapmak hala zorluk teşkil etmektedir (Delden et al., 2021).

Pazar Rekabeti: Sübvansiyonlarla desteklenen geleneksel tarım ürünleriyle rekabet etmek, dikey tarım ürünleri için bir ekonomik zorluk oluşturur (Gurung et al., 2024, p. 109).

2.4. Teknolojik Altyapı ve Gereksinimler

Kapalı ve dikey bitkisel üretim sistemlerinin başarılı bir şekilde çalışabilmesi için entegre bir teknolojik altyapıya ihtiyaç duyulmaktadır:

Yapay Aydınlatma Sistemleri: Özellikle LED'ler, bitki büyümesi için gerekli spektral kalitede ve yoğunlukta ışık sağlayarak fotosentezi optimize eder (Steward & Avery, 2022, p. 1).

İklim Kontrol Sistemleri: Sıcaklık, nem ve CO2 seviyelerini hassas bir şekilde düzenleyerek bitkiler için ideal bir mikroklima oluşturur.

Topraksız Yetiştirme Sistemleri: Hidroponik, aeroponik ve akuaponik gibi yöntemler, bitkilerin su ve besin maddelerini verimli bir şekilde almasını sağlar (kaur, 2021, p. 2).

Sensör Teknolojileri: Çevresel parametreleri (sıcaklık, nem, CO2, ışık yoğunluğu) ve bitki fizyolojik durumunu (pH, EC) sürekli olarak izler (Uyeh et al., 2022).

Otomasyon ve Kontrol Sistemleri: Sensör verilerine dayanarak aydınlatma, sulama, besin dağıtımı ve iklimlendirme sistemlerini otomatik olarak yönetir (Sezhian et al., 2024).

Veri Analizi ve Yapay Zekâ: Toplanan büyük veri setlerini analiz ederek büyüme modellerini tahmin eder, sistem performansını optimize eder ve karar alma süreçlerini destekler (Dietze et al., 2024; Ojo & Zahid, 2022).

Bu sistemlerin entegrasyonu ve verimli çalışması, yapay zekâ tabanlı optimizasyon stratejilerini vazgeçilmez kılmaktadır. Gelecek bölümde, ışık yönetiminin temel prensipleri ve optimal spektrum stratejileri detaylandırılacaktır.

3. Işık Yönetimi ve Optimal Spektrum Stratejileri

Bitkisel üretimde ışık, fotosentezin temel enerji kaynağı olmasının yanı sıra, bitkinin büyümesini, gelişimini ve morfolojisini doğrudan etkileyen kritik bir çevresel faktördür (Amirshekari & Fakhroleslam, 2025). Kapalı ve dikey bitkisel üretim sistemlerinde, doğal güneş ışığının sınırlı veya hiç olmaması nedeniyle, yapay aydınlatma sistemleri bitki gelişimi için vazgeçilmez bir unsurdur. Bu sistemlerde ışık yönetimi, sadece yeterli ışık miktarını sağlamakla kalmayıp, aynı zamanda ışığın kalitesini (spektral kompozisyon), yoğunluğunu ve fotoperiyodunu bitkinin ihtiyaçlarına göre optimize etmeyi gerektirir (Sena et al., 2024). Optimal ışık stratejileri, bitki verimini ve kalitesini artırırken, enerji tüketimini minimize etme potansiyeli sunar (Amirshekari & Fakhroleslam, 2025).

3.1. Fotosentezin Temelleri ve Işık Spektrumu İlişkisi

Fotosentez, bitkilerin ışık enerjisini kimyasal enerjiye dönüştürerek organik madde sentezlediği biyokimyasal bir süreçtir. Bu süreçte klorofil a ve klorofil b başta olmak üzere farklı pigmentler, ışığın belirli dalga boylarını absorbe eder. Fotosentetik aktivite, görünür ışık

spektrumunun (400-700 nm) belirli bölgelerinde yoğunlaşır; özellikle mavi (420-430 nm) ve kırmızı (620-670 nm) ışık, fotosentez için en etkili dalga boylarıdır (Wu et al., 2024). Kırmızı ışık, fotosentezin ana itici gücü olup, bitki biyokütlesi birikimi ve boy uzaması üzerinde önemli etkilere sahiptir (Тараканов et al., 2021). Mavi ışık ise, klorofil sentezini, stomaların açılmasını, gövde kısalmasını ve yaprak kalınlığını etkileyerek bitkinin morfolojik gelişiminde kilit rol oynar (Cavallaro & Muleo, 2022). Yeşil ışığın fotosentezdeki rolü daha önce düşük olarak kabul edilse de, son araştırmalar yeşil ışığın bitki kanopisinin derinliklerine nüfuz ederek fotosentetik verimliliğe katkıda bulunabildiğini ve fotoprotektif etkileri olduğunu göstermektedir (Trojak & Skowron, 2021). Amber ışık (590-620 nm) da fotosentetik verimlilik açısından önemli dalga boyları arasında yer almaktadır (Wu et al., 2024).

Bitkilerin ışığa verdikleri tepkiler, sadece klorofilin ışık absorbsiyonu ile sınırlı değildir; fitokromlar, kriptokromlar ve fototropinler gibi çeşitli fotoreseptörler, ışığın spektral kalitesindeki değişimleri algılayarak bitkinin fotomorfogenetik tepkilerini düzenler (Paradiso & Proietti, 2021). Bu fotoreseptörler, bitkinin çevresel koşullara adaptasyonunu sağlayarak tohum çimlenmesinden çiçeklenmeye kadar birçok gelişimsel süreci kontrol eder (Тараканов et al., 2021). Bu nedenle, ışık spektrumunun hassas bir şekilde ayarlanması, yalnızca fotosentetik verimi artırmakla kalmaz, aynı zamanda istenen bitki morfolojisi ve biyokimyasal bileşen profili elde etmek için de kullanılır (Stamford et al., 2023).

3.2. Optimal Spektrum Bileşimleri ve Bitki Tepkileri

Farklı bitki türleri ve hatta aynı bitkinin farklı gelişim evreleri, optimum büyüme ve metabolit üretimi için farklı ışık spektrumu bileşimlerine ihtiyaç duyar (Stamford et al., 2023). Bu durum, dinamik ve ayarlanabilir ışık kaynaklarının kapalı tarım sistemlerindeki önemini vurgular.

Mavi ve Kırmızı Işık Oranları: Genellikle bitki büyümesi ve biyokütle birikimi için kırmızı ışığın baskın olduğu, ancak mavi ışığın belirli bir oranda bulunmasının gerekli olduğu kabul edilir. Mavi ışık, stomatal iletkenliği artırarak CO2 alımını ve dolayısıyla fotosentezi teşvik edebilir. Aşırı mavi ışık ise bitki boyunu kısaltabilir ve yaprak alanını azaltabilirken, uygun oranlarda mavi-kırmızı kombinasyonları, yüksek fotosentetik performans ve bitki büyümesini teşvik etmektedir (Modarelli et al., 2022).

Yeşil Işığın Rolü: Yeşil ışık, bitki kanopisinin alt katmanlarına nüfuz etme yeteneği sayesinde, yüksek yoğunluklu aydınlatma altında alt yaprakların fotosentezine katkıda bulunur (Trojak & Skowron, 2021). Ayrıca, bitkilerin strese tepkilerini modüle ettiği ve bazı durumlarda büyüme stimülasyonuna yol açtığı gözlemlenmiştir (Тараканов et al., 2021).

Uzak Kırmızı ve Ultraviyole Işık: Uzak kırmızı ışık (700-800 nm), fitokrom sistemi aracılığıyla gövde uzamasını ve yaprak genişlemesini teşvik eder. Ultraviyole ışık (UV-A: 315-400 nm, UV-B: 280-315 nm), bitki metabolizmasında ikincil metabolitlerin üretimini (örneğin, antioksidanlar ve flavonoidler) tetikleyebilir, ancak yüksek yoğunluklarda bitkilere zarar verebilir (Stamford et al., 2023). Bu dalga boylarının dikkatli kullanımı, bitki kalitesini artırabilir.

Optimal spektrum bileşimleri, bitki türüne, büyüme aşamasına ve istenen ürün özelliklerine göre özelleştirilmelidir. Örneğin, marul gibi yapraklı sebzeler için belirli mavi-kırmızı oranları, antosiyanin gibi faydalı bileşenlerin üretimini artırabilirken, domates gibi meyveli bitkiler için farklı spektral stratejiler gerekebilir (Stamford et al., 2023). Bu karmaşık ilişkilerin yönetimi, yapay zekâ destekli sistemlerin devreye girdiği noktadır.

3.3. Enerji Verimli Aydınlatma Teknolojileri: LED Sistemler

Geleneksel aydınlatma kaynakları (örneğin, yüksek basınçlı sodyum lambalar), yüksek enerji tüketimi, ısı üretimi ve sınırlı spektrum ayarlanabilirliği nedeniyle kapalı bitkisel üretim sistemlerinde verimlilik sorunları yaratmaktadır. Bu bağlamda, Işık Yayan Diyot teknolojileri, sunduğu avantajlarla devrim niteliğinde bir çözüm sunmuştur (Cavallaro & Muleo, 2022; Sena et al., 2024).

Spektral Ayarlanabilirlik: LED'ler, farklı dalga boylarında (mavi, yeşil, kırmızı, uzak kırmızı vb.) hassas bir şekilde ışık üretebilme kapasitesine sahiptir. Bu özellik, bitkinin spesifik ihtiyaçlarına göre özelleştirilmiş ışık spektrumlarının oluşturulmasına olanak tanır. Büyümenin farklı aşamalarında veya belirli fizyolojik tepkileri tetiklemek için spektrumun dinamik olarak ayarlanabilmesi, bitki verimini ve kalitesini optimize eder (Lozano-Castellanos et al., 2025).

Yüksek Enerji Verimliliği: LED'ler, geleneksel lambalara kıyasla daha düşük enerji tüketimi ve daha yüksek lümen verimliliği sunar. Bu durum, özellikle dikey çiftliklerde aydınlatma kaynaklı yüksek enerji maliyetlerini önemli ölçüde düşürme potansiyeli taşır (Sena et al., 2024).

Düşük Isı Üretimi: LED'ler, ışık enerjisinin çoğunu bitkiye yönlendirirken, geleneksel lambalara göre çok daha az ısı üretir. Bu özellik, iklimlendirme yükünü azaltarak ek enerji tasarrufu sağlar ve bitki etrafındaki mikroklimanın daha hassas kontrolüne olanak tanır.

Uzun Ömür ve Küçük Boyut: LED'lerin uzun ömrü ve kompakt tasarımı, bakım maliyetlerini düşürür ve dikey tarım sistemlerinde alan kullanımını maksimize eder.

Dinamik Kontrol Yeteneği: LED sistemleri, ışık yoğunluğunun, spektrumun ve fotoperiyodun hassas bir şekilde kontrol edilmesine imkan tanır (Lozano-Castellanos et al., 2025). Bu dinamik kontrol, bitki büyümesini ve enerji tüketimini optimize etmek için kritik öneme sahiptir. Örneğin, dar spektrumlu ışık kullanımı, bitkisel materyalin kalitesini artırırken enerji tasarrufu sağlayabilir.

Bu teknolojik gelişmeler, bitkisel üretimde ışık yönetiminin pasif bir süreç olmaktan çıkıp, bitki fizyolojisine ve enerji verimliliğine duyarlı, aktif bir optimizasyon alanına dönüşmesine olanak sağlamıştır. Bir sonraki bölümde, yapay zekânın bu karmaşık ışık yönetimi stratejilerini nasıl daha ileriye taşıdığı incelenecektir.

4. Enerji Yönetimi ve İklimlendirme Stratejileri

Kapalı ve dikey bitkisel üretim sistemlerinde enerji maliyetleri, özellikle yapay aydınlatma ve iklimlendirme sistemlerinden kaynaklanan yüksek tüketim nedeniyle, işletme giderlerinin önemli bir kısmını oluşturmaktadır. Aydınlatma dışındaki iklim kontrol sistemleri, toplam enerji tüketiminin %10 ila %20'sini teşkil edebilir (Arcasi et al., 2023). Bitki büyümesi ve gelişimi için optimal çevresel koşulların sürdürülmesi hayati olmakla birlikte, bu koşulların sağlanması genellikle yoğun enerji girdisi gerektirir (Zhang et al., 2023). Bu nedenle, enerji yönetiminin etkin bir şekilde yapılması ve iklimlendirme stratejilerinin optimize edilmesi, KVBÜS'ün ekonomik sürdürülebilirliği ve çevresel ayak izinin azaltılması açısından kritik öneme sahiptir.

4.1. HVAC Sistemleri ve Enerji Verimliliği

Isıtma, Havalandırma ve İklimlendirme sistemleri, KVBÜS içinde sıcaklık, nem ve hava sirkülasyonunu kontrol eden temel bileşenlerdir. Bu sistemler, bitkilerin fotosentetik aktivitesini ve transpirasyon oranlarını doğrudan etkileyen mikroklimayı düzenler. Ancak,

geleneksel HVAC sistemlerinin yüksek enerji tüketimi, KVBÜS'ün karlılığını tehdit eden başlıca unsurlardan biridir (Zhang et al., 2023).

Enerji verimliliğini artırmak için modern KVBÜS'lerde çeşitli yaklaşımlar benimsenmektedir:

Akıllı HVAC Kontrolü: Sensörlerden gelen gerçek zamanlı verilerle entegre çalışan akıllı kontrol sistemleri, bitki türüne, büyüme evresine ve dış iklim koşullarına göre HVAC sistemlerinin çalışma parametrelerini dinamik olarak ayarlayabilir. Bu, gereksiz enerji harcamasını önler ve optimal koşulları daha verimli bir şekilde sürdürür (Mun et al., 2025). Örneğin, bir model, iklim kontrol stratejisini optimize ederek ve saatlik spesifik enerji tüketimini minimize ederek dış iklim koşullarının enerji tüketimi üzerindeki etkisini değerlendirmiştir. Bu tür gelişmiş kontrol, özellikle yaz aylarında çok düşük enerji tüketimine olanak tanıyabilir.

Enerji Geri Kazanım Sistemleri: KVBÜS'lerde hava değişimi sırasında kaybedilen ısı veya serinlik, enerji geri kazanım üniteleri (örneğin, ısı pompaları ve ısı geri kazanımlı vantilatörler) aracılığıyla geri dönüştürülebilir (Ng et al., 2023). Bu sistemler, dışarı atılan havadaki termal enerjiyi taze havaya aktararak ısıtma ve soğutma yüklerini azaltır. Özellikle soğuk ve ılıman iklimlerde, binaların enerji sistemleriyle entegre edilen dikey çiftlikler, ısıtma ve soğutma için önemli enerji tasarrufları sağlayabilir.

Yalıtım ve Yapı Malzemeleri: Yüksek yalıtım performansına sahip yapı malzemeleri ve tesis tasarımında termal köprülerin azaltılması, ısı transferini minimize ederek HVAC sistemlerinin yükünü düşürür (Şirin et al., 2024). Bu, özellikle soğuk iklimlerde enerji kayıplarını engellemek için kritik bir faktördür.

Pasif Soğutma ve Isıtma Teknikleri: Jeotermal enerji, gölgelendirme sistemleri, doğal havalandırma (uygun yerleşim ve tasarım ile) gibi pasif stratejiler, mekanik HVAC sistemlerine olan bağımlılığı azaltarak enerji tüketimini düşürebilir (Weidner et al., 2021, p. 114338).

4.2. Karbondioksit Yönetimi ve Nem Kontrolü

CO2 ve nem, KVBÜS içindeki bitki büyümesini ve enerji tüketimini etkileyen diğer önemli çevresel parametrelerdir.

CO2 Zenginleştirme: CO2, fotosentez için temel bir reaktanttır. KVBÜS'lerde CO2 konsantrasyonunun atmosferik seviyelerin (yaklaşık 400 ppm) üzerine çıkarılması (genellikle 800-1200 ppm'e kadar), bitkilerin fotosentetik verimliliğini ve büyüme oranlarını önemli ölçüde artırabilir. Ancak, CO2 zenginleştirme maliyetli bir süreç olabilir ve bu maliyeti optimize etmek için CO2'nin mekansal dağılımının ve bitki kanopisi içindeki emiliminin doğru bir şekilde yönetilmesi gerekir. Örneğin, ticari seralarda CO2 zenginleştirme verimliliği, artan fotosentezin enerji (CO2 eşdeğeri) miktarına oranı hesaplanarak analiz edilebilir (Zhang et al., 2023, p. 17277). Optimum CO2 konsantrasyonunun bitki türüne ve gelişim evresine göre belirlenmesi, hem verimliliği hem de maliyet etkinliğini artırır (Orsini et al., 2020, p. 300).

Nem Kontrolü: Bağıl nem, bitki transpirasyonunu, besin alımını ve hastalık gelişimini doğrudan etkiler. Optimal nem seviyeleri, bitkinin sağlıklı büyümesi için önemlidir. Yüksek nem, mantar hastalıklarına yol açabilirken, düşük nem transpirasyonu aşırı artırarak bitki stresine neden olabilir. Nem kontrolü genellikle yoğuşturma (havayı soğutarak) veya buharlaştırma (nem ekleyerek) yoluyla yapılır, her iki işlem de enerji gerektirir (Zhang et al., 2020). Termoelektrik klima sistemleri gibi yeni teknolojiler, geleneksel sistemlere kıyasla nem kontrolünde enerji maliyetlerini önemli ölçüde azaltma potansiyeli sunmaktadır.

Nem Geri Kazanımı: Bitki transpirasyonu sonucu açığa çıkan nem, dezenfekte edilerek bitkilerin sulanmasında yeniden kullanılabilir. Bu yaklaşım, su tasarrufu sağlarken, aynı

zamanda ortamdaki nem yükünü yöneterek iklimlendirme sistemlerinin dehumidifikasyon yükünü potansiyel olarak düşürebilir.

4.3. Entegre Kontrol ve Optimizasyon

KVBÜS'lerde enerji yönetimi ve iklimlendirme stratejilerinin başarısı, tüm çevresel faktörlerin (ışık, sıcaklık, nem, CO2) entegre bir şekilde yönetilmesine bağlıdır. Her bir faktör birbiriyle etkileşim halindedir; örneğin, yüksek ışık yoğunluğu sıcaklığı artırırken, CO2 zenginleştirme fotosentezi hızlandırabilir ve bitkinin suya olan ihtiyacını değiştirebilir. Bu karmaşık dinamikler, tekil faktörlere odaklanan yaklaşımların sınırlı kalmasına neden olur.

Bu nedenle, yapay zekâ tabanlı optimizasyon stratejileri, bu entegrasyonu sağlamak için vazgeçilmezdir. Sensör ağlarından gelen büyük veri setlerini (sıcaklık, nem, CO2, bitki büyüme hızı, enerji tüketimi vb.) analiz ederek, YZ algoritmaları, bitki büyümesini maksimize ederken enerji tüketimini minimize eden dinamik ve uyarlanabilir kontrol stratejileri geliştirebilir (Kaiser et al., 2024). Örneğin, YZ algoritmaları, elektrik fiyatlarındaki dalgalanmaları ve bitki fizyolojisindeki değişimleri dikkate alarak optimum üretim koşullarını ve ilgili maliyetleri sürekli olarak ayarlayabilir (Kaiser et al., 2024). Talep yanıt kontrolü gibi stratejiler, elektrik maliyetlerini %5 ila %30 oranında azaltabilir.

Sonuç olarak, KVBÜS'de enerji yönetimi ve iklimlendirme, sadece çevresel parametreleri kontrol etmekten öte, maliyet etkinliği ve sürdürülebilirlik hedeflerine ulaşmak için yenilikçi, entegre ve yapay zekâ destekli yaklaşımlar gerektiren karmaşık bir mühendislik alanıdır. Gelecek bölümde, yapay zekâ tabanlı optimizasyon stratejileri daha detaylı ele alınacaktır.

5. Yapay Zekâ Tabanlı Optimizasyon Stratejileri

Yapay zekâ ve özellikle makine öğrenimi ile derin öğrenme teknikleri, kapalı ve dikey bitkisel üretim sistemlerinde karşılaşılan karmaşık optimizasyon problemlerini çözmek için güçlü araçlar sunmaktadır. Bu sistemlerdeki çok sayıda çevresel değişken (ışık, sıcaklık, nem, CO2 konsantrasyonu vb.) ve bitki fizyolojisinin dinamik yapısı, geleneksel kontrol yöntemlerinin ötesine geçen adaptif ve akıllı yaklaşımları zorunlu kılmaktadır (Ojo & Zahid, 2022). YZ, bu değişkenler arasındaki karmaşık etkileşimleri analiz ederek bitki büyümesini, verimliliğini ve kalitesini maksimize ederken enerji ve kaynak tüketimini minimize etme potansiyeli taşır.

5.1. Işık Yönetiminde Yapay Zekâ Uygulamaları

Yapay aydınlatma, KVBÜS'deki en büyük enerji tüketicilerinden biri olduğundan, ışık parametrelerinin YZ ile optimize edilmesi büyük önem taşır (Lozano-Castellanos et al., 2025). YZ algoritmaları, bitki türüne, büyüme evresine ve istenen morfolojik veya biyokimyasal özelliklere göre ışık spektrumunu, yoğunluğunu ve fotoperiyodunu dinamik olarak ayarlayabilir:

Spektral Optimizasyon: ML modelleri, farklı ışık spektrumlarının bitki gelişimi, fotosentetik verimlilik ve metabolit üretimi üzerindeki etkilerini analiz ederek, belirli hedefler için (örneğin, biyokütle artışı, besin değeri, aroma profili) en uygun spektral bileşimleri belirleyebilir (Manoharan et al., 2024, p. 177). Sensörlerden (örneğin, spektral sensörler) toplanan verilerle beslenen bu modeller, bitkilerin anlık tepkilerine göre spektrumu gerçek zamanlı olarak modifiye edebilir.

Dinamik Işık Rejimleri: YZ, bitki büyüme modelleri, dış enerji fiyatları ve hatta bitkilerin fotosentetik kapasitesindeki günlük dalgalanmalar gibi faktörleri hesaba katarak ışık yoğunluğunu ve süresini (fotoperiyodu) optimize edebilir. Örneğin, bitkilerin ışık kesintilerine tolerans gösterme yeteneği kullanılarak, YZ tabanlı sistemler güncel enerji fiyatlarıyla uyumlu,

enerji maliyetlerini düşüren dinamik 24 saatlik aydınlatma programları tasarlayabilir (Abbaspour et al., 2025).

Enerji Verimli Aydınlatma Kontrolü: YZ destekli IoT sistemleri, LED aydınlatmanın spektral ayarlanabilirliğini kullanarak bitkinin ihtiyacından fazla veya az ışık vermeden en verimli şekilde aydınlatmayı sağlar (Kharraz et al., 2025). Bu sistemler, akıllı LED sistemleri aracılığıyla renk sıcaklığı ve ışık yoğunluğu üzerinde dinamik kontrol sağlayarak enerji kullanımını optimize eder (Manoharan et al., 2024, p. 177).

5.2. İklim Kontrolünde Yapay Zekâ Uygulamaları

İklim kontrolü, sıcaklık, nem, CO2 ve hava akışı gibi parametrelerin hassas yönetimini içerir. YZ, bu kompleks sistemi daha verimli ve adaptif hale getirir:

Tahmine Dayalı Kontrol: Derin öğrenme ve diğer ML teknikleri, sera ikliminin tarihsel verilerini, dış hava koşullarını ve bitki tepkilerini analiz ederek gelecekteki çevresel koşulları tahmin edebilir (Lee et al., 2024). Bu tahminler, HVAC sistemlerinin önleyici bir şekilde ayarlanmasına olanak tanır, böylece enerji tüketimi minimize edilirken bitki stresi önlenir (Ajagekar et al., 2022).

Optimal Kontrol Politikaları: Pekiştirmeli öğrenme algoritmaları, deneme-yanılma yoluyla çevresel koşulları öğrenir ve belirli bir ödül fonksiyonunu (örneğin, maksimum verim ve minimum enerji tüketimi) optimize eden kontrol politikaları geliştirir. Bu algoritmalar, zamanla adaptasyon yeteneği sayesinde değişen bitki büyüme evrelerine ve çevresel perturbasyonlara dinamik olarak yanıt verebilir (Ajagekar et al., 2022).

Sensör Füzyonu ve Veri Analizi: KVBÜS'lerdeki sensör ağlarından toplanan büyük hacimli veriler, YZ algoritmaları tarafından gerçek zamanlı olarak işlenir (Rathor et al., 2024). Bu veri füzyonu, bitki sağlığı, büyüme hızı ve çevresel koşullar hakkında kapsamlı bir anlayış sağlayarak, anormalliklerin tespiti ve hedefli müdahaleler için temel oluşturur.

5.3. Bitki Fizyolojisi ve Büyüme Tahmininde Yapay Zekâ

YZ, bitki fizyolojisinin ve büyüme dinamiklerinin daha derinlemesine anlaşılmasına ve tahmin edilmesine olanak tanır:

Büyüme Modeli Oluşturma: ML ve DL modelleri, çevresel veriler, genetik bilgiler ve görüntü işleme teknikleriyle toplanan bitki fenotipik verilerini kullanarak bitki büyüme modellerini oluşturabilir. Bu modeller, farklı çevresel rejimler altında bitki verimini, kalitesini ve gelişim hızını doğru bir şekilde tahmin edebilir (Hu & You, 2023).

Hastalık ve Stres Tespiti: YZ destekli bilgisayar görüşü ve görüntü işleme algoritmaları, bitkilerdeki hastalıkları, besin eksikliklerini veya stres belirtilerini erken aşamalarda tespit edebilir. Bu, hızlı müdahale ile verim kayıplarını önler ve pestisit/herbisit kullanımını azaltır (Rathor et al., 2024).

Verim ve Hasat Tahmini: YZ modelleri, bitki büyüme verilerini ve çevresel koşulları analiz ederek hasat zamanını ve beklenen verimi yüksek doğrulukla tahmin edebilir (Akintuyi, 2024, p. 118). Bu tahminler, tedarik zinciri yönetimini ve pazar stratejilerini optimize etmeye yardımcı olur.

5.4. Çok Amaçlı Optimizasyon ve Karar Destek Sistemleri

KVBÜS'lerdeki optimizasyon problemleri genellikle enerji tüketimini minimize etme, verimi maksimize etme ve ürün kalitesini artırma gibi birbiriyle çelişen birden çok hedefi içerir

(Arteaga-Cabrera et al., 2025). YZ, bu çok amaçlı optimizasyon problemlerini çözmek için etkili yöntemler sunar:

Evrimsel Algoritmalar: Genetik algoritmalar gibi evrimsel algoritmalar, doğal seçilim prensiplerinden ilham alarak potansiyel çözümlerden oluşan bir popülasyonu iteratif olarak geliştirir (Poyatos et al., 2025, p. 7). Bu algoritmalar, enerji optimizasyonunda sağlam ve esnek bir yaklaşım sağlayarak, karmaşık çözüm uzaylarında arama yapabilir ve Pareto optimal çözümler sunabilir.

Pekiştirmeli Öğrenme ve Derin Pekiştirmeli Öğrenme: RL, enerji optimizasyonu gibi dinamik karar verme problemlerinde uygulanabilir. DRL algoritmaları, özellikle çok amaçlı problemlerle başa çıkmada yüksek boyutlu durumlarda geleneksel EA'lardan daha iyi performans gösterebilir. RL, keşfetme (exploration) ve kullanma (exploitation) dengesini kurarak suboptimal öğrenme sonuçlarını engellemeyi hedefler (Hamdan et al., 2024, p. 722).

Hibrit Yaklaşımlar: İstatistiksel yöntemleri meta-sezgisel algoritmalarla birleştiren hibrit yaklaşımlar, hidroponik seralarda bitki üretim verimini maksimize ederken maliyetleri minimize etmeyi hedefleyen çok amaçlı problemleri çözmek için geliştirilmiştir (Sriprateep et al., 2024).

Dijital İkizler: Fiziksel sistemlerin sanal kopyaları olan dijital ikizler (digital twins), KVBÜS'ün iç mikroklimasını ve bitki durumlarını yüksek doğrulukla modellemek için YZ (özellikle fizik tabanlı derin öğrenme) tekniklerinden yararlanır (Lozano-Castellanos et al., 2025). Bu ikizler, kontrol değişkenlerini optimize etmek ve bitki büyümesini tahmin etmek için kullanılır, böylece kontrol ve karar verme süreçlerinde doğruluk artar (Hu & You, 2023).

Yapay zekâ tabanlı optimizasyon stratejileri, KVBÜS'ün sadece teknik verimliliğini değil, aynı zamanda ekonomik ve çevresel sürdürülebilirliğini de artırarak, gıda üretiminde yeni bir dönemin kapılarını aralamaktadır (Chowdhury et al., 2023; Sezhian et al., 2024). Gelecek bölümde, bu stratejilerin uygulanmasında karşılaşılan zorluklar ve gelecekteki araştırma yönelimleri ele alınacaktır.

6. Zorluklar, Gelecek Yönelimler

Kapalı ve dikey bitkisel üretim sistemlerinde yapay zekâ tabanlı ışık ve enerji optimizasyonu stratejileri, sürdürülebilir gıda üretimi için önemli potansiyeller sunsa da, bu teknolojilerin geniş çapta benimsenmesi ve tam potansiyeline ulaşması önünde bir dizi zorluk bulunmaktadır. Bu zorluklar, teknolojik, ekonomik, sosyal ve etik boyutlarda incelenebilir. Bununla birlikte, mevcut kısıtlamaların üstesinden gelmeye yönelik devam eden araştırmalar ve yenilikçi yaklaşımlar, gelecekte KVBÜS'ün gelişimini şekillendirecektir.

6.1. Mevcut Zorluklar

KVBÜS'lerde YZ tabanlı optimizasyonun etkinliğini sınırlayan temel engeller şunlardır:

Yüksek Başlangıç Maliyetleri ve Ekonomik Fizibilite: YZ destekli sistemlerin kurulumu, ileri teknoloji sensörler, otomasyon ekipmanları ve sofistike yazılım altyapısı gerektirdiğinden önemli sermaye yatırımları gerektirir. Bu yüksek peşin harcamalar, özellikle küçük ve orta ölçekli işletmeler için teknolojiye erişimde önemli bir engel teşkil etmektedir (Abbaspour et al., 2025, p. 1). Ayrıca, YZ sistemlerinin hesaplama maliyetlerini (donanım ve işletim) doğru bir şekilde tahmin etmek zor olabilir; bu durum, YZ'nin tarımdaki genel uygulanabilirliğine ilişkin kapsamlı maliyet analizlerinin eksikliğini ortaya koymaktadır.

Veri Yönetimi ve Analiz Zorlukları: KVBÜS'lerde büyük hacimli ve heterojen veri setleri (çevresel, bitkisel, enerji tüketimi) üretilmektedir. Bu verilerin toplanması, depolanması,

işlenmesi ve analiz edilmesi karmaşık veri yönetimi ve analiz yetenekleri gerektirir. Sensör yerleşimi, kalibrasyonu ve veri bütünlüğü sorunları, YZ modellerinin güvenilirliğini ve doğruluğunu etkileyebilir. Gerçek dünya verilerinin yetersizliği ve tutarsız raporlama standartları, YZ modellerinin geliştirilmesini ve doğrulanmasını zorlaştırmaktadır (Aborujilah, 2025).

Teknolojik Entegrasyon ve Uyumluluk: Farklı üreticilerin donanım ve yazılım bileşenlerinin (aydınlatma sistemleri, HVAC, sensörler) sorunsuz bir şekilde entegre edilmesi ve birlikte çalışabilmesi önemlidir. Özellikle çok katmanlı dikey hidroponik sistemlerin fiziksel yapısı, kablosuz sinyal girişimine neden olarak bağlantı ve iletişim sorunları yaratabilir (Azmi et al., 2024, p. 8). Bu entegrasyonun sağlanması, karmaşık mühendislik becerileri gerektirir ve uyumluluk sorunları operasyonel verimliliği düşürebilir.

Uzman Personel ve Dijital Okuryazarlık Eksikliği: YZ tabanlı sistemlerin tasarımı, uygulanması, yönetimi ve bakımı için tarım, mühendislik ve veri bilimi alanlarında yetkin personele ihtiyaç duyulmaktadır (Aborujilah, 2025). Nitelikli işgücüne erişimdeki sınırlamalar ve çiftçiler arasındaki dijital okuryazarlık farkı, bu teknolojilerin geniş çapta benimsenmesini engelleyebilir. Etkili uygulama için eğitim ve desteğin sağlanması kritik öneme sahiptir.

Bitki Biyolojisinin Karmaşıklığı ve Dinamik Modeller: Bitkilerin çevresel faktörlere verdiği tepkiler, türler arasında, gelişim evreleri arasında ve hatta aynı türün varyeteleri arasında önemli farklılıklar gösterir. Optimal ışık programlarının veya iklim kontrol stratejilerinin bitki türüne göre belirlenmesi kolay değildir. YZ modellerinin bu biyolojik karmaşıklığı tam olarak yakalayabilmesi ve dinamik koşullara adaptif olarak yanıt verebilmesi hala devam eden bir araştırma konusudur (Hu & You, 2023).

Siber Güvenlik ve Gizlilik Endişeleri: IoT cihazları ve YZ sistemleri, veri topladıkça ve paylaştıkça siber güvenlik risklerini ve veri gizliliği endişelerini beraberinde getirir (Azmi et al., 2024, p. 8). Çiftçi verilerinin sahipliği, kullanımı ve korunmasına ilişkin açık kurallar ve mekanizmalar oluşturulması gerekmektedir.

Etik ve Sosyal Meseleler: YZ'nin tarımda yaygınlaşması, işgücü piyasaları üzerinde (otomasyon nedeniyle işten çıkarmalar), çiftçilerin mahremiyeti üzerinde (gelişmiş izleme teknolojileri) ve teknolojiye erişimde eşitsizlikler yaratma potansiyeli gibi etik soruları gündeme getirmektedir. Geleneksel tarım ürünlerine kıyasla dikey çiftlik ürünlerinin "doğallığı"na ilişkin tüketici algıları da sosyal bir zorluk teşkil edebilir (Gurung et al., 2024, p. 109).

6.2. Gelecek Yönelimler

KVBÜS'lerde YZ tabanlı ışık ve enerji yönetiminin geleceği, mevcut zorlukların üstesinden gelmeye ve yeni araştırma alanlarını keşfetmeye odaklanacaktır:

Daha Kapsamlı ve Standartlaştırılmış Veri Altyapısı: YZ modellerinin etkinliğini artırmak için çok disiplinli, uzunlamasına saha çalışmaları ve standardize edilmiş metrik tanımlarına dayalı kapsamlı veri setlerinin oluşturulması gerekmektedir (Aborujilah, 2025). Bitki performans metriklerinin yanı sıra operasyonel maliyetleri içeren detaylı veri toplama, YZ teknolojilerinin fizibilitesinin daha bütünsel bir şekilde anlaşılmasını sağlayacaktır.

Yenilenebilir Enerji Entegrasyonu ve Hibrit Sistemler: Yüksek enerji tüketimi sorununu çözmek için KVBÜS'lerin yenilenebilir enerji kaynaklarıyla (güneş, rüzgar) stratejik entegrasyonu büyük önem taşımaktadır (Aborujilah, 2025). YZ, bu hibrit enerji sistemlerinin verimli yönetiminde ve elektrik şebekesiyle entegrasyonunda kritik bir rol oynayacaktır.

İleri Düzey YZ Modelleri ve Algoritmaları: Gelecekteki araştırmalar, özellikle pekiştirmeli öğrenme ve model tahmine dayalı kontrol gibi ileri düzey algoritmaların entegrasyonuna odaklanacaktır. Bu, belirsizliklere (örneğin, öngörülemeyen hava koşulları, sensör hataları) karşı daha sağlam ve uyarlanabilir kontrol stratejilerinin geliştirilmesini sağlayacaktır. YZ modellerinin farklı bitki türlerine genellenebilirliğini artırmak, tek bir mahsule özgü çözümler yerine daha genel RL kontrolörlerinin geliştirilmesiyle mümkün olacaktır (Laatum et al., 2024, p. 6).

Dijital İkizler ve Siber-Fiziksel-Biyolojik Sistemler: Fizik-bilgilendirilmiş derin öğrenme tekniklerinden yararlanılarak geliştirilen dijital ikizler, KVBÜS'ün iç mikroklimasını ve bitki durumlarını yüksek doğrulukla modelleyerek kontrol değişkenlerini optimize etmek ve bitki büyümesini tahmin etmek için kullanılmaya devam edecektir. Bu CPBS yaklaşımları, enerji yönetimi ve mahsul üretiminin entegre ve akıllı kontrolünü sağlayacaktır (Hu & You, 2023).

Etik ve Sosyal Çerçeveler: YZ'nin tarımda sorumlu ve sürdürülebilir bir şekilde uygulanmasını sağlamak için veri gizliliği, teknolojiye eşit erişim ve işgücü etkileri gibi etik sorunlara yönelik net yönergeler ve politikalar geliştirilmesi gerekmektedir.

Modülerlik ve Ölçeklenebilirlik: YZ tabanlı çözümlerin modüler ve ölçeklenebilir olması, farklı boyutlardaki ve yapılandırmalardaki KVBÜS'lere kolayca uygulanabilmesini sağlayacaktır.

7. Sonuç

Kapalı ve dikey bitkisel üretim sistemleri, küresel gıda güvenliği ve sürdürülebilirlik hedeflerine ulaşmada kilit bir rol oynamaktadır. Ancak, bu sistemlerin yaygınlaşmasının önündeki en büyük engellerden biri olan yüksek enerji tüketimi ve operasyonel maliyetler, YZ tabanlı optimizasyon stratejileri aracılığıyla aşılabilir. Bu derleme makalesi, ışık ve enerji yönetiminde YZ'nin sunduğu dönüştürücü potansiyeli; ışık spektrumunun fotosentez ve bitki morfolojisi üzerindeki etkilerinden, enerji verimli LED teknolojilerinin dinamik kontrolüne ve HVAC sistemlerinin akıllı yönetimine kadar teknik bir yaklaşımla ele almıştır.

Yapay zekâ algoritmaları, özellikle makine öğrenimi, derin öğrenme ve pekiştirmeli öğrenme teknikleri sayesinde, bitki büyümesini maksimize ederken enerji tüketimini ve operasyonel maliyetleri minimize eden adaptif ve özerk kontrol stratejileri geliştirilmesine olanak sağlamaktadır. Spektral optimizasyon, dinamik ışık rejimleri, tahmine dayalı iklim kontrolü ve bitki fizyolojisi tahminleri gibi YZ uygulamaları, KVBÜS'ün verimliliğini, mahsul kalitesini ve sürdürülebilirliğini artırmaktadır. Dijital ikizler ve çok amaçlı optimizasyon teknikleri ise, karmaşık sistem dinamiğini yöneterek en uygun çözüm setlerini sunmaktadır.

Bununla birlikte, YZ teknolojilerinin yaygın olarak benimsenmesinin önünde hala yüksek başlangıç maliyetleri, veri yönetimi zorlukları, uzman personel eksikliği ve etik kaygılar gibi önemli engeller bulunmaktadır. Gelecekteki araştırmalar, bu zorlukların üstesinden gelmeye, yenilenebilir enerji entegrasyonu, daha kapsamlı veri altyapıları, ileri düzey algoritmalar ve modüler sistem tasarımları aracılığıyla YZ tabanlı KVBÜS çözümlerinin etkinliğini ve erişilebilirliğini artırmaya odaklanacaktır. Yapay zekâ, kapalı ve dikey bitkisel üretim sistemlerini daha verimli, ekonomik ve sürdürülebilir hale getirerek, tarımın geleceğinde devrim yaratma potansiyelini taşımaktadır.

Yapay Zekâ Katkı Beyanı

Bu çalışmanın yazım sürecinde, yalnızca dil düzenleme, yazım kuralları, açıklık ve akıcılığın artırılması gibi amaçlarla yapay zekâ temelli yazılım programlarından yararlanılmıştır.

ORCID: 0000-0002-0087-5814

ÖZET

Küresel enerji talebinin artışı ve iklim değişikliğiyle mücadele hedefleri doğrultusunda, tarımsal kalıntılardan elde edilen pelet yakıtları, fosil yakıtlara sürdürülebilir bir alternatif olarak öne çıkmaktadır. Bu derleme makalesi, tarım kaynaklı pelet yakıtlarının yaşam döngüsü değerlendirmesi, emisyon-enerji optimizasyonu stratejileri, çevresel ve ekonomik etkileri ile gelecek perspektiflerini kapsamlı bir şekilde incelemektedir. Makale, bu yakıtların çevresel performansını ve sürdürülebilirlik potansiyelini nesnel bir şekilde değerlendirmek için Uluslararası Standardizasyon Örgütü'nün belirlediği 14040 ve 14044 standartlarına uygun LCA metodolojisinin önemini vurgulamaktadır.Analizler, tarımsal biyokütle hammaddelerinin (selüloz, hemiselüloz, lignin, kül içeriği) kimyasal ve fiziksel özelliklerinin pelet kalitesi ve yanma davranışı üzerindeki belirleyici etkilerini ortaya koymaktadır. Özellikle külün bileşimi ve miktarı, korozyon ve cüruf oluşumu gibi yanma problemlerini tetikleyebilmektedir. Pelet üretim sürecindeki kurutma ve yoğunlaştırma aşamalarının enerji yoğunluğu, atık ısı geri kazanımı ve ileri peletleme teknikleri (örneğin geç buhar enjeksiyonu) ile minimize edilebilirken, yanma sistemlerinde emisyon kontrolü için yanma odası tasarımı, hava beslemesi optimizasyonu ve ileri yanma kontrol sistemleri kritik öneme sahiptir. Ayrıca, biyokömür (torrefaction) gibi ön işlemler, hem yakıt kalitesini iyileştirmekte hem de emisyonları azaltmaktadır.Çevresel açıdan, tarım kaynaklı peletler genellikle karbon nötr bir yakıt olarak değerlendirilmekle birlikte, LCA çalışmaları, üretim ve taşıma aşamalarındaki fosil yakıt tüketiminin net sera gazı dengesi üzerindeki etkilerini göstermektedir. Makale, arazi kullanım değişiklikleri ve su kaynakları üzerindeki etkiler gibi diğer çevresel faktörlerin de bütünsel değerlendirilmesi gerektiğini belirtmektedir. Ekonomik perspektiften bakıldığında, tarımsal peletler yüksek pazar potansiyeline sahiptir ve kırsal ekonomilere katkıda bulunurken istihdam yaratma kapasitesine sahiptir. Ancak, rekabetçilik, üretim maliyetleri ve hükümet politikalarına bağlıdır.Gelecek perspektifleri, ileri proses teknolojileri, döngüsel biyoekonomi entegrasyonu, geliştirilmiş politika ve pazar mekanizmaları ile sürekli teknolojik gelişmeleri içermektedir. Bu alanlardaki sürekli araştırma ve geliştirme, tarım kaynaklı pelet yakıtlarının sürdürülebilir enerji dönüşümündeki rolünü pekiştirecek, çevresel faydalarını maksimize ederken ekonomik uygulanabilirliğini ve toplumsal kabulünü artıracaktır.

Anahtar Kelimeler Tarımsal pelet yakıtları, Yaşam döngüsü değerlendirmesi (LCA), Emisyon ve enerji optimizasyonu, Pelet kalitesi ve yanma davranışı, Sürdürülebilir biyoenerji.

LIFE CYCLE ASSESSMENT AND EMISSION–ENERGY OPTIMIZATION IN AGRICULTURAL BIOMASS PELLET FUELS

ABSTRACT

In line with the increasing global energy demand and the goals of combating climate change, pellet fuels derived from agricultural residues are emerging as a sustainable alternative to fossil fuels. This review article comprehensively examines the life cycle assessment, emission-energy optimization strategies, environmental and economic impacts, and future perspectives of agricultural pellet fuels. The article emphasizes the importance of the LCA methodology, compliant with the International Organization for Standardization (IOS) standards 14040 and 14044, to objectively assess the environmental performance and sustainability potential of these fuels. The analyses reveal the decisive effects of the chemical and physical properties of agricultural biomass feedstocks (cellulose, hemicellulose, lignin, ash content) on pellet quality and combustion behavior. In particular, the composition and amount of ash can trigger combustion problems such as corrosion and slag formation. The energy intensity of the drying and densification stages of the pellet production process can be minimized through waste heat recovery and advanced pelletization techniques (e.g., late steam injection). Combustion chamber design, air supply optimization, and advanced combustion control systems are critical for emission control in combustion systems. Furthermore, pretreatments such as biochar (torrefaction) both improve fuel quality and reduce emissions. From an environmental perspective, while agricultural pellets are generally considered a carbon-neutral fuel, LCA studies demonstrate the impact of fossil fuel consumption during production and transportation on the net greenhouse gas balance. The article suggests that other environmental factors, such as land use changes and impacts on water resources, should also be considered holistically. From an economic perspective, agricultural pellets have high market potential and can contribute to rural economies and create employment. However, competitiveness depends on production costs and government policies. Future perspectives include advanced process technologies, integration with the circular bioeconomy, improved policy and market mechanisms, and continued technological advancements. Continued research and development in these areas will reinforce the role of agricultural pellet fuels in the sustainable energy transition, increasing their economic viability and societal acceptance while maximizing their environmental benefits.

Keywords: Agricultural pellet fuels, Life Cycle Assessment (LCA), Emission and energy optimization, Pellet quality and combustion behavior, Sustainable bioenergy.

1. Giriş

Küresel enerji sistemlerinde fosil yakıtlara olan bağımlılığın azaltılması yönündeki acil ihtiyaç, yenilenebilir enerji kaynaklarına geçişi hızlandırmış ve bu dönüşümde biyokütlenin stratejik rolünü ön plana çıkarmıştır (Nosenzo & Kelman, 2025, p. 1). Biyokütle, özellikle tarımsal kalıntılardan elde edilen pelet yakıtları formunda, karbon nötr bir enerji kaynağı olarak değerlendirilmekte ve küresel dekarbonizasyon hedeflerine ulaşmada önemli bir potansiyel taşımaktadır. Bu yakıtların kullanımı, sadece enerji güvenliğini artırmakla kalmayıp, aynı zamanda tarım sektöründeki atıkların değerlendirilmesi ve döngüsel biyoekonomik modellerin desteklenmesi açısından da kritik bir fonksiyon icra etmektedir (Ibrahim et al., 2025; Svensson et al., 2024). Ancak, biyokütle peletlerinin enerji dönüşüm sistemlerindeki yaygınlaşması, hammaddenin karakteristik özelliklerinden nihai ürünün kalitesine, lojistik süreçlerden çevresel etkilerine kadar uzanan bir dizi teknik ve çevresel optimizasyonu zorunlu kılmaktadır.

Tarımsal atıkların peletlenerek enerjiye dönüştürülmesi, atık yönetimi sorunlarına sürdürülebilir bir çözüm sunarken, aynı zamanda hava kalitesi üzerindeki olumsuz etkileri azaltma potansiyeli taşımaktadır (Nosenzo & Kelman, 2025, p. 3). Geleneksel olarak yakılarak veya depolanarak bertaraf edilen büyük miktardaki tarımsal kalıntılar, pelet formunda sıkıştırıldığında hem nakliye ve depolama maliyetlerini düşürür hem de daha verimli ve temiz bir yanma profili sunar (Ibrahim et al., 2025). Özellikle mısır sapı ve pirinç kabuğu gibi lignoselülozik biyokütle kaynakları, yüksek ısıtma değerleri sayesinde kömüre eşdeğer enerji içeriği sağlayarak yenilenebilir enerji üretimi için cazip bir alternatif oluşturmaktadır (Mujtaba et al., 2023). Bu dönüşüm süreci, hammaddenin başlangıçtaki düşük yoğunluk ve yüksek nem içeriği gibi dezavantajlarını gidermekle birlikte (Găgeanu et al., 2021), nihai peletin fiziksel, mekanik, kimyasal ve termal özelliklerinin optimize edilmesi yoluyla yakıt kalitesini maksimize etmeyi hedefler.

Bu derleme makalesi, tarım kaynaklı pelet yakıtlarının yaşam döngüsü değerlendirmesi ve emisyon-enerji optimizasyonu üzerine odaklanacaktır. LCA, biyoyakıt üretiminin çevresel yüklerini, hammadde temininden nihai enerji kullanımına kadar tüm yaşam döngüsü boyunca kapsamlı bir şekilde değerlendiren bilimsel bir metodolojidir (Osman et al., 2024). Bu yaklaşım, pelet üretimi ve kullanımından kaynaklanan sera gazı emisyonları, enerji tüketimi ve diğer çevresel etkilerin nicel analizini sağlayarak, sürdürülebilirlik potansiyelinin objektif bir şekilde belirlenmesine olanak tanır (Martín-Gamboa et al., 2020). Ayrıca, makale, pelet üretim süreçlerinde ve yanma sistemlerinde emisyonları minimize etmeye ve enerji verimliliğini maksimize etmeye yönelik teknik yaklaşımları ve optimizasyon stratejilerini de detaylı bir şekilde inceleyecektir. Bu analiz, tarım kaynaklı pelet yakıtlarının çevresel performansını artırma ve enerji sektöründeki sürdürülebilir entegrasyonlarını destekleme amacıyla kritik mühendislik ve bilimsel perspektifler sunmayı hedeflemektedir.

2. Yaşam Döngüsü Değerlendirmesi Metodolojileri ve Uygulamaları

Tarımsal kaynaklı pelet yakıtlarının çevresel performansını ve sürdürülebilirlik potansiyelini nesnel bir şekilde değerlendirmek için Yaşam Döngüsü Değerlendirmesi metodolojisi kritik bir araçtır (Prasad et al., 2020). LCA, bir ürünün veya hizmetin, hammaddelerin temininden nihai bertarafına kadar uzanan tüm yaşam döngüsü boyunca çevresel etkilerini sistematik olarak nicelendirir. Bu bütünsel yaklaşım, sadece doğrudan emisyonları değil, aynı zamanda üretim, taşıma, işleme ve kullanım aşamalarındaki enerji tüketimi ve kaynak kullanımı gibi dolaylı etkileri de dikkate alarak, gizli çevresel yüklerin ortaya çıkarılmasını sağlar (Sgarbossa et al., 2020). Böylece, tarım kaynaklı peletlerin geleneksel fosil yakıtlara göre gerçek çevresel avantajlarını veya potansiyel dezavantajlarını belirlemek mümkün hale gelirken, aynı zamanda süreç iyileştirmeleri için de yol gösterici veriler sunulur (Osman et al., 2021, p. 4092).

2.1. LCA'nın Temel Prensipleri ve ISO Standartları

Yaşam Döngüsü Değerlendirmesi, Uluslararası Standardizasyon Örgütü tarafından geliştirilen ISO 14040 ve ISO 14044 standartları ile uluslararası düzeyde kabul görmüş bir metodolojik çerçeveye sahiptir (Khan, 2022, p. 61). Bu standartlar, LCA çalışmalarının şeffaflığını, karşılaştırılabilirliğini ve tekrarlanabilirliğini sağlamak amacıyla temel prensipleri ve aşamaları belirler. Ancak, aynı ürün sistemleri üzerinde yapılan LCA çalışmalarında bile geniş bir sonuç çeşitliliğinin gözlemlenmesi, metodolojik tercihlerin ve uygulama farklılıklarının önemini vurgular. Bu farklılıklar, özellikle biyoyakıtların LCA'sında, kullanılan modellerin ve veri tabanlarının çeşitliliği ile birlikte, standardizasyonun detaylı uygulama kılavuzlarına olan ihtiyacını ortaya koymaktadır. LCA'nın nihai amacı, çevresel sürdürülebilirliği artırmak ve politika yapıcılar için uzun vadeli stratejik kararların alınmasında kanıta dayalı veriler sunmaktır (Osman et al., 2021, p. 4092).

2.2. Yaşam Döngüsü Değerlendirme Aşamaları

ISO 14040 ve 14044 standartlarına göre, bir LCA çalışması dört ana aşamadan oluşur:

Hedef ve Kapsam Tanımı: Bu aşama, çalışmanın amacını, hedeflerini ve sınırlarını belirler. Fonksiyonel birim, yani değerlendirilen ürün veya hizmetin nicel ölçüsü ve sistem sınırları, bu adımda tanımlanır (Rashedi et al., 2022, p. 6). Örneğin, tarım kaynaklı pelet yakıtları için fonksiyonel birim, bir kilogram peletin veya belirli bir enerji miktarının (örneğin 1 MJ enerji) üretimi olabilir. Sistem sınırları ise, hammadde temininden pelet üretimine, taşımasına ve nihai kullanımına kadar tüm süreçleri kapsar (Miller & Orton, 2021, p. 4). Bu tanımlar, sonuçların güvenilirliği ve karşılaştırılabilirliği için hayati öneme sahiptir.

Yaşam Döngüsü Envanter Analizi: Bu aşamada, tanımlanan sistem sınırları içinde tüm girdi ve çıktı akışları (hammadde, enerji, su, hava emisyonları, atıklar vb.) toplanır ve nicelendirilir. Tarım kaynaklı pelet üretiminde, tarımsal kalıntıların toplanması, kurutulması, öğütülmesi, peletlenmesi ve taşınması gibi her bir aşamadaki enerji ve malzeme tüketimleri, sera gazı emisyonları ve diğer çevresel çıktılar detaylı olarak kaydedilir (Sadaghiani et al., 2023). LCI verileri, bir sonraki etki değerlendirme aşamasının temelini oluşturur.

Yaşam Döngüsü Etki Değerlendirmesi: Bu aşamada, LCI'den elde edilen girdi ve çıktı verileri, çeşitli çevresel etki kategorileri (örneğin, küresel ısınma potansiyeli, asitlenme, ötrofikasyon, fosil yakıt tükenmesi, insan sağlığı üzerindeki etkiler) altında çevresel etkilere dönüştürülür (Sadaghiani et al., 2023). Her bir emisyon veya kaynak kullanımı, ilgili etki kategorisi için bir karakterizasyon faktörü ile çarpılarak potansiyel çevresel etki hesaplanır. Örneğin, karbondioksit emisyonları, küresel ısınma potansiyeli kategorisi altında birim olarak CO2 eşdeğeri (CO2e) cinsinden ifade edilir.

Yaşam Döngüsü Yorumlaması: Son aşama, envanter analizi ve etki değerlendirme sonuçlarının derlenip, tanımlanan hedef ve kapsama göre yorumlanmasını içerir (Osman et al., 2021, p. 4092). Bu aşamada, çevresel açıdan en kritik noktalar (hotspotlar) belirlenir, hassasiyet analizleri yapılır ve sonuçların belirsizlikleri değerlendirilir. Elde edilen bulgular, ürünün çevresel performansını iyileştirmek için öneriler sunmak, farklı alternatifler arasında karşılaştırma yapmak ve politika kararlarını bilgilendirmek amacıyla kullanılır.

2.3. Tarım Kaynaklı Pelet Yakıtlarında LCA Uygulamalarına Özgü Hususlar

Tarım kaynaklı pelet yakıtlarının LCA'sında, biyokütlenin doğasından kaynaklanan bazı özel hususlar bulunmaktadır. Özellikle, biyoenerji sistemlerinin karbon ayak izinin belirlenmesinde, biyojenik karbonun modellenmesi büyük önem taşır (Martín-Gamboa et al., 2020). Biyokütle büyümesi sırasında atmosferden alınan CO2 ile yanma sonucu atmosfere salınan CO2

arasındaki denge, karbon nötrlüğü argümanının temelini oluşturur. Ancak, arazi kullanım değişiklikleri veya dolaylı arazi kullanım değişiklikleri (iLUC) gibi faktörler, LCA sonuçlarını önemli ölçüde etkileyebilir. Ayrıca, tarımsal atıkların "atık" olarak kabul edilmesi ve bunların alternatif kullanım senaryoları (örneğin toprakta bırakılması) ile kıyaslanması, LCA'nın sistem sınırları ve çok fonksiyonluluk (multifunctionality) ile ilgili tahsisat (allocation) yöntemlerinin dikkatli bir şekilde seçilmesini gerektirir. Bu metodolojik seçimler, LCA sonuçlarının güvenilirliğini ve uygulanabilirliğini doğrudan etkiler, bu nedenle literatürdeki geniş varyasyonun ana nedenlerinden biridir (Martín-Gamboa et al., 2020).

3. Tarımsal Biyokütle Hammaddeleri ve Peletleme Süreci

Tarımsal kaynaklı pelet yakıtlarının çevresel performansının yaşam döngüsü değerlendirmesi ve emisyon-enerji optimizasyonu, büyük ölçüde kullanılan biyokütle hammaddelerinin karakteristik özelliklerine ve uygulanan peletleme süreçlerine bağlıdır. Hammaddelerin kimyasal ve fiziksel özellikleri, peletlerin nihai yakıt kalitesini, depolama davranışını ve yanma özelliklerini doğrudan etkilerken, peletleme süreci parametreleri ise üretim verimliliği ve ürün dayanıklılığı açısından kritik rol oynar (Lavergne et al., 2021).

3.1. Tarımsal Biyokütle Hammaddelerinin Özellikleri

Tarımsal kalıntılar, lignoselülozik yapıya sahip olup, temel olarak selüloz, hemiselüloz ve lignin içerirler (Mujtaba et al., 2023). Bu bileşenlerin oranları, biyokütlenin türüne ve menşeine göre değişiklik gösterir ve peletlerin mekanik dayanımı ile enerji içeriği üzerinde belirleyici etkilere sahiptir. Örneğin, yüksek lignin içeriği, peletleme sırasında doğal bir bağlayıcı görevi görerek peletlerin dayanıklılığını artırabilir.

Kimyasal Bileşim:

Selüloz ve Hemiselüloz: Biyokütlenin ana yapısal bileşenleridir ve yüksek kalorifik değere katkıda bulunurlar. Termal bozunma sıcaklıkları genellikle lignine göre daha düşüktür; hemiselüloz yaklaşık 200-220 °C'den itibaren, selüloz ise yaklaşık 270-315 °C'den itibaren bozunmaya başlarken, lignin daha geniş bir sıcaklık aralığında, daha yüksek sıcaklıklara kadar bozunur (El-Sayed et al., 2023, p. 17779).

Lignin: Biyokütleye rijitlik ve su geçirmezlik sağlayan amorf bir polimerdir. Peletleme esnasında yüksek sıcaklık ve basınç altında yumuşayarak partiküller arası bağ oluşumunu destekler.

Kül İçeriği: Tarımsal kalıntıların önemli bir özelliği olan yüksek kül içeriği, pelet yakıtlarının yanma verimliliğini düşürebilir ve külün erime noktasına bağlı olarak cüruf oluşumuna neden olabilir (Peng & Lau, 2019, p. 226). Külün bileşimi, özellikle alkali metaller (potasyum, sodyum) ve klor gibi elementlerin varlığı, kül erime davranışını, depozit oluşumunu ve yanma sistemlerinde yüksek sıcaklık korozyon potansiyelini önemli ölçüde artırır (Karczewski et al., 2016, p. 113).

Uçucu Madde ve Sabit Karbon: Bu oranlar, yakıtın yanma davranışını ve tutuşma karakteristiğini belirler. Yüksek uçucu madde içeriği hızlı tutuşmaya yol açarken, sabit karbon yakıtın ısıtma değerine önemli katkıda bulunur (FİGEN et al., 2016, p. 3).

Fiziksel Özellikler:

Nem İçeriği: Peletleme süreci için kritik bir parametredir. Optimal nem içeriği aralığı, biyokütle türüne göre değişmekle birlikte, genellikle %10-20 civarındadır (Jiang et al., 2019, p. 558). Aşırı nem, pelet dayanıklılığını düşürürken, çok düşük nem de bağlayıcıların

aktivasyonunu zorlaştırabilir ve üretim için daha fazla enerji gerektirebilir (Găgeanu et al., 2021).

Partikül Boyutu: Peletleme öncesinde hammaddenin öğütülerek homojen bir partikül boyutuna getirilmesi, pelet kalitesi ve yoğunluğu için hayati öneme sahiptir. Daha küçük partikül boyutları, daha fazla temas yüzeyi sağlayarak partiküller arası bağ oluşumunu kolaylaştırır ve daha dayanıklı peletler elde edilmesini sağlar (Labbé et al., 2019). Ancak çok ince partiküllerin aşırı üretimi, eleme sırasında toz oluşumuna yol açabilir ve bu tozlar, depolama ve taşıma süreçlerinde sağlık, güvenlik riskleri (toz patlamaları) ile yanma sistemlerinde sorunlara neden olabilir.

Yığın Yoğunluğu: Hammaddenin düşük yığın yoğunluğu, depolama ve taşıma maliyetlerini artıran temel bir dezavantajdır. Peletleme işlemi, bu yığın yoğunluğunu önemli ölçüde artırarak bu lojistik sorunları giderir (Rashedi et al., 2022, p. 2).

3.2. Peletleme Süreci Aşamaları

Peletleme süreci, tarımsal biyokütleyi yüksek yoğunluklu, homojen ve standartlaştırılmış yakıtlara dönüştüren bir dizi adımdan oluşur (Ibitoye et al., 2021). Bu süreç genellikle ön işlemler, yoğunlaştırma ve son işlemler olarak üç ana aşamada incelenebilir:

Ön İşlemler:

Kurutma: Yüksek nem içeriği, pelet üretimini olumsuz etkilediği için biyokütle genellikle optimal nem seviyesine kadar kurutulur. Kurutma, pelet kalitesini artırırken, aynı zamanda enerji yoğun bir süreçtir ve LCA'da önemli bir çevresel yüke neden olabilir (Jacob-Lopes & Zepka, 2017, p. 485).

Boyut Küçültme: Hammadde, homojen bir partikül boyutu dağılımı elde etmek için öğütülür veya parçalanır. Bu adım, peletleme verimliliğini ve nihai ürün kalitesini doğrudan etkiler (Zăbavă et al., 2018, p. 4).

Karıştırma ve Kondisyonlama: Farklı biyokütle türleri karıştırılabilir ve bazen bağlayıcı maddeler (örneğin nişasta, melas) veya su buharı ile kondisyonlama yapılabilir. Bu, peletleme sürecini kolaylaştırır ve peletlerin mekanik dayanımını artırır (Nath et al., 2023, p. 2).

Yoğunlaştırma:

Bu aşamada, ön işlemden geçmiş biyokütle, pelet değirmenleri (halka kalıp veya düz kalıp tipi) veya ekstrüzyon presleri gibi ekipmanlar kullanılarak yüksek basınç ve sıcaklık altında sıkıştırılır (Tumuluru et al., 2010, p. 2). Sıkıştırma sırasında oluşan sürtünme ve basınç, biyokütlenin doğal bağlayıcıları olan lignin ve hemiselülozun yumuşamasını sağlar. Bu durum, partiküllerin birbirine yapışmasını ve pelet formunu korumasını sağlar (Rashedi et al., 2022, p. 2).

İşlem sırasında sıcaklık genellikle 90-100°C'ye ulaşabilir, bu da biyokütlenin yapısal bütünlüğünü güçlendirir (Jacob-Lopes & Zepka, 2017, p. 485).

Son İşlemler:

Soğutma: Peletler, yoğunlaştırma sonrası yüksek sıcaklıkta oldukları için soğutulmalıdır. Soğutma işlemi, peletlerin sertleşmesini ve şekillerini korumasını sağlar.

Eleme: Soğutma sonrası oluşan ince partiküller (toz) elenerek çıkarılır. Bu, peletlerin kalitesini ve depolama/taşıma güvenliğini artırır.

3.3. Pelet Kalitesini Etkileyen Faktörler ve Optimizasyon

Pelet kalitesi, nihai kullanım performansını ve ekonomik değeri belirleyen çeşitli parametrelerle tanımlanır. Bu parametrelerin optimizasyonu, üretim maliyetlerini düşürme ve çevresel etkiyi azaltma açısından önemlidir.

Hammaddenin Özellikleri: Biyokütlenin nem içeriği, partikül boyutu ve kimyasal bileşimi (kül, lignin içeriği) pelet dayanıklılığı, yoğunluğu ve ısıtma değeri üzerinde doğrudan etkilidir (Lavergne et al., 2021). Örneğin, optimal nem içeriği, peletin mekanik dayanımını ve yığın yoğunluğunu artırırken (Lavergne et al., 2021), daha küçük partikül boyutları daha yüksek yoğunluk ve dayanıklılık sağlayabilir.

İşlem Parametreleri: Peletleme sıcaklığı ve basıncı, pelet oluşum mekanizmasını etkileyen temel faktörlerdir. Yüksek sıcaklıklar ve basınçlar, lignin akışını artırarak daha güçlü bağlar ve dolayısıyla daha dayanıklı peletler oluşturabilir. Pelet değirmeninin die çapı ve sıkıştırma oranı da peletlerin yoğunluğunu ve dayanıklılığını etkiler (Ibitoye et al., 2021, p. 80).

Bağlayıcı Kullanımı: Bazı biyokütle türleri, özellikle düşük lignin içeriğine sahip olanlar, pelet dayanıklılığını artırmak için harici bağlayıcılara (örneğin melas, nişasta) ihtiyaç duyabilir (Nath et al., 2023, p. 2). Bu bağlayıcıların türü ve miktarı, nihai pelet kalitesini ve üretim maliyetini etkiler.

4. Emisyon ve Enerji Optimizasyonu Stratejileri

Tarımsal pelet yakıtlarının çevresel performansını ve ekonomik uygulanabilirliğini artırmak, hem üretim aşamalarında enerji tüketiminin azaltılmasını hem de yanma süreçlerinde emisyonların kontrol altına alınmasını gerektirir. Bu iki anahtar alan, pelet yakıtlarının sürdürülebilir enerji sistemlerine entegrasyonu için kritik optimizasyon stratejileri sunmaktadır.

4.1. Pelet Üretiminde Enerji Optimizasyonu

Pelet üretimi, özellikle kurutma ve yoğunlaştırma (peletleme) aşamaları nedeniyle enerji yoğun bir süreçtir. Bu süreçlerin optimizasyonu, hem operasyonel maliyetleri düşürmek hem de üretimden kaynaklanan çevresel ayak izini azaltmak için elzemdir (Asif et al., 2024).

Kurutma Süreçlerinin Verimliliği: Biyokütlenin peletleme öncesinde optimal nem içeriğine getirilmesi gerekliliği, kurutma operasyonunu enerji tüketiminde önemli bir paya sahip kılar. Bu nedenle, kurutma proseslerinin enerji ve ekserji analizi yoluyla optimizasyonu büyük önem taşır (Silva et al., 2021). Atık ısı geri kazanımı ve entegre kurutma sistemleri, bu aşamanın enerji verimliliğini artırmak için etkili yöntemlerdir. Örneğin, baca gazlarından veya diğer proseslerden elde edilen düşük dereceli atık ısının, biyokütlenin ön kurutması için kullanılması, enerji girdilerini ve dolayısıyla üretim maliyetlerini önemli ölçüde azaltabilir (Rudolfsson et al., 2020).

İleri Peletleme Teknikleri: Peletleme süreci sırasında enerji tüketimini azaltmaya yönelik yenilikçi teknikler geliştirilmektedir. "Geç buhar enjeksiyonu" (late-steam injection) gibi yöntemler, peletleme sırasında buhar tüketimini ve hammaddenin kurutma ihtiyacını önemli ölçüde azaltarak enerji tasarrufu ve daha iyi çevresel performans sağlamaktadır. Bu tür teknikler, pelet üretiminde kullanılan enerjinin ekonomik ve çevresel profilini iyileştirir (Rudolfsson et al., 2020).

Ön İşlem Optimizasyonu: Peletleme adımı tek başına değil, tüm ön işlem zinciri, yani taşıma, ön işleme ve depolama aşamaları enerji tüketimi ve maliyetler açısından kritik rol oynar. Malzeme kaybını minimize ederken işlenebilirliği ve yakıt verimini artırmak için partikül

boyutunun dengelenmesi gibi stratejiler, hem teknik hem de ekonomik verimlilik için önemlidir (Thompson et al., 2024). Ayrıca, geleneksel peletleme süreçleri, yüksek nemli peletleme süreçleri ve amonyak fiber genişlemesi gibi farklı peletleme teknolojilerinin karşılaştırmalı analizi, en verimli ve ekonomik yöntemin seçilmesinde yol göstericidir (Tazzit et al., 2021).

Süreç Parametrelerinin Kontrolü: Peletleme hızı, maksimum kuvvet ve peletleme kalıp sıcaklığı gibi kontrol parametreleri, pelet yoğunluğunu ve dolayısıyla enerji tüketimini etkiler. Optimal nem içeriği ve basınçla birleştirilmiş yüksek sıcaklıklar, pelet yoğunluğunu artırabilirken (Găgeanu et al., 2021), bu parametrelerin hassas kontrolü enerji verimliliğini sağlamada esastır.

4.2. Yanma Sistemlerinde Emisyon Kontrolü

Tarımsal pelet yakıtlarının yakılması sırasında ortaya çıkan emisyonlar (CO, NOx, PM2.5, vb.), hem insan sağlığı hem de çevre için olumsuz etkiler yaratabilir. Bu emisyonların etkin bir şekilde kontrol edilmesi, biyokütlenin sürdürülebilir bir enerji kaynağı olarak kabulünü artırmak için hayati öneme sahiptir.

Yanma Odası ve Hava Beslemesi Optimizasyonu: Pelet kazanlarında ve sobalarında, yanma odası tasarımı ve hava beslemesinin optimize edilmesi, emisyonları azaltmanın temelini oluşturur. Özellikle, çok katmanlı sekonder hava dağılımının optimize edilmesi, mısır sapı ve pirinç kabuğu peletlerinin yanmasından kaynaklanan NOx ve CO emisyonlarını düşürürken yanma verimliliğini artırabilir (He et al., 2022). Primer ve sekonder hava akışının doğru oranlarda dağıtılması, özellikle zorlamalı çekişli biyokütle sobalarında, karbon monoksit, azot oksitler ve partikül madde emisyonlarını optimize edebilir (Deng et al., 2020).

İleri Yanma Kontrol Sistemleri: Pelet sobaları, pelet kazanlarına kıyasla yakıt kalitesi varyasyonlarına daha duyarlı olup, bu durum düzensiz emisyonlara yol açabilir. Yakıt besleme hızının fırın sıcaklığı veya lambda sensörleri aracılığıyla kontrol edildiği gelişmiş yanma kontrol sistemleri, hem emisyonları azaltma hem de verimliliği artırma potansiyeli sunar. Yanma yoğunlaştırıcılarının uygulanması, odun ve tarımsal peletlerin yanmasında yanmamış kirletici emisyonlarında önemli düşüşler sağlayabilir (Horvat et al., 2021).

Yakıt Kalitesinin Etkisi: Peletin nem içeriği, uzunluğu ve ince partikül oranı gibi fiziksel özellikleri, yanma performansını ve emisyonları doğrudan etkiler. Optimal nem içeriği, daha düşük emisyonlara yol açarken, aşırı ince partiküllerin varlığı gaz salınımındaki varyasyonları artırarak emisyonları yükseltebilir. Bu nedenle, ENplus veya ISO 17225-2 gibi standartlar çerçevesinde yakıt kalitesinin iyileştirilmesi, emisyon kontrolü için kritik bir adımdır (Mack et al., 2022, p. 26842).

Katkı Maddeleri Kullanımı: Kül birikimi ve korozyonu azaltmak amacıyla kül önleyici katkı maddelerinin kullanımı, CO emisyonlarını düşürme potansiyeli sunabilir. Ancak, bu katkı maddelerinin NOx emisyonları üzerindeki etkisi yakıt türüne ve katkı maddesine göre değişiklik gösterebilir. Azot oksit emisyonlarını azaltmak için ise hava sınıflandırması gibi bilinen teknikler veya az miktarda inorganik tuzun katı katalizör olarak kullanılması değerlendirilmelidir (Mirowski et al., 2020, p. 83).

Ön İşlem ve Yakıt Dönüşümü: Biyokömür (torrefaction) teknolojileri, biyokütlenin termal ön işlemden geçirilmesiyle peletlerin enerji yoğunluğunu artırabilir ve böylece mevcut pulverize kömür santrallerinde kömürle birlikte yakılmalarını sağlayarak net karbondioksit emisyonlarında büyük azalmalar sağlayabilir. Torrefaction gibi ön işlemler, özellikle daha derin hava kademeleme ile NOx emisyonlarını ve yanmamış karbon salınımını azaltabilirken, kazan verimliliğini de artırır (Lee et al., 2020).

4.3. Süreç Entegrasyonu ve Atık Isı Geri Kazanımı

Pelet üretim tesislerinin ve biyokütle bazlı enerji sistemlerinin genel enerji verimliliğini artırmak için süreç entegrasyonu ve atık ısı geri kazanımı stratejileri büyük fırsatlar sunar. Bu yaklaşımlar, bir tesisteki enerji akışlarını optimize ederek, harici enerji ihtiyacını minimize eder ve çevresel etkiyi daha da azaltır.

Birleşik Isı ve Güç Sistemleri: Pelet üretim tesislerinde veya biyokütle yakma tesislerinde birleşik ısı ve güç sistemlerinin entegrasyonu, hem elektrik hem de ısı üretimine olanak tanır. Bu, toplam enerji verimliliğini önemli ölçüde artırır ve özellikle kurutma gibi prosesler için düşük dereceli ısı ihtiyacını karşılayabilir (Nhien et al., 2021).

Tesisler Arası Isı ve Kütle Değişimi: Farklı endüstriyel tesisler arasında ısı ve kütle değişimi ağlarının entegrasyonu, atık enerjinin ve kaynakların yeniden kullanımını teşvik eder (Isafiade, 2024). Bu, biyoenerji üretim tesislerinde genel kaynak verimliliğini artırmak için geniş ölçekli bir optimizasyon stratejisidir.

Baca Gazı Isı Geri Kazanımı: Biyokütle yakma sistemlerinden çıkan baca gazları, önemli miktarda atık ısı taşır. Bu ısının geri kazanılması, özellikle biyokütle kurutma veya diğer termal prosesler için kullanılabilir (Khan et al., 2022). Baca gazından elde edilen ısının membran distilasyonu gibi teknolojilerle entegrasyonu, biyogaz tesislerinde besin konsantrasyonunu ve proses suyu geri kazanımını sağlayarak ek faydalar sunabilir (Khan et al., 2022).

Holistik Entegrasyon Yaklaşımları: Biyokütleden türetilmiş sentez gazı saflaştırma süreçleri gibi entegre sistemlerde, atık ısı geri kazanımı ve ejektör teknolojisinin entegrasyonu, proses maliyetlerini düşürürken enerji verimliliğini önemli ölçüde iyileştirebilir (Bashiri et al., 2021). Süreç tasarımında bütünsel bir yaklaşım benimsemek, gizli enerji verimsizliklerini ortaya çıkarabilir ve sistem genelinde optimum performans sağlayabilir

5. Tarımsal Pelet Yakıtlarının Çevresel ve Ekonomik Etkileri

Tarımsal kaynaklı pelet yakıtlarının geniş ölçekli benimsenmesi ve sürdürülebilir bir enerji kaynağı olarak potansiyeli, çevresel performansları ve ekonomik uygulanabilirlikleriyle doğrudan ilişkilidir. Bu bölüm, yaşam döngüsü perspektifinden tarımsal peletlerin çevresel faydalarını ve zorluklarını incelerken, aynı zamanda pazar potansiyeli, maliyet etkinliği ve politika desteklerini de analiz etmektedir.

5.1. Yaşam Döngüsü Çevresel Performansı

Tarımsal pelet yakıtlarının çevresel performansı, esas olarak Yaşam Döngüsü Değerlendirmesi metodolojileri ile nicel olarak belirlenmektedir. Bu değerlendirmeler, hammaddenin tarladan toplanmasından, işlenmesine, peletlenmesine, taşınmasına ve son olarak enerji üretimi için yakılmasına kadar tüm aşamaları kapsar (Prasad et al., 2020).

Sera Gazı Emisyonları: Tarımsal peletlerin en önemli çevresel faydalarından biri, genellikle karbon nötr bir yakıt olarak kabul edilmeleridir. Biyokütle büyüme süreçlerinde atmosferden CO2 emer ve yandıklarında bu CO2'yi serbest bırakır. LCA çalışmaları, pelet üretimi ve taşınması sırasında kullanılan fosil yakıtlardan kaynaklanan emisyonları da dikkate alarak net bir sera gazı dengesi ortaya koyar (Ebadian et al., 2021). Odun peletlerinin fosil yakıtların yerine kullanılmasıyla sera gazı emisyonlarında önemli düşüşler elde edildiği belirtilmektedir (Sgarbossa et al., 2020). Tarım kaynaklı peletlerin sera gazı emisyon azaltım potansiyeli, iklim değişikliğiyle mücadelede önemli bir rol oynamaktadır (Nosenzo & Kelman, 2025, p. 1).

Diğer Çevresel Etki Kategorileri: Sera gazı emisyonlarının yanı sıra, LCA, asitlenme, ötrofikasyon, insan sağlığı üzerindeki partikül madde etkileri ve su kıtlığı gibi diğer çevresel

etki kategorilerini de değerlendirir (Rashedi et al., 2022). Tarımsal pelet üretimi ve kullanımında, bu kategorilerdeki etkiler hammadde türü, işleme teknolojileri ve lojistik zincire bağlı olarak değişiklik gösterir. Örneğin, tarımsal pelet biyoyakıtlarının üretimi için su kıtlığı endeksine en fazla katkı, hammadde toplama ve taşıma, ezme, eleme, yapıştırıcı ekleme, peletleme, soğutma ve son eleme gibi faaliyetlerden gelmektedir (Rashedi et al., 2022).

Arazi Kullanımı ve Biyoçeşitlilik: Biyoenerji ürünleri için arazi kullanımı, LCA çalışmalarında önemli bir konudur. Birinci nesil biyoyakıtlar, özellikle arazi kullanım değişiklikleri dahil edildiğinde, çevresel açıdan fosil yakıtlardan daha kötü performans gösterebilir. Ancak, tarımsal atıklar gibi ikinci nesil biyokütle kaynakları, gıda üretimiyle rekabet etmedikleri ve arazi kullanım değişikliklerine neden olmadıkları için bu tür çevresel baskıları azaltma potansiyeline sahiptir. Biyoenerji kullanımı, ekosistem hizmetleri ve biyoçeşitliliğin korunması gibi hedeflere katkıda bulunabilir (Englund et al., 2021, p. 2).

Su Kaynakları Üzerindeki Etkiler: Biyoyakıt üretimi, özellikle enerji mahsullerinin yetiştirilmesi için yüksek miktarda su gerektirebilir. Ancak tarımsal kalıntılardan pelet üretimi sırasında su ayak izi, özellikle yağlama yağı ve elektrik tüketimi gibi kalemlerden kaynaklanırken, buğday nişastası ve elektrik gibi girdilerin katkısı daha azdır (Rashedi et al., 2022).

5.2. Ekonomik Değerlendirme ve Pazar Potansiyeli

Tarımsal pelet yakıtlarının ekonomik uygulanabilirliği, üretim maliyetleri, pazar fiyatları, rekabet gücü ve politika destekleri gibi birçok faktöre bağlıdır.

Üretim Maliyetleri: Pelet üretim maliyetleri, hammadde temini, taşıma, ön işleme (kurutma, öğütme), peletleme ve depolama gibi bileşenlerden oluşur (Asif et al., 2024). Tarımsal atıkların hammadde olarak kullanılması, düşük maliyet avantajı sunsa da, hammadde kaynaklarının dağınık olması nedeniyle toplama, taşıma ve depolama maliyetleri üretim maliyetlerini artırabilir. Pelet üretiminde, bağlayıcı maliyeti, hammadde maliyeti ve işçilik maliyetleri gibi faktörler, üretim maliyetlerini önemli ölçüde etkilerken, pelet satış fiyatı ekonomik getiriyi en çok etkileyen faktördür (Asif et al., 2024).

Pazar Potansiyeli ve Fiyat Rekabetçiliği: Tarımsal peletler, özellikle endüstriyel ve konut sektörlerinde fosil yakıtlara alternatif olarak büyük bir pazar potansiyeline sahiptir. Ancak, küresel pelet pazarı genellikle odun peletleri tarafından domine edilmekte olup, tarımsal peletlerin bu pazarda yer edinebilmesi için fiyat rekabetçiliğini sağlaması gerekmektedir. Nosenzo ve Kelman, tarım kaynaklı peletlerin birçok pazarda geleneksel fosil yakıtlara karşı rekabetçi fiyatlar elde edebileceğini belirtmektedir (Nosenzo & Kelman, 2025).

Sosyo-ekonomik Faydalar: Tarımsal pelet üretimi, kırsal bölgelerde yeni istihdam fırsatları yaratma ve tarım sektörüne ek gelir sağlama potansiyeline sahiptir (Ebadian et al., 2021). Biyoenerji sektörünün gelişimi, enerji ve tarım gibi doğrudan ilgili sektörlerin yanı sıra, ulaştırma, ticaret, hizmetler ve imalat gibi dolaylı sektörlerde de istihdamı olumlu etkileyebilir (Roszkowska & Szubska-Włodarczyk, 2021, p. 76). Örneğin, bir tesisin tüm tedarik zinciri boyunca 2.477 iş yaratabileceği ve çiftçilere önemli gelir sağlayabileceği belirtilmiştir. Biyogaz teknolojisi, kırsal bölgelerde önemli sosyoekonomik etkiler göstermiş, ev ekonomilerinde yakıt maliyetlerini düşürerek tasarruf sağlamıştır.

Tedarik Zinciri Yönetimi: Tarımsal atıkların sürdürülebilir bir şekilde toplanması, depolanması ve pelet üretim tesislerine taşınması, etkin bir tedarik zinciri yönetimi gerektirir. Bu, lojistik maliyetlerini minimize etmek ve hammaddenin sürekli tedarikini sağlamak için kritik öneme sahiptir.

5.3. Sürdürülebilirlik Kriterleri ve Politika Destekleri

Tarımsal pelet yakıtlarının sürdürülebilir bir enerji çözümü olarak kabul görmesi ve yaygınlaşması, net sürdürülebilirlik kriterlerinin belirlenmesi ve destekleyici politikaların uygulanmasıyla mümkündür.

Sürdürülebilirlik Sertifikasyonları: Biyokütle yakıtlarının etik üretimi ve sürdürülebilirlik sorunlarını ele almak için sertifikasyon programları kritik rol oynamaktadır. Bu programlar, sosyal, çevresel ve kaynak verimliliği konularına dikkat ederek sürdürülebilir biyoenerji üretimine geçişi kolaylaştırmak amacıyla tasarlanmıştır. Avrupa Birliği'nde sürdürülebilir biyoenerji çözümleri, sürdürülebilirlik kriterlerine uymak zorundadır (Englund et al., 2021, p. 2).

Devlet Politikaları ve Teşvikler: Hükümet politikaları ve teşvik mekanizmaları, tarımsal pelet pazarının gelişiminde belirleyici bir role sahiptir. Biyoenerji stratejisinin önemli bir bileşeni olan politikalar, ekonomik çıkarları çevresel sürdürülebilirlikle uyumlu hale getiren bir çerçeve oluşturur (Rabbani et al., 2023, p. 698). Örneğin, Pakistan'da hükümet biyoyakıt sektörünü teşvik etmek için vergi muafiyetleri ve teşvikler getirmişken, Çin de mahsul kalıntılarına dayalı biyoenerjiyi desteklemek için önlemler almıştır. Ancak, yetersiz uzun vadeli planlama ve finansal destek gibi zorluklar da bulunmaktadır (Osman et al., 2024, p. 1141).

Döngüsel Biyoekonomi Entegrasyonu: Tarımsal atıkların biyoenerjiye dönüştürülmesi, döngüsel biyoekonominin önemli bir parçasıdır. Bu yaklaşım, atıkların azaltılması, yeniden kullanılması ve geri dönüştürülmesini vurgulayarak, tarımsal atık biyokütle yönetiminde stratejik bir rol oynar (Prado-Acebo et al., 2024). Örneğin, mantar yetiştirme atıklarının briket performansının optimize edilmesi, döngüsel ekonomi yaklaşımıyla değerlendirilmektedir. Tarımsal atıklardan elde edilen lignoselülozik biyokütle, biyoyakıtlar, biyo-kompozitler ve biyo-plastikler gibi çeşitli ürünlerin geliştirilmesi için sürdürülebilir bir kaynak sunar (Mujtaba et al., 2023).

Sosyal Kabul ve Bilinçlendirme: Yenilenebilir enerji projelerine geçiş, kamuoyunun ve etkilenen toplulukların muhalefetiyle karşılaşabilir. Bu nedenle, enerji geçiş projelerinde katılım ve eşitlik arasındaki bağlantılar hakkında incelikli bir anlayış gereklidir. Toplum katılımı ve şeffaf iletişim akışı, yerel halkın biyoenerji sistemlerine yönelik algısını olumlu yönde değiştirmede kritik öneme sahiptir. Enerji geçişinde karşılaşılan zorluklar arasında düzenleyici çerçeveler, mevcut altyapıyla entegrasyon ve kamu algıları gibi teknik olmayan faktörler de bulunmaktadır (Menghwani et al., 2022).

6. Sonuç ve Gelecek Perspektifleri

Bu derleme makalesi, tarım kaynaklı pelet yakıtlarının yaşam döngüsü değerlendirmesi ve emisyon-enerji optimizasyonu üzerine kapsamlı bir bakış sunmuştur. Analizler, tarımsal kalıntılardan elde edilen pelet yakıtlarının, fosil yakıtlara kıyasla önemli çevresel faydalar sağlama potansiyeline sahip olduğunu ve sürdürülebilir bir enerji geleceği için kritik bir rol oynayabileceğini göstermektedir (Nosenzo & Kelman, 2025, p. 1). Ancak, bu potansiyelin tam olarak gerçekleştirilmesi, hem üretim süreçlerinde hem de enerji dönüşüm sistemlerinde sürekli optimizasyon ve yenilikçi yaklaşımlar gerektirmektedir.

Yaşam Döngüsü Değerlendirmesi metodolojisi, tarım kaynaklı pelet yakıtlarının çevresel etkilerini bütünsel olarak anlamak için vazgeçilmez bir araçtır. LCA sonuçları, sera gazı emisyonlarının azaltılması başta olmak üzere, çeşitli çevresel etki kategorilerinde genellikle olumlu bir tablo çizmektedir (Sgarbossa et al., 2020). Ancak, LCA çalışmalarının kapsam, sistem sınırları ve veri kalitesindeki farklılıklar, sonuçların karşılaştırılabilirliğini

etkileyebilmekte ve bu alanda daha fazla standardizasyona ihtiyaç duyulmaktadır. Tarımsal atıkların "atık" tanımı, arazi kullanım değişiklikleri ve tahsisat yöntemleri gibi metodolojik kararlar, sonuçların yorumlanmasında kritik bir rol oynamaktadır (Pandey & Erbaugh, 2024).

Pelet üretim süreçlerinin enerji yoğunluğu ve yanma sırasında oluşan emisyonlar, bu teknolojilerin çevresel performansını belirleyen ana zorluklardır. Kurutma ve peletleme aşamalarında enerji verimliliğini artıran teknolojiler ve entegre sistemler (örneğin, atık ısı geri kazanımı, CHP uygulamaları), üretim sürecinin çevresel ayak izini önemli ölçüde azaltabilir (Bashiri et al., 2021; Ibrahim et al., 2025). Yanma sistemlerinde ise, primer ve sekonder emisyon kontrol stratejileri (yanma optimizasyonu, partikül filtreleri, NOx azaltma sistemleri), hava kalitesi üzerindeki olumsuz etkileri minimize etmek için elzemdir (He et al., 2022). Hammaddelerin karakteristik özelliklerinin (kül içeriği, alkali metal konsantrasyonu) iyi anlaşılması ve yönetilmesi, yanma verimliliğini artırmanın ve korozyon gibi operasyonel sorunları önlemenin temelini oluşturur (Nosenzo & Kelman, 2025, p. 1).

Ekonomik açıdan, tarımsal pelet yakıtlarının pazar potansiyeli yüksektir, ancak rekabetçilik fosil yakıt fiyatları, üretim maliyetleri ve hükümet politikaları tarafından şekillenmektedir. Yerel istihdam yaratma ve kırsal ekonomilere katkı sağlama potansiyeli, bu yakıtların sosyal faydalarını artırmaktadır (Ebadian et al., 2021). Sürdürülebilirlik sertifikasyonları ve destekleyici politikalar, sektörün gelişimini teşvik etmek ve tüketicinin güvenini sağlamak için hayati öneme sahiptir. Ancak, sürdürülebilirliğin sosyal boyutu henüz ekonomik ve çevresel boyutlar kadar detaylı incelenmemiştir (Svensson et al., 2024).

Gelecek Perspektifleri

Tarımsal pelet yakıtlarının geleceği, aşağıdaki alanlarda yapılacak araştırmalar ve gelişmelerle şekillenecektir:

İleri Proses Teknolojileri: Yüksek pelet kalitesi elde etmek için işleme metodolojilerinin iyileştirilmesi, özellikle geleneksel olmayan biyokütlelerden ve enerji tüketimini azaltarak fiziki pelet kalitesini optimize eden teknolojiler üzerinde daha fazla araştırma ve geliştirme gerekmektedir. Özellikle kırsal toplulukların ekonomisini desteklemek ve enerji bağımsızlığını sağlamak için katkısız ve ön işlem gerektirmeyen küçük ölçekli pelet üretiminin geliştirilmesi önemlidir. Çeşitli biyokütle kaynakları ve ortak peletleme teknolojileri ile biyokütle enerjisinin daha iyi ve daha verimli kullanılması gereklidir (Cui et al., 2021).

Döngüsel Biyoekonomi Entegrasyonu: Tarımsal atıklar, biyoyakıtlar, biyo-kompozitler ve biyo-plastikler gibi geniş bir ürün portföyü geliştirmek için lignoselülozik biyokütle kaynakları sağlamaktadır (Mujtaba et al., 2023). Tek tek proseslerin karlılığı düşük olduğundan, tüm biyokütle fraksiyonlarını sıfır atık yaklaşımıyla kullanan entegre çoklu besleme stoğu ve çoklu ürün biyolojik rafineri şemaları daha iyi bir alternatiftir. Döngüsel ekonomi, tarımsal atık biyokütle yönetiminde ve agro-endüstriyel atıkların değerli ürünlere dönüştürülmesinde anahtar bir stratejik yaklaşımdır (Đorđević et al., 2024). Bu yaklaşım, atıkların azaltılması, geri dönüşümü, geri kazanımı, yeniden kullanımı ve yenilenmesini vurgulayarak, gıda ve tarım sektöründe sürdürülebilirliği artırmayı hedeflerken, ekonomik değer temelli bir perspektifle maliyetler, faydalar ve dağıtım etkileri dengelenmelidir. Tarımsal artık atıklar, düşük maliyetle ve bol miktarda bulunabilen bir hammadde kaynağı olarak ekonomik kazanç için etkin bir şekilde değerlendirilebilir ve daha temiz yakıtlar gibi katma değerli ürünler üretilebilir (Sharma et al., 2024).

Politika ve Pazar Mekanizmalarının Geliştirilmesi: Tarımsal peletlerin tam potansiyelini ortaya çıkarmak için hedeflenmiş yatırımlar, teknolojik gelişmeler ve destekleyici politikalar gereklidir. Ürün tutarlılığını sağlamak, mevcut enerji sistemlerine entegrasyonu kolaylaştırmak

ve güvenilir tedarik zincirlerinin geliştirilmesini desteklemek için pelet üretimi ve kalite güvencesi için açık teknik standartların oluşturulması kritik öneme sahiptir. İthalatçı ülkelerin yerel biyokütle tüketim teşvikleri ve sürdürülebilirlik kriterleri, pelet ihracatını önemli ölçüde artırmaktadır. Biyoenerji projelerinin başarısı için uluslararası paydaşlar arasında işbirliği ve eşgüdüm hayati önem taşımaktadır (Svensson et al., 2024).

Teknolojik Gelişmeler: Daha iyi emisyon kontrolü için yakıt tasarımı ve soba teknolojisinde sürekli araştırma ve geliştirme önerilmektedir. Pelet sıcaklığı ve kalıp içinde kalış süresi gibi işlem parametrelerinin optimize edilmesi, fiziki pelet kalitesini iyileştirirken enerji tüketimini azaltabilir (Benders et al., 2025).

Sonuç olarak, tarım kaynaklı pelet yakıtları, yenilenebilir enerji portföyünün ayrılmaz bir parçası olarak, enerji güvenliği ve iklim değişikliğiyle mücadelede önemli katkılar sunmaktadır. Bilimsel ve mühendislik tabanlı optimizasyon yaklaşımlarının sürekli uygulanması, bu yakıtların çevresel faydalarını maksimize ederken, ekonomik uygulanabilirliğini ve toplumsal kabulünü artıracaktır. Gelecekteki araştırmalar ve politika destekleri, tarım kaynaklı pelet yakıtlarının sürdürülebilir enerji dönüşümündeki rolünü daha da pekiştirecektir.

Yapay Zekâ Katkı Beyanı

Bu çalışmanın yazım sürecinde, yalnızca dil düzenleme, yazım kuralları, açıklık ve akıcılığın artırılması gibi amaçlarla yapay zekâ temelli yazılım programlarından yararlanılmıştır.

ÖZET

Teknolojideki son gelişmeler, yumuşak robot teknolojilerinin biyomedikal alanlarda kullanımını önemli ölçüde artırmıştır. Bu sistemler esnek yapıları sayesinde canlı dokulara zarar vermeden etkileşime girebilmekte ve minimal invaziv cerrahi, ilaç taşıma ve mikro manipülatör gibi alanlarda önemli avantajlar sağlamaktadır. Manyetik alanla kontrol edilen yumuşak robotlar ise temassız ve uzaktan hassas yönlendirilebilmeleri sayesinde bu alanda öne çıkan bir çalışma konusudur. Bu çalışmada, biyomedikal uygulamalarda kullanılmak üzere manyetik alanla kontrol edilen, küçük ölçekli ve tek eklemli bir manyetik ters sarkaç mekanizmasının matematiksel modeli oluşturulmuş ve MATLAB/Simulink ortamında oransal-integral-türevsel denetleyici (proportional-integral-derivative, PID) kontrollü sayısal benzetimi gerçekleştirilmiştir. Öncelikle sistem yalnızca yerçekimi etkisi altında test edilerek mekanik modelin fiziksel doğruluğu kontrol edilmiştir. Ardından manyetik tork ve kuvvet etkileri, sönüm katsayısı, sarım sayısı ve akım gibi parametrelerin değiştirilmesiyle sistem incelenmiştir. İnceleme sonucunda, sönüm katsayısının azalmasının salınım süresini uzattığını; sarım sayısı ve akım artışının ise manyetik momenti yükselterek sistemin daha hızlı ve kararlı tepki verdiğini göstermiştir. Ardından sistemin kararlılığını incelemek için PID kontrol sistemine referans değer girilmiş ve sarkacın referans değerine yakınsadığı gözlemlenmiştir. Elde edilen sonuçlar, hem mekanik hem de elektromanyetik modelin doğru şekilde tanımlandığını ve sistemin istenilen dinamik özellikleri yansıttığını ortaya koymuştur. Geliştirilen bu model, gelecekte manyetik manipülatör sistemlerinin gelişmiş kontrol algoritmaları ve konum takip yöntemleriyle birleştirilerek biyomedikal alanda kullanılabilecek yüksek hassasiyetli, uzaktan kontrollü robotik sistemlerin geliştirilmesine temel oluşturmaktadır.

Anahtar Kelimeler: Sarkaç, Manyetik Sarkaç, PID Kontrol, Yumuşak Robot, Mikro Robot

COMPUTER-AIDED SIMULATION OF A SMALL-SCALE, SINGLE-JOINT MAGNETIC INVERTED PENDULUM MECHANISM

ABSTRACT

Recent technological advancements have significantly expanded the utilization of soft robotic technologies in biomedical applications. Due to flexible structures, soft robotic systems can interact with living tissues without causing damage and provide major advantages in minimally invasive surgery, targeted drug delivery, and micro-manipulation. Magnetically actuated soft robots have gained prominence in this field because of their ability to be remotely and precisely controlled without physical contact. The present study developed a mathematical model of a small-scale, single-joint magnetic inverted pendulum mechanism actuated by a magnetic field and performed a proportional–integral–derivative (PID) controlled numerical simulation in the MATLAB/Simulink environment for potential biomedical applications. The system was initially examined under gravitational effects only to validate the physical accuracy of the mechanical model. Subsequently, variations in magnetic torque and force, damping coefficient, number of coil windings, and electric current were analyzed to evaluate system performance. Simulation results indicated that a lower damping coefficient extended oscillation duration, whereas higher number of coil windings and current increased the magnetic moment, yielding faster and more stable responses. The findings confirmed that both the mechanical and electromagnetic models were accurately defined and successfully represented the intended dynamic behavior. The developed model establishes a foundation for future studies combining advanced control algorithms and position-tracking methods to design high-precision, remotely controlled magnetic manipulator systems for biomedical applications.

Keywords: Pendulum, Magnetic Pendulum, PID Control, Soft Robot, Micro Robot

1. GİRİŞ

Teknolojik gelişmeler, insan hayatını kolaylaştırmak ve yaşam kalitesini arttırmak için birçok alanda yeni çözümler oluşturmuştur. Bu amaçla geliştirilen robotik sistemler, otomotiv, beyaz eşya, savunma sanayi gibi endüstriyel sanayiden günlük yaşama kadar pek çok farklı alanda kullanılmaya başlanmıştır (Singh ve Banga, 2022; Urrea ve Kern, 2025; Palčič ve Prester, 2024). Son yıllarda biyomedikal alanındaki gelişmelerle birlikte, geleneksel robotların tıp ve cerrahi uygulamalarında kullanımı artmıştır. Bu robotlar, hassas cerrahi işlemler, rehabilitasyon cihazları ve minimal invaziv girişimler gibi alanlarda büyük avantajlar sağlasa da sert malzemelerden üretilmiş olmaları nedeniyle canlı dokularla etkileşimde yetersiz kalmaktadır. Canlı vücudu içerisinde hareket edebilecek, dokuya zarar vermeyecek ve uyum sağlayabilecek esnek sistemlere olan ihtiyaç araştırmacıları yeni robotik çözümler geliştirmeye yönlendirmiştir. Bu bağlamda, yumuşak (soft) robotlar ön plana çıkmıştır (Chatterjee ve diğerleri, 2024; Chaparro-Cárdenas ve diğerleri, 2018; Kim ve diğerleri, 2018; Minig ve diğerleri, 2017).

Yumuşak robotlar, biyolojik sistemlerden ilham alınarak geliştirilmiş esnek ve uyumlu malzemelerden üretilen robotik sistemlerdir. Kullanılan malzemelerin elastisite modülü 10^4 ile 10^9 Pa arasında olup, bu değerler biyolojik malzemelerin mekanik özelliklerine yakındır (Kim ve Zhao, 2022). Araştırmacılar tarafından en çok kullanılan tanım Cianchetti ve ekibi tarafından 2015 yılında şu şekilde verilmiştir: Çevreyle aktif olarak etkileşime girebilen ve doğal veya yapısal uyuma bağlı olarak büyük deformasyonlara uğrayabilen yumuşak robotlar-cihazlardır (Cianchetti ve diğerleri, 2015).

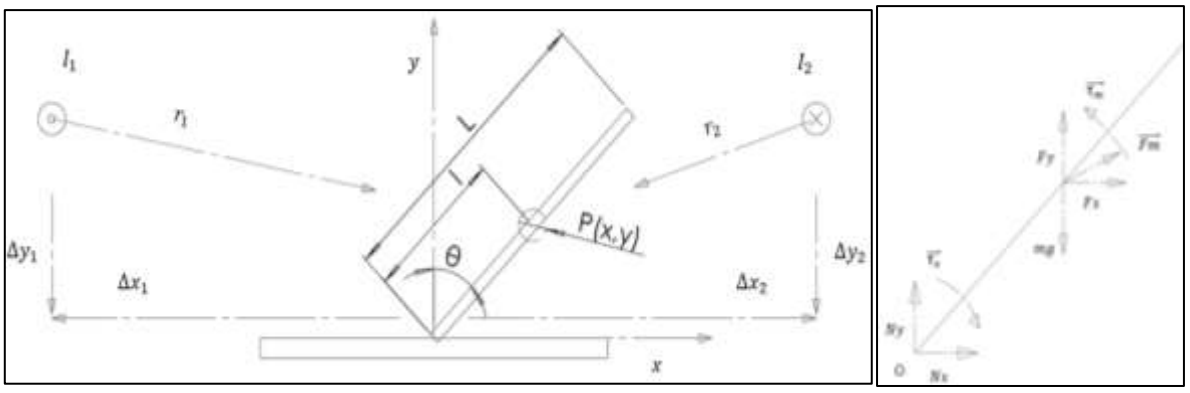
Yumuşak robotların kontrol yöntemi kullanım alanı ve ihtiyaca göre değişiklik göstermektedir. Güç ihtiyacının yüksek olduğu uygulamalarda pnömatik (Decroly ve diğerleri, 2021) ve hidrolik (Tilvawala ve diğerleri, 2021) kontrol yöntemleri kullanılırken, hassas ve küçük boyutlu sistemlerde manyetik alan (Yang ve diğerleri, 2024), elektrik alan (Guo ve diğerleri, 2021; Duduta ve diğerleri, 2017) ve ışık (Cunha ve diğerleri, 2020) ile kontrol edilirler.

Yumuşak robotlar geleneksel robotlara göre birçok avantaj sağlar. Özellikle biyomedikal uygulamalarda yumuşak robotların çevre ile etkileşime girebilmesi, kuvvetleri geniş alanlarda eşit dağıtarak doku hasarını minimize etmesi minimal invaziv gibi operasyonlarda insan dokusuna zarar vermeden güvenli bir şekilde çalışmayı sağlar. Esnek ve karmaşık yapısı ile düzensiz yüzeylere uyum sağlar, çok yönlü kullanıma açıktır. Bir diğer önemli avantajı ise biyouyumlu malzemelerden üretilir olmasıdır. Hidrojel, elastomer gibi esnek ve vücut dostu malzemeler bu robotların temel malzemeleridir.

Öte yandan, yumuşak robotlar yük kapasiteleri sınırlı olmasına karşın, canlı dokulara temasta avantaj oluşturan hassas hareket kabiliyeti sunarlar, güç yüklemezler. Sonsuz serbestlik derecesine sahip olmaları nedeniyle yumuşak robotların tasarımında matematiksel ve sayısal modelleme yapılır. Böylelikle hassas ve daha fazla kontrol edilebilir hale gelirler (Ashuri ve diğerleri, 2020). Ayrıca yapay zeka tabanlı kontrol stratejileri, robotların davranışlarını tahmin etme ve çevresel koşullara dinamik olarak uyum sağlama yeteneklerini geliştirerek, yumuşak robotların etkileşim kabiliyetini ve hareket hassasiyetini önemli ölçüde arttırır (Cao ve diğerleri, 2024).

Manyetik yumuşak robotlar, manyetik alanlar altında şekil değiştirebilme yeteneğine sahip esnek, yumuşak robotlardır. Kompozit bir malzeme yapısına sahiptirler. Manyetik katkıların yumuşak polimerik matrislere gömülmesiyle oluşturulurlar. Manyetik alan uygulandığında uzaktan kontrol edilerek hızlı ve kontrollü bir şekilde şekil değiştirir ve çevresiyle etkileşime girerler. Bu özellik onları biyomedikal uygulamalarda son derece önemli kılar (Mao ve

diğerleri, 2022; Wang ve diğerleri, 2020; Ke ve diğerleri, 2024). Minimal invaziv cerrahi müdahaleler (Jin ve diğerleri, 2023; Chautems ve diğerleri, 2019), ilaç taşıma sistemleri (Zheng ve diğerleri, 2023) ve hassas tıbbi uygulamalar (Ye ve diğerleri, 2022; Kim ve diğerleri, 2022) gibi alanlarda kullanılabilecek farklı görevler için büyük potansiyele sahiptirler.



Manyetik yumuşak robotların avantajları arasında temassız uzaktan kontrol edilebilme, çok yönlülük, düşük güç tüketimi, hafiflik hatta ısı üretimine varan özellikleri bulunmaktadır. Ayrıca yuvarlanma, emekleme (Hu ve diğerleri, 2018) ve yüzme (Huang ve diğerleri, 2019) gibi farklı hareket modları gerçekleştirerek çevresel koşulları aşabilme yeteneğine sahiptirler. Ancak manyetik alanla istenilen şekilde hareket edebilmesi için, robotların malzeme yapısındaki manyetik partiküllerin dağılımı, yönlendirilmesi ve hareket kontrolü gibi faktörlerin optimize edilmesi gerekmektedir. Bu noktada, matematiksel modelleme ve yapay zeka tabanlı stratejiler, robotların etkinliğini ve hassasiyetini artırmak için kritik rol oynamaktadır. Ayrıca çevresel faktörler, manyetik alanın etkisini sınırlar ve robotun beklenen performansını etkiler (Wu ve diğerleri, 2020).

Bu çalışmada yumuşak robotlarda kullanılmak üzere manyetik alanla çalışan tek eksenli bir robot parmak mekanizmasının (sarkaç) kavramsal tasarımı, matematiksel modeli ve bilgisayar destekli benzetimi yapılmıştır. İlk bölümde literatür taraması ve manyetik yumuşak robotlar hakkında genel bilgiler verilmiştir. İkinci bölümde sarkaç model için mekanik ve manyetik alan denklemleri paylaşılmıştır. Üçüncü bölümde Matlab/Simulink ile benzetim çalışmaları yapılıp yorumlanmıştır. Dördüncü bölümde sonuçlar paylaşılıp gelecekte yapılabilecek çalışmalar için tavsiyeler verilmiştir.

2. MATERYAL VE YÖNTEM

Şekil 2.1. a) manyetik sarkaç modelinin kesit görünüşünü vermektedir. Uzunluğu 2L olan sarkaç, x-y düzleminde dönme hareketi yapabilmektedir ve bu düzlemde y ekseniyle θ açısı oluşturmaktadır. Sarkaç manyetik özelliklere sahip olup, bu özelliklerin tümünün sarkacın kütle merkezinde toplandığı varsayılmaktadır. Manyetik özellik, m ile gösterilen bir manyetik dipol momenti ile tanımlanır.

Sistemin kontrolü, koordinat düzleminde yer alan $x_1y_1z_1$ ve $x_2y_2z_2$ noktalarına yerleştirilmiş sonsuz uzunlukta çizgisel bobinler aracılığıyla sağlanmaktadır. Bu bobinlerden sırasıyla I_1 ve I_2 akımları geçirilmektedir. Kütlesi M olan çubuk, koordinat başlangıç noktası olan (0,0) konumundan sonra dönme serbestliğine sahiptir. Çubuğun, y ekseniyle yaptığı açı θ ile tanımlanır ve bu çubuğun orijine göre atalet momenti J olarak alınmaktadır.

a) b)

Şekil 2.1. a) problemin tanımı, b) serbest cisim diyagramı

Tablo 2.1. Problemin tanımı

Parametre	Değer	Açıklama
L (m)	0.02	Sarkaç uzunluğu
l (m)	0.01	Kütle merkezi uzunluğu
M (kg)	0.005	Sarkaç kütlesi
θ (Derece)	10°	Sarkaç açısı (sarkaç ve Y ekseni arasındaki açı)
I (A)	2	Kontrol akımı
N	200	Bobin sarım sayısı
m ($A.m^2$)		Mıknatıs manyetik dipol momenti
$\Delta x, \Delta y$		Bobin sargısının bulunduğu yarıçap
J (kg.m^2)		Sarkaç uç noktasına göre atalet momenti
x, y		Sarkacın ağırlık merkezinin koordinatları
F (N)		Manyetik kuvvetler
T (N.m)		Tork

Kabuller:

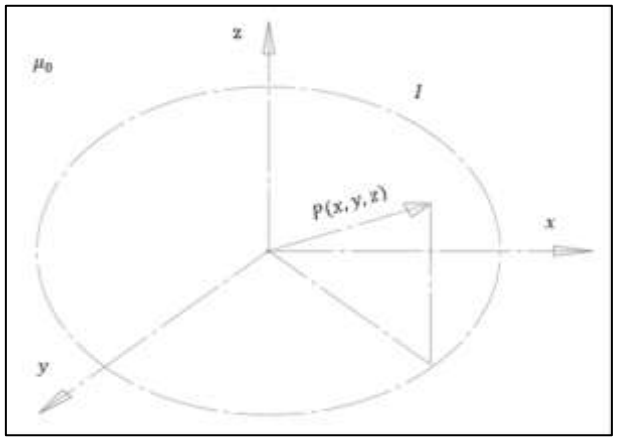
1. Çubuk homojen ve $\vec{m}$ manyetik dipol momentine sahiptir.
2. Bobini N sarım sayısına sahip olupi koorinat merkezinden Δ_x, Δ_y mesafelerinde konumlandırılmıştır.

2.1. Mekanik Etkilerin Hesabı

Cisme etki eden mekanik etkilerin hesabı için Newton denklemleri yazılır. O noktasına göre moment alınır.

$$\sum M_o = J.\ddot{\theta} \quad (1)$$

$$T_m - T_s - mglcos\theta - {F_x}^m lsin\theta + {F_y}^m lcos\theta = J.\ddot{\theta} \quad (2)$$



Burada dikkat edilir ise $T_m, {F_x}^m$ ve ${F_y}^m$ manyetik alana bağlı büyüklüklerdir. Bu nedenle manyetik alanı biliyorsak bu denklem sarkaç hareketini modellemeye yetecektir.

Eşitlik 2 düzenlenir ise manyetik sarkacın hareketini yöneten kısmi diferansiyel denklem elde edilir (Eşitlik 3). Eşitlik 3 ve Eşitlik 4 denklemlerinin birlikte çözümü sarkacın zamana bağlı davranışını vermektedir.

$$\ddot{\theta} = \frac{1}{J}\left[T_m - b.\dot{\theta} + mglsin\theta - {F_x}^m lsin\theta + {F_y}^m lcos\theta\right] \quad (3)$$

$$\dot{\theta} = \frac{d\theta}{dt} \quad (4)$$

2.2. Silindirik Koordinatlarda Boşluktaki Bobin İçin Manyetik Alan Hesabı

Şekil 2.2.1. silindirik koordinat sistemi

Sistemin ana davranışı Maxwell denklemleri ile hesaplanır.

$\nabla . \vec{E} = \frac{\rho}{E_0}$ (Gauss yasası) (5)

$\nabla x \vec{E} = -\frac{\partial B}{\partial t}$ (Faraday yasası) (6)

$\nabla x \left(\frac{1}{\mu} B\right) = \vec{J} + \varepsilon \frac{\partial \vec{E}}{\partial t}$ (Maxwell – Ampere yasası) (7)

Yukarıdaki Maxwell denklemleri vektörel formda verilmiştir. Burada;

∇: Nabla operatörü,

ρ: Yük yoğunluğu,

ε: Dielektrik permabiliti,

μ: Manyetik permabiliti,

$\vec{E}$: Elektrik alan vektörü,

$\overrightarrow{B}$: Manyetik alan vektörü,

$\vec{J}$: Elektrik akım yoğunluğunu ifade etmektedir.

Vektörel formda bulunan denklemler istenilen koordinat ekseninde yazılarak çözüm aranır.

Kartezyen koordinatlarda r_0 yarıçapına sahip içinden I akımı geçen bir bobinin manyetik alan bileşenleri, bobin merkezine göre;

$B_x = \frac{C\ x\ z}{2\ \alpha^2 B \rho^2}[(r_0{}^2 + r^2)E(k^2) - \alpha^2 K(k^2)]$
(8)

$B_y = \frac{y}{x} B_x = \frac{C\ y\ z}{2\ \alpha^2 B \rho^2}[(r_0{}^2 + r^2)E(k^2) - \alpha^2 K(k^2)]$ (9)

$B_z = \frac{C}{2\ \alpha^2 B}[(\alpha^2 - r^2)E(k^2) + \alpha^2 K(k^2)]$
(10)

Burada;

x,y,z: Kartezyen koordinatlarda hesaplanacak nokta (bobin merkezine göre), r_0: Bobin sarım yarıçapı, I: akım, μ_0: Boşluğun manyetik permabilitisi ($4\pi 10^{-7}$),N: Sargı sayısını göstermektedir.

Bu formüller, NASA tarafından yayımlanan "Simple Analytic Expressions for the Magnetic Field of a Circular Current Loop" başlıklı çalışmadan alınmıştır. Formüller, sabit akım durumunda geçerlidir. Manyetik alan $\vec{B}$ vektörü bilindiğine göre (Denklem 9) uzayda bulunan bir manyetik dipol $\vec{m}$ 'ye uyguladığı döndürme momenti (T/tork) ve kuvvet hesaplanır.

$$T = \vec{m}x\vec{B} \tag{11}$$

$$F = \vec{m}.\nabla\vec{B} \tag{12}$$

Sarkacın dönme serbestliği z ekseni etrafında olup, xyz eksenlerinde doğrusal hareketi sınırlandırılmıştır.

$$\vec{B}(x,z) = B_x\vec{\imath} + B_z\vec{k} \tag{13}$$

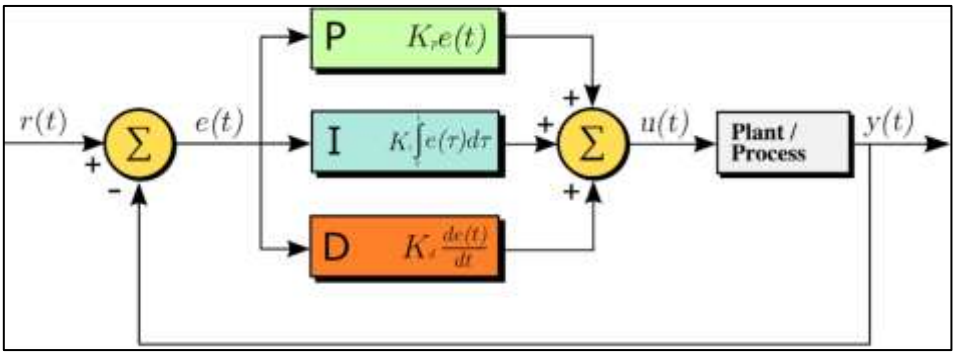
$$\vec{m} = m_x\vec{\imath} + m_z mz\vec{k} \tag{14}$$

$$T = [m_z B_x - m_x B_z]\vec{\jmath} \tag{15}$$

Yukarıdaki denklemde sadece y ekseninde döndürme momenti uygulandığı anlaşılmaktadır.

$$F = \left(mx\frac{\partial Bx}{\partial x} + mz\frac{\partial Bx}{\partial z}\right)\vec{\imath} + \left(mx\frac{\partial Bz}{\partial x} + mz\frac{\partial Bz}{\partial z}\right)\vec{k} \tag{16}$$

$$\vec{F} = F_x\vec{\imath} + F_z\vec{k} \tag{17}$$



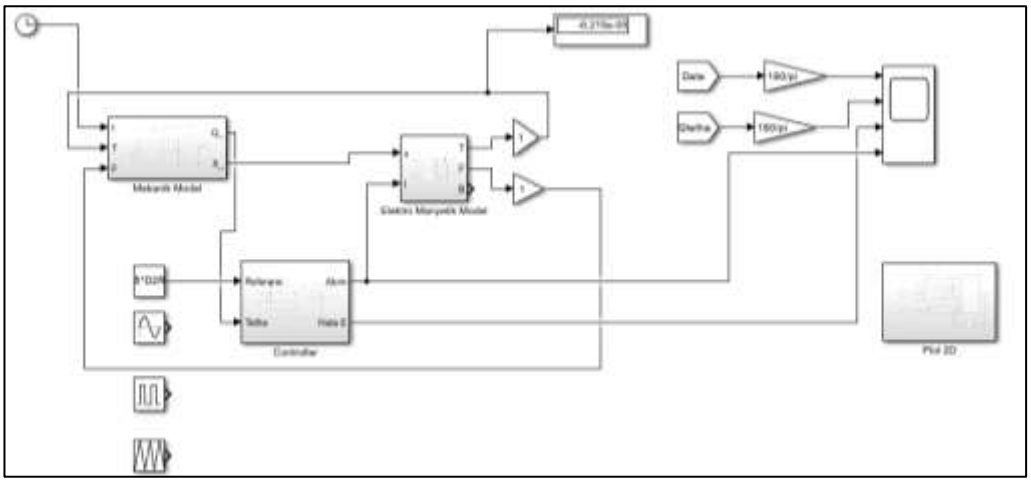
Böylelikle $\vec{T}$ ve $\vec{F}$ vektörleri hesaplanır. I akımı kontrol edilerek sarkacın konumu kontrol edilir.

2.3. Kontrolcü Tasarımı

Mekanik sistemler için birçok kontrolör mevcuttur. En yaygın olarak PID (oransal-integral-türevsel) kontrolör kullanılmaktadır. Kontrol yapısında hata sinyali e, referans açı θ_r ile mevcut açı θ arasındaki fark olarak tanımlanır. Kontrolcüden çıkan akım I_c hata sinyalinin değeri ile hatanın türevi ve integrali dikkate alınarak hesaplanır. Denklem 18 ve 19 bu kısmı ifade etmektedir. PID kontrol sistemlerinde kontrol karakteristiğini belirleyen K_p oransal, K_i integral ve K_d türevsel katsayılar bulunur. Bu katsayıların başlangıç değerinin bulunmasında Ziegler-Nichols yöntemi sıklıkla kullanılır (Yıldız ve diğerleri,2025).

$$e = \theta_r - \theta \tag{18}$$

$$I_c = K_p e + \frac{de}{dt}K_d + K_i \int e.dt \tag{19}$$

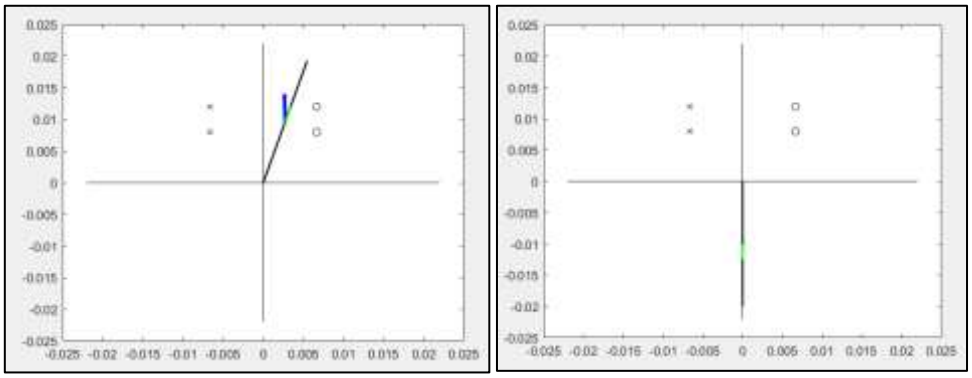


Şekil 2.3.1. PID kontrol algoritması

Kontrolcü tasarımı ile sarkacın istenilen konuma yakınsaması mümkün hale gelmiştir.

3. BULGULAR VE TARTIŞMA

Şekil 3'te benzetim programının Matlab/Simulink ara yüzü görünümü verilmiştir. Program 3 ana bileşenden oluşan bir yapıdadır. Elektro manyetik model bölümünde manyetik kuvvetlerin hesabı ile manyetik tork değerini hesaplamaktadır. Mekanik model ise zamana ve oluşan manyetik torka bağlı olarak sarkacın konumunu ve açısını hesaplamaktadır. Kontrolcü kısmı ise PID kontrolü gerçekleştirip sarkacın istenilen referans değerine ulaştırmaktadır.

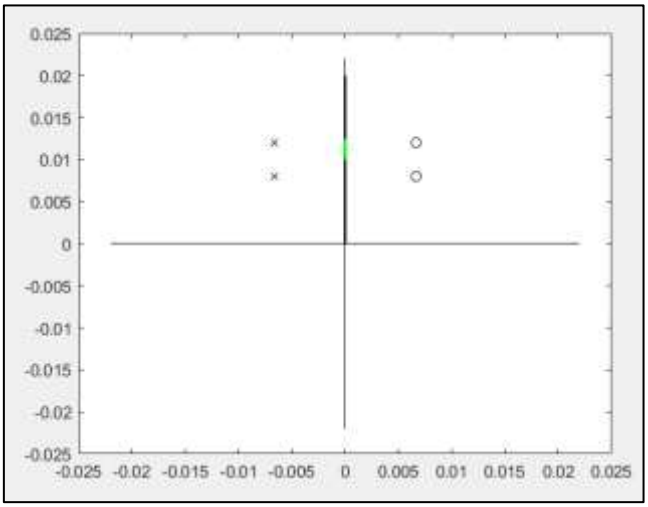


Şekil 3.1. Matlab/Simulink blok gösterimi

Benzetim çalışmalarında kullanılan fiziksel büyüklükler ve değerleri Tablo 2 ile verilmiştir. Benzetimler 3s boyunca 0.001s sabit adımla gerçekleştirilmiş olup, integrasyon işlemleri için matlab kütüphanelerinde yer alan 4. derece Runge-Kutta metodu kullanılmıştır.

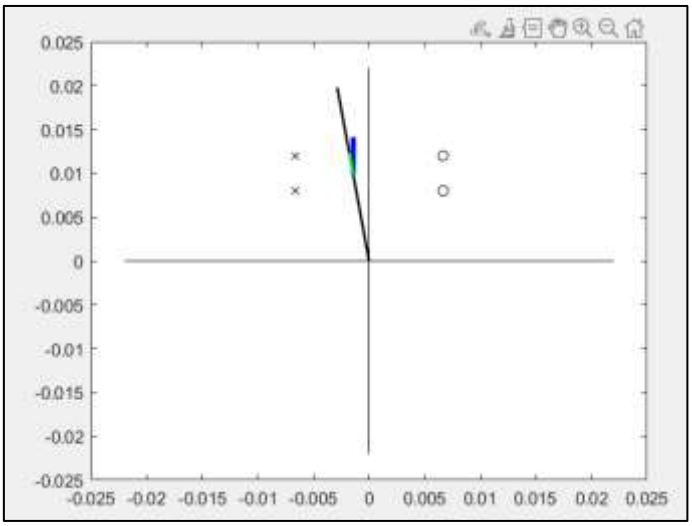
Tablo 3.1. Fiziksel büyüklükler

Sembol	Değer	Birim	Açıklama
D_{X1}	0.006	m	1. bobinin x koordinatı
D_{X2}	0.006	m	2. bobinin x koordinatı
D_{y1}	0.008	m	1. bobinin y koordinatı
D_{y2}	0.012	m	2. bobinin y koordinatı
b	1e-5	N.m.s/rad	Sürtünme kuvveti
μ_0	4π e-07	H/m	Boşluğun manyetik geçirgenliği



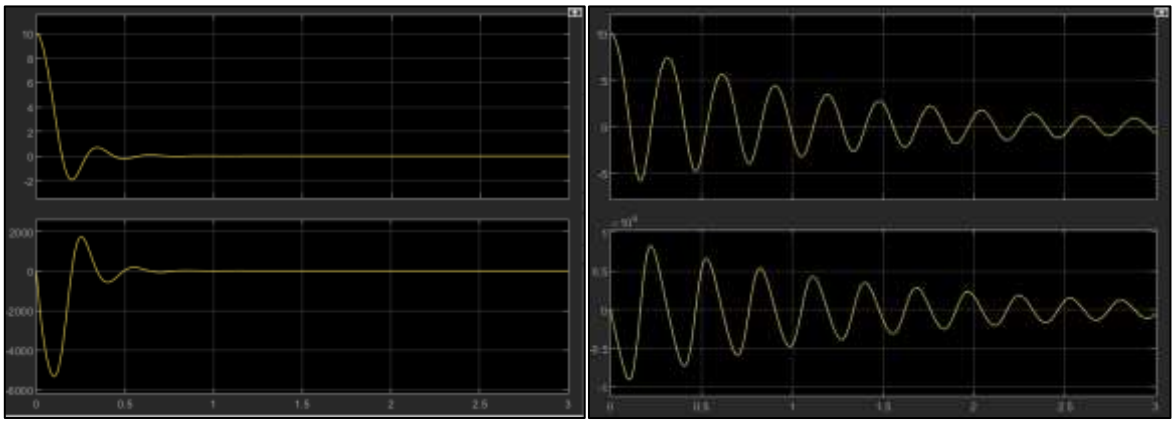
3.1. Sarkaç Sonuçları

a) b)



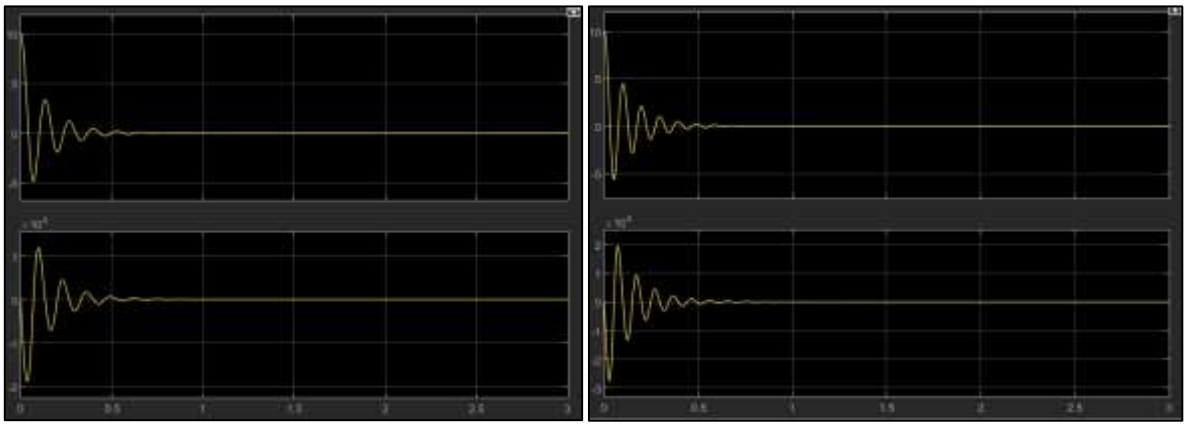
Şekil 3.1.1. a) sarkaç başlangıç durumu, b) sarkacın son durumu

Şekil 3.1.1.a)'da sarkaç sistemi başlangıçta +y ekseniyle 10° açı yapacak şekilde konumlandırılmış ve manyetik tork ile manyetik kuvvet sıfır kabul edilmiştir. Bu durumda yalnızca yerçekimi kuvveti etkili olmaktadır. Simülasyon sonucunda 3.1.1. b) sarkaç, yerçekimi momenti etkisiyle denge konumundan saparak -y eksenine doğru devrilmiştir. Bu davranış, sistemin fiziksel gerçeklikle uyumlu olduğunu ve mekanik modelin doğru şekilde çalıştığını göstermektedir.



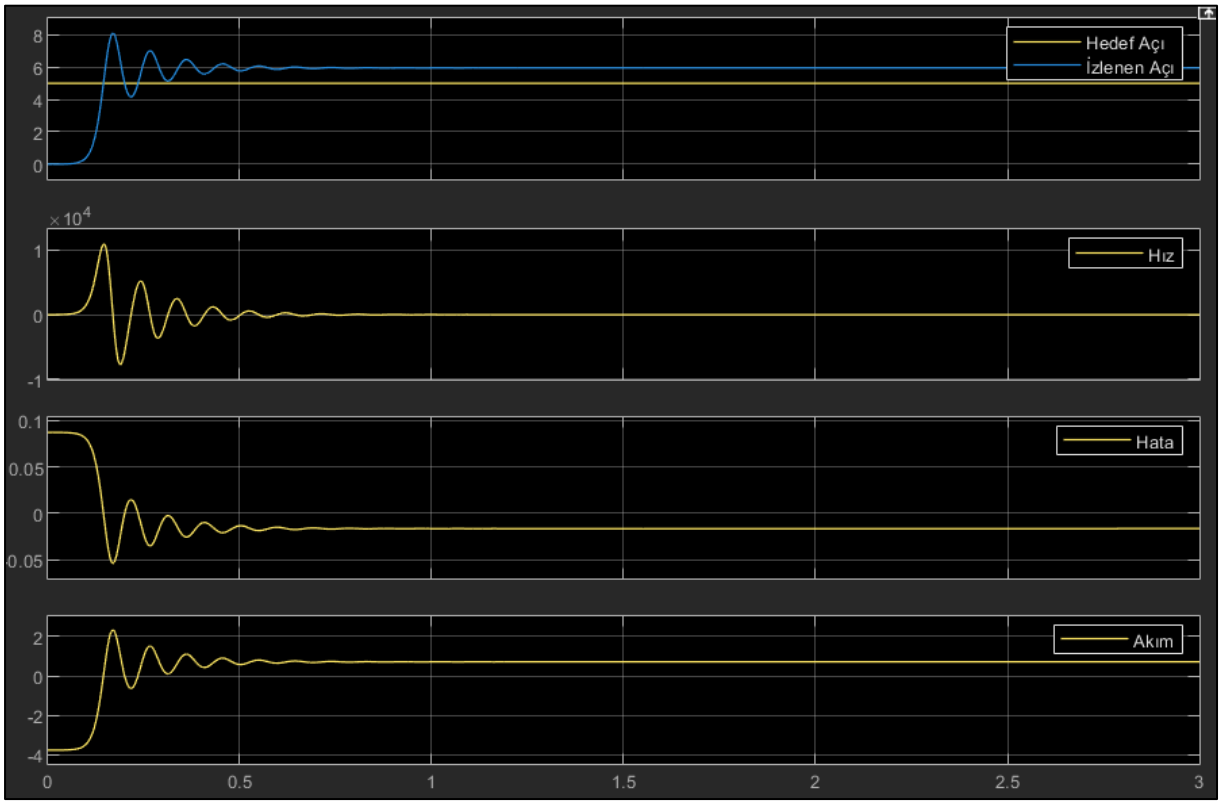
Şekil 3.1.2. açı 0° değerindeyken sarkaç modeli

Başka bir durumda ise sarkaç başlangıç açısı 0° olarak denenmiştir, +y ekseni doğrultusunda dik konumda başlatılmıştır. Sistemde manyetik tork ve manyetik kuvvet sıfır alınmış; yalnızca yerçekimi etkisi altındadır. Bu durumda sarkaç, yerçekimi kuvveti doğrultusuyla aynı eksende bulunduğundan herhangi bir net moment oluşmamış ve sistem, başlangıç durumunu koruyarak hareketsiz kalmıştır.



Şekil 3.1.3. açı -10° değerindeyken sarkaç modeli

Başlangıç açısı -10° olarak verildiğinde, sarkacın simülasyona y ekseninin sol tarafından başladığı gözlemlenmiştir. Bu durum, açının yönünün fiziksel modelde doğru tanımlandığını göstermektedir.



a) **b)**

c) **d)**

Şekil 3.1.4. a) sönüm katsayısı b=1e-5, sarım sayısı N:200, durağan sistem akımı I:1, b) sönüm katsayısı b=1e-6, c) sarım sayısı N:500, d) durağan sistem akımı I:4

Şekil 3.1.4.'de, ters sarkaç sisteminin farklı manyetik ve mekanik parametreler altındaki dinamik davranışı incelenmiştir. Her bir şekilde ilk grafik açıyı, ikinci grafik ise açısal hızı göstermektedir. Şekil 3.1.4. a), referans durum olarak belirlenmiş olup, sönüm katsayısı b=1e-5, sarım sayısı N=200 ve durağan sistem akımı I=1 A olarak alınmıştır. Şekil 3.1.4. b)'de yalnızca sönüm katsayısı b=1e-6 olarak azaltılmış ve sistemin daha az dirençle daha uzun süre salınım yaptığı gözlemlenmiştir. Bu durum, sönümleme katsayısının sistemin kararlılığı ve enerji kaybı üzerindeki etkisini açıkça göstermektedir. Şekil 3.1.4. c)'de ise yalnızca sarım sayısı artırılarak N=500 yapılmış ve manyetik torkun büyüklüğündeki artışla birlikte sistemin daha hızlı ivmelendiği görülmüştür. Sarım sayısındaki bu artış, oluşturulan manyetik momenti doğrudan etkilemiştir. Şekil 3.1.4. d)'de ise sadece akım değeri I=4 A seviyesine çıkarılmıştır. Bu durumda, sabit sarım sayısına rağmen manyetik kuvvetin ve torkun büyümesi nedeniyle sarkaç sisteminin çok daha güçlü bir tepki verdiği tespit edilmiştir.

Şekil 3.1.5. sarkaç modelini sabit 5° açı değerinde kontrolcü çalışması

Son olarak ters sarkaç sisteminin sabit **5°** açıda dengede kalması hedeflenmiştir. PID katsayılarının belirlenmesi için Ziegler-Nichols ikinci yöntemi uygulanmıştır. Yapılan analizler sonucunda kritik kazanç K_c= 72 ve salınım periyodu T_c= 0.05 olarak elde edilmiştir. Ziegler-Nichols yöntemine göre kontrol katsayıları şu şekilde hesaplanmıştır:

$K_p = 0.6xK_c$

$K_d = 0.12xT_c$

$K_i = 0.5xT_c$

Elde edilen bu katsayılar MATLAB/Simulink ortamında uygulanmış ve sistemin referans açı olan **5°** civarında kararlı hale gelmesi sağlanmıştır. PID kontrolör, sarkaç hareketinin referans nokta etrafında salınımını azaltmış ve kısa sürede kararlı konuma yakınsama sağlamıştır.

4. SONUÇ

- Bu çalışmada, biyomedikal uygulamalarda kullanılmak üzere küçük ölçekli, tek eklemli manyetik ters tek sarkaç mekanizmasının tasarımı, matematiksel modellenmesi ve PID kontrollü sayısal benzetimi gerçekleştirilmiştir. Geliştirilen modelin hem mekanik hem de elektromanyetik bileşenleri ayrı ayrı analiz edilerek sistemin fiziksel gerçekliğe uygunluğu doğrulanmıştır.

- Parametrik incelemeler sonucunda, sönüm katsayısı, sarım sayısı ve akım gibi değişkenlerin sistem üzerindeki etkileri değerlendirilmiştir. Sönümün azalmasıyla salınım süresinin uzadığı, sarım sayısı ve akımın artmasıyla sistemin tepki hızının yükseldiği gözlemlenmiştir. MATLAB/Simulink tabanlı model, farklı çalışma koşullarında kararlı ve beklenen tepkileri sergilemiştir. PID kontrol uygulamasıyla sistemin belirlenen referans açı etrafında dengeye yakınsaması sağlanmıştır.

- Bu model, daha ileri kontrol algoritmaları ve görev bazlı uygulamalar için güçlü bir temel oluşturmaktadır. Tüm bu çalışmalar, gelecekte biyomedikal uygulamalarda kullanılabilecek yüksek hassasiyetli ve uzaktan kontrollü manyetik manipülatör sistemlerinin geliştirilmesine katkı sağlayacaktır.

5. TEŞEKKÜR

Bu çalışmanın gerçekleştirilmesinde sundukları bilgi, teknik destek ve rehberlik imkanları için DOMEKS Makine A.Ş. Tasarım Merkezi'ne teşekkür ederiz.

ABSTRACT

One of the mosit important difficulties in the logistics sector is “verifying delivery processes manually”. Addition to this, document management is also another problem. Because of these problems, in this sector, digital and automatic processes are less than desired. This paper investigates one point of this situation. For this reason, first of all a tracking system is investigated. Tracking systems are important components of logistic sector. The system analyzed in this paper handles the processes in a real time concept. The system obtains some data that can be visual data (pictures and so on). This system has a special name as Proof of Delivery and an abbrevation as POD and the system was constituted in TLS Logistics Inc. TLS Logistics Inc. is a large-scale and leader logistic company in Turkey which is located in Tuzla, Istanbul. The POD system used and tested the companies’ real data so the processes of the system tracked a real process. The company currenty used another system whose name is Transportation Management System and abbrevation is TMS. POD system also developed to integrate this existing system, so by combining the powers of the two systems, it is planned to increase the company's performance and increase efficiency.

Keywords: Logistic, Proof of Delivery, Transportation Management System

1. Introduction

This section explains the need for such a study and provides a general explanation of the study's purpose to address these needs. Published studies in the literature that provide support for the study are cited to demonstrate its potential to achieve this goal. A review of the studies in the literature reveals many similarities to the present study.

As in many other sectors, ensuring smooth delivery processes in the logistics and supply chain sector is crucial. Accurate data acquisition is crucial in this process. Data can be received from many different sources, in different formats, and in different formats; the structures of the documents containing the data may not be compatible with the structures used by logistics companies. In such cases, undesirable outcomes can include complete data or document loss, corruption, processing of incorrect data, incorrect calculations in payment transactions, and errors and omissions in filing. All of these can lead to delays in the process and the supply chain. In such cases, it is necessary to first conduct data acquisition studies, then to examine system compatibility. Unfortunately, even more concerning is the fact that these processes are still largely carried out in a traditional manner in these sectors, and the rate of digitalization and automation remains very limited. In the literature, the problems that arise due to the abundance of manual processes and the scarcity of digital/automatic processes have found their place in many articles.The articles are summarized in Table 1.

As studies in the literature demonstrate, companies in the logistics sector are undertaking digital transformations to solve many problems. These problems include meeting customer expectations and all issues related to deliveries. Furthermore, because the logistics sector is a global sector, serving all sectors, it is observed that there is global competition among companies, pushing companies to be pioneers in digital transformation. According to the Digital Supply Chain Survey conducted by PwC, all digital transformation structures in the sector provide advantages across many different criteria in logistics and supply chain processes. These advantages include speed, transparency, and efficiency (Geissbauer et al., 2018). The importance of real-time data flow in the logistics sector within the framework of Industry 4.0 is well known. This is clearly evident when considering the instantaneous changes in data in the logistics sector. Zhang's (2017) study also emphasizes this point.

Table1: Literature Review

Ref	Year	Explanation
Dölek	2015	Examines the role of information technologies in logistics operations and their contribution to efficiency.
Ramos et al.	2020	Highlights general issues between the fields of logistics and supply chain management.
Freichel et al.	2020	Analyzes the challenges of supply chain visibility in logistics.
Ekanayake et al.	2024	Investigates how documentation errors in the supply chain lead to process delays.
MechSoft	2024	Addresses general information, emphasizes that digital transformation eliminates the inefficiencies of traditional processes in the logistics sector, increasing both data accuracy and process visibility.
Okumuş et al.	2024	Examines the challenges of logistics and supply chain processes.
The Select Optimus	2024	Addresses the importance of digitalization in logistics.
Aktepe	2025	Demonstrates the advantages of TMS software during digital transformation in the logistics sector.
Evren Bilgisayar	2025	States that traditional logistics methods require digital transformation and the replacement of manual systems with digital and automated processes.

This study introduces the POD Tracking System, developed by TLS Logistics to address operational challenges by digitizing document management through the collection of photo and signature data at the time of delivery. The primary goal of the study is to prevent document loss by uploading scanned delivery documents to the system, thus addressing one of the persistent problem areas in logistics. By establishing a digital bridge between drivers, operations specialists, and archiving units, the system transforms the delivery verification process into a fully traceable and auditable workflow.

2. Materials and Methods

This section describes the materials and methods used in the study. This section consists of several separate sections. The first section describes the materials used in the study. This material includes numerous elements, including the data format used, the programming language and environment used, control mechanisms, testing options, and procedures

implemented for user-friendly use. The second section of this section is entirely devoted to the methodology, focusing specifically on the modules within the system architecture that could be the output of the study. The system was designed in a modular structure, and the integration of the modules within the system was subsequently implemented.

2.1. Methodology and Technology

This part explains the materials of the study. This material includes numerous elements, including the data format used, the programming language and environment used, control mechanisms, testing options, and procedures implemented for user-friendly use.

This study was designed based on the principles of Business Process Management (BPM) methodology and structured upon a multi-tier software architecture. BPM, as defined by Gartner, employs methods to discover, model, analyze, measure, improve and optimize business strategy and processes. While it is sometimes confused with task and project management, the business process management scope is broader than these adjacent topics. Task management focuses on individual tasks whereas BPM observes the whole end-to-end process. Project management refers to a one-time scope of work while BPM focuses specifically on processes that are repeatable. Through continuous process reengineering, organizations can streamline their overall workflows, leading to increased efficiencies and cost-savings. This concept isn't new; six sigma and lean principles are examples of BPM methodologies. By incorporating advanced analytics, activity monitoring, and decision management capabilities, business process management suites are able to coordinate people, systems, and information and material to achieve business outcomes. As a result, they have been particularly helpful in accelerating digital transformation strategies.

Koç and Akın (2025) particularly conceptualized this framework within the context of digital archiving and data integrity in delivery verification processes. The BPM approach aims to model, analyze, monitor, and continuously improve organizational processes in a systematic manner, thereby enhancing operational efficiency.

The system architecture developed for this study consists of three main components: a presentation layer, a business logic layer, and a data access layer. This layered structure improves the system's maintainability, modularity, and reusability, providing a sustainable and long-term solution. Performance and scalability were prioritized during the development process, and a .NET Framework-based infrastructure was selected.

This decision was made due to the framework's platform-independent development capabilities and high compatibility with existing enterprise systems. Microsoft SQL Server was used as the database management system for data management and storage. Microsoft SQL Server is a relational database management system (RDBMS). Applications and tools connect to a SQL Server instance or database, and communicate using Transact-SQL (T-SQL). SQL Server's robust data integrity checks, security mechanisms, and transactional performance ensured the reliable processing of high-volume data streams. User testing, scenario-based validation, and role-based authorization mechanisms were implemented throughout the system development phase.

User tests were conducted to evaluate system functionality and user experience under various scenarios, while scenario-based validations simulated real-world operational processes to measure the system's fault tolerance. Furthermore, role-based access control (RBAC) mechanisms were defined to strengthen system security, ensuring each user only accessed authorized modules. This structure effectively protected data confidentiality, integrity, and traceability.

Consequently, the developed system offers an integrated solution for digitizing corporate processes, both technically and methodologically. It establishes a sustainable infrastructure that enhances process automation, data accuracy, and operational traceability.

2.2. System Components and Integration

This part is entirely devoted to the methodology, focusing specifically on the modules within the system architecture that could be the output of the study. The system was designed in a modular structure, and the integration of the modules within the system was subsequently implemented.

The POD Tracking System consists of four core components: the Web-Based Management Panel, Mobile Driver Application, TMS Integration Layer, and Power BI (Business Intelligence) Reporting Component.These components are summarized in the table.

Table 2: POD Tracking System Components

Name	Explanation
Web-Based Management Panel	Primary interface used by operations specialists and archiving units to manage delivery data, monitor ongoing processes, and access reporting dashboards.
Mobile Driver Application	Used by field drivers to take photos during deliveries, collect digital signatures, and scan and upload delivery documents, enabling real-time data transmission.
TMS Integration Layer	Manages workflow by exchanging data with the existing Cyber Transportation Management System (TMS) through real-time API integrations. Integration reduces administrative costs, automates booking and documentation processes, and thus increases operational efficiency.
Power BI Reporting Component	Provides real-time Key Performance Indicators and operational efficiency analytics for management. The data-driven insights generated by this component help logistics managers make strategic, evidence-based decisions.

3. Results

The main findings obtained from the study are summarized as follows in the table.

Table 3:The Main Findings of POD System

Findings	Explanation
Digital Archiving Potential and Document Loss Prevention	The mobile app's ability to instantly and dynamically collect visual data (signatures, photos, etc.) at the point of delivery reduces the amount of manual documentation in workflows.
Operational Speedup Expectation	Real-time transmission of delivery data to the TMS accelerates both the confirmation of deliveries and the initiation of subsequent financial processes. As a result, an operational efficiency increase of 30% to 40% is expected. This finding aligns with the general academic view that digital technologies increase the flexibility and responsiveness of logistics and supply chain networks.
Real-Time Management and Visibility:	Dynamic reports generated through Power BI allow managers to monitor key performance indicators in real time, significantly accelerating operational decision-making. Real-time monitoring and visibility are among the most valuable benefits offered by modern TMS software. This feature provides management with continuous visibility into delivery confirmations, allowing them to proactively identify process bottlenecks and performance anomalies.

Visual representations of the system are presented below:

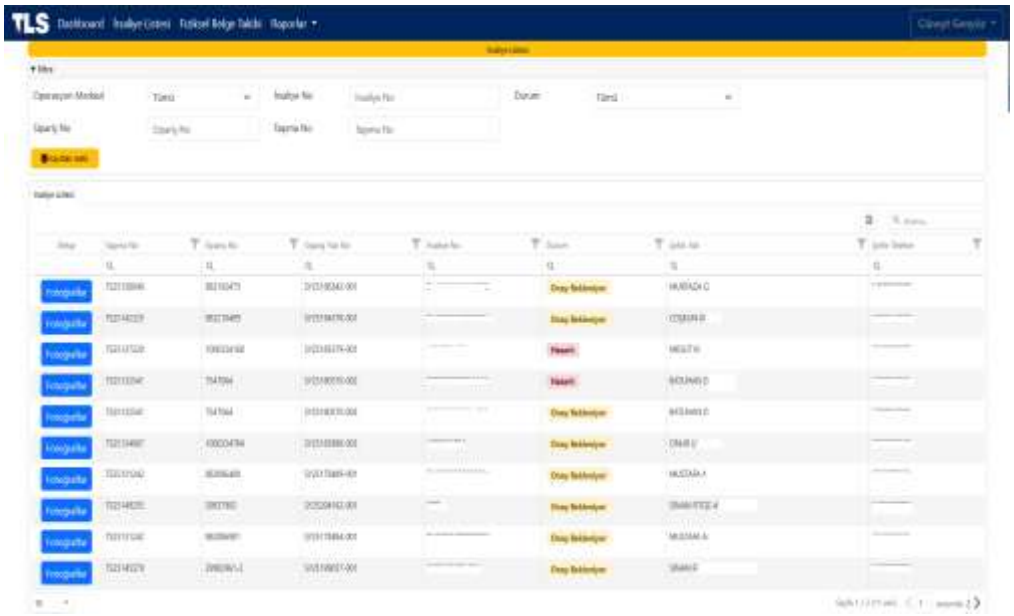

Figure 1: TLS POD Tracking System – 1

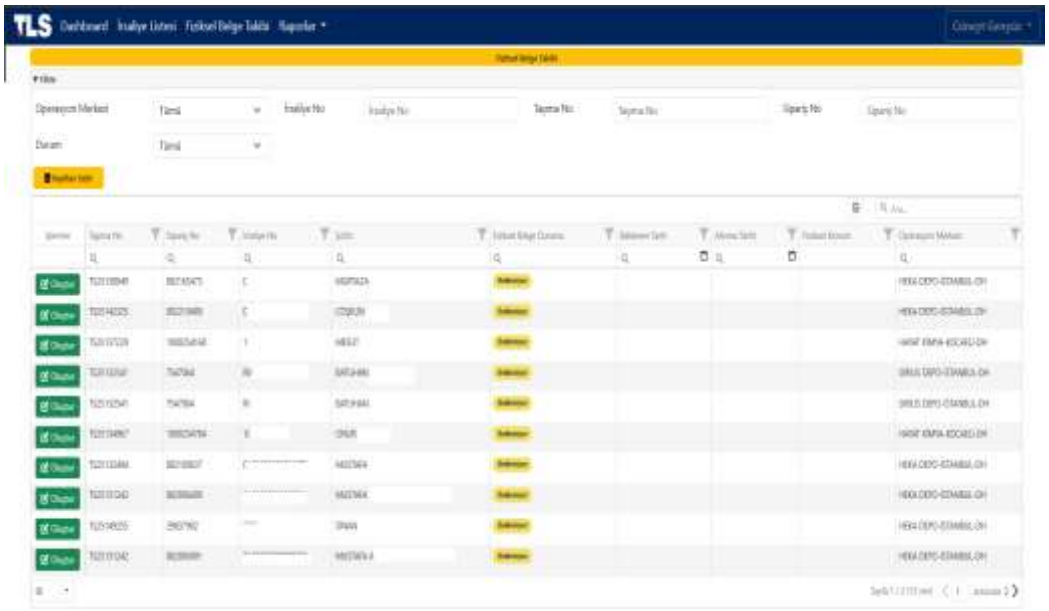

Figure 2: TLS POD Tracking System – 2

Following the initial deployment of the system, implementation outcomes and early operational data indicate strong evidence that the project will successfully address the initially targeted operational problems. These early results confirm that the system is capable of producing measurable improvements in accuracy, traceability, and speed across delivery verification processes.

4. Discussions and Conclusions

This study presents the design, technological infrastructure, and implementation results of a POD Tracking System developed to digitize delivery verification and document management processes in the logistics sector. Key findings demonstrate that digital transformation provides significant gains not only in operational speed and accuracy, but also in corporate information management and process traceability. The systematic elimination of chronic problems such as document loss, data inconsistencies, and approval delays in manual processes was made possible through digital archiving and real-time data synchronization. The results demonstrate an approximately 30-40% operational speedup in delivery verification processes and a significant reduction in document loss incidents. These findings are consistent with literature emphasizing that digitalization increases supply chain visibility and process efficiency. Furthermore, thanks to the system's multi-layered architecture and real-time integration with the TMS, information flows are integrated and fully traceable. Consequently, communication between field operations and central management units is streamlined, and processes are end-to-end traceable and auditable. The Power BI-based reporting component provides analytical visibility that strengthens a data-driven management culture in decision-making. However, some limitations were observed during implementation. First, differences in mobile device infrastructure and fluctuating internet connection quality in the field led to periodic inconsistencies in data transfer speeds. Furthermore, user adaptation to the digital system took time, requiring additional training and user support in the early stages of deployment. These challenges demonstrate that the human factor remains a decisive factor in digital transformation projects. Future work related to this study and the topic can be summarized as follows in the table.

Table 4: Future Work

Name	Explanation
Artificial Intelligence-Based Image Processing and Document Verification	Integration of Artificial Intelligence-based image processing systems is planned to automate the manual document verification and data entry tasks currently performed by warehouse personnel. The system will automatically detect signatures, stamps, and key verification elements on uploaded invoices and delivery notes to verify their legal accuracy. Shipment data from shipping documents will be directly transferred to TMS and ERP systems, eliminating the need for manual data entry. This enhancement is expected to increase data accuracy and reduce personnel-related operational costs.
Financial Process Integrations	The system scope should be expanded to include integration with financial processes such as invoicing, payment tracking, and cost analysis. The financial integration capabilities of TMS platforms are critical for improving cost control and strategic decision-making in logistics operations.
Customer Portal Module	The addition of a customer-centric portal that allows customers to track orders and view digital signatures or documents will enrich the customer experience and improve service quality.

In conclusion, the POD Tracking System represents a significant milestone in TLS Logistics' digital transformation journey. This study provides an integrated digital infrastructure that reduces manual workload, increases process transparency, and supports operational excellence in the logistics sector. In this respect, it serves as a model of digitalization that holds value for both industry applications and academic research.

Abbrevation List:

BI : Business Intelligence

BPM : Business Process Management

NET: Network

POD : Proof of Delivery

RBAC: Role-Based Access Control

RDBMS : Relational Database Management System

SQL : Structured Query Language

TMS : Transportation Management System

T-SQL: Transact-SQL

ABSTRACT

Industrial robotic arms not only provide precision, efficiency, and flexibility in manufacturing systems but also play a critical role in modeling kinematic and dynamic analyses within academic research. The study of robots with multiple degrees of freedom requires complex mathematical computations, posing significant challenges in both educational and research contexts. In this study, interactive simulation software was developed to enable such analyses to be performed in a more accessible, simplified, and modellable manner. In the proposed system, all mathematical computations and three-dimensional visualization processes were carried out using the Python programming language. Advanced algorithms such as the Denavit–Hartenberg matrix method, the inverse Jacobian technique, the Euler–Lagrange formulation, the Newton–Euler method, and the Recursive Newton–Euler Algorithm (RNEA) were employed for the mathematical operations. The application includes forward and inverse kinematics, forward and inverse dynamics, a Python-based simulation environment for the Kinematics, Dynamics, and Trajectory Planning of Industrial Robot Arms, as well as trajectory planning and workspace simulations. The accuracy, speed, and usability performance of the software were evaluated in detail. The results demonstrate that the system produces reliable solutions across different joint configurations and accurately computes end-effector positions. Therefore, this study provides a low-cost, interactive, and extensible simulation platform suitable for both educational and research purposes, offering a significant contribution to the academic field.

Keywords: Robotic Arms, Robotic Kinematics, Robotic Dynamics, Simulation Software, Mathematical Analysis, Trajectory, Workspace

1. INTRODUCTION

Industrial robots are among the fundamental components of modern manufacturing and automation systems, playing a critical role in achieving high precision, repeatability, and increased production speed. Multi-degree-of-freedom robotic arms are widely used across various industries such as automotive, aerospace, electronics, and healthcare. The effective utilization of these systems depends on the accurate execution of kinematic and dynamic analyses. Such analyses enable the mathematical modeling of a robot's motion capabilities, ensure that the end effector reliably reaches designated task points, and provide the precision required in industrial processes. Consequently, the importance of software and simulation tools developed in the field of robotics has been steadily increasing.

Studies on the kinematic and dynamic analyses of industrial robotic arms particularly emphasize the significance of software-based simulation tools. Among the most widely used methods in the literature are Denavit–Hartenberg (DH) transformations, homogeneous transformation matrices, and recursive algorithms [1]. While these methods offer reliable solutions for forward and inverse kinematic computations, numerical approaches that provide general solutions are also frequently preferred, especially when compared to analytical methods that are valid only for specific robot configurations.

A review of studies on dynamic modeling reveals that this topic has been addressed in the literature with a narrower scope compared to kinematics. A limited number of works have examined forward and inverse dynamic models using specialized tools such as the ARAT Toolbox or by implementing multibody dynamic algorithms in Python environments [2]. However, most research has overlooked dynamic modeling and has focused predominantly on kinematic computations and trajectory planning. Various approaches to trajectory planning have been reported. Some studies employing sampling-based algorithms (RRT, PRM, EST) have achieved task completion rates of up to 27.9% and reduced task durations to under 20 minutes [3]. Other works have utilized hybrid optimization methods (PSO, SSO, GWO, etc.) to improve path length, jerk, and acceleration values [4]. Artificial neural networks [5] and computer-vision–based artificial intelligence techniques [6] have also been applied in inverse kinematics and object recognition processes. Research findings indicate that MATLAB/Simulink-based tools dominate the literature, although Python-supported 3D interfaces have recently begun to gain prominence [7]. The open-source libraries offered by Python provide flexible solutions for both kinematic/dynamic computations and three-dimensional visualization, enabling the development of user-friendly interfaces. Reported performance metrics show that one study achieved an accuracy of 0.2 mm, while another reported error values ranging between 0 and 22 mm [8]. The Denavit–Hartenberg (DH) method is among the most widely used techniques in forward kinematic analysis (Denavit & Hartenberg, 1955). Through homogeneous transformation matrices defined via coordinate frames assigned to each joint, the DH method expresses the geometric relationship between adjacent joints. The transformation matrix representing the relationship between two consecutive joints is denoted as ${}^{i-1}_{i}T$, where "i" indicates the link number.

$$ {}^{i-1}_{i}T = \begin{bmatrix} {}^{i-1}_{i}R & D \\ 0\ 0\ 0 & 1 \end{bmatrix} \tag{1} $$

Here ${}^{i-1}_{i}R$, represents the rotational relationship between two consecutive joints, while D denotes the translational displacement vector. By multiplying the resulting transformation matrices, the position of the end effector with respect to the base coordinate frame is obtained:

$$ {}^{0}_{5}T = {}^{0}_{1}T\,{}^{1}_{2}T\,{}^{2}_{3}T\,{}^{3}_{4}T\,{}^{4}_{5}T\,{}^{5}_{e}T \tag{2} $$

Here, "e" denotes the end effector, and each ${}_{i}^{i-1}T$ m matrix defines the transformation relationship between consecutive joints. Thus, the homogeneous transformation matrix of the end effector with respect to the base is obtained, and from this matrix both the position components p_x, p_y, p_z and the orientation components n, s, α can be extracted. The first column of the matrix represents the normal vector n, the second column represents the sliding vector s, and the third column represents the approach vector α. Inverse kinematics is the process of determining the joint variables when the position and orientation of the end effector are given. Unlike forward kinematics, a solution may not always exist. The forward kinematics of a six-degree-of-freedom robot can be expressed as follows: [9] [10]

$$ {}_{6}^{0}T = {}_{1}^{0}T\,{}_{2}^{1}T\,{}_{3}^{2}T\,{}_{4}^{3}T\,{}_{5}^{4}T\,{}_{6}^{5}T \tag{3} $$

By multiplying both sides of the equation by $[{}_{i}^{i-1}T]^{-1}$ the expression is rearranged to obtain the required relationships. The remaining equations can be derived in a similar manner.

$$ [{}_{1}^{0}T]^{-1}\,{}_{6}^{0}T = {}_{2}^{1}T\,{}_{3}^{2}T\,{}_{4}^{3}T\,{}_{5}^{4}T\,{}_{6}^{5}T \tag{4} $$

These equations yield the solutions to the inverse kinematics problem by equating the matrix elements on both sides of the expression. To accurately compute the forces and moments encountered during the robot's motion, a dynamic analysis is required. Dynamic analysis not only considers the kinematic solutions but also accounts for the inertia, mass, and gravitational effects acting on the robot. One of the most commonly used methods for this purpose is the Lagrange formulation. In the Lagrangian approach, the system's kinetic energy

$K(q, q')$ and potential energy $P(q)$ are first defined. The Lagrange function is then expressed as follows [11]:

$$ L(q, q') = K(q, q') - P(q) \tag{5} $$

The equations of motion are derived using the Lagrange equations.

$$ \frac{d\left(\frac{\partial L(q,q')}{\partial q'}\right)}{dt} - \frac{\partial L(q,q')}{\partial q} = \tau \tag{6} $$

When these expressions are rearranged, the dynamic model of the robotic arm can be written in the following form:

$$ M(q, q'') + C(q, q')q' + g(q) = \tau \tag{7} $$

Here:

- $q \in R^n$ is the vector of joint coordinates,
- $M(q, q') \in R^{n \times n}$, is the inertia matrix,
- $C(q, q')q' \in R^n$ is the vector of Coriolis and centrifugal forces,
- $g(q) \in R^n$ is the vector of gravitational forces,
- $\tau \in R^n$ represents the vector of joint torques.

The Coriolis and centrifugal effects are defined as follows:

$$ C(q, q')q' = M'(q, q') - \frac{1}{2}\frac{\partial\left(q'^{T} M(q) q'\right)}{\partial q} \tag{8} $$

The gravitational effect is derived from the potential energy function.

$$g(q) = \frac{\partial(P(q)}{\partial q} \tag{9}$$

The dynamic model obtained from the analysis not only facilitates the derivation of the robot's equations of motion but also provides a critical foundation for control design, trajectory planning, and the development of optimization algorithms. Although some studies in the literature have performed dynamic analyses using tools such as MATLAB/Simulink or the ARAT Toolbox, Python-based solutions have become increasingly widespread [7] [2]. This study aims to offer both an academic and practical solution for the kinematic and dynamic analyses of industrial robotic arms. The developed software serves as a platform that helps students in educational institutions better understand complex robotic computations, while also supporting simulation-based testing processes in applications that enable researchers to develop new algorithms.

METHODOLOGY

1.1. Model Preparation

In the developed software, the three-dimensional CAD models of the robotic arms were initially designed in SolidWorks, and the axes and origins were arranged according to the widely used right-hand rule in the literature. These models were then exported in the commonly used STL (.stl) format (Figure 1). Subsequently, the models were imported into the Python environment through Unified Robot Description Format (URDF) files, which define the kinematic chain of the robot. Through this process, the coordinate system of each joint was established, and the corresponding homogeneous transformation relationships were made available for use within the software (Figures 2–3). The system's user interface was developed using the PyQt5 framework.

1.2. Forward Kinematics Analysis

The system is built upon the integration of the mathematical framework and dynamic analyses. For forward kinematic computations, homogeneous transformation matrices were defined using the Denavit–Hartenberg (DH) parameters, and the position and orientation of the end effector with respect to the base coordinate frame were obtained. Figure 4 illustrates the six-degree-of-freedom joint structure of the KUKA KR5 R650 industrial robot, in which the rotation axes of each joint are shown with colored coordinate frames. This representation clearly defines the kinematic chain from the base coordinate system to the end effector and provides the fundamental infrastructure for constructing the forward kinematic model.

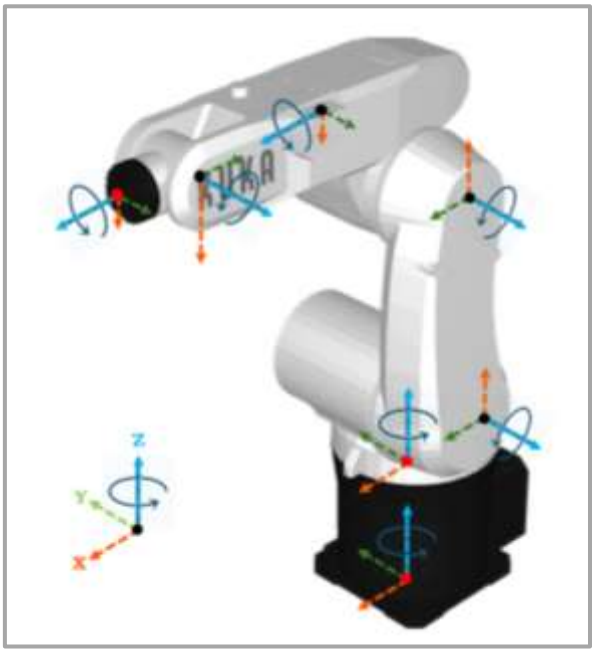

Figure 4 Joint Axes of the KUKA KR5 R650 Robot

Figure 5 shows the link lengths and joint limits used in constructing the forward kinematic model of the KUKA KR5 R650 robot. The robot has six degrees of freedom, and the rotational

angles defined for each joint are expressed as (Q1…Q6). The angle limits provided on the right indicate the mechanical constraints of the robot and play a critical role in determining its workspace. This kinematic scheme forms the basis for defining the Denavit–Hartenberg parameters and deriving the forward kinematic equations.

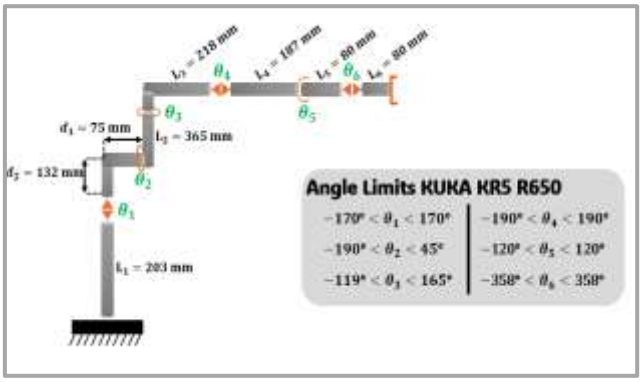

Figure 5 Kinematic Structure and Joint Limits of the KUKA KR5 R650 Robot

In this section, the forward kinematic model of the manipulator is defined using the Denavit–Hartenberg (D–H) parameters. Each homogeneous transformation matrix represents the position and orientation relationship between successive coordinate frames. The multiplication of all transformation matrices yields the position and orientation of the end effector with respect to the base coordinate frame.

$$T_{01} = \begin{bmatrix} cos\,\theta^1 & 0 & sin\,\theta^1 & 75\,cos\,\theta^1 \\ sin\,\theta^1 & 0 & -cos\,\theta^1 & 75\,sin\,\theta^1 \\ 0 & 1 & 0 & 135 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (10)$$

$$T_{12} = \begin{bmatrix} cos\,\theta^2 & -sin\,\theta^2 & 0 & 283\,cos\,\theta^2 \\ sin\,\theta^2 & cos\,\theta^2 & 0 & 283\,sin\,\theta^2 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (11)$$

$$T_{23} = \begin{bmatrix} cos\,\theta^3 & 0 & sin\,\theta^3 & 0 \\ sin\,\theta^3 & 0 & -cos\,\theta^3 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (12)$$

$$T_{34} = \begin{bmatrix} cos\,\theta^4 & 0 & -sin\,\theta^4 & 0 \\ sin\,\theta^4 & 0 & cos\,\theta^4 & 0 \\ 0 & -1 & 0 & 295 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (13)$$

$$T_{45} = \begin{bmatrix} cos\,\theta^5 & 0 & sin\,\theta^5 & 0 \\ sin\,\theta^5 & 0 & -cos\,\theta^5 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (14)$$

$$T_{56} = \begin{bmatrix} cos\,\theta^6 & -sin\,\theta^6 & 0 & 0 \\ sin\,\theta^6 & cos\,\theta^6 & 0 & 0 \\ 0 & 0 & 1 & 80 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (15)$$

The general transformation matrix of the end effector is obtained by multiplying all consecutive transformation matrices.

$$T = T^{01} \cdot T^{12} \cdot T^{23} \cdot T^{34} \cdot T^{45} \cdot T^{56} \quad (16)$$

The Cartesian position (X, Y, Z) of the end effector is computed from the last column of the resulting transformation matrix.

$$X = cos(\theta_1)\,(283cos(\theta_2) + 1200sin(\theta_2) + 1545cos(\theta_2+\theta_3) + 145sin(\theta_2+\theta_3) + 158cos(\theta_2+\theta_3+\theta_4)) \quad (17)$$

$$Y = sin(\theta_1)\,(283cos(\theta_2) + 1200sin(\theta_2) + 1545cos(\theta_2+\theta_3) + 145sin(\theta_2+\theta_3) + 158cos(\theta_2+\theta_3+\theta_4)) \quad (18)$$

$$Z = 135 + 1200cos(\theta_2) - 283sin(\theta_2) + 145cos(\theta_2+\theta_3) - 1545sin(\theta_2+\theta_3) + 158sin(\theta_2+\theta_3+\theta_4) \quad (19)$$

The algorithm used in forward kinematic calculations is shown in Figure 6. This structure enables the construction of transformation matrices for each joint and the computation of inter-joint relationships through sequential multiplications. Through the resulting transformation matrices, the position and orientation of the manipulator with respect to the base coordinate frame can be determined for any joint configuration. The determination of the end effector's Cartesian coordinates is illustrated in Figure 7. At this stage, the X, Y, and Z components of the end effector are obtained using the last column of the transformation matrix, thereby computing the manipulator's position within its workspace. This method has been validated through MATLAB/NumPy-based numerical computations for different joint angles.

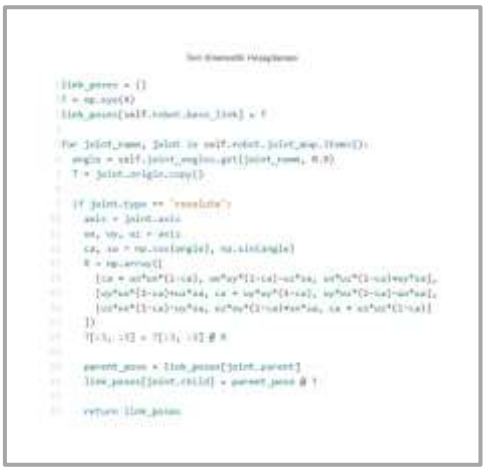

Figure 6 Forward Kinematic Calculations

Figure 7 Computation of the End Effector Position

1.3. Inverse Kinematics Analysis

Inverse kinematic solutions were obtained using closed-form approaches when analytical methods were applicable, while numerical optimization techniques were employed in more general cases. In the dynamic analysis stage, the Newton–Euler formulation and the Recursive Newton–Euler Algorithm (RNEA) were used, enabling the systematic computation of the forces and torques acting on the joints.

1.4. Workspace Representation

In this study, a numerical sampling–based method was used to compute the workspace. First, the minimum and maximum allowable joint angle ranges for each joint of the robot arm were defined. Then, samples were selected from these ranges either randomly or at regular intervals. For each selected joint combination, the forward kinematic equations were solved to compute the position of the end effector with respect to the base coordinate frame [Figure 8]. The obtained positions were recorded and visualized as a three-dimensional point cloud [Figure 9]. In this way, the workspace was visually represented by the set of all points that the robot can reach.

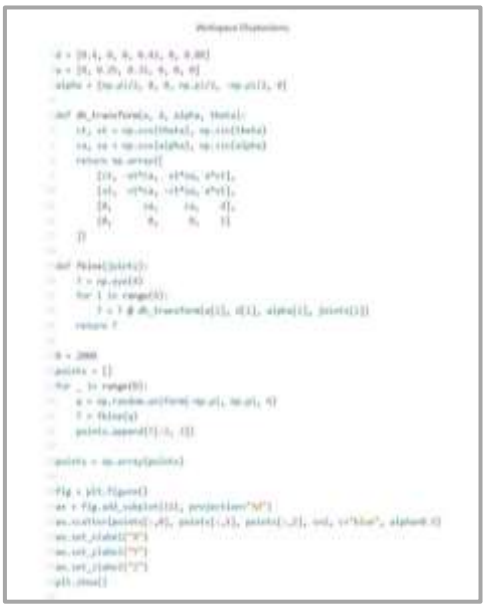

Figure 8 Extraction of the Robot Workspace

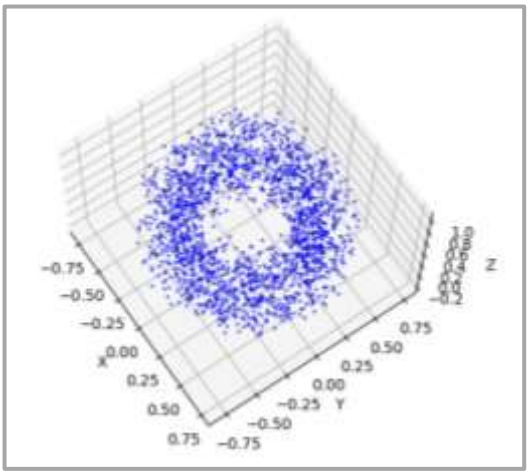

Figure 9 Robot Workspace

1.5. Dynamic Analysis

The software architecture was built on the Python programming language and developed using open-source libraries. NumPy and SciPy were utilized for mathematical computations, while the user interface was designed with PyQt5. Through the interface, each component can be controlled, and the position and orientation of the end effector can be computed and visualized in real time. For the integration of three-dimensional models, URDF files were processed using the yourdfpy library, and the robot's 3D model was visually rendered with the support of Open3D and PyQtGraph. This approach shows strong parallels with Python-based 3D interface development studies reported in the literature [7] [6].

2. RESULTS

Using the simulation software developed in this study, forward and inverse kinematics, dynamic analysis, trajectory planning, and workspace simulations were performed. Figure 10 shows the developed user interface. On the interface, the joint angle limits defined for each joint can be adjusted using slider bars, allowing the user to interactively test different configurations of the manipulator. The obtained joint angles are applied to the forward kinematic equations, enabling the real-time computation and display of the end effector's position in the X, Y, and Z coordinates. This approach not only supports the validation of the model but also allows the user to visualize the manipulator's workspace.

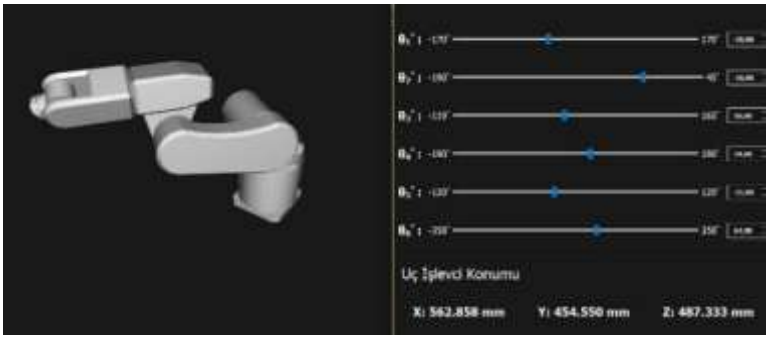

Figure 10 Forward Kinematic Interface

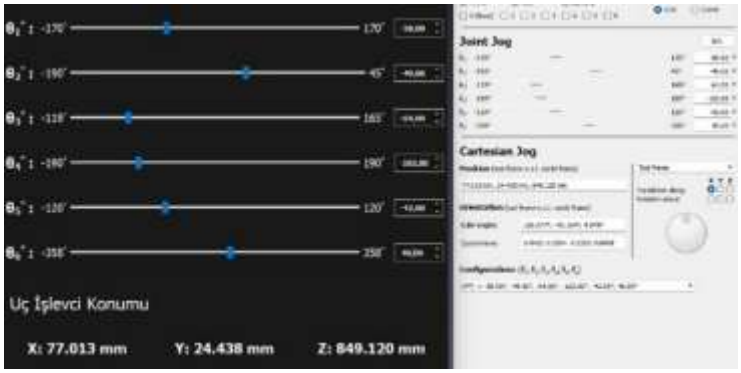

Figure 11 Comparison of the Developed Software with the RokiSim Program

First, the forward kinematic calculations were tested, and the position and orientation of the end effector with respect to the base coordinate frame were obtained for the given joint angles. The obtained values were compared with the theoretical results calculated using the Denavit–Hartenberg parameters and the results obtained from the RokiSim program, and they were determined to be error-free (Figure 11).

In the inverse kinematic analysis, joint angles were computed using numerical methods for different end effector positions and orientations, and the results were validated through forward kinematics. The tests showed that when only the position was targeted, the end effector position error was at the micrometer level. When both position and orientation were targeted, the average error was approximately ±5 mm, with 95% of the cases remaining within the ±2–3 mm range. The orientation error was found to be 0.16° on average, reaching a maximum of 5°. These results demonstrate that the developed software provides high accuracy and reliability in inverse kinematic solutions (Figures 11–13).

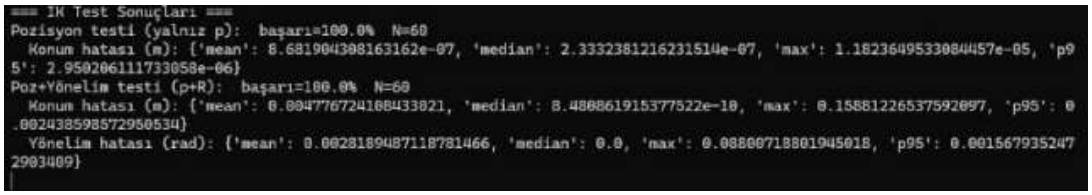

Figure 12 Inverse Kinematic Results

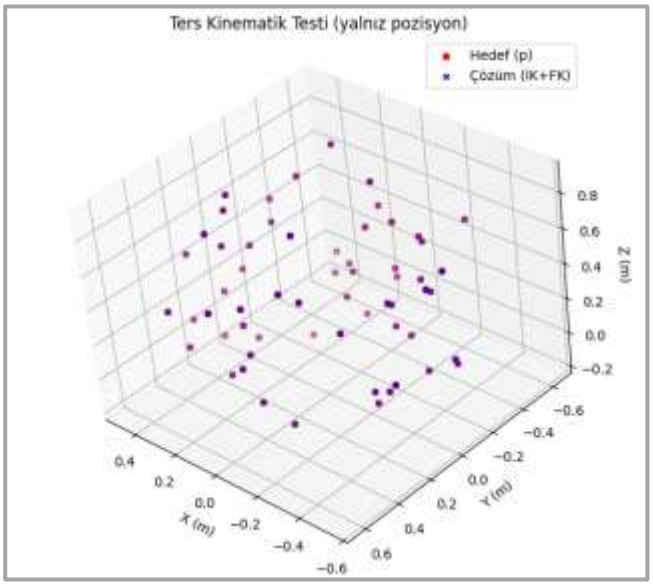

Figure 13 Results Obtained for Inverse Kinematics

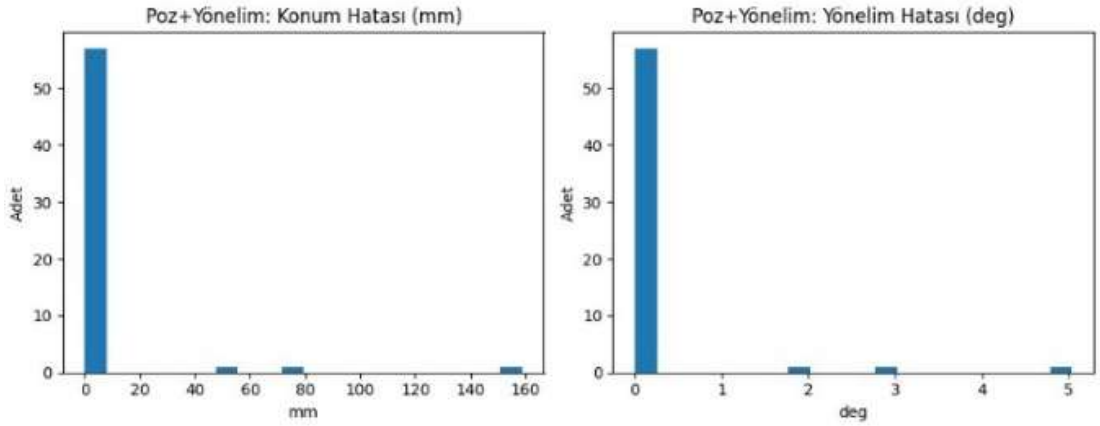

Figure 14 Results Obtained for Inverse Kinematics

For dynamic validation, time-dependent joint trajectories were generated on a two-degree-of-freedom planar test system, and the torque components were decomposed using the equations

derived from the Lagrange and RNEA formulations. The total torque was plotted together with the inertia term $M(q,q'')$, the Coriolis and centrifugal term $C(q,q')q'$ and the gravity term $g(q)$[Figure 15]. Energy consistency and the numerical consistency of the Lagrange formulation were demonstrated [Figure 16]. Finally, a 0.5 kg load was added to the end effector, and the corresponding increase in the torque curves was illustrated (Figure 17). The obtained results confirm that the model is physically consistent and exhibits the expected behavior under dynamic loads.

3. CONCLUSIONS

In this study, a system was developed that performs the forward and inverse kinematics, dynamic analysis, and trajectory planning of industrial robotic arms within an integrated software platform. Built using Python-based open-source libraries, the software not only solves theoretical equations but also provides users with an interactive simulation environment through its three-dimensional visualization capability. In forward kinematic analysis, the position and orientation of the end effector were calculated with high accuracy, while in inverse kinematic analysis, the target points were reached with an average error on the millimeter scale. In the dynamic analyses, joint torques were decomposed using the Recursive Newton–Euler Algorithm, and the physical consistency of the system was validated through energy and power relationships. The workspace simulations visually revealed the robot's reachable volume. The obtained findings demonstrate that the developed software offers a low-cost and flexible solution suitable for educational and research purposes. In this respect, the study constitutes an academic tool that serves as an alternative to commercial robot simulation software. Future work will expand the platform's scope by integrating more complex optimization-based trajectory planning methods, control algorithms, and compatibility with different robotic arms.

ÖZET

Bu derleme, Sivas ilinde şeker pancarı üretiminin agroekonomik önemi ve bitki koruma sorunlarını entegre mücadele yaklaşımı çerçevesinde değerlendirilmek amacıyla hazırlanmıştır. Şeker pancarı (*Beta vulgaris* L.), Amaranthaceae familyasına ait, iki yıllık, yazlık bir endüstri bitkisi olup, Türkiye'de özellikle Orta ve Doğu Anadolu'nun başlıca endüstriyel tarla bitkileri arasında yer almaktadır. Makalede, şeker pancarının Türkiye şeker üretimindeki payı, ekim alanı, verim düzeyi ve sözleşmeli üretim yapısı özetlenmekte; Sivas'ın karasal iklimi ve ekolojik koşulları altında ürünün tarımsal önemi vurgulanmaktadır. Sivas ilinde şeker pancarı verimini sınırlayan biyotik ve abiyotik etmenler içinde fungal hastalıklar ön plandadır. Özellikle Cercospora yaprak lekesi, Rhizomania (kök sakallanması) ve Rhizoctonia kaynaklı taç-kök çürüklüğü hastalıkları bölgede yaygın olarak görülmekte ve önemli düzeyde verim kayıplarına neden olmaktadır. Buna ek olarak, külleme, pas hastalıkları ve Fusarium spp.'nin oluşturduğu kök çürüklükleri, bazı üretim yıllarında ve belirli alanlarda önemli boyuta ulaşabilmektedir. Hastalık ve zararlılarla mücadele için, etkin bir hastalık yönetimi; dayanıklı çeşitlerin tercih edilmesi, sağlıklı ve sertifikalı tohum kullanımı, uygun kültürel önlemler, erken tahmin–uyarı sistemlerine dayalı fungusit uygulamalarının birlikte planlanmasını gerektirmektedir. Fungal hastalıkların yanı sıra yabancı otlar ve nematodlar da Sivas koşullarında şeker pancarı verim ve kalitesini sınırlayan önemli biyotik etmenlerdendir. Pancar–tahıl ekim rotasyonu, hastalık ve yabancı ot döngülerinin kırılmasına katkı sağlamakta, buğday ve arpa ekimlerinde verim artışı sağlamaktadır. Şeker pancarında biyotik etmenlere bağlı toplam ürün kayıplarının %45,2'ye ulaşabildiği; bunun %16,5'inin zararlılardan, %16,5'inin hastalıklardan ve %12,2'sinin yabancı otlardan kaynaklandığı bildirilmektedir. Bu derleme, mevcut bilgi birikimini Sivas ili özelinde sunarak entegre bitki koruma stratejilerinin gerekliliğini ortaya koymayı ve geleceğe yönelik araştırma boşluklarını tanımlamayı amaçlamaktadır.

Anahtar kelimeler: Şeker pancarı, Sivas, fungal hastalıklar, yabancı ot ve zararlılar, entegre mücadele

Giriş

Şeker pancarı (*Beta vulgaris* L.), Amaranthaceae familyasına ait, iki yıllık, yazlık bir endüstri bitkisidir. Dünyada şeker üretiminde şeker kamışından sonra en fazla yetiştirilen tür olup, yıllık şeker üretiminin yaklaşık %30'unu karşılamaktadır. Şeker pancarı, Türkiye'de özellikle Orta ve Doğu Anadolu'nun önemli endüstriyel tarla bitkileri arasında yer almakta; Sivas gibi belirgin karasal iklime sahip, yüksek rakımlı illerde sulu tarımın temelini oluşturmaktadır (Kandil ve ark., 2020). Sivas ilinde pancar üretimi, sadece şeker sanayisine hammadde sağlamanın ötesinde, başta küspe ve melas olmak üzere yem ve gıda sanayinde kullanılan önemli bir hammadde kaynağıdır (Şiray, 1990; Anonim, 2007). Türkiye'de şeker pancarı üretimi 2024 yılında 23,0 milyon ton olarak gerçekleşmiştir. 2023 yılında ise şeker pancarı ekim alanı 3.555.950 da, üretim 23,5 milyon ton ve ortalama verim 6.609 kg/da olarak bildirilmiştir (TÜİK, 2025). Sivas'ın agroekolojik koşulları değerlendirildiğinde, üreticilerin vegetasyon süresi boyunca genellikle 5–10 sulama yapması gerekmektedir. Sulama zamanlamasının doğru planlanması ve su verimliliğinin artırılması, hem verim ve kalite parametrelerini iyileştirmekte hem de yerüstü ve yeraltı kaynaklarının etkin kullanımına katkı sağlamaktadır. Şeker pancarı; Akıncılar, Altınyayla, Gemerek, Kangal, Merkez, Suşehri, Şarkışla, Ulaş ve Yıldızeli ilçelerinde düzenli olarak yetiştirilmektedir. Bu geniş dağılım, ilin agroekolojik uygunluğunu ve sulama kapasitesini yansıtmaktadır. Ürün, sözleşmeli üretim modeliyle ve çoğunlukla il dışındaki fabrikalara Erzincan, Kayseri, Tokat/Turhal, Malatya illerinde çoklu tedarik ilişkileri üzerinden pazarlanır. Sulama yönetimi ve hasat konusunda, vejetatif büyüme ve şeker birikimi dönemlerinde hassas sulama zamanlaması verim ve polarizasyonu artırır. Sonbaharda bitki hasat olgunluğuna ulaşıldığında söküm yapılmalı; toprak bulaşıklığı ve tepe kesim kayıpları minimize edilerek polar kalitesi korunmalıdır.

Sivas ilinde şeker pancarı verimini etkileyen biyotik ve abiyotik faktörlerin başında fungal hastalıklar yer almaktadır. Özellikle bölgede Cercospora yaprak lekesi, Rhizomania (kök sakallanması) ve Rhizoctonia kaynaklı taç/kök çürüklüğü hastalıkları sıklıkla görülmekte ve önemli düzeyde verim kayıplarına yol açmaktadır. Ayrıca, külleme, pas hastalıkları ve *Fusarium* spp. tarafından oluşturulan kök çürüklükleri, belirli bölgelerde veya bazı üretim sezonlarında önem kazanabilmektedir. Etkin bir hastalık kontrol programı; dayanıklı çeşitlerin kullanılması, sağlıklı ve sertifikalı tohum materyali, uygun kültürel önlemler, erken tahmin–uyarı sistemlerine dayalı mücadele zamanlaması ve direnç yönetimini gözeten fungusit uygulamalarının birlikte ele alınmasını gerektirmektedir. Fungal hastalıkların yanı sıra, yabancı otlar ve nematodlar da bölgede şeker pancarı verim ve kalitesini sınırlayan önemli etmenler arasındadır. Sivas ekolojik koşullarına uygun olarak uygulanan pancar–tahıl ekim rotasyonu, hastalık ve yabancı ot döngülerinin kırılmasına katkı sağlamakta; uygun yönetim koşullarında, buğday ve arpa ekimlerinde verim artışına olanak tanımaktadır.

Bu derlemede, Sivas ili koşullarında şeker pancarı üretiminin agroekonomik önemi ve yetiştirme özellikleri ortaya konulmakta; verim ve kaliteyi sınırlayan başlıca bitki koruma sorunlarının özellikle fungal hastalıklar, yabancı otlar ve nematodlar epidemiyolojisi ve zarar düzeyleri literatür ışığında değerlendirilmektedir. Ayrıca, sürdürülebilir şeker pancarı üretimi için sulama yönetimi ve ekim nöbeti gibi agronomik uygulamalarla entegre mücadele stratejilerinin tartışılması hedeflenmiştir.

Bitki Koruma Sorunları ve Entegre Mücadele Yaklaşımları

Şeker pancarında verim ve kaliteyi sınırlayan başlıca etmenler; yabancı otlar, hastalıklar ve zararlılardır. Şeker pancarı ve şeker kamışında biyotik faktörlere bağlı yıllık ürün kayıplarının %45,2'ye ulaşabildiği, bu kayıpların %16,5'inin zararlılardan, %16,5'inin hastalıklardan ve %12,2'sinin yabancı otlardan kaynaklandığı bildirilmiştir (Yiğit, 2001). Sivas koşullarında

sürdürülebilir şeker pancarı üretiminin sağlanabilmesi için entegre mücadele ilkelerinin düzenli ve sistematik biçimde uygulanması zorunludur. Entegre mücadele kapsamında; tarımsal ekosistemin izlenmesi, ekonomik zarar eşiği (EZE) değerlerin dikkate alınması, uygun kültürel önlemler, biyolojik ve biyoteknik yöntemlerin desteklenmesi ile kimyasal mücadelenin rasyonel ve hedefe yönelik kullanımı, uzun vadeli üretim ve sürdürülebilirlik açısından kritik öneme sahiptir.

Rhizoctonia Kök Çürüklüğü Hastalığı (*Rhizoctonia solani)*

Şeker pancarı, toprak kökenli birçok patojene karşı savunmasızdır. Basidiomycetes sınıfında yer alan *Rhizoctonia solani* (Wibberg ve ark.,)'nin neden olduğu kök çürüklüğü dünya çapında şeker pancarı üretiminde en önemli toprak kökenli hastalıklardan biridir. Şeker pancarı üretimi için giderek artan bir sorun haline gelmiş olan Rhizoctonia kök çürüklüğünden kaynaklanan verim kayıplarını azaltmak için tarımsal önlemler almak oldukça önemlidir (Holmquist ve ark., 2021). *R. solani* nin neden olduğu kök ve taç çürüklüğü, genellikle yetiştirme sezonunun ileri dönemlerinde, yapraklarda solma, kloroz ve yaprak saplarının tabanında koyu kahverengi lezyonlar gibi toprak üstü semptomlar şeklinde görülür. Kök ve taç çürüklükleri, yüksek sıcaklık ve düzensiz sulama-kabuklanma koşullarında hastalık şiddetlenir; söküm kayıpları artar (Barreto ve ark., 2020). Rhizoctonia kök çürüklüğü, hastalığı 22-35 °C arasındaki sıcaklıklarda nemli koşullarda optimum gelişir (Neher ve Gallian, 2013). Hastalık nedeniyle, ticari şeker pancarı tarlalarında %50 veya daha fazla verim kayıplarının olduğu, depolanmış köklerde şeker miktarını azalttığı ve fabrikada işlemede zorluklara yol açabildiği bildirilmiştir (Tallgren ve ark., 1999; Büttner ve ark., 2004). Jacobsen (2005) şeker pancarında yaptığı bir çalışmada *Rhizoctonia solani, Rhizoctonia crocorum* ve *Macrophomina phaseolina'nın* kök çürüklüğüne neden olarak, önemli miktarda zararlara neden toprak kökenli patojenler olduğunu bildirmiştir.

Çökerten: *R. solani* (AG IV) ile enfekteli bitkiler suya batırılmış gibi görünür. Gövdede ve toprak yüzeyinin hemen altında kararmalar şeklinde belirti verir ve belirtiler hipokotile doğru yayılma gösterir. Bu durumdaki fideler çoğunlukla solar ve ölür (Neher ve Galligan, 2011). Verim kayıpları, köklerin kaybından, köklerin bozulmasından dolayı azalan tonaj miktarından ve şeker oranının azalmasından kaynaklanmaktadır. Yapraklarda solma ve yaprak sapında koyu kahverenginden siyaha doğru renk değişikliği görülür. Zamanla yapraklar toprak yüzeyinde çöker ve ölür. Ölümden sonra yaprak sapları taça bağlı olarak kalır ve ölü yapraklar siyah rozet oluşturur (Neher ve Galligan, 2011).

Taç ve kök çürüklüğü: Enfeksiyon taçlarda, şeker pancarı köklerinde veya toprak yüzeyinin altında taç çürüklüğü şeklinde kendini gösterir. Hastalık enfeksiyon noktasından aşağı doğru yayılır. Hastalık ilerledikçe koyu renkli lezyonlar birleşerek dairesel ya da oval lekeler şeklini alır. Rhizoctonia kök çürüklüğü şeker pancarında ani solma yapabildiği gibi kalıcı solma şeklinde de kendini gösterebilir. (Harveson, 2008).

Kök belirtileri Hastalık şeker pancarı köklerinde koyu kahverengiden siyaha renk değişimine yol açarken bitkide kanserler ve çatlaklar da meydana getirebilir. Bitkide çürüyen kök dokuları katı haldeyken ikincil fungus ve bakteri istilası sonucu yumuşak hale gelebilir. Kök belirtileri genellikle oval şeklindedir, koyu lezyonlar ise dairesel olarak gelişir (Harveson, 2008).

Yaprak belirtileri Hastalık şeker pancarı bitkisinde bodur yaprak gelişimine, mat yaprak rengine, ani ve kalıcı yaprak solmasına neden olur. Solan dokuda sararma ve öncelikle yaşlı yapraklardan başlayan ölüm şeklinde kendini gösterir. Hastalığa yakalanan yaprak sapı zamanla koyu kahverengiden siyaha giden renk alır.

Hastalıkla mücadelede kültürel önlemlerin uygulanması önemlidir. Bu amaçla, patojenin konukçusu olmayan kültür bitkileri ile 4–5 yıl rotasyon yapılması, enfekteli bitki kısımlarının toplanması ve depolanmış ürünlere bulaşmayı engellemek için enfekteli köklerin uzaklaştırılması önerilmektedir. Etmenin kimyasal mücadelesi zordur ve ancak sınırlı alanlarda kısmen başarılı olabilmektedir (Mohammadi ve ark., 2003). Fungisitler (Tolclofos-methyl, Azoxystrobin, Flutolanil, Prothioconazole, Difenoconazole/Propiconazole, Pyraclostrobin, Trifloxystrobin, Pencycuron, Tebuconazole) Rhizoctonia kök çürüklüğü ve fide çökerten kontrolünde kullanılabilir (Kiewnick ve ark., 2001). Etmene karşı yapılan biyolojik mücadele çalışmalarında *Trichoderma* spp., *Gliocladium* spp., binükleit Rhizoctonia, *Pseudomonas* spp., *Bacillus* spp., *Streptomyces* spp. gibi antagonistlerle çalışmalar yürütülmüş ve etkili sonuçlar alınmıştır (Trillas ve ark., 2006).

Cercospora yaprak lekesi (*Cercospora beticola* Sacc.)

Şeker pancarında Cercospora yaprak lekesi, dünya genelinde yaygındır ve yol açtığı kalite/verim kayıpları nedeniyle en önemli yaprak hastalığı olarak kabul edilmektedir; sıcak ve nispi nemin yüksek seyrettiği üretim alanlarında önemli zararlara yol açar (Weiland & Koch, 2004; Skaracis ve ark., 2010). Özellikle ortalama sıcaklığın 20 °C ve üzerinde olduğu dönemlerde, yaprak ıslaklık süresinin uzun olduğu, yoğun yağış alan ya da yağmurlama sulama yapılan tarlalarda enfeksiyon riski önemli ölçüde artar (Khan ve ark., 2008; Skaracis ve ark., 2010; Stevanato ve ark., 2015).

Hastalık belirtileri tipik olarak yapraklarda mor-kırmızımsı kahverengi sınırlı, ortası açık gri renkte küçük dairesel lekeler şeklinde başlar; lekeler kısa sürede çoğalır ve birleşerek geniş nekrotik alanlara dönüşür. Hastalık ilerledikçe yapraklar kenardan merkeze doğru kurur ve ölür. Enfeksiyon çoğu zaman dış yapraklardan başlar, iç kısımlara doğru ilerleyerek tüm yaprakların kurumasına neden olur (Tan ve ark, 2023) Bitki, bu durumda taç (göbek) kısmından yeni yapraklar oluşturmaya yönelir; ancak bu büyüme kök gelişimine ayrılacak karbonu azaltır, kök iriliği ile şeker oranını (polar) düşürür (Weiland & Koch, 2004; Khan ve ark., 2008). Uygun iklim koşullarında ve yetersiz hastalık kontrolü durumunda, şeker veriminde belirgin düşüşler ve buna bağlı ekonomik kayıplar görülür. Hastalığın şiddeti bölgeden bölgeye değişmekle birlikte etmenle mücadele yapılmadığı taktirde şeker pancarının kök verimini % 26, ve şeker verimini %55'e kadar düştüğü bildirilmiştir. Etmen bir sonraki yıla taşınması, tarlada kalan bitki artıkları veya bulaşık tohumlarla olurken bitkiden bitkiye taşınma yağmur sularının sıçraması ve rüzgar etkisi ile gerçekleşir. Hastalıkla mücadelede, fungisit uygulamaları, dayanıklı çeşitlerin yetiştirilmesi ve ürün rotasyonunun birlikte uygulandı entegre mücadele esasına dayanır (Miller et al., 1994; Skaracis ve ark., 2010; Stevanato ve ark., 2015) Ancak, epidemi koşulları oluştuğunda yalnız kültürel önlemler çoğu zaman yetersiz kalır; zamanında ve doğru seçilmiş fungisitlerin kullanımı gereklidir (Khan ve ark., 2008; Stevanato ve ark., 2015). Erken uyarı eşiğine gelindiğinde hastalık için optimum koşullar geliştiğinde, her 100 yapraktan en az 5'inde tipik Cercospora lekesi saptanması (≈%5 yaprak enfeksiyonu) durumunda koruyucu ilaçlamaya başlanması önerilir (Khan ve ark., 2008; Sushmita ve ark, 2025). Hastalıkla mücadelede; sertifikalı temiz tohumluk kullanmak, tarlada görülen hastalıklı bitkilerin toplanıp yakılması, etkili yabancı ot mücadelesi yapılması ve en az 3 yıl süreyle ekim rotasyonu yapılması önerilmektedir. Hastalığın kimyasal mücadelesi yeşil aksam ilaçlaması şeklinde yapılır.

Rhizomania Kök Sakallanması Hastalığı

Rhizomania Kök Salkallanması hastalığı, *Polymyxa betae* vektörlüğünde Beet necrotic yellow vein virusun (BNYVV) neden olduğu ve şeker pancarı yetiştirilen tüm alanlarda görülen en tahripkar hastalıkların başında gelmektedir (Tamada ve ark., 1975; Rush, 2003; EFSA, 2020).

Vektör fungus, *P. betae* 1964 yılında ilk defa Keskin 1964 tarafından tanımlanmıştır. Etmen, Chenopodiaceae üzerinde zorunlu endoparazit olarak yaşar hastalık şeker pancarı yetiştirilen tüm bölgelerde büyük oranda görülmektedir (Keskin, 1964; Blunt ve ark., 1991). *P. betae* kalın duvarlı dinlenme yapıları ile uzun süre toprakta canlı kalabilir (Ertunç, 1998). Böylece virüs toprakta en az 15 yıl bulaşık kalabildiği ve vektörün virüsü çok uzun süre taşıyabildiği bildirilmiştir (Abe ve Tamada, 1986; Duffus, 1991; Rush ve Heidel, 1995). Hastalık Türkiye'de Marmara, Orta Karadeniz ve İç Anadolu bölgesinde varlığı bildirilmiş olup yayılış devam etmektedir (Kaya ve ark., 2019). BNYVV çoğu bitki patojeni virüs gibi RNA virüsüdür; RNA1–2 replikasyon ve hareket için zorunlu, RNA3–4 patojeniteye katkıda bulunur ve bazı soyların taşıdığı ek RNA5 yüksek saldırganlık ile direnç kırma kapasitesiyle ilişkilidir (EFSA, 2020; Tamada ve ark., 2021; Liebe ve Varrelmann, 2023).

Rhizomania kök sakallanması hastalığı, bulaşık toprak ve su hareketiyle, hasat artıklarıyla ve şeker fabrikalarının atık suları ile yayılabilir (Cariolle, 1987; Heijbroek, 1987; Asher, 1994). Erken dönem enfeksiyonu sonucu kökte yan köklerin aşırı çoğalması nedeniyle "sakallı kök" görüntüsü geç dönem enfeksiyonu sonucunda da köklerde çürüme ve taç bölgesinde görülen kahverengilileşme hastalığın tipik simptomudur. Ayrıca hasta bitkilerin iletim demetlerinde renk değişimi, yapraklarında solma, sararma şeklinde belirtiler görülür (Rush ve Heidel, 1995). Hastalık nedeniyle enfeksiyon şiddetine bağlı olarak kökte %30–90 ve şeker veriminde ise %70'e varan kayıplara neden olduğu bildirilmiştir (Asher, 1993; Asher ve Kerr, 1996; Putz ve ark., 1990; Whitney ve Duffus, 1991; Rush ve Heidel, 1995). Hastalıkla mücadelede en önemli yöntem dayanıklı çeşit yetiştirmektir (Asher, 1994; Richard-Molard, 1996). Dayanıklı çeşit geliştirmek amacıyla yapılan ıslah çalışmaları uzun soluklu çalışmalar olup, Rz1 ve Rz2 genleriyle ve bunların kombinasyonları ile (Rz1+Rz2) tarladaki kontrol şansının arttığı, RNA5 taşıyan popülasyonlara karşı olumlu sonuçlara varıldığı bildirilmiştir. (Wetzel ve ark., 2021; Müllender ve ark., 2022). Hastalıkla kültürel mücadelede; ürün rotasyonu, iyi drenaj ve toprak havalanması ile erken ekim (Tosic ve ark., 1985), sulama suyu yönetimi, kendi gelen ve yabani pancarların eradikasyonu oldukça önemlidir. Tek başına rotasyon toprakta uzun süre canlı kalan vektörü kontrol etmede yetersiz kalabilmektedir (Abe ve Tamada, 1986; Rush ve Heidel, 1995; EFSA, 2020).olive

Fusarium Kök Çürüklüğü (*Fusarium* spp)

Fusarium spp, şeker pancarı dahil olmak üzere birçok tarımsal üründe ciddi zarara neden olan toprak kaynaklı patojenlerden biridir. Fusarium spp. erken dönemde; çökerten ve kök çürüklüklerine neden olurken geç dönemde ise bitkilerinin yeşil aksamında genel bir kloroz, solgunluk ve yaşlı yapraklarda kurumalar şeklinde belirti verir. Hastalıktan etkilenen bitkilerin köklerinde iletim demetlerinde renk değişikliği görülür. Şeker pancarındaki kök çürüklüğü hastalıkları, kök-gövde verimi ve şeker oranı önemli ölçüde azaltır (Cao ve ark., 2018). Tarlada optimal bir kök-gövde ve şeker verimi sağlamak için şeker pancarının kök çürüklüğüne neden olan toprak kaynaklı patojenlerinden korunması gerekmektedir (De Lucchi ve ark., 2017).

Külleme *Erysiphe betae*

Şeker pancarında külleme (*Erysiphe betae*) hastalığı dünya genelindeki şeker pancarı üretimi yapılan tüm alanlarında görülmektedir. Hastalık nedeniyle elde edilen üründe şeker oranında %30'lara varan kayıplar açıklamıştır (Francis, 2002). Hastalık oluşumu için en uygun zaman, kurak hava koşullarının yanı sıra yüksek gündüz fakat düşük gece sıcaklıkları, yani gece-gündüz sıcaklık farkının fazla olduğu periyotlardır. Hastalığın ilk belirtileri; genellikle yaşlı yaprakların alt yüzeyinde küçük, dağınık ve seyrek beyaz miselyum kitleleri halinde seyreder. İlerleyen zamanlarda tüm yaprak yüzeyi beyaz pudra serpilmiş gibi görünür. Hastalık uygun ortam koşullarında hızlı bir şekilde gelişerek bütün yaprak yüzeyini kap Kandilci (2006) ise

Adana'da yapmış olduğu bir araştırmada, Türkiye'de ki şeker pancarı ekim alanlarının şeker pancarı olgunlaşma evresinde yoğun bir şekilde külleme hastalığının epidemi yaptığını açıklamıştır.

Yabancı Otlar

Yabancı otlar, şeker pancarı kültürünün en önemli sorunlarından biridir. Şeker pancarı, ilk büyüme döneminde yabancı ot rekabetine karşı son derece hassastır, bu nedenle bu aşamada etkili yabancı ot kontrolü çok önemlidir. (Jalali & Salehi 2013; Marwitz et al 2014). Kültür bitkileriyle, su, besin maddesi ve ışık yönünden rekabete giren yabancı otlar; şeker pancarının başlangıçtaki gelişme hızının yavaş ve rekabet kabiliyetinin zayıf olması nedeniyle ürünün kalite ve kantitesi üzerinde büyük zararlara neden olmaktadır (Güncan, 1993; Özer ve ark., 2001). Dünyada şeker pancarında yabancı otlardan ileri gelen ürün kaybı ortalama %5,8 iken, bu kayıp Türkiye'de ortalama %6-40 arasında değişmektedir (Güncan 2010).

Ekimden sonra 8 hafta içinde veya şeker pancarı bitkisinin iki yaprak aşamasına 4 hafta içinde çıkan kontrolsüz yıllık yabancı otlar, kök verimlerini %26 ila %100 arasında azaltabilir (Schweizer ve Dexter 1987; Rosso vd. 1996). Farklı zamanlarda çıkan yabancı otların şeker pancarı verim kayıplarına etkisi üzerine sürenin etkisiyle ilgili veriler, gereken yabancı ot kontrol sürelerini belirleme temelini oluşturur. Şeker pancarı tarlalarında bulunan yabancı otların yaklaşık %70'i geniş yapraklı türlerden oluşurken, %30'u dar yapraklı türlerdir (May ve Wilson 2006). Şeker pancarı üretiminde sorun olan yabancı otlar arasında sirken (*Chenopodium album*) yabani yabani hardal (*Sinapis arvensis*) ile horozibiği (*Amaranthus* spp.). ve tarla sarmaşığı (*Convolvulus arvensis*) gibi hızlı büyüyen yazlık türler öne çıkar.

Küsküt (*Cuscuta campestris*), Cuscuta cinsi, Convolvulaceae familyasına ait yıllık ve tam parazit bir bitkidir. C. campestris'in şeker pancarı, havuç, biber, sarımsak, soğan, domates, baklagiller, kavun, karpuz, patates, üçgül ve yoncada zarar verdiği ve bazı durumlarda zarar oranının %50-90 arasında değiştiği bildirilmektedir (Dawson et al. 1994, Lanini and Kogan 2005, Lian et al. 2006, NadlerHassar and Rubin 2003, Parker and Riches 1993). Şeker pancarı veriminde de 3.5-4 ton/ha azalmaya neden olmuştur (Aly et al. 2003).

Yabancı otlarla mücadelede; Temiz tohum, ekipman hijyeni, tarla kenarı ve su kanalı bakımının düzenli yapılması. Uygun ekim sıklığı ve sıra aralığı, rekabet gücü yüksek sıra üzeri bitki yoğunluğu dikkat edilmesi gereken kültürel mücadele yöntemleridir. Toprak işleme ile tek yıllık yabancı otların mücadelesinde daha iyi sonuç alınmaktadır. Çok yıllık yabancı otlarda ise yüzeysel köklü olanlar sürümle azaltılabilir. Ancak bunların toprak altı organları tarladan uzaklaştırılarak imha edilmelidir. Derin köklü çok yıllık yabancı otlar (Tarla sarmaşığı, köygöçüren, ayrık vs.), birkaç yıl üst üste yetiştirme dönemi süresince tekrarlanacak toprak işlemesi ile baskı altına alınabilir. Ekim nöbeti uygulanmalıdır. Kimyasal mücadelede ise, Pre-/post-emergence programlarının rotasyon ilkelerine göre planlanması; etki mekanizması farklılığına dayalı ardışık uygulamalar ile direnç riskinin azaltılması. Herbisit uygulaması, kullanılacak ilaçlara bağlı olarak ekim öncesi, çıkış öncesi, çıkış sonrası ve çıkış öncesi+çıkış sonrası olmak üzere dört şekilde yapılır (Tagem,2020).

Şeker Pancarı Zararlıları

Şeker Pancarı Kist Nematodu (*Heterodera schachtii*),

Şeker pancarı kist nematodu (*Heterodera schachtii*), şeker pancarında en önemli nematod zararlılarından biri olarak kabul edilir ve çoğu şeker pancarı yetiştirme alanında bulunur (Stevanato ve ark., 2015). Sarı pancar kist nematodu (*Heterodera betae*) daha az yaygın olsa da pancara zarar verdiği tespit edilmiştir (Vandenbossche ve ark., 2011). Nematodlar

(*Heterodera schachtii*): bitkide kök gelişimini baskılar; verim ve polarizasyonda düşüşe neden olur. Bitkinin yaşı, mevsim sıcaklığı ve popülasyon yoğunluğuna bağlı olarak bitkide büyüme geriliği ve verim kaybı görülür; sıcak dönemlerde yapraklarda belirgin pörsüme/solma meydana gelir. Kök sisteminde, özellikle ince yan köklerde aşırı saçaklanma ve çalılaşmalar ortaya çıkar; yoğun bulaşıklık durumunda bitki tamamen ölebilir. Şeker pancarı kist nematodu ile bulaşık topraklarda yetişen bitkilerde, genellikle bodurlaşma görülür, bitkinin gelişmesi zayıflar, yapraklar küçük kalır. Günün sıcak saatlerinde kökler vasıtasıyla normal su alım düzeni bozulduğundan, solgun bir durum arz ederler. 75 g toprak içindeki her bir canlı kist, dekarda 4 kg şeker ve 25 kg pancar ağırlığı kaybına neden olmakta ve şeker pancarı tarlalarında %50'ye varan ürün kaybı meydana getirebilmektedir. Şeker pancarı kist nematodu karantina etmeni olmamasına rağmen kist nematodları bulaştıktan sonra eradike edilmesi çok zor bir grup olduğundan, karantina tedbirlerinin üzerinde önemle durulmalıdır. Ülkemizde ve bölgede yaygın olarak görülen bu zararlının mücadelesinin zorluğu nedeniyle üretim alanlarında 4 yıllık zorunlu münavebe uygulanmaktadır.

Zararlılar

Bozkurtlar; *Agrotis ipsilon, Agrotis segetum* (Lepidoptera: Noctuidae), tarlada bitki çıkışını takiben toprak seviyesinin hemen altında köklerin kesildiği görülebilir , kök boğazının altından kesilen veya derince yaralanan bitkilerde solgunluk görülmesi, yaprakların sap dibinden kesilmesi veya yaprakların sadece orta damarlar kalacak şekilde yenilmesi şeklinde zarar verirler.

Kalkan Böcekleri (*Cassida* spp.), Ana zararı larvalar yaprakların alt veya üst yüzeylerinde küçük yuvarlak (1-2 mm) yüzeysel yenikler şeklinde yaparlar.

Yaprak bitleri (*Myzus persicae, Aphis fabae*): Emgi zararı ve virüs vektörlüğü yoluyla kaliteyi düşürür.

Yaprak galerisi sinekleri (*Pegomya hyoscyami var. betae*): Yaprak dokusunda galeriler açarak fotosentezi sınırlar.

Sonuç ve Öneriler

Sivas, farklı ilçelere yayılmış geniş şeker pancarı ekim alanları, güvenilir sulama olanakları ve sözleşmeli üretim–fabrika bağlantılarıyla Türkiye'nin şeker pancarı ekonomisi açısından stratejik bir konuma sahiptir. Ancak bu potansiyelin tam olarak değerlendirilebilmesi, fungal hastalıklar, yabancı otlar ve nematodlar başta olmak üzere tüm bitki koruma sorunlarının entegre mücadele ilkeleri doğrultusunda yönetilmesine bağlıdır. En yüksek kazanç; sulama, çeşit seçimi, ekim nöbeti, toprak işleme, yabancı ot kontrolü ve fungusit uygulamalarının, epidemiolojik veriler ve erken uyarı sistemleriyle desteklenen doğru zamanlama çerçevesinde planlanması ile sağlanacaktır.

Geleceğe yönelik sürdürülebilir ilerleme; verim ve polarizasyonu yüksek üretim modellerinin benimsenmesine, entegre bitki koruma uygulamalarının yaygınlaştırılmasına ve çiftçi eğitimlerinin güçlendirilmesine bağlıdır. Bunun için, sulama verimliliğini artıran teknolojilerin benimsenmesi, hastalıklara dayanıklı/toleranslı çeşitlerin kullanımının desteklenmesi, pancar–tahıl ekim rotasyonlarının bölge koşullarına uyarlanması önem taşımaktadır. Sonuç olarak, Sivas'ta şeker pancarı üretim zincirinin; entegre mücadele stratejilerini benimseyen su kaynaklarını koruyan, çiftçi gelirini istikrara kavuşturan bir yaklaşımla yürütülmesi, hem bölgesel rekabet gücü hem de uzun vadeli tarımsal sürdürülebilirlik için temel bir gereklilik olarak değerlendirilmektedir.

ÖZET

Mavi yemiş (*Vaccinium corymbosum*), yüksek antioksidan ve anti-enflamatuar içeriği sayesinde fonksiyonel gıdalar arasında ön plana çıkan değerli bir küçük meyve türüdür. Ancak bu ürün hem vejetasyon süresince hem de hasat sonrası dönemde başta fungal ve bakteriyel etmenler olmak üzere çeşitli patojenlerin saldırısına maruz kalmakta; özellikle *Botrytis cinerea* kaynaklı gri küf ve *Colletotrichum* spp. neden olduğu antraknoz gibi hastalıklar kalite kaybına ve ticari değerinde azalmaya yol açmaktadır. Hastalıklara karşı geleneksel olarak sentetik fungisitler en yaygın kontrol aracı olarak kullanılmakla birlikte, bu kimyasalların insan sağlığı, çevre ve kalıntı problemleri gibi riskleri nedeniyle sürdürülebilir alternatif yaklaşımlar giderek daha fazla önem kazanmaktadır. Son yıllarda, modifiye atmosfer koşulları, ultraviyole (UV) ışın uygulamaları, kitosan ve uçucu yağlar gibi bitkisel kökenli antimikrobiyal bileşikler ile biyolojik mücadelede kullanılan mikrobiyal antagonistler gibi çevre dostu stratejiler ön plana çıkmaktadır. Bu derleme, Türkiye ve dünyada Mavi yemiş üretiminde karşılaşılan başlıca patojenleri analiz etmeyi; ayrıca hem hasat öncesi hem de hasat sonrası dönemde uygulanan kimyasal, fiziksel ve biyolojik kontrol yöntemlerini, bunların muhtemel etki mekanizmalarını ve meyve kalitesi üzerindeki etkilerini bütüncül bir yaklaşımla ele almayı amaçlamaktadır. Bu çalışma ile Mavi yemiş üretiminde sürdürülebilir hastalık yönetimi uygulamalarına katkı sağlanması hedeflenmektedir.

Anahtar kelimeler: *Vaccinium corymbosum*, hastalık etmenleri, Mücadele yöntemleri biyolojik kontrol, sürdürülebilir tarım

1.Giriş

Türkiye, sahip olduğu farklı iklim kuşakları ve zengin ekolojik çeşitliliği sayesinde, çok sayıda meyve türünün farklı bölgelerde ve mevsimlerde başarıyla yetiştirilebildiği nadir ülkelerden biridir (Ercişli, 2004). Bu çeşitlilik içerisinde yer alan Mavi yemiş (*Vaccinium* spp.), son yıllarda hem dünyada hem de Türkiye'de artan bir ilgi görmektedir. Özellikle,yüksek boylu bir tür olan *Vaccinium corymbosum* içerdiği biyolojik aktif bileşikler açısından zengin bir profille ön plana çıkmaktadır. Bu bileşikler arasında yer alan antikanserojen etkili bir fenol olan ellajik asit, flavonoid sınıfına ait antosiyaninler, kersetin, kaempferol ve mirisetin gibi bileşenler güçlü antioksidan ve anti-inflamatuar özellikler göstermektedir (Michalska ve Łysiak, 2015). Modern yaşamın getirdiği oksidatif stres ve kronik hastalık yüküne karşı koruyucu etkileri, Mavi yemişnin tüketimini teşvik eden başlıca etkenlerden biridir (Kılıç Topuz, 2019; Tosun ve Yüksel, 2003).

Tarım açısından bakıldığında, *Vaccinium* spp. türleri küçük meyveli, mavimsi-mor (yüksek boylu) veya kırmızı (alçak boylu) tanelere sahip çalı formlu bitkilerdir. Kültürü yapılan başlıca türler; yüksek boylu (*V. corymbosum*), alçak boylu (*V. angustifolium*) ve tavşan gözü (*V. virgatum*) Mavi yemiş çeşitleridir (Defilippi ve ark., 2017). Meyvenin küçük yapısı ve ince kabuğu, hasat öncesi ve sonrası dönemde özellikle sıcaklık ve bağıl nem gibi çevresel faktörlere karşı duyarlılığını artırmakta ve bu koşullar altında fungal ve bakteriyel patojenlerin gelişimiyle %20'lere varan ürün kayıpları meydana gelebilmektedir.

TÜİK (2023) verilerine göre, 2022 yılı itibarıyla Türkiye'de 4.197 dekar alanda yaklaşık 5.200 ton Mavi yemiş üretimi gerçekleştirilmiştir. Yetiştiricilik esas olarak Karadeniz, Marmara ve Doğu Anadolu bölgelerinde yoğunlaşmakta olup, bu bölgelerdeki düşük pH'lı (asidik) toprak yapısı ve serin iklim koşulları, bitkinin morfolojik ve fizyolojik gereksinimlerini büyük ölçüde karşılamaktadır. Dünya genelinde ise ABD, Kanada, Şili, Polonya ve Almanya başta olmak üzere birçok ülkede üretim yoğun şekilde artmakta ve FAOSTAT (2023) verilerine göre küresel Mavi yemiş üretimi 1,7 milyon metrik tonu aşmış durumdadır. Türkiye'nin bu potansiyelden daha fazla pay alabilmesi, entegre üretim sistemlerinin geliştirilmesi ve sürdürülebilir hastalık yönetimi stratejilerinin benimsenmesiyle mümkün olacaktır. Mavi yemişin üreticiler tarafından benimsenmesinde; erkencilik (dikimden sonraki yılda ürün verebilme), sanayiye uygun işlenebilirlik, aile işletmeleri için uygunluk, estetik meyve görünümü ve yüksek birim fiyat gibi önemli avantajlar etkili olmaktadır (Ağaoğlu, 1986; Kılıç Topuz, 2019).Mavi yemişe yönelik küresel talebin hızla arttığı günümüzde, hastalık etmenlerinin biyolojisini ve epidemiyolojisini anlamak, bitkinin savunma mekanizmalarını çözümlemek ve entegre mücadele stratejileri geliştirmek temel bir gereklilik haline gelmiştir.

Bu derleme, hasat öncesi ve sonrası dönemde karşılaşılan başlıca patojenleri, hastalıkların etki mekanizmalarını, konukçu savunma tepkilerini ve mevcut kontrol stratejilerini literatür temelli bir yaklaşımla incelemeyi amaçlamaktadır. Böylece hem akademik bilgi birikimine katkı sağlanması hem de Mavi yemiş üretim sistemlerine uygulanabilir öneriler sunulması hedeflenmektedir.

2. Mavi Yemişte Önemli Patojenler

Mavi yemiş üretim sistemleri hem vejetatif büyüme dönemi boyunca hem de hasat sonrası süreçte çeşitli fitopatojenlerin baskısıyla karşı karşıya kalmaktadır. Özellikle fungal, bakteriyel ve viral kaynaklı hastalıklar, uygun çevresel koşullarda epidemi oluşturarak meyve kalitesini ve pazarlanabilirliğini ciddi biçimde tehdit etmektedir. Bu bölümde, Mavi yemişde en yaygın görülen ve ekonomik kayıplara neden olan başlıca patojenler, biyolojik özellikleri ve enfeksiyon dinamikleri açısından analiz edilmiştir.

2.1. Fungal Hastalık etmenleri

2.1.1. Gri küf (*Botrytis cinerea*)

Gri küf (*Botrytis cinerea*), 1400'den fazla bitki türünü etkileyen, geniş bir konukçu yelpazesine sahip nekrotrofik bir fungustur hem hasat öncesi hem de hasat sonrası Mavi yemişi etkileyen önemli bir patojendir (Roca-Couso ve ark, 2021; Rui ve ark, 2023; Li ve ark, 2023). *B. cinerea,* Mavi yemişte hem çiçeklenme hem de meyve olgunlaşma döneminde özellikle %90'dan fazla bağıl nem ve 15–20°C sıcaklıkta optimum gelişme gösterir. Gri renkli miselyal örtü ve sporulasyon ile karakterize edilen bu hastalık, hasat sonrası taşımada ve depolama sürecinde de meyvelerin çürümesine yol açar. Mavi yemişte bu etmenle oluşan kayıplar %30 40'a kadar çıkabileceği rapor edilmiştir (Polashock, ve ark. 2017). Bu hastalığın belirtileri çiçeklerde, yapraklarda ve meyvelerde görülür. Başlangıçta meyvede küçük, sert, açık kahverengi lezyonlar gelişir ve bunlar hızla genişler ve gri renkli misel tabakasıyla kaplanır. Çiçeklerde çürüme semptomları görülür ve şiddetli enfeksiyonlar sonucunda tamamen solmaya yol açar. Yapraklarda kahverengi-gri lezyonlar oluşur ve yüksek nem koşulları altında bu lezyonlarda gri miselyum ve konidi kitleleri gelişebilir (Kwon ve ark., 2011). Gri küf, Mavi yemişte yalnızca doğrudan çürümeye neden olmakla kalmaz, aynı zamanda su kaybını ve besin bozulmasını hızlandırarak raf ömrünü de azaltır. Gri küf, büyüme ve meyve gelişiminin ilk aşamalarında latent bir enfeksiyon süreci gösterir ve hasat sonrası dönemde belirtiler gösterir. Olgun meyvelerde hastalık belirtileri, meyvenin yumuşaması, meyve suyu salınımı, susuz kalma ve gri renkli miselyum kütlesinin gelişmesiyle karakterizedir (Rivera ve ark., 2013). *B. cinerea,* toksin üretimi, oksijene reaktif türler, parçalayıcı enzimlerin üretimi ve programlanmış hücre ölümü indüksiyonu gibi virülans faktörlerini aktive ederek meyve dokusunda ölüme neden olur (Williamson ve ark., 2007). In vitro kültürde, başlangıçta beyaz koloniler oluşturur ve daha sonra renk gri veya kahverengiye döner ve siyah sklerotlar üretir. Konidioforlar ince ve dallıdır, konidia ise oval ila yuvarlak şekillidir (Li ve ark,2011; Chean ve ark, 2013; Saito ve ark,2016; Apolonio- Rodríguez ve ark., 2017). Işık mikroskobu altında, uzun konidioforlar, septalı, pürüzsüz, apikal olarak dallanmış ve konidia demetleri görülebilir. Konidia, yaklaşık 8–15 µm çapında, tek hücreli, oval, pürüzsüz ve küresel formdadır (Fillinger ve Elad, 2015). Fungus, düşük sıcaklıklarda (0–4 °C) ve nemli koşullarda aktif kalır ve bu da Mavi yemişin hasat sonrası depolanması sırasında %60–100 gibi yüksek gri küf görülme oranlarına yol açar (Mamode ve ark., 2021).

Türkiye'de Akdeniz/Doğu Anadolu bölgelerinin bahar ve yaz dönemlerinde nemli gece koşulları göstermesi nedeniyle, *B. cinerea'*nın hem hasat öncesi çiçek dönemi hem de hasat sonrası süre için potansiyel risk oluşturmaktadır. Latent enfeksiyonlara karşı erken uyarı sistemlerinin geliştirilmesi hastalıkla mücadelede önemli bir faktör olarak görülmektedir.

Gri küf yönetimi: Hasat öncesi hava sirkülasyonunun artırılması, hasat sonrası hızlı soğutma, UV-C ışınlama, kitosan kaplama ve biyolojik ajanlar (*Trichoderma harzianum* vb.) kullanımı olarak sıralanabilir.

2.1.2. Antraknoz (*Colletotrichum* spp.)

Colletotrichum acutatum ve *C. gloeosporioides* türleri Mavi yemişte antraknoz enfeksiyonlarının başlıca etmenleri arasında yer alır. Hastalık nemli ve sıcak iklim koşullarında hızla yayılır. Meyvelerde batık lekeler ve meyve çürüklüğü şeklinde görülür. Yapraklarda ise kıvrılma ve erken dökülme söz konusu olabilir. Mavi yemişte antraknoz kaynaklı kayıplar %10 20 düzeyinde bildirilmiştir. Mavi yemişler, çiçeklenmeden hasada kadar herhangi bir anda enfekte olabilir. *Colletotrichum* türleri, meyve olgunlaşmaya başlayana kadar latent evrede kalır. Mavi yemişnde antraknozun ana belirtisi, hasat sırasında ve sonrasında meyvenin

çürümesidir. Bu çürüme, meyve yüzeyinde çökük alanlar ve ardından pembe veya somon rengi konidial kitle yayan acervuli oluşumuyla kendini gösterir (Siddiqui ve Ali, 2014). İnvitro koşullarda *Colletotrichum* spp. gelişmesi 18 ila 30 °C arasında gerçekleşir. Koloni gelişimi genellikle pamuksu beyazdan griye kadar değişen bir renge sahiptir ve türe bağlı olarak renkleri değişen eş merkezli halkalar şeklinde büyür (Bordoh ve ark., 2020).

Antraknoz Yönetimi. Hastalık öncelikle fungisit uygulamasıyla kontrol altına alınır. Uygulamalar tam çiçeklenme döneminde başlatılmalı ve 7-10 günlük aralıklarla devam ettirilmelidir. Meyve salkımları etrafında iyi bir hava sirkülasyonu önerilir. Uygun hava koşullarında hastalıklı meyveden sağlam meyvelere hızlı yayılmayı önlemek için meyveler sık sık toplanmalıdır. Yoğun azotlu gübreleme, hastalık insidansını artırma eğilimindedir. Berkeley, Bluecrop, Blueray, Coville ve Jersey oldukça hassastır bu nedenle hastalığa dayanıklı çeşitlerin dikimi tercih edilmelidir.

2.1.3. Meyve çürümesi (*Alternaria* spp.)

Alternaria spp. meyveye yaralar, doğal açıklıklar veya doğrudan konukçunun kütikülündeki bir yırtık yoluyla nüfuz edebilen fırsatçı saprofit bir fungustur (Troncoso-Rojas ve ark., 2014). Meyve çürüme belirtileri, meyvede koyu ve çökük yaralar, beyazdan yeşilimsi griye kadar miselyum ve yeşil zeytin konidial büyümesi ile karakterizedir. (Zhu ve Xiao, 2015). *Alternaria* spp., bitki patolojisini ve gıda güvenliğini etkileyen çeşitli toksinler içeren ikincil metabolitler üretir. Bu toksinler arasında en önemlileri tenuazonic asit, alternariol ve alternariol monometil eterdir (Munitz ve ark., 2013). *Alternaria* spp, 20 ila 30 °C arasında, optimum gelişme gösterir, koloniler genellikle koyu yeşil renktedir ve merkezlerinde hif kilitleri bulunan pamuksu bir görünüme sahiptir (Zhu ve Xiao, 2015). Sporlar oval şekilli olup, enine duvarlar ve dikeylerle bölünmüştür, el bombasını andırır ve boyutları türe bağlı olarak 13 ila 15,0 µm arasında değişir.

Hastalık Yönetimi: *A. alternata* gibi türler, Mavi yemişte geç dönem yaprak lekeleri ve meyve çürümeleri oluşturabilir. Meyvede koyu renkli, dairesel lekelerle karakterize olur. Özellikle depolama sürecinde latent enfeksiyonlar aktive olabilir. Hasattan sonra soğuk zincirin bozulmaması, meyvelerde biyofilm kaplama ve fitokimyasallarla koruma mücadelede önerilmektedir.

2.1.4. Mumya meyvesi (*Monilinia vaccinii-corymbosi*)

Bu hastalık genellikle her yıl görülür, ancak şiddeti yıldan yıla büyük ölçüde değişir. Mayıs ayındaki serin ve yağmurlu hava, fungusun enfeksiyonunu kolaylaştırır. Patojen *Monilinia vaccinii-corymbosi'nin* iki enfeksiyon evresi vardır. Kışlayan askosporlar, yeni çıkan tomurcukları enfekte ederek yaprak ve sürgün yanıklığına neden olur. Bu enfekte dokuda üretilen konidyumlar daha sonra çiçekleri ve genç meyveleri enfekte eder. Enfekte meyveler açık ten rengi veya pembedir ve sertleşen meyveler buruşup yere düşer.

Mumya meyvesi hastalığının yönetimi. Hastalığın yönetimi birkaç strateji içerir, en önemlisi sanitasyondur. Mumyalar tırmıklanıp küçük dikimlerde atılmalıdır. Hassas Bluehaven, Bluegold, Coville, Northblue ve Sierra çeşitlerin dikiminden kaçınılmalıdır. Bluejay, Bleucrop, Darrow, Duke, Elliott, Jersey ve Stanley hastalığın sürgün yanıklığı evresine dayanıklıdır. Fungisit uygulamaları birincil enfeksiyona karşı hedeflenmelidir; yeşil uç büyüme aşamasında ilk uygulama 10 gün sonra ikinci bir uygulama ile takip edilmelidir. İkincil enfeksiyonu kontrol etmek için çiçeklenme sırasında ek fungisitler uygulanabilir. Genel olarak, bitkinin toprak üstü kısmını etkileyen fungal hastalıklar, bitkilerin etrafında iyi hava sirkülasyonu sağlamak için doğru dikim ve düzenli budama ile daha etkili bir şekilde yönetilebilir. Ayrıca, bitkileri sularken damla sulama tercih edilir. Yağmurlama sulama kullanılıyorsa, yaprakların, çiçeklerin ve meyvelerin hızlı kurumasını sağlamak için bu uygulama sabahın erken saatlerinde yapılmalıdır.

2.1.5. Phomopsis dal yanıklığı (*Phomopsis vaccinii*)

Hastalık, bitkiler soğuk veya kuraklık hasarı nedeniyle strese girdiği dönemlerde daha sık görülür. *Phomopsis vaccinii* gövdelerde küçük kanserler oluşturabilir veya tüm dallar, özellikle gövdedeki birkaç lezyon birbiriyle birleştiğinde dallarda ölüm görülebilir. Patojen ayrıca nadiren meyve çürümesine de neden olabilir.

Phomopsis dal yanıklığının yönetimi: Hastalık, yanlış budama veya toprak işlemeden kaynaklanan bitki hasarlarından kaçınılarak yönetilebilir. Kuraklık stresinden kaçınmak için bitkiler sulanmalıdır. Büyüme mevsimi boyunca fungisit uygulamaları inokulum baskısını azaltmaya ve enfeksiyonu önlemeye yardımcı olsa da, en önemli fungisit uygulaması uyku halindeki kireç-kükürt uygulamasıdır. Sonbaharda yaprak dökülmesinden sonra uygulanabilir, ancak tomurcuklar uyku halinden çıkmadan önce kış sonu veya ilkbahar başında uygulandığında daha etkilidir. Tomurcuklar büyümeye başladıktan sonra uygulamadan kaçınılmalıdır, aksi takdirde genç doku zarar görür. Sezon sonu büyümesi engellenmeli ve doğru gübre kullanımıyla bitkilerin erken sertleşmesi teşvik edilmelidir. Dayanıklı olduğu bilinen çeşitlerin dikimine özen gösterilmelidir.

2.1.6. Phytophthora kök çürüklüğü (*Phytophthora cinnamomi*)

Phytophthora kök çürüklüğü (*Phytophthora cinnamomi*), Mavi yemiş tarlasındaki drenajı yetersiz alanlarda daha fazla görülür. Kök sistemleri patojen tarafından enfekte edilip kök miktarı azaldıkça, bitkiler sonunda bodurlaşıp renksizleşecek ve meyve üretimi önemli ölçüde azalacaktır. Bitkinin tamamı, bazen tek bir yetiştirme sezonu içinde ölebilir. Etkilenmiş bitkiler seyrekleşmeye başlar ve her yıl daha az sürgün oluşturur. Enfekte bitkiler genellikle yapraklanır, çiçek açar ve meyve tutmaya başlar; ancak meyveler olgunlaşmadan önce sürgünler ölür, yapraklar kırılgan hâle gelir ve sararır; üzerinde kahverengimsi-kırmızı çizgiler görülür. Gelişmekte olan meyveler kurur ve buruşur. Hastalık etmeni *P. Cinnamomi*, toprakta doğal olarak bulunabilir, uzun yıllar canlılığını koruyabilir, sulama suyu ile; makineler, aletler, ayaklar ve enfekte bitkilerle hızla yayılabilir.

Phytophthora kök çürüklüğünün yönetimi. Hastalık, doğru yer seçimi ile önlenebilir. Ağır killi topraklar ve uzun süre su birikintisi olan alçak alanlara dikim yapılmamalıdır. Tarlanın sorunlu bölgelerinde drenaj iyileştirilmelidir. Geçmişte kök çürüklüğü sorunu yaşanmışsa veya drenaj optimumdan düşükse, ekim sırasında Metalaxyl (Ridomil) veya Fosetyl-Al (Aliette) kullanılmalıdır. Enfekteli plantasyonlarda kök çürüklüğünü kontrol edebilecek fungisitler mevcuttur; ancak bu fungisitler oldukça pahalıdır ve hastalığı kontrol etmede, yükseltilmiş yastıklar ve dayanıklı çeşitler kullanımı kadar etkili değildir.

2.1.7. *Penicillium* spp.

Penicillium expansum, hasat sonrası çürüklükte sorumlu en yaygın türlerdendir. Özellikle soğuk depolama sırasında düşük sıcaklık toleransı ile gelişebilir. Mikotoksin (patulin) üretme potansiyeli açısından halk sağlığı için de risk teşkil eder.

Hastalık Yönetimi: Yüzey dezenfeksiyonu, kontrollü atmosfer (CA) teknolojileri kullanmak önerilmektedir.

2.1.8. *Cladosporium* spp.

Mavi yemişte yaprak ve meyve üzerinde siyah leke oluşumuna neden olabilir. Özellikle nemli koşullarda hızlı gelişim gösteren *Cladosporium herbarum*, estetik kaliteyi düşürerek pazarlanabilirliği azaltır.

2.2. Bakteriyel Hastalık etmenleri

Pseudomonas syringae* ve *Xanthomonas spp.

Yapraklarda nekrotik lekelere, sürgün uçlarında kurumaya ve çiçek yanıklıklarına neden olabilen bakteriyel hastalıklar, özellikle ilkbahar yağışları ve dolu sonrası yaralanmalarla yayılmaktadır. Türkiye'de henüz sınırlı raporlanmış olmakla birlikte, ABD ve Avrupa ülkelerinde ciddi ekonomik kayıplara neden olmaktadır. Hastalıkla mücadele stratejisi: Bakırlı preparatlar, biyolojik ajanlar (*Bacillus subtilis*), enfekte doku uzaklaştırması olarak sıralanabilir.

Mavi yemişin hasat sonrası kayıpları, toprak veya su yoluyla bulaşabilen *Salmonella typhimurium, Escherichia coli* ve *Listeria monocytogenes* gibi Gram pozitif veya Gram negatif patojenik bakterilerin saldırısından da kaynaklanmaktadır (Zhang ve ark., 2021). Bu bakteriler, su, toprak veya hava yoluyla yayıldıktan sonra bitkiye doğal açıklıklar veya yaralar yoluyla girebilir. Ayrıca Mavi yemişin üretimi ve hasat zinciri sırasında, meyvenin bu patojenler tarafından kontaminasyonunun çeşitli kaynakları vardır (Cao ve ark., 2017). Fungal patojenlerden daha az ölçüde etkili olsa da, bu mikrobiyal patojenler yalnızca meyvenin kalitesini düşürmekle kalmaz, aynı zamanda tüketicilerde sağlıkları için ciddi sonuçlar doğuran gıda reaksiyonlarına da neden olabilir. Dolayısıyla, bu patojenlerin saldırısını kontrol altına almanın ve önlemenin önemi, meyveye büyümesinin farklı aşamalarında zarar verebilir.

2.3.Viral hastalıklar ve vektörler

Mavi yemiş bitkilerinde yaygın olarak görülen virüsler, Blueberry scorch virus (BlScV) — Carlavirus, Blueberry shock virus (BlShV) — Ilarvirus, Blueberry shoestring virus (BSSV) — Sobemovirus, Blueberry red ringspot virus (BRRV) — Soymovirus, Caulimoviridae (pararetrovirüs), Blueberry necrotic ring blotch virus (BNRBV) — Kitavirus, Blueberry leaf mottle virus (BLMoV) — Nepovirus. Blueberry mosaic-associated virus (BlMaV) — Ophiovirus, Mavi yemişte görülen halkalı leke Nepovirüsleri: Tobacco ringspot virus (TRSV) & Tomato ringspot virus (ToRSV) — Nepovirus olarak sıralanmaktadır. Ülkemizde 2025 yılında yapılan bir çalışma ile Karadeniz bölgesinde BlMaV ve BLMoV virüsleri rapor edilmiştir. Bu virüslerden Scorch (BlScV): Duyarlı çeşitlerde %80'e varan verim kaybı, Shoestring (BSSV) ise Enfekteli bitkilerde yaklaşık %25'e kadar verim kaybına neden olduğu bilinmektedir. Virüsler vektörler vasıtasıyla yayılım gösterirler örneğin; afitler (BlScV, BSSV), polinatörler/polen (BlShV), eriophyid akarlar (BNRBV), hançer nematodları (TRSV/ToRSV), aşı/çoğaltım (BRRV, BlMaV) ile yayılırlar. Ayrıca, sertifikasız ve hastalıklı çoğaltım materyali (fidan/çelik) kullanılmasında çoğu virüslerin yayılmasında önemlidir. Virüs hastalıkları ile mücadelede hastalıklı üretim materyalinin imhası ve vektörle savaş esastır.

3. Hasat Öncesi ve Sonrası Entegre Mücadele Yöntemleri

3.1.1. Kültürel Önlemler

Hava sirkülasyonunun artırılması: Bitkiler arası mesafe ve budama uygulamalarıyla nemli mikroiklim koşulları azaltılarak *B.cinera* ve *Colletotrichum* spp. gibi nem seven patojenlerin gelişimi sınırlandırılabilir. Bitkiler arası uygun mesafe bırakılması, yoğun sürgünlerin budanarak hava sirkülasyonunun artırılması ve yaprak dokusunun uzun süre nemli kalmasını önleme gibi uygulamalar, hem hastalık etmenlerinin başlangıç inokulumunu azaltmak hem de mikro-iklimi patojenler için daha az elverişli hâle getirmek açısından önemlidir. Çiçek/çiçeklenme sonrası kalan bitki kalıntılarının uzaklaştırılması, latent enfeksiyon kaynaklarının bastırılmasında etkilidir. Damlama sulama yaparak, yaprak yüzeyinin daha az

ıslanmasını sağlamak özellikle sporların su yardımıyla taşınmasını önlemeye yardımcı olur. Bu yaklaşım, özellikle nemin yüksek olduğu bölgelerde patojen baskısını azaltmada etkilidir.

3.1.2. Kimyasal Mücadele

Sentetik fungisitler (fenilpirazol, strobilurin grubu) hâlen birçok ülkede kullanılsa da, kalıntı sorunları ve direnç gelişimi nedeniyle kontrollü ve rotasyon esasına dayalı kullanım önerilmektedir. Geleneksel fungisit uygulamaları patojenlerde fungisit direnç gelişimi konusu ciddi bir sorun olarak literatürde yer almaktadır.

Mavi yemişteki gri küfü kontrol altına almak için benzimidazoller, dimetilimidazoller, triazoller, strobilurinler ve süksinat dehidrogenaz inhibitörleri (SDHI'ler) dahil olmak üzere çeşitli fungisitler kullanılmıştır. Her fungisit farklı mekanizmalar aracılığıyla etki eder (Shao ve ark., 2021). Örneğin, benzimidazol fungisitleri öncelikle patojenlerde mikrotübül proteinlerinin sentezini engelleyerek mitozlarını bozar ve böylece fungisidal etki gösterir (Oliveira ve ark., 2017). *B. cinerea*'nın manganez inhibitörleri ya da strobilurin grubu fungisitlere karşı direnç geliştirdiği bildirilmiştir (Saito ve ark., 2016). Gri küfü kontrol altına almak için aktif bileşenlerin geliştirilmesinde son zamanlarda ilerlemeler kaydedilmiştir. Benzovindiflupir gibi bazı yeni fungisitler, gri küfe karşı güçlü inhibitör aktivite göstermektedir (He ve ark.,2018). Potasyum bikarbonat, kalsiyum şelatlar ve sodyum silikat gibi tuz çözeltileri, fungus yapısını ve hücresel işlevleri değiştirerek *B. cinerea* üzerinde dikkate değer inhibitör etkiler göstermiştir (Youssef ve ark., 2019). *B. cinerea'*ya karşı belirgin aktiviteye sahip yeni bileşiklere ilişkin diğer raporlar arasında benzoylurea'nın belirli türevleri pirimidin, flavonoid ve 1,2,4-triazolo [4,3-c]triflorometilpirimidin yer almaktadır; bu moleküllerin daha fazla incelenmesi, gri küfe karşı yeni fungisitlerin geliştirilmesini sağlayabilir (An ve ark.,2023; Pan ve ark.,2024; Meng ve ark., 2024). Birden fazla fungisite karşı direncin ortaya çıkması, *B. cinerea'*da fungisit direncinin yaygınlığı artmaya devam ettikçe Mavi yemiş gri küfünün yönetimi için önemli bir zorluk oluşturmaktadır (Shao ve ark., 2021; Oliveira ve ark., 2017). Michigan'da yürütülen bir çalışmada, özellikle piraklostrobin ve difenokonazol için azalmış duyarlılık sıklıkları ile birlikte, birden fazla fungisite karşı artan bir direnç sıklığı bildirilmiştir (Baral ve ark., 2025). Benzer şekilde, Pasifik Kuzeybatısı'nda, *B. cinerea,* SDHI fungisitlerine karşı direnç geliştirmiştir ve belirli mutasyonlar çeşitli SDHI aktif bileşenlerine karşı çapraz dirençle sonuçlanmıştır (Abbey ve ark., 2024). Bu, direnci etkili bir şekilde yönetmek için dengeli fungisit kullanımı ve fungisit rotasyonu uygulanmalıdır.

Özellikle *B. cinerea* Gri küf yönetiminde hastalığın oluştuğu iklim ne çevre koşullarını belirlemek fungisit uygulamalarını azaltmak bakımından oldukça önemlidir. Şili'de yapılan bir çalışmada mavi yemişlerde gri küf kontrolü için geliştirilen bir modelin daha düşük gri küf görülme sıklığıyla sonuçlandığı bildirilmiştir. Çalışma, erken tahmin uyarı sisteminin (DSS) kullanılmasının eşit veya daha az fungisit kullanımıyla etkili gri küf kontrolü sağladığını göstermiştir (Van der Marwe ve ark., 2022). *B. cinerea* enfeksiyonunun erken ve en az zarar oluşumunu tespiti için hiperspektral görüntüleme (HSI) uygulamaları da araştırılmıştır. HSI ve kemometrik analizin entegrasyonu, depolama sırasında fungusla enfekte olmuş meyvelerin hızlı ve zararsız değerlendirilmesi için önemli bir potansiyel göstermiştir (Hanghbin ve ark., 2023).

Kimyasal mücadele, en eski ve en ucuz yöntemlerden biri olmasına rağmen, meyve kalitesi açısından iyi sonuçlar vermektedir. Bununla birlikte, çevre ve insan sağlığı açısından önemli sonuçları vardır.

3.1.3. Biyolojik Mücadele

Hasat öncesi uygulamalarda biyolojik ajanların kullanılması, latent enfeksiyonları önlemeye yardımcı olur; bu da hasadın kalitesini ve raf ömrünü olumlu yönde etkiler. *Trichoderma harzianum*, *Bacillus subtilis* ve *Pseudomonas fluorescens* gibi mikrobiyal ajanlar, bitki yüzeyinde rekabet ve antibiyotik üretimi yoluyla patojen gelişimini baskılamaktadır. Bazı mikrobiyal preparatlar, bitkide sistemik direnç (ISR) yanıtını da uyararak koruyucu etki sağlar. Mikrobiyal antagonistler, biyolojik mücadelede önemli bir yer tutar. *Trichoderma asperellum* TM11 izolatının, Mavi yemiş kök çürüklüğü etmeni üzerindeki etkisi detaylı olarak incelenmiş ve hastalık kontrolünde ümitvar bulunmuştur (Li ve ark.,2023). Gomes ve ark 2023 yılında yaptıkları çalışmada yerel mikrobiyal toplulukların karakterizasyonu da biyolojik mücadelenin etkinliğini artırmak açısından araştırıcılar ve Mavi yemiş rizosferinde *Trichoderma* sp. ve *Bacillus* sp. gibi faydalı mikroorganizmaların izole edildiği bildirilmişlerdir. Kurniawan ve ark. (2018), Mavi yemiş meyvelerinde, in vitro koşullarda *Bacillus* sp.ve *Pseudomonas* sp. kullanılmışlar, bakterilerin etki mekanizmasının bir parçası olarak antimikrobiyal özelliklere sahip peptit kökenli bileşikler ürettiğini ve *B. cinerea* ve *A. alternata* için sırasıyla %42 ve %27'lik değerlerle in vitro büyümesini engellediğini bildirmişlerdir.

Trichoderma sp. meyvelerde fungusların neden olduğu hastalıkları engelleme kapasitesi nedeniyle, Mavi yemişin hasat sonrası hastalıklarını kontrol eden en önemli antagonist tür olarak kabul edilir (Romero-Arenas ve ark., 2017). Ayrıca, antibiyotik üretmedikleri, toksik olmadıkları ve çevreyi kirletmedikleri *için Debaryomyces hansenii, Meyerozyma caribbica, Rhodotorula minuta* gibi mayaların etkisini inceleye araştırmacılar, ana etki mekanizmalarının antibiyotik olduğunu ve uçucu bileşiklerin üretimi ile direnç indüksiyonu olduğunu bilidirmişlerdir. Yapılan çalışmada izole edilen bakterilerin etki mekanizmasının bir parçası olarak antimikrobiyal özelliklere sahip peptit kökenli bileşikler ürettiğini ve *B. cinerea* ve *A. alternata* için sırasıyla %42 ve %27'lik değerlerle in vitro büyümesini engellediğini bildirmişlerdir (HernándezMontiel ve ark., 2018). *Bacillus* sp*, Streptomyces* sp*, Pseudomonas* spp. ve *Candida oleophila* dahil olmak üzere çeşitli mikroorganizmaların mahsullerde gri küfü kontrol ettiği bilinmektedir. Besin rekabeti, hifsel parazitizm, indüklenen sistemik direnç ve doğal antagonistik bileşikler yoluyla hasat sonrası gri küfün biyolojik kontrolünü sağlarlar (Wang ve ark., 2022). Özellikle, Mavi yemişten izole edilen *Bacillus siamensis* YJ15 suşunun, *B. cinerea* ve 11 diğer bitki patojenik fungusları etkili bir şekilde inhibe eden uçucu organik bileşikler (VOC'ler) ürettiği bulunmuştur.

3.2. Hasat Sonrası Uygulamalar

Mavi yemiş meyveleri, ince kabuk yapısı ve yüksek nem içeriği nedeniyle hasat sonrası dönemde hızla bozulabilmektedir. Bu nedenle patojen gelişimini engelleyici hasat sonrası yapılacak uygulamalar kritik önemdedir.

3.2.1. Soğuk Zincir Yönetimi

Hasat sonrası en hızlı uygulanabilen yöntemlerden biridir. Hızlı ön soğutma (0–4 °C), patojen gelişimi ve solunum hızını yavaşlatarak raf ömrünü artırır. Mavi yemiş meyvelerinde 0-4 °C sıcaklık ve yüksek bağıl nem (%90-95) koşullarının sağlanması, solunum hızını ve patojen gelişimini azaltmada etkilidir. Bir çalışmada kitosan, nano-kaplama uygulamasının soğuk depolama ile kombinasyonunda meyvede ağırlık kaybının %2.22 gibi düşük bir düzeyde kaldığı bildirilmiştir (Li ve ark., 2021).

3.2.2. Modifiye Atmosfer ve Kontrollü Atmosfer

Mavi yemişin hasat sonrası raf ömrünü uzatmak için kullanılan modifiye atmosfer ve kontrollü atmosferler teknolojileri, depolama ve taşıma sırasında gaz bileşiminin (O2 ve CO2) değiştirilmesine dayanmaktadır (Defilippi ve ark, 2017). Düşük O_2 (1–5%) ve yüksek CO_2 (10–20%) ortamında meyveler muhafaza edilerek spor gelişimi ve etilen üretimi baskılanabilir. *Colletotrichum* ve *Penicillium* gibi aerobik patojenlere karşı etkilidir. Düşük O_2 ve yüksek CO_2 içeren atmosferlerde, meyve solunumu baskılanır, etilen üretimi azalır ve aerobik patojenlerin gelişimi gecikir. Şu ana kadar bildirilenlere göre, hastalık kontrolünde rol oynayan Mavi yemiş meyvesinin fiziksel ve kimyasal özelliklerini koruma yöntemi olarak modifiye edilmiş ve kontrollü atmosferler kullanılmaktadır. Bununla birlikte, bu teknolojinin antimikrobiyal etkisini artırmak için UV radyasyonu, kükürt dioksit, 1-metilsiklopropen veya antioksidan aktiviteye sahip bileşikler gibi diğer yöntemlerle birleştirilmesi gerekmektedir (Chiabrando ve Giacalone, 2011; Follett ve Neven, 2020; Rodriguez ve Zoffoli, 2016).

UV Uygulamaları

UV C ışınlama ve ozon uygulamaları, yüzeydeki patojen sporlara doğrudan etki ederek çürüme başlangıcını geciktirebilir. Literatürde UV C uygulamalarının Mavi yemiş gibi küçük meyvelerde bakteri/mikrobiyal yükü düşürmede başarılı olduğuna dair bulgular yer almaktadır. Bu fiziksel uygulamalardan önce meyve yüzeyinin hasarsız ve temiz olması, etkinliğin artmasına katkı sağlar. Özellikle *B. cinerea* ve *Alternaria* sp. için etkili olduğu bilinmektedir. Ozon uygulamaları: Oksidatif stres yaratarak mikrobiyal hücre duvarını tahrip eder. Latorre ve ark., (2012), Mavi yemişden izole edilen *B. cinerea, C. cladosporioides ve C. herbarum* konidiyaları üzerindeki UV-A, UV-B ve UV-C radyasyonunu değerlendirerek orta ve kısa ışık kullanarak çok daha büyük bir etki elde edilebileceğini ve bu fungus türlerinin popülasyonunun azaltılabileceğini kanıtlamıştır. Öte yandan, diğer araştırmalar bu yeni teknolojinin hasat sonrası çürümeyi %10 oranında iyileştirebileceğini bildirmiştir (Nguyen ve ark., 2014). Son zamanlarda yapılan bir değerlendirme (Yang ve ark., 2019), hasat sonrası Mavi yemişe uygulanan UV-C radyasyonunun DPPH antioksidan kapasitesini ve süperoksit dismutazı kontrole kıyasla sırasıyla %33 ve %54 oranında artırdığını doğrulamaktadır. İşlem görmüş meyvelerdeki antosiyanin içeriği %23,7 artmıştır; bu, bitkinin savunmasında rol oynayan bir parametredir ve kalitesini daha uzun süre korur.

Kitosan, Bitki ekstrakları ve Uçucu Yağ Uygulamaları

Son yıllarda, patojen popülasyonunu azaltmak amacıyla yararlı mikroorganizmalar ve hasat sonrası dönemde patojenleri kontrol etmek için alternatif bir biyopolimer olan kitosan gibi diğer doğal kökenli bileşiklerin kullanılmasıyla biyolojik mücadele yöntemlerinin kullanımı artmıştır (Gutierrez-Martinez ve ark., 2018). Yüksek biyolojik değere sahip uçucu yağlar ve bitki extratları da sentetik fungisitler yerine hasat sonrası hastalıkların kontrolünde etkili bir alternatif olarak kabul edilmektedir.

Mavi yemiş meyvelerinde kitosan bazlı kaplamaların uygulandığı çalışmalarda, fiziksel bariyer oluşturarak, anti-mikrobiyal etki gösterdiği ve raf ömrünü uzattığı bilinmektedir. Li ve ark (2021), yaptıkları çalışmada nano-kitosan film uygulamasında yeşil / mavi renk kaybı, ağırlık kaybı ve mikrobiyal popülasyon artışının bastırıldığı bildirilmiştir. Çalışmalarda kitosan ile birlikte salisilik asit uygulamasının, *B. cinerea*'ya karşı etkili olduğu gösterilmiştir. Vieira ve ark. (2016), kitosanın Mavi yemiş meyvelerinin kaplaması için aloe vera ile birlikte kitosanı kullanmışlar ve *B. cinerea* büyümesinde yaklaşık %50 oranında bir azalma, su kaybında azalma ve fenolik bileşik içeriğinde artış elde etmişlerdir. Kitosanın diğer bileşiklerle birlikte kullanımı inceleyen Yang ve ark., (2014) Mavi yemiş yapraklarından elde edilen biyolojik

değere sahip bir özütü kitosan ile karıştırarak kullanmışlar ve bu kombinasyonun meyvelerin hasat sonrası raf ömrünü 2 °C ve %95 bağıl nemde 35 gün uzatmaktığını bildirmişlerdir. Yang ve ark. (2014), Mavi yemiş yaprak özütlerini *Staphylococcus aureus, Listeria monocytogenes, Salmonella typhimurium* ve *Escherichia coli* üzerinde 25 g/L'lik minimum inhibitör konsantrasyonu ile 7,5 mm'den büyük bir inhibisyon elde etmişlerdir.

Bitki özleri kullanarak mavi yemişte gri küfünün biyolojik kontrolünde araştırmalar, ayçiçeği başağı özlerinde bulunan diterpenoid bileşiklerinin *B. cinerea*'ya karşı belirgin antifungal özelliklere sahip olduğunu ve belirli bileşiklerin önemli inhibitör etkiler gösterdiğini göstermektedir. Ayçiçeği başağı özlerinden elde edilen etil asetat özütü, 1,6 mg/mL konsantrasyonda test edilen Mavi yemiş meyvelerinin %42,9'unu *B. cinerea* enfeksiyonundan korumuş ve bu da meyvelerde hasat sonrası hastalıkların hafifletilmesinde biyolojik bir kontrol olarak potansiyelini göstermektedir (Santoro ve ark., 2018).

Sonuç

Mavi yemiş (*Vaccinium corymbosum*), yüksek antioksidan kapasitesi ve kronik hastalıkların önlenmesine katkı potansiyeli nedeniyle yoğun talep gören bir meyvedir. Bununla birlikte, çeşitli fitopatojenlere karşı belirgin duyarlılık göstermesi, ticari değerin korunması için etkili hastalık yönetimi stratejilerini zorunlu kılar. Hasat sonrası kalite ve raf ömrünün sürdürülebilmesi amacıyla, patojen kaynaklı bozulmaların kontrolüne yönelik alternatif yaklaşımların araştırılması güncelliğini korumaktadır. Mavi yemiş yetiştiriciliğinde hastalık yönetiminde birincil yaklaşım kültürel önlemlerdir. Bu kapsamda, plantasyonlarda optimum hava akışı ve ışık koşullarının sağlanması, hastalıklı bitki artıklarının hızla uzaklaştırılması ve inokulum kaynaklarının azaltılması esastır. Ayrıca, uygun budama ve bitki yoğunluğunun düzenlenmesiyle kanopi içinde nemin düşürülmesi, gri küf gelişimi için elverişsiz bir mikroklima oluşturur (He ve ark.,2018).

Kimyasal ve biyolojik kontrol stratejilerinin rasyonel entegrasyonu, üretim sistemlerinde yaygın biçimde benimsenmektedir. Sürdürülebilir yönetim yaklaşımları ise uzun vadeli ve çevre dostu ilkeleri benimsenerek kimyasal girdilere bağımlılığı azaltmayı hedefler. Özellikle Mavi yemişte en fazla ekonomik zarar yapan patojen olan *B. cinerea* karşı yüksek düzeyde dayanıklılık gösteren çeşitlerin seçimi ve ıslahı, hastalığın görülme sıklığını kökten azaltabilecek temel stratejidir. Dayanıklılık genlerinin belirlenmesi için yabani Mavi yemiş genetik kaynaklarının taranması ve bu genlerin melez ıslah teknikleriyle kültüre alınmış çeşitlere aktarılması bu sürecin en önemli adımlarıdır.

Entegre Zararlı Yönetimi, farklı etki mekanizmalarına sahip kontrol metotlarını uyumlu ve uygulanabilir bir yönetim çerçevesinde bir araya getirmek önemli bir mücadele şeklidir. Yetiştirme sezonu boyunca, fenolojik gelişme dönemleri, iklim ve çevre koşulları izlenmeli, kültürel önlem, biyolojik kontrol ajanlarının kullanımı ve gerektiğinde seçici fungisit uygulamaları stratejik olarak uygulanmalıdır. Hasat sonrası dönemde *B. cinerea* 'nın baskılanması için uygun kimyasal seçenekler mevcuttur; ancak bu uygulamalar, kalıntı limitleri ve ticari raf ömrü hedefleri gözetilerek, biyoteknik ve fiziksel yöntemlerle birlikte değerlendirilmelidir. Tüm bu yaklaşımların etkinliğini artırmak üzere tahmin-uyarı sistemlerinin geliştirilmesi ve uygulanması oldukça önemlidir. Tahmin- erken uyarı sistemleri iklim verileri ve hastalık gelişim modellerini kullanarak karar verme süreçlerini destekler ve gereksiz fungisit uygulamalarını en aza indirir.

Bu derleme, mavi yemişin hasat öncesi ve sonrası hastalıkların önlenmesine yönelik uygulanabilir alternatif mücadele yöntemlerine ve bunların etki mekanizmalarına odaklanarak, gelecekteki araştırmalar için yol gösterici ilkeler sunmayı amaçlamaktadır.

ABSTRACT

Monitoring urban expansion in secondary cities is essential for understanding regional development patterns and guiding sustainable planning. Using VIIRS Night-Time Light (NTL) annual composites and MODIS land cover (MCD12Q1) data within the Google Earth Engine (GEE) environment, this study explores the spatio-temporal pattern of urban growth in Rangpur District, Bangladesh for the period 2013-2022. MODIS Level-1 land-cover classifications were combined with annual NTL radiance to exclude urban (Class 13) and agriculture (Classes 10, 12, 14) and calculate sum of lights (SOL) for each class. For the SOL analysis, radiance increases without exceptions in both habitat and agricultural categories. Urban SOL rose from 356.90 nW/cm²/sr in 2013 to 603.72 nW/cm²/sr in 2022, supporting increasingly luminous built-up activity. A steep rise was also observed in agricultural zones (from 4,350.43 nW/cm²/sr in 2013 to 9,078.00 nW/cm²/sr in 2022), reflecting the spread of peri-ran growth and perhaps farmland-to-urban land use change. In the study period, total district-wide SOL increased from 4,889.33 to 10,006.91 nW/cm²/sr ($p < 0.01$). Socially the four representative years (2013, 2016, 2019, 2022) illustrate evident radiance intensification surrounding Rangpur city, major corridors, and upcoming urban centers. The research shows that combining NTL and LULC data offers an affordable, high-resolution and near-continuous framework for tracking urbanisation, particularly where field-based measurements are constrained. This demonstrates the fully GEE-based workflow that offers fast processing and reproducibility of urbanization assessments in Bangladesh and other developing areas.

Keywords: Night-Time Light, Urban Expansion, VIIRS, MODIS, Google Earth Engine, Land-Use Change, SOL Analysis.

1. INTRODUCTION

Urbanization is the most truly transformative phenomena of the twenty-first century. Cities are undergoing rapid growth across the globe, transforming their built environments, affecting their surrounding biophysical and socio-ecological systems (Seto et al., 2012). Although megacities are often the most highlights, secondary cities–medium-size urban hubs that link rural and metropolitan areas–have key impacts on development paths (UN-Habitat, 2020). These cities are undergoing unprecedented but poorly documented change due to rising mobility, commercial activity, electrification, and migration in the developing world. Bangladesh reflects this trend. While a considerable body of literature exists on the Dhaka urban agglomeration, secondary cities, including Rangpur, are becoming significant in terms of effective regional planning, dispersing economic activity away from the capital as well as achieving balanced national development (Islam & Adnan, 2020). The utilization of remote sensing has made a new horizon for monitoring urban change more efficiently. Of all satellite-based tools, Night-Time Light (NTL) imagery has emerged as a critical proxy for human activities, economic growth, electrification and urban sprawl (Li et al., 2020). Compared with the historical DMSP-OLS system, the VIIRS Day/Night Band (DNB) provides enhanced radiometric sensitivity, less saturation, and greater temporal stability, allowing it to be well-suited for examining urban expansion in medium-sized cities (Elvidge et al., 2017; Ghosh et al., 2013). NTL has limitations owing to its lower spatial resolution, but when combined with the MODIS MCD12Q1 products, which provide up-to-date global land-use classifications every year, NTL may be used for improved spatial interpretation and stronger links between radiance intensification in the NTL and land-use classes (Herold et al., 2018; Zhang et al., 2021).

The combination of NTL and land-cover data has been especially effective in identifying peri-urban growth. Several studies in Asia and Africa have shown the gradual increase in radiance in the agricultural areas typically align with urban growth as well as informal settlements or developing business corridors over time (Pandey et al.2019, 2022; Deval & Das, 2021). Although there is an increasing level of remote sensing application over Bangladesh, continued integrated assessments of secondary cities are much limited in the long run. Despite Rangpur District as an important new administrative and commercial centre of northern Bangladesh being a subject of great infrastructural and socio-economic change in the last decade, little analytical attention has been given to the urban dynamics of the area in the academic literature. This study helps to fill that gap by studying spatio-temporal urban growth in Rangpur from 2013 to 2022 using a VIIRS–MODIS fusion methodology performed on Google Earth Engine. The trinity of NTL time series- land-use change-dynamics of urban growth The aim is to quantify strength and direction of urban brightness change, evaluate spatial footprint of peri-urban land-transformation and extent of NTL–LULC-coupled data for appraising urban process in medium-sized cities. By producing annual statistics and spatial maps for key years, this study provides an evidence-based account of the changing extent of Rangpur's urban footprint and demonstrates the methodological potential of broader applications in Bangladesh and similar developing regions.

2. STUDY AREA

Rangpur District located in northern Bangladesh is one of the important administrative, commercial and educational centers of Rangpur Division (Figure 1). It is located at 25.20°–25.80° N latitude and 89.00°–89.50° E longitude and covers an area of about 2,307 km² (Banglapedia, 2023; BBS, 2022). The landforms in the area consist of agricultural areas, villages, urban neighborhoods, corridors of transportation, and a quickly developing commercial area. Rangpur city serves as the main urban center with characteristics of peri-

urban growth along some key highways and pastoral developments within the alluvial plains of the Teesta Basin are dominant factors to agricultural and settlement practices (Hossain & Rahman, 2020). More than 3 million people live in Rangpur, which offers an active rural–urban interface in an urban growth hotspot, making it a perfect place to study land-use change over time.

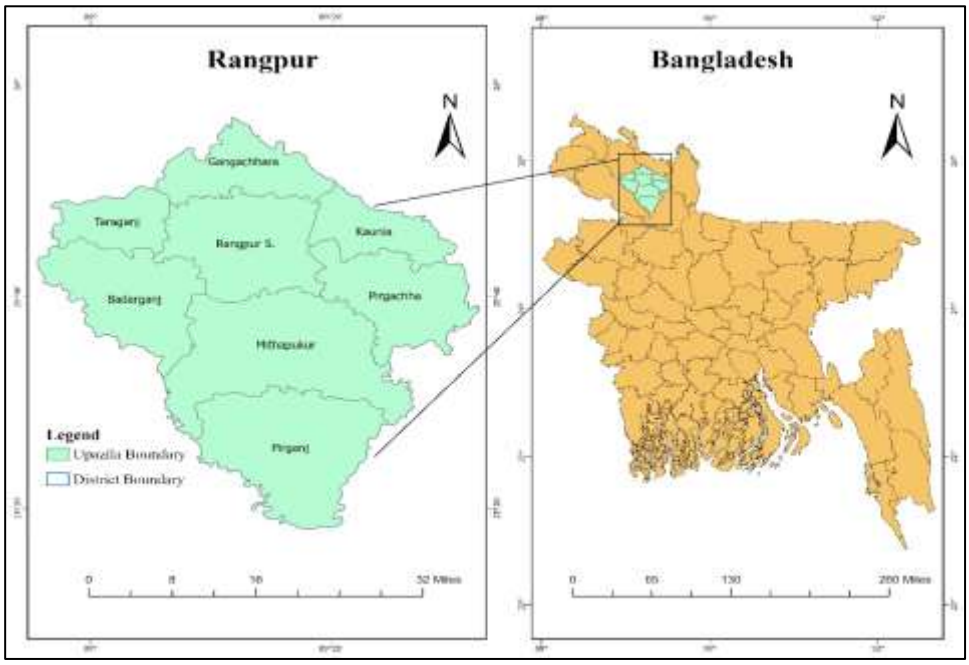

Figure 1: Map of the study region

3. DATA AND METHODOLOGY

The present study was based on two large geospatial datasets that were processed on the Google Earth Engine. Annual NTL composites (V21 and V22) from VIIRS were assembled for the years 2013–2022. This method effectively eliminates temporary lights including fire and short-lived events, yielding more accurate radiance values (Miller et al., 2020). For an annual land-cover classification, MODIS MCD12Q1 land-cover dataset was applied for distinguishing urban (Class 13) and agricultural (Classes 10, 12, 14) areas.

Urban and Agricultural masks for the years were generated as well as a mask to pinpoint areas that may be converting from agriculture to urban use. To quantify brightness associated with each land-use category, we applied the masked SOL methodology which sums all radiance values in the study area (Zhao et al., 2020). This methodology has been useful to identify the urban sprawl dynamics, economic growth and the urban expansion (Shi et al., 2014).

Spatial visualization of four representative years (2013, 2016, 2019 and 2022) were selected with the aim of capturing the early, mid and late phases of urban development. The GEE workflow provided the advantages of computational efficiency, reproducibility and scalability. These outputs consist of a ten year SOL dataset and spatial interpretation in the form of four combined radiance maps. Figure 2 represents the main methodological procedure of the study.

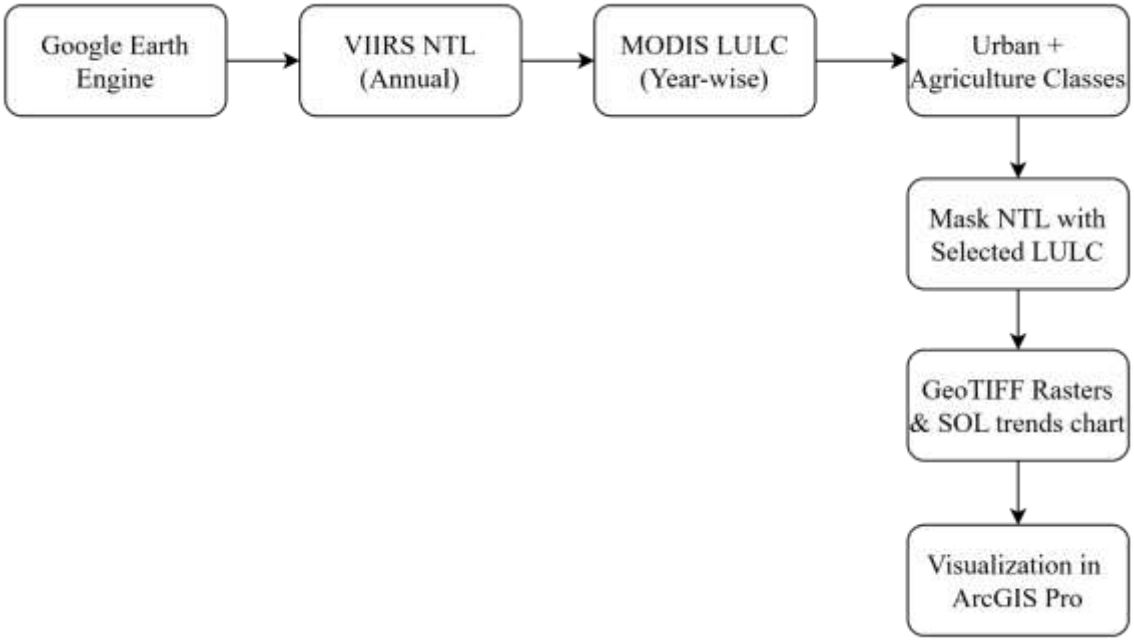

Figure 2: Flowchart of the overall methodology

4. RESULTS

The SOL analysis shows an increasing tendency of brightness in Rangpur District during the ten years (Figure 3). Urban SOL growth was consistent in nature, which is indicative of the progressive aggregation of built-up infrastructure, commercial facilities and electrified households. Radiance originally high only in densified areas, with agricultural places showing up in peri-urban parts near the city, gradually getting brighter. Such pattern reveals a sequential change in land use from agriculture to mixed farm with development of human settlements, spurred by population increase, economic diversification and improvement in transport.

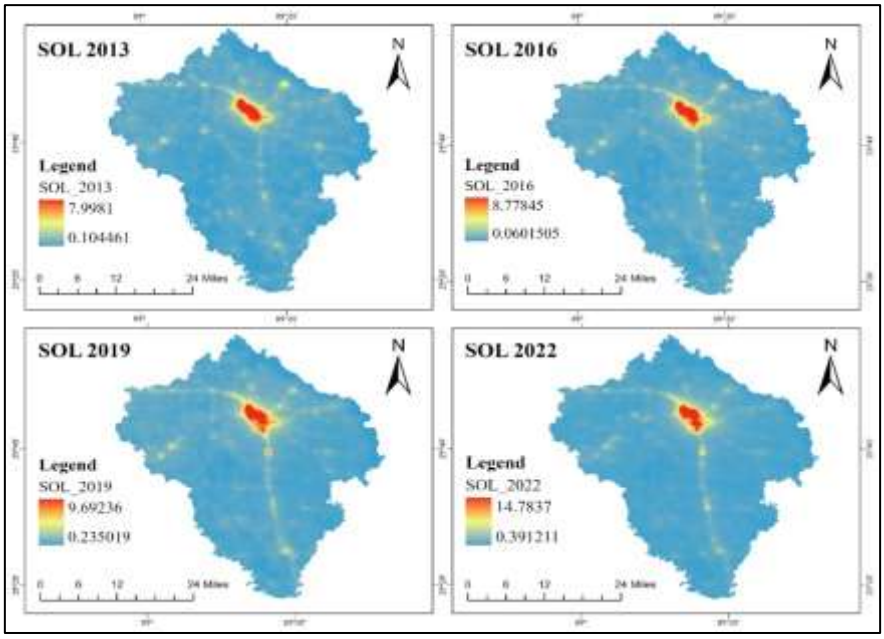

Figure 3: Spatial distribution of combined radiance (SOL) in Rangpur District for 2013, 2016, 2019, and 2022.

The spatial maps demonstrate the phase of greater illumination. The map for 2013 shows a concentrated bright area around the core of the Rangpur city and faintness along the main roads. In 2016, brightness extended outwards, especially to the south and southwest of the explosion. This indicates significant peri-urbanization, while the medium-intensity illumination observed in the 2019 map shows that medium-intensity illumination is able to grasp wide areas. The urban sprawl is greatly augmented and shines brighter, signifying continued economic activity and urbanization if another 2022 year of mega data is to be assumed. This spatial agreement between radiance intensification and the known development corridors supports the usefulness of NTL data to monitor urban growth.

5. DISCUSSION

The SOL of Rangpur in the spatiotemporal analysis displays a gradual increase in focus of nighttime light radiation between 2013 and 2022 particularly for 2013, 2014 and 2022, suggesting a rapid social-economic transition for the area (Table 1). Recently documented similar associations between increasing night-time radiance and urban expansion in regions of India, Pakistan and Nepal have shown that high radiance growth corresponded with economic expansion and infrastructure development (Pandey et al., 2022; Small et al., 2018). SOL maps indicate the relative persistence of the urban core as the most dominant illumination hotspot over the course of the study period but progressively enlarged lighted areas correspond to urban expansion and increased human activity in outer urban areas. A distinct transition observable from a dim core in 2013, to a much more luminous and spatially broad feature by 2022.

Table 1: Change of sum of lights (SOL) for urban, agricultural, and total areas

Year	Urban SOL (nW/cm²/sr)	Agriculture SOL (nW/cm²/sr)	Total SOL (nW/cm²/sr)
2013	356.895	4,350.43	4,889.33
2016	383.24	4,388.22	4,960.78
2019	407.673	7,166.47	7,696.20
2022	603.715	9,078.00	10,006.91

A SOL aggregation chart further supports these observations with the quantification of Urban SOL, Agriculture SOL, and Total SOL (Figure 4). The total SOL goes from about 4,800 units in 2013 to almost 10,000 units in 2022, meaning the increase over the decade is more than twice. Rapid agriculture and urbanization are accelerating this trend. Remarkably, Agriculture SOL has remained the largest single component, implying considerable growth in electrification and nighttime agricultural operations, especially pumping irrigation, crop processing, and rural infrastructure development. These results are also consistent with more general processes of peri-urbanisation in secondary cities in South Asia, as the rural–urban interface fades in the context of emerging settlements, markets and transport corridors (Sahana & Patel, 2019).

However, Urban SOL, which is also much lower in order of magnitude, steadily rises between 2013-2022. A more substantial increase is noticeable after 2019, consistent with the spatial spread seen in the maps. This implies densification of urban form, increase in economic activities, and new settlements are being constructed at the urban periphery level. The very prominent linear features seen in 2019 and 2022 maps also coincide with transport corridors

further highlighting the significance of road-led development nature of the urban growth of Rangpur.

By looking at the spatial maps separately and the aggregated values separately you can see that while the urban core becomes brighter, the agricultural landscapes are the most brightest and have the most noticeable overall change coming from them as it is the most bright area and is taking hold on to total illumination as they become increasingly bright. This pattern indicates a hybrid growth model with urbanization as well as rural modernization as the contributors to energy consumption and nighttime lights.

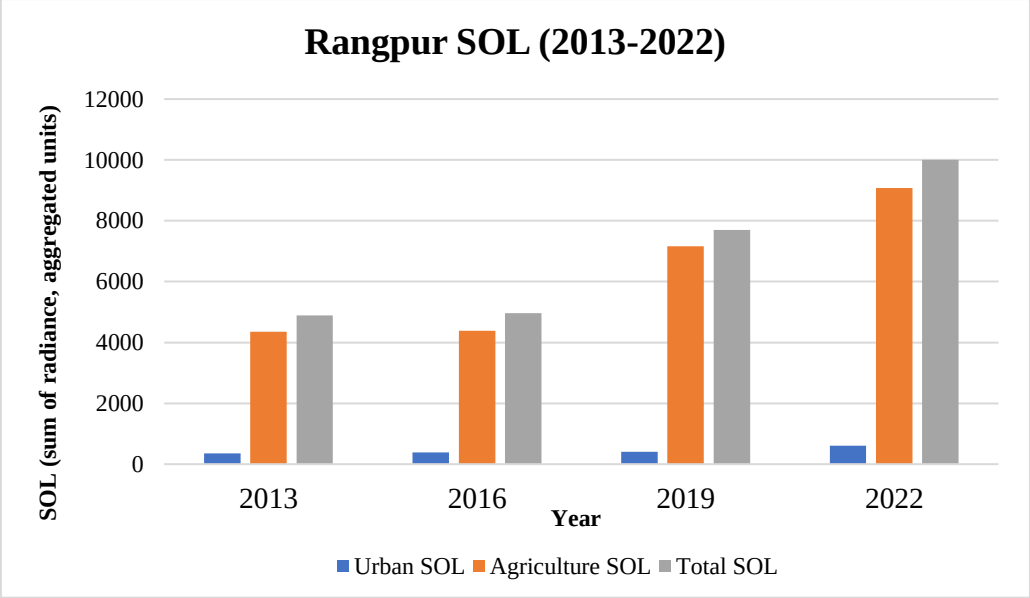

Figure 4: Temporal trend of sum of lights (SOL) for urban, agricultural, and total areas in Rangpur District (2013–2022).

Combining VIIRS NTL and MODIS LULC data was very useful for characterizing radiance change drivers. Although VIIRS by itself picks up where MODIS leaves off in terms of brightness, it does not distinguish land types, and so the MODIS classification clarifies if urban, agriculture, or some other land type is responsible for illumination trends. The ability to return multi-year processed results without local computational restraints was significantly improved through the use of Google Earth Engine (GEE) (Gorelick et al., 2017).

From the perspectives of environmental and planning, the increase of SOL may reflect the higher demand for energy, the elevated artificial light spreading, even the effect on heat island effect and disturbance of ecology. Previous studies conducted in South Asia have shown how NTL-based tracking provides a feasible, cost-effective solution to spatially inform unplanned urban sprawl vulnerability and can serve as a complementary input for formulating evidence-based growth-management measures (Pandey et al., 2022; Sahana & Patel, 2019). Hence, SOL can be a strong candidate for monitoring land development pressure, rural transformation and sustainability challenges in fast changing region such as Rangpur.

In summary, the integrated SOL evidence from map-based and aggregated data indicates that between 2013 and 2022, Rangpur has undergone significant urban and agricultural growth, characterized by the enlarging size of lighted regions, increasing total radiance, along with a close coupling between rapid expansion of built-up area and economic activities.

6. CONCLUSION

The results of this study represent a first-ever fully integrated spatio-temporal assessment at high resolution of urban growth in Rangpur District from 2013 to 2022. It shows considerable increases in nocturnal brightness, indicative of regional urbanisation and continuing changes over peri-urban agricultural land. It sheds light on regional socio-economic progress and better infrastructure: The increasing illuminated footprint. The method is inexpensive, scalable and ideal for the developing world, where urban-survey data are sparse. In future works, other socio-economic indicators, road-network data or even machine learning methods can be used in conjunction with our models to improve the prediction of urban-growth and to further understand urbanization processes.

ÖZET

Havacılıkta kullanılan malzemeler; yüksek sıcaklık, basınç değişimleri, aerodinamik yükler, darbe ve yorulma etkileri nedeniyle sürekli bir hasar riski altındadır. Bu koşullar, uçak yapılarında zamanla mikro çatlakların veya yüzey bozulmalarının oluşmasına yol açmaktadır. Bu nedenle bakım ve onarım süreçleri, uçuş güvenliğini sağlamak açısından kritik bir role sahiptir. Ancak geleneksel bakım yöntemleri, yüksek maliyetli olmaları, uzun işlem süreleri gerektirmeleri ve insan hatalarına açık olmaları nedeniyle istenen verimliliği her zaman sağlayamamaktadır. Kendini iyileştiren malzemeler, hasarı dış bir müdahaleye ihtiyaç duymadan otonom şekilde onarma yeteneği sunarak bu sınırlılıkları önemli ölçüde azaltmaktadır. Mikro çatlakları kendi içinde iyileştirebilme, kullanım ömrünü uzatma ve bakım ihtiyacını azaltma gibi avantajlar, bu malzemeleri havacılık yapıları için oldukça cazip hale getirmektedir. Ayrıca daha az malzeme kullanımı ve daha uzun servis ömrü sayesinde çevresel sürdürülebilirliğe de katkı sağlamaktadır. Bu çalışmada, kendini iyileştiren malzemelerin otonom bakım-onarım sistemlerine entegrasyonu incelenmektedir. Literatürde yer alan polimer, seramik ve metalik malzemelerde kullanılan farklı onarım mekanizmaları karşılaştırmalı olarak değerlendirilmiştir. Özellikle mikro kapsül ve mikro damar sistemleri, tersinir kimyasal bağlar ve şekil hafızalı alaşımlar, otonom iyileşme mekanizmalarının temelini oluşturan başlıca yöntemlerdir. Her mekanizmanın yapısal bütünlük, onarım hızı, tekrar

kullanılabilirlik ve malzeme uyumluluğu açısından farklı avantajları bulunmaktadır. Elde edilen değerlendirmeler, kendini iyileştiren malzemelerin havacılık sektöründe önemli bir potansiyele sahip olduğunu göstermektedir. Mevcut teknik zorluklara rağmen bu malzemelerin, gelecekte bakım süreçlerini otonom hale getirerek daha güvenilir, hafif ve uzun ömürlü havacılık yapılarının geliştirilmesine katkı sağlaması beklenmektedir.

Anahtar Kelimeler: Otonom bakım-onarım, kendini iyileştiren malzemeler, mikro kapsül sistemleri, şekil hafızalı alaşımlar, havacılık.

SELF-HEALING MATERIALS FOR AUTONOMOUS MAINTENANCE AND REPAIR IN AEROSPACE

ABSTRACT

Aerospace materials operate under harsh environmental and mechanical conditions, such as high temperatures, pressure fluctuations, aerodynamic loads, impact, and fatigue loading. These factors cause continuous risks of micro-crack formation and structural degradation in aircraft components. Therefore, maintenance and repair activities are essential for ensuring flight safety. However, traditional maintenance methods have major drawbacks, including high cost, long processing times, and susceptibility to human error. Self-healing materials offer a promising solution by enabling autonomous repair of damage without external intervention. Their ability to heal micro-cracks extends service life, and reduce maintenance demands, hence, making self-healing materials highly attractive for aerospace applications. Additionally, by minimizing material waste and increasing component durability, these materials contribute to environmental sustainability. This study examines the integration of self-healing materials into autonomous maintenance and repair systems for aviation structures. Various healing mechanisms reported in the literature are evaluated comparatively across polymeric, ceramic, and metallic material classes. Among these mechanisms, microcapsule- and microvascular-based systems, reversible chemical bonds, and shape memory alloys stand out as prominent self-healing strategies. Each mechanism offers different advantages in terms of structural compatibility, healing speed, reusability, and applicability to aerospace components. The overall assessment indicates that self-healing materials have strong potential for transforming maintenance operations in the aviation sector. Despite existing technical challenges, such as integration with composite structures, long-term reliability, and environmental stability, current research trends show that these materials may play a key role in developing safer, lighter, and more durable aerospace systems.

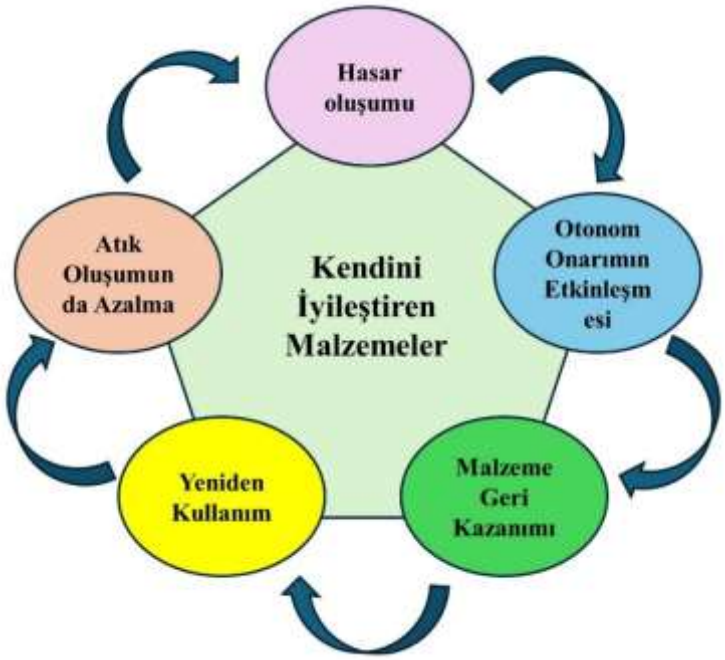
Keywords: Autonomous maintenance, self-healing materials, microcapsule systems, shape memory alloys, aerospace.

1.GİRİŞ

Endüstride kullanılan malzemelerin bakım onarım süreçleri, insan müdahalesi dahilinde periyodik muayeneler ile yapılmaktadır. Geleneksel yöntemler uzun yıllardır kullanılmasına rağmen aslında hem zaman hem de maliyet açısından sınırlamalar içermektedir. Özellikle zorlu koşullara maruz kalınan ve yüksek güvenlik gerektiren sektörlerde malzemelerin bakım ve onarım süreçleri aksamalara yol açabilmektedir.

Bu bağlamda kendini iyileştirebilen malzemeler geleneksel yöntemlerin ötesine geçebilecek yenilikçi bir çözüm önerisi sunmaktadır. Bu yaklaşım, havacılık gibi yüksek güvenlik standartları gerektiren sektörler de dahil olmak üzere geniş uygulama alanlarına uyarlanabilir olup büyük bir potansiyel taşımaktadır. Bu çalışma geleneksel yöntemlere alternatif olarak kendini iyileştiren malzemelerin yenilikçi olanaklarını ve özellikle havacılık alanındaki potansiyel rolünü incelemeyi amaçlamaktadır.

1.1. Havacılık Malzemelerindeki Hasar Riskleri ve Geleneksel Bakım Sınırlamaları

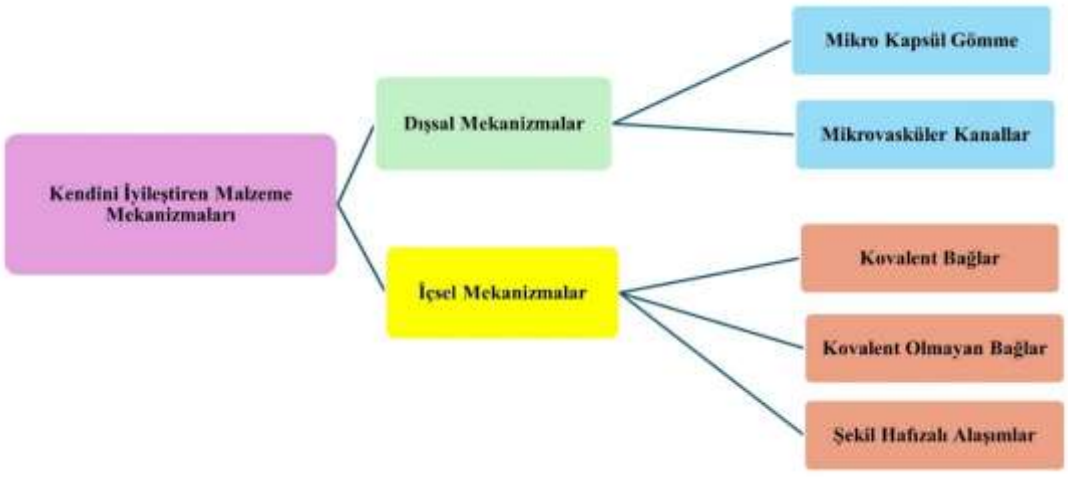


Hava araçları görevleri boyunca çeşitli çevresel etkiler altında çalışırlar. Zaman içinde yapısal bileşenlerde belirli düzeyde deformasyon oluşumu kaçınılmaz hale gelir. Maruz kaldıkları UV ışınları, tekrarlı basınç çevrimleri, nem ve sürekli sıcaklık değişimleri gibi faktörler hava araçlarında korozyon, delaminasyon ve mikro çatlaklar gibi yapısal hasar risklerine neden olabilmektedir. Bu nedenle kullanılan malzemeler ve bu malzemelerin bakım onarım süreçleri, zorlu çevresel koşullar nedeniyle büyük önem taşımaktadır. Hasar risklerine karşı sürekli bakım onarım faaliyetleri uçuş güvenliği açısından oldukça önemlidir. Bu süreçler havacılığın en kritik faaliyetlerinden olup havayoluna ait gider maliyetinin yaklaşık olarak %11'ini oluşturmaktadır (Verhagen et al., 2023). Geleneksel bakım süreçleri, hasarların erken tespiti için yetersiz kalabilmekte, bunda insan hatası da önemli bir paya sahip olmaktadır. Periyodik bakımlarda tespit edilemeyen hasarlar beklenmeyen arızalara sebep olabilir. Ayrıca geleneksel bakım süreçleri boyunca hava aracının yerde tutulması gerektiği için operasyonel süreklilik sekteye uğramaktadır.

1.2. Kendini İyileştiren Malzemelerin Rolü

Geleneksel bakım onarım yöntemlerinin yaygınlığını azaltabilecek, kendini onarabilen akıllı malzemeler mevcut sınırlamalar karşısında önemli bir çözüm potansiyeline sahiptir. Bu malzemeler, yaklaşık son 15 yılda artan performans gereksinimleri ve gelişen teknoloji sayesinde daha yaygın bir seçenek haline gelmiştir. Özellikle bakım ihtiyacının giderilmesinin zorlu olacağı uzay ortamları için gelecek vaadetmektedir (Pernigoni et al., 2021). Kendini iyileştiren malzemelerin havacılıkta bakım onarıma sunduğu avantajlar başlıca şu şekilde sıralanabilir:

- İnsan hatalarına karşı operasyonel verimliliği artırarak uçuş güvenliğinin sağlanması,
- Bakım sıklığının azaltılması ve böylece maliyetin düşmesi,
- İyileşmenin otonom olarak gerçekleşmesi sayesinde onarım giderlerinin düşmesi,
- Arıza oluşumundan önce onarım sayesinde uzun ömürlü yapıların geliştirilmesi, böylece atık oluşumunu en aza indirerek sürdürülebilirliğe katkı sağlaması.



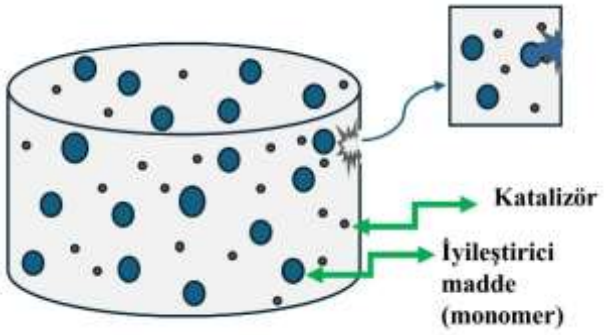
Şekil 1'de kendini iyileştiren malzemelerin döngüsel süreci gösterilmektedir. Bu döngü hasar oluşumunun otonom onarımı etkinleştirmesini ve böylece malzeme geri kazanımının gerçekleşmesiyle atık oluşumunda azalma sağlandığını vurgulamaktadır.

Şekil 1. Kendini onaran malzemelerde otonom onarım döngüsünün şematik gösterimi

2. KENDİNİ İYİLEŞTİREN MALZEMELERİN SINIFLANDIRILMASI VE İYİLEŞME MEKANİZMALARI

Kendini iyileştirme mekanizmaları farklı malzeme türlerinde benzer prensiplere dayalı olarak gerçekleşir. Bu mekanizma çeşitlerini dışsal ve içsel onarım olarak iki başlık altında incelemek mümkündür. Dışsal onarım mekanizmaları malzeme içine gömülmüş halde bulunan bileşenlere dayanarak onarım gerçekleştiren, kendiliğinden onarım yeteneğine sahip olmayan mekanizmalardır. İçsel onarm ise kimyasal bağlar ve fiziksel etkileşimler ile dışarıdan eklenmiş bir bileşene ihtiyaç duymadan çalışan iyileşme mekanizmalarıdır (Paul et al., 2025). Sınıflandırma birçok farklı başlık ile yapılabilir. Bu çalışmada bahsedilecek mekanizmalar için genel çerçeve Şekil 2'de gösterilmiştir.

Şekil 2. Kendini İyileştiren Malzeme Mekanizmalarının Sınıflandırılması



Malzeme türüne ve özelliklerine göre kullanılan mekanizma çeşitleri Tablo1'de gösterilmiştir. Tabloda polimer, seramik ve metal malzemelerin hangi yöntemler ile uyumlu olduğu ve bahsedilen mekanizmaların hangi sıklık derecesinde kullanıldığı görülebilir.

Tablo 1. Malzeme türlerine göre kullanılan mekanizma çeşitleri [Hücrelerdeki X işareti sayısı ilgili mekanizmanın malzeme sınıfında kullanım sıklığını göstermektedir. XXX: yaygın, X: daha az yaygın, Boşluk: kullanımı neredeyse bulunmamakta]

Malzeme Türü/ Mekanizma	Polimer & Kompozit	Seramik	Metal
Kapsülleme	XXX	XXX	X
Kanal Taşımacılığı	XXX	XXX	X
Tersinir Çapraz Bağlar	XXX		
Şekil Hafızalı Alaşımlar	X		XXX

2.1. Polimerik Malzemelerde İyileşme Mekanizmaları ve Uygulama Potansiyelleri

Polimer matrisli kompozit (PMC) malzemeler kolay işlenebilirlik, düşük ağırlık ve yüksek dayanım özelliklerinden ötürü en çok tercih edilen kompozit yapılar arasında yer alır. Ancak zorlu koşullarda hasara karşı hassas olmaları onları riskli kılar (Danaci, 2023; Paladugu et al., 2022). Şekil 3'te gösterildiği üzere polimerlerde mikro kapsül gömme mekanizmasında iyileşme süreci çatlak oluşumu ile başlar. Oluşan çatlak ilerledikçe malzemenin içine gömülmüş halde bulunan mikrokapsülleri kırarak iyileştirici maddenin serbest kalmasını sağlar. Serbest kalan iyileştirici madde çatlak boyunca ilerleyip katalizör ile birleşerek katılaşır ve böylece otonom iyileşme süreci tamamlanır. Bu mekanizmanın en büyük dezavantajı ise iyileşmenin yalnızca bir kere gerçekleşebilecek olmasıdır.

Şekil 3. Mikro kapsül gömme mekanizması

Takviyeli kompozit malzemeler, matris ve kompozit fazlarının birleşimi ile oluşan gelişmiş mühendislik malzemeleridir(Erden et al., 2023). Lif takviyeli epoksi kompozitlerin havacılık uygulamalarındaki kullanımı çok yaygındır. Boeing 787 Dreamliner'ın birincil yapısal bileşenlerinde %50'nin üstünde bir oranda karbonfiber takviyeli kompozit kullanımı bu malzeme grubunun sektör açısından en önemli örneğidir (Danaci, 2023; Zhang et al., 2023). Havacılıkta kullanılan kendini iyileştiren polimer kompozitler ile yapılan çalışmalarda, sıkıştırma ve darbe testlerinden sonra iyileşme oranının %92 ve %97 oranında olduğu

belirtilmiştir (Paladugu et al., 2022).Bu oranlar malzemenin oldukça yüksek iyileşme yeteneği kazanabildiğini ve kritik alanlarda kullanımı açısından yüksek potansiyele sahip olduğunun göstergesidir.

Havacılık sınıfı fiber takviyeli polimer kompozitlerde mikrovasküler kanal yapısına dayanan mekanizma ile yapılan çalışmalardan biri, havacılıkta otonom bakım uygulamalarının kendini iyileştirme teknolojisi ile geliştirilebileceğini desteklemektedir. Coope ve arkadaşlarının yaptığı bu çalışma, farklı sıcaklık koşulları altında gerçekleşen kendini iyileştirme süreçlerindeki kırılma tokluğu özelliği üzerinde durmuştur. Deneyler sonucunda kırılma tokluğu geri kazanımında oda sıcaklığında dahi yaklaşık %84 verimlilik sağlandığı, yüksek katalizör yüklemesi yapılırsa verimliliğin %352'ye kadar ulaştığı gözlemlenmiştir (Coope et al., 2014).

Yang ve arkadaşları epoksi reçine içeren mikro kapsüller kullanarak kendini iyileştiren bir antikorozyon kaplama geliştirmişlerdir. Kaplamalar çizildikten sonraki süreçte kontrol numunelerinde korozyon oluşurken çelik yüzey üzerine kaplanan epoksi mikro kapsüllü malzemede korozyon gözlenmemiş olması, polimer tabanlı bu mekanizmanın etkili iyileşmesini deneysel olarak doğrulamaktadır (Zhao et al., 2011).

Literatürde sunulan çalışmalar birlikte değerlendirildiğinde kendini iyileştiren polimerlerin özellikle polimer kompozitlerin önemli iyileşme verimliliği gösterdiği anlaşılmaktadır. Bu durum gelecekte havacılıkta otonom bakım onarım için uygulanabilirliğinde artış olmasını desteklemektedir. Polimerik malzemelerden oluşan yapılarda çoklu iyileşme dögüleri üstünde çalışmalar yapılması, böylece uzun dönemli onarım ve dayanım sağlanması sektörde büyük bir ilerleme sağlayacaktır.

Çoklu iyileşme döngüsü açısından polimerlerde içsel iyileşme mekanizmaları çözüm sunmaktadır. Literatüre göre içsel sistemler kovalent (Diels-Alder (DA) reaksiyonları, tranesterifikasyon) ve kovalent olmayan (π–π etkileşimleri, van der Waals kuvvetleri, iyonik etkileşimler, hidrojen bağları) bağlarla çalışmaktadır (Paul et al., 2025).

Kovalent sistemlerde dış bir uyaran (ısı, pH, nem vs.) ile geri dönüşümlü bağlar yeniden kurulur. 2021 yılında yayımlanan çalışmada araştırmacılar, DA reaksiyonları içeren çapraz bağlı polimer filmler üretmiş ve 0.5 mm derinliğinde çizikler oluşturmuşlardır. 120°C de sadece 5 dakika ısıtılan çiziklerin 10 dakika sonra tamamen iyileştiği gözlemlenmiştir. Numuneler soğutulduktan sonra yapılan çekme testlerinde iyileşme verimliliğinin %92,33 olduğu kaydedilmiştir (Pandey et al., 2024). Bu sonuçlar kovalent bağların kendini iyileştirme potansiyelini gösterse ve yüksek mekanik dayanım sağlasalar da, iyileşmenin gerçekleşmesi için yüksek enerji gerektirdikleri için kullanım koşullarına dikkat edilmesi gerekir. Kovalent olmayan bağlar kovalent bağlara göre daha düşük enerjilere sahip olduklarından normal sıcaklıklarda dahi kolayca oluşarak kendini iyileştirmeyi sağlayabilmektedir (Paul et al., 2025). Ancak mekanik dayanımları kovalent bağlara göre düşük olduğunu göz önüne alırsak, havacılıkta otonom bakım onarım potansiyeli sunsa da, birincil yapılarda kullanımları sınırlı kalmaktadır.

2.2 Seramik ve Metalik Malzemelerde İyileşme Mekanizmaları ve Uygulama Potansiyelleri

Seramik kompozitler kırılgan doğaları gereği üretimde ve kullanımda mikro çatlak oluşumuna yatkındır. Bu nedenle havacılık sektöründe yüksek sıcaklık koşulları altında çalışan jet motorları ve gaz türbinleri gibi uygulamalarda kullanımı kritik olan bu malzemelerin kendini iyileştirme mekanizmalarının geliştirilmesi bir gerekliliktir (Erden, 2025). Seramik malzemelerde, polimerde bahsedilen mikro kapsül ve mikrovasküler yöntemin yanı sıra oksidasyon temelli kendini iyileştirme mekanizması da yer almaktadır. Osada ve çalışma

arkadaşları seramik matrisli kompozitler ile yaptıkları çalışmada malzemenin kırılganlığına bir çözüm olarak oksidasyon temelli kendini iyileştirme mekanizmasını incelemişlerdir. Çalışmada SiC parçacıkları içeren malzemenin çatlaması sonucunda oksijenle etkileşime girerek SiO_2 fazını oluşturduğu, bu sayede çatlakları doldurduğu ve malzemenin dayanımını geri kazandırdığı gözlemlenmiştir. Bu çalışmada Si_3N_4/SiC patrikül takviyeli kompozitlerin farklı gerilme seviyelerindeki kendini iyileştirme potansiyelleri üstüne yoğunlaşılmıştır. 200 MPa uygulama gerilmesi ve 500 Pa oksijen kısmi basıncı (iyleşmenin gerçekleşmesi için gerekli olan pasif oksidasyon değeri) koşullarında bile iyileşme olduğu kaydedilmiştir (Osada et al., 2014). Oksijen kısmi basıncının artmasıyla iyileşme süresinin kısaldığı ayrıca belirtilmiştir. Bu sonuç kendini iyileştiren sistem mekanizmasının türbin koşullarında da etkin olabileceğini açıkça göstermektedir.

Metalik malzemelerin atomik yapıları ve metalik bağların özellikleri nedeniyle, kendini iyileştirme süreci polimer ve seramiklere kıyasla farklıdır (Erden et al., 2023; Hager et al., 2010). Metalik malzemeler içerisinde en dikkat çekici gruplardan biri şekil hafızalı alaşımlardır. Şekil hafızalı alaşımlar ısı değişimine bağlı olarak kristal yapısını değiştiren malzemelerdir. Bu malzemeler 2 temel faz arasında çalışırlar. Bunlar östenit (yüksek sıcaklık) fazı ve martenzit (düşük sıcaklık) fazıdır. Martenzit fazında malzeme kolay şekil değiştirebilen yumuşak bir yapıdadır. Malzeme martenzit fazındayken uygulanan yük etkisiyle malzemenin kristal düzeninde kalıcı olmayan bir değişim gerçekleşir. Malzeme ısıtıldığında değişen kristal yapı eski haline yani östenit fazına döner. Östenit fazı malzemenin orijinal geometrisinin saklandığı fazdır. Bu olaya "şekil bellek etkisi" denmektedir. Bu çalışma prensibi Şekil 4'te gösterilmektedir.

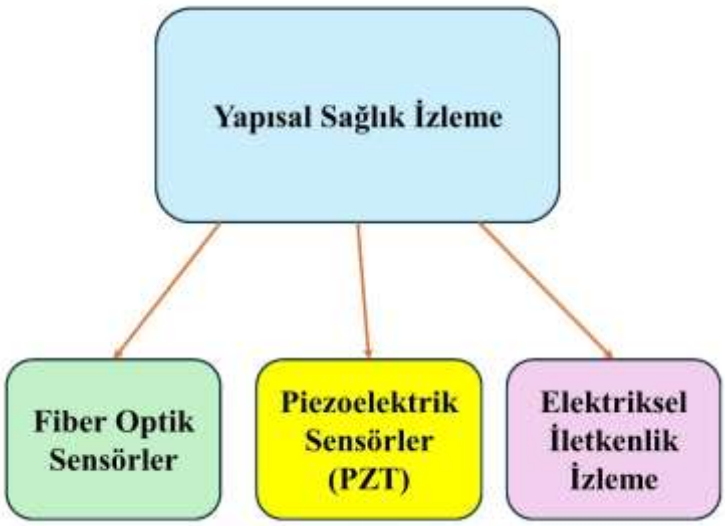
Şekil 4. Şekil hafızalı alaşımların çalışma prensibi

Eğer malzeme östenit fazındayken yük uygulanırsa uygulanan yükün etkisi malzemeyi martenzit fazına döndürür. Yük kaldırılınca tekrar östenit fazına dönerek eski şeklini alır. Bu olaya ise "süperelastisite" denir (Naresh et al., 2016).

Ti-Bi alaşımlarından oluşan tellerin kompozit içine yerleştirildiği çalışmada, tellerin şekil bellek etkisi göstermesi doğrultusunda şekil değişimlerine dayanabilmesi ve çatlak yüzeyleri arasında bağlantı oluşturması gösterilmiştir. Bu bağlantının, östenit fazı sıcaklığının üstünde ısıtılmasıyla çatlak ile ayrılmış yüzeyleri birbirine çekerek iyileşme sağladığı kaydedilmiştir. (Hager et al., 2010). Ferguson, Schultz ve Rohatgi yapmış oldukları çalışmalarında Ni-Ti şekil hafızalı alaşımları ZA-8 çinko alaşımı içine takviye olarak kullanarak kendini iyileştiren metal matrisli kompozit geliştirmişlerdir. Ni-Ti şekil hafızalı alaşım tellerin faz dönüşümü sırasında kırık yüzeyleri birbirine çektiği ve ısıl işlem sırasında matrisin erimesiyle yeniden bağ oluşturduğu gösterilmiştir. Ayrıca kullanılan numunelerin iyileşme sonrası çekme dayanımının %30'unu geri kazandığı doğrulanmıştır (Ferguson et al., 2015). Bu çalışmalar metalik malzemelerin kendini iyileştirme mekanizmaları açısından kullanılabilirliğin mümkün olduğunu göstermektedir.

3. HAVACILIKTA OTONOM BAKIM VE ONARIM SİSTEMLERİNİN ENTEGRASYONU

Otonom bakım kavramı toplam üretken bakım sisteminde kullanılan bir terimdir ve operatörlerin kendi ekipmanlarını günlük bakımını, temizlik, kontrol, yağlama ve basit ayarlamalarını kendilerinin yapmasıdır. Kısacası otonom bakım bir sistemin veya bileşenin durumunu sürekli olarak izleyebilen ve herhangi bir hasar, çatlak veya arıza durumu yaşandığında tespit eden ve gerekirse kendi kendine ihtiyaç duyulan bakımı yapabilen bir süreç bütünüdür.



Otonom onarım ise bakımın ileri aşamalarındadır, bir sistemin veya bileşenin manuel bir müdahale bulunmadan kendi kendine onarabilmesi anlamına gelir. Otonom onarımın temeli malzeme içine yerleştirilmiş olan ve herhangi bir arıza, hasar veya olumsuz başka bir durum oluştuğunda kendi kendine reaksiyon alan onarım elemanlarına dayanır. Günümüzde otonom bakım terimi doğrudan kendini iyileştirebilen malzemelere dayanır ve otonom onarım süreçlerinin büyük bir çoğunluğu kendini iyileştirebilen malzemeler sayesinde gerçekleşir.

Kendini iyileştiren malzemeler hem servis ömrünü uzatmak hem de bakım maliyetlerini azaltmak adına önemli bir ilerlemeyi temsil eder. Genellikle hafifliğin ve yüksek mukavemetin kritik olduğu bölgelerde kullanım potansiyeli taşıyan bu malzeme türü aynı zamanda mikro hasar ve yorulma riskinin yüksek olduğu yapısal bileşenlerde ve yüzeylerde uygulama gelişimine açıktır.

Havacılıkta kullanılan birçok parça veya bileşen yüksek darbe yüküne, sıcaklığa ve yorulmalara maruz kalır. Bu sebeple mikro çatlaklar gibi küçük hasarlar bile uçuş esnasında büyük felaketlere yol açabilir. Bu felaketleri önleyebilmek adına sürekli hasar riski altında çalışan bileşenlerde otonom bakım ve onarım havacılık alanında birçok soruna çözüm olacaktır.

3.1. Yapısal İzleme ve Hasar Tespiti

Kendini iyileştirebilen malzemelerin en temel özelliği otonom onarım yetenekleridir fakat bunu gerçekleştirebilmeleri için bileşenin veya parçanın öncelikle bir hasarın var olduğunu algılayabilmesi gerekmektedir. Yapısal sağlık izleme (Structural health monitoring) havacılık yapılarının durumunu sürekli, gerçek zamanlı ve uzaktan izlemek için kullanılabilecek olan bir teknolojidir. Geleneksel bakım yöntemleri yüksek maliyet ve uzun işlem süreleri gerektirdiğinden dolayı bu yönteme alternatif olarak hasar tespitini ve onarımını tek bir döngüde birleştirerek hem vakit hem de masrafalar sınırlandırılmaya çalışılmaktadır. Yapısal sağlık izleme yapıya kalıcı olarak yerleştirilir ve zaman içinde pasif veya aktif olarak izlenebilen sensörlere dayanır. Havacılıkta üç temel sensör tipi kullanılmaktadır. Şekil 5'te havacılıkta yapısal sağlık izleme kapsamında kullanılan temel sensör tipleri gösterilmiştir. Fiber optik sensörler, piezoelektrik sensörler ve elektriksel iletkenlik izleme yöntemleri yapıların gerçek zamanlı izlenmesinde önemli role sahiptir. Bu sensörler ile yapısal bütünlük sürekli olarak kontrol edilebilmektedir.

Şekil 5. Havacılıkta yapısal sağlık izlemede kullanılan sensör tipleri

Bu sensörler, kompozit yapının izlenmesinde kullanılan fiziksel prensibe bağlı olarak statik ve dinamik rejimlerde çalışabilir. Geniş alan ölçümlerine dayalı diğer hasar ölçüm yöntemleri (ultrasonik C-taramaları, taramalı Doppler lazer hız ölçümü, termografi, vb.) YSİ geliştirmede hasarın tanımlanması ve teyidi veya önerilen YSİ yaklaşımını anlamak için kullanılabilir (Eroğlu, Diltemiz, & Kuşhan, 2022).

3.2 Kendini İyileştiren Malzemelerin Havacılık Yapılarına Entegrasyonu

Boeing 787 ve Airbus A350 gibi yeni sivil uçakların gövde kısmında %50'ye varan oranda kullanılan fiberle güçlendirilmiş polimer kompozitler darbelere karşı hassastır ve tespit edilmesi zor olan hasarlar nedeniyle bakım ihtiyacı çok fazladır. Şekil 6'da uçak gövde panellerinden kanat yapılarına kadar kompozit malzemenin kullanıldığı alanlar özetlenmekte ve böylece bakım ihtiyacının önemi göz önüne serilmektedir.

Şekil 6. Uçaklarda fiberle güçlendirilmiş polimer kompozitlerin kullanıldığı alanlar

Hem bakım ihtiyacını aşmak hem de hafif kompozit gövde tasarlamak için en umut verici çalışmalardan biri kendini iyileştiren malzemelerdir. Das, Melchior ve Karumbaiah (2011) bu

kapsamda kendini iyileştirebilen bir malzeme seçeneği hakkında çalışmalar gerçekleştirmiştir. Bu çalışmayı dikkate aldığımızda Hollow Glass Fibre malzemesi yani oyuk cam elyaflı epoksi kompozitlerinin hem darbe hassasiyetine karşı yapısal direnci arattırma potansiyeline hem de kendi kendini iyileştirebilen malzeme özelliğine sahip olduğu tespit edilmiştir. Yapılan çalışmalarda bu malzemenin hasar sonrasında eğilme dayanımında %47'ye varan bir geri kazanım gösterdiği ve karbon elyaf takviyeli epoksi laminantlarında gömülü oyuk cam elyaflı epoksiler kullanarak basma dayanımında %92'lik bir geri kazanma oranı rapor edilmiştir.

Bu duruma benzer olarak GE Aviation LEAP-1A, GE9X (Boeing 777X) ve Pratt & Whitney PW1100G-JM gibi hava araçlarının motorlarının yüksek basınçlı türbinlerinde, yanma odasında ve egzoz nozullarında seramik matrisli kompozitler (CMC) kullanılır (Paladugu et al. (2022)). Bunun sebebi oluşan yüksek ısı dereceleridir. Seramik matrisli kompozitler çok yüksek seviyede ısıya dayanabilme kabiliyetine sahiptirler. Fakat bu malzeme tipinin temel problemlerinden biri gevrek arızaya ve darbe hassasiyetlerine karşı çok hassas olmasıdır. Bu da yine yüksek bakım ihtiyacına sebebiyet vermektedir.

Paladugu et al. (2022) bu anlamda kendini iyileştirebilen seramik matrisli kompozitleri incelemiştir. Bu malzeme tipinin kendini iyileştirebilme mekanizması (örneğin Si-B-C matris + SiC lifleri) bor içerikli bileşenlerin oksitlenerek B_2O_3 (bor oksit) oluşturması ve mikro çatlakları doldurulması sayesinde gerçekleşir. Kendini iyileştirebilen bor oksit bileşenli seramik matris kompoziti hava aracı motorlarında karşımıza çıkabilecek olan 1000 °C, 1200 °C ve 1350 °C sıcaklıklarında denenmiştir (Paladugu et al., 2022). Bor bileşikleri ve bor silikon cam bileşikleri oksitlendiğinde kendi kendini iyileştirme sağlanmış ve bu da fazların matris çatlaklarına akmasına ve bunları kapatmasına yol açmıştır. Üç noktalı eğilme testi ve çekme testinden, bu CMC'lerin mukavemetinin sıcaklıkla arttığı görülmüştür. Kendi kendini iyileştirme de tetiklenmiş ve kendini iyileştiren CMC'lerin uçak motoru yanma odaları için uygun potansiyelde olduğu tespit edilmiştir.

Havacılıkta bor kullanımı daha ayrıntılı olarak incelenmiş ve bor katkılı matrise pirokarbon ilavesinin korozyon direncini ve kendi kendini iyileştirme özelliklerini artırdığı bulunmuştur. Bor katkılı pirokarbon ve B_4C ve SiC katmanları ile SiC-SiC fiber takviyeleri içeren çok katmanlı matris incelenmiş ve faz arası katmanlarda ve matrisin kendisinde bulunan bor içeren elementlerin, oksitleyici ortamda B_4C oluşturarak kendi kendini iyileştirme yeteneği sağladığı gözlemlenmiştir. Bu tür kompozitlerin mekanik yükler ve sıcaklık direnci altında mükemmel korozyon direncine sahip olduğu ve jet motoru yanma odaları için uygun olduğu tespit edilmiştir. Bor katkılı pirokarbon katmanları ve B_4C içeren çok katmanlı matrisli SiC-SiC fiber takviyeli kompozitler, mekanik yükler ve yüksek sıcaklıklar altında mükemmel korozyon direnci sergilediği yapılan çalışmalarda gösterilmiştir (Paladugu et al., 2022).

Kendini iyileştirme teknolojisi jet motorlarının türbin kanatçıklarında kullanılan nikel süper alaşımlı kanatçıkların yerine geçme potansiyeli de göstermektedir (Das et al., 2011). Kendini iyileştiren seramik kanatların kullanılması, nikel süper alaşımlı kanatların yerine geçerek daha yüksek çalışma sıcaklıklarına izin verme potansiyeline sahiptir. Daha yüksek çalışma sıcaklıkları ise doğrudan türbin verimliliğini artıracaktır. Mevcut CMC'lere nazaran kendini iyileştirme teknolojisine sahip olan bu malzeme bu sorunun üstesinden gelerek seramik kanatçıkların güvenirliğini arttırmayı amaçlamaktadır.

Şekil hafızalı polimer kompozitler özellikle askeri ve yeni sivil uçakların yapısal uygulamalarında yaygın olarak kullanılmaktadır. Airbus A350XWB ve Boeing 787 Dreamliner gibi uçaklar yapısal uygulamalarda bu malzemeyi aktif olarak kullanmaktadır. Yapılan deneysel bir çalışmaya göz attığımızda (Das et al., 2011) bir karbon elyaf takviyeli polimer matris kompozit, şekil hafızalı bir polimerin karbon nanotüpler ve karbon elyafı ile

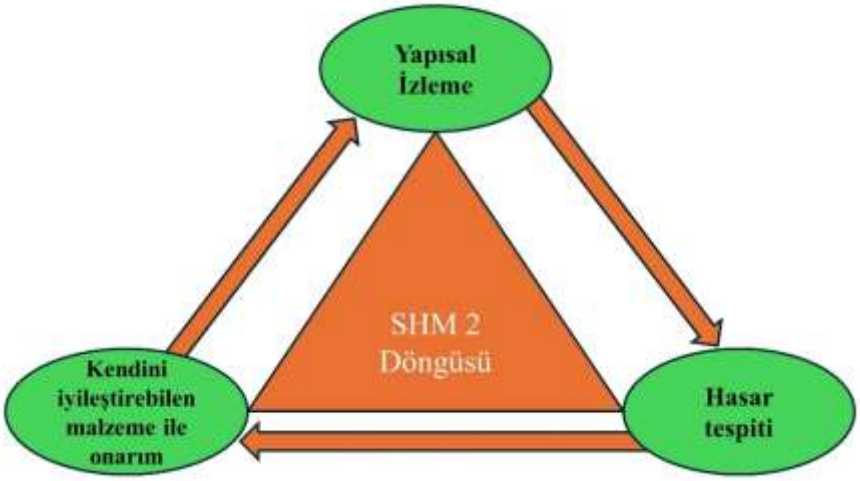
birleştirilmesiyle yüksek basınçlı kalıplama süreci kullanılarak üretilmiştir. Yapılan deneysel çalışmalarda kompozitin yorulma sonrasında matris çatlaklarını verimli bir şekilde iyileştirdiği görülmüştür. İyileşme sonrasında orijinal mekanik özelliklerinin %72'ye kadarını geri kazandığı tespit edilmiştir. Kendi kendini iyileştiren polimer kompozitler, mevcut bazı havacılık yapısal kompozitlerinin yerini alabilir, böylece uçağın hasar toleransını, servis ömrünü ve güvenliğini artırabilir.

Tablo 2'de farklı uçak bileşenlerinde kullanılabilecek kendini iyileştirebilen malzemelerin örnekleri ve sağlanılan iyileşme düzeyleri özetlenmiştir. Gövde, motor ve aeroyapılarda hangi tür kendini iyileştirebilen malzemelerin kullanılabileceği ve ne tür performans kazanımları elde edilebileceği gösterilmektedir.

Tablo 2. Kendini iyileştiren malzemelerin havacılığa entegrasyonuyla ilgili özet

Kullanım alanı	Örnek hava aracı	Aktif kullanılan malzeme	Kendini iyileştirebilen malzeme seçeneği	Kendini iyileştirebilme düzeyi
Gövde	Boeing 787 ve Airbus A350	Fiberle güçlendirilmiş polimer kompozit	Oyuk cam elyaflı epoxy kompoziti	%47
Motor ve yüksek sıcaklık oluşan bölgeler	GE Aviation LEAP-1A, GE9X (Boeing 777X) ve Pratt & Whitney PW1100G-JM	Seramik matrisli kompozitler	Kendini iyileştirebilen kendini iyileştirebilen seramik matrisli kompozit. (örneğin Si-B-C matris + SiC lifleri)	Hem sıcaklık hem de mukavemet direnci büyük oranda artmıştır
Aeroyapılar	Airbus A350XWB ve Boeing 787 Dreamliner	Şekil hafızalı polimer kompozitler	Karbon elyaf takviyeli polimer matris kompozit, şekil hafızalı bir polimerin karbon nanotüpler ve karbon elyafı ile birleştirilmesi	%72

4. TEKNİK ZORLUKLAR VE GELECEK PERSPEKTİFLERİ



Kendini iyileştirebilen malzemelerin havacılık uygulamalarında kullanımı hem bakım maliyetlerini azaltması hem yapısal güvenliğin arttırması sebebiyle büyük potansiyel taşıyor fakat uygulanabilirlik, performans süresi gibi çeşitli teknik konularda bazı zorluklar bulunduruyor.

4.1 Teknik Zorluklar

Havacılıkta kullanılan bileşenler ve parçalar çok yüksek termal döngülere, UV radyasyonuna, kuvvetli titreşim yüklerine ve çeşitli basınç ortamlarına maruz kalmaktadır. Otonom bakım sağlayabilen kendini iyileştirebilen malzemelerin bu koşullara ayak uydurabilmesi hala önemli bir sorundur ve tam olarak netlik kazanmış durumda değildir (Erden, 2025). Özellikle mikro kapsüllerin kırılma dayanımı ve iyileştirici stabilitesi kritik sınırlayıcı faktörlerden birdir. Bir diğer teknik zorluk ise havacılık alanında kullanılan kompozitlerde kendini iyileştirme mekanizması eklemenin çoğu zaman imalat sırasında malzemenin özgül dayanımını azaltabiliyor olmasıdır. Mikro kapsül veya damar ağlarının kompozit içinde oluşturduğu boşluklar uzun dönem yorulma durumunu tetikleyebilmektedir. Özellikle vasküler ağların entegre edilmesi yapıya ilave boşluklar ve dolayısıyla ek ağırlık ya da hacim getirir (Tsilimigkra et al., 2016). Mikro kapsül tabanlı sistemlerin imalat sırasında özgül dayanımının azalması dışında bu sistemlerin çoğu tek seferlik iyileştirme sağlamaktadır ve uçağın ömrü boyunca tekrar eden mikro çatlakların onarımı için çok döngülü sistemler henüz yeterince geliştirilmemiştir (Cordier et al., 2008).

4.2 Gelecek Perspektifleri

Bu konuda özellikle bahsedilmesi gereken yöntem SHM2 yöntemidir. Bu yöntem yapısal sağlık izleme yöntemiyle kendini iyileştirebilen malzemelerin bir döngü halinde onarım yapabilmesini amaçlamaktadır (Haider, Srivastava, Rohatgi & Salowitz, 2024). Bu çalışma sayesinde hem hasar tespiti hem de onarım tetiklenecek ve hava araçlarında bakım ve onarım süreçleri otomatikleşecektir. Yapısal sağlık izleme ile kendini iyileştiren malzemelerin entegre edildiği SHM2 yöntemi ve bu yöntemin bir kapalı döngü halinde nasıl işlediği Şekil 7'de gösterilmektedir. Bu döngü hasarın sensörler tarafından tespit edilmesi ile başlar ve daha sonrasında kendini iyileştiren malzemeler devreye girerek onarım gerçekleştirmesiyle devam eder.

Şekil 7. SHM2 Döngüsü

Otonom bakım ve onarım yeteneğine sahip sistemlerin geliştirilmesi, havacılık endüstrisinde yapısal güvenirlik ve süreklilik açısından önemli bir araştırma konusu ve geleceğe yönelik önemli bir atılım haline gelmiştir. Eroğlu et al. (2022) çalışmasında bahsettiği yapısal sağlık izleme tekniği sayesinde bir parça veya bileşene yerleştirilen sensörler aracılığıyla hasarın konumu ve boyutu tespit edilebilmekte olduğunu ancak tespit edilen hasarın yine insan müdahalesiyle onarılması gerektiğini belirtmiştir. Bu durum hem zaman hem de maliyet artışına sebebiyet vermektedir. Haider et al. (2024) yapısal sağlık izleme ve kendini iyileştirebilen malzemelerin entegrasyonu sonucunda SHM2 döngüsünden bahsetmektedir. Bu döngü sayesinde hava aracında hasar gören bileşenlerde hem hasar tespitini hem de onarım sürecini otomatik olarak tetikleyen kapalı bir döngü mümkün kılınabilmektedir.

Çalışmada nikel-titanyum (NiTi) şekil hafızalı alaşım (SMA) lifleriyle güçlendirilmiş bizmut-kalay (BiSn) matrisi kullanılmıştır. Kullanılan malzeme hem yük taşıma kapasitesine sahip olması hem de hasar sonrası ilk mukavemet seviyelerine yakın değerlere ulaşabilmesiyle dikkat çekmiştir. Yapısal sağlık izleme için kullanılan piezoelektrik sensörler hasar seviyesini ultrasonik sinyal değişimlerine göre ölçmüş, ardından malzeme ısıtılarak NiTi teller aktive edilmiş ve kompozit yapı kendi kendini başarıyla iyileştirmiştir. Ancak, yapılan işlemler sırasında piezoelektrik sensörlerden biri ayrılmakta olup hem piezoelektrik sensörünün yeniden yapıştırma gerekliliği hem de sistemlerin entegrasyonu sırasasında yaşanan zorluklar başarılı bir sistem entegrasyonu için daha fazla araştırma gerektiğini göstermiştir. Bu çalışmaya gelecek perspektifi gözüyle bakılırsa ilk sonuçlar, otonom hasar tespiti ve kendi kendini iyileştiren malzemelerin kombinasyonu olan SHM2 sistemlerinin otonom bakım ve onarım için umut verici olduğunu göstermektedir.

5. SONUÇ

Kendini iyileştiren malzemelerin havacılıkta otonom bakım onarım uygulamalarına uyarlanması, literatürde belirtilen bulguların ışığında hem önemli bir potansiyel hem de belirgin sınırlamalar barındırmaktadır. İncelenen çalışmalar ile yapılan değerlendirmelerde, ısı girdisinin kontrol gereksiniminin veya iyileşme verimi ile mekanik dayanım arasında kurulmak istenen dengenin en belirgin sınırlamalardan olduğu görülmüştür. Bu bağlamda özellikle havacılıkta çok yaygın kullanılan kompozit yapıların iyileşme sonrası kapasitesinin korunması, tekrarlı iyileşmenin gelişimi ve bu mekanizmaların hava araçlarının asıl servis koşullarındaki davranışları üzerinde durulması gerektiği sonucuna varılmıştır. Kendini iyileştirme mekanizmalarının uzun dönemli davranışlarının hem içsel hem dışsal olmak üzere oluşturulacak hibrit sistem çalışmalarının ve yapısal izleme yöntemi ile döngü halinde işleyen mekanizmaların incelenmesinin önemli olduğu düşünülmektedir.

Genel olarak değerlendirildiğinde havacılık sektöründeki yüksek güvenlik standartlarının da bu malzemelerin kullanımının henüz yaygınlaşmamış olmasının sebeplerinden birisi olarak görülebilir. Dolayısıyla teknolojinin ve araştırmaların ilerlemesi ile kendini iyileştirme mekanizmalarında mekanik kaybın minimize edilmesi, uzun ömürlü, hızlı ve tekrarlı iyileşmenin geliştirilmesi beklenmektedir. Sonuç olarak maliyetleri düşürecek ve sürdürülebilirliği artıracak olan bu malzemelerin geleceğin otonom bakım onarım sistemlerinde kritik rol üstleneceği öngörülmektedir.

ÖZET

Günümüzde artan enerji ihtiyacı ve küresel ölçekte yaşanan enerji krizi, sürdürülebilir ve yüksek verimli enerji dönüşüm teknolojilerinin geliştirilmesini zorunlu hâle getirmektedir. Bu bağlamda, atık ısının doğrudan elektrik enerjisine dönüştürülmesine olanak sağlayan termoelektrik malzemelere yönelik ilgi son yıllarda belirgin biçimde artmıştır. Termoelektrik malzemeler arasında, karbon nanotüpler (CNT) ile iletken polimerlerin oluşturduğu kompozitler özel bir önem taşımaktadır; çünkü bu yapılar mekanik esneklik ile görece yüksek termoelektrik verimi harmanlayabilmektedir. Bu çalışmada, geri katkılama (re-doping) işlemi sırasında kullanılan m-cresol miktarının, amin fonksiyonlu tek duvarlı karbon nanotüp/poli(anilin-ko-akrilonitril) kompozitlerinin termoelektrik özellikleri üzerindeki etkisi incelenmiştir. Kompozitler, aynı polimerizasyon koşulları altında sentezlenmiş ve ardından farklı m-cresol oranlarında (%0,60– %0,72 – %0,90 – %1,20,- %1,80,- %3,60 w/w) geri katkılanmıştır. Geri katkılama işlemi oda sıcaklığında yapılmış ve sonrasında yapılan ölçümlerle elektriksel iletkenlik (σ), Seebeck katsayısı (S) ve güç faktörü (PF = $S^2\sigma$) değerleri belirlenmiştir. Sonuçlar, m-cresol oranındaki artışın belirli bir düzeye kadar (yaklaşık %1,20) zincir hizalanmasını ve taşıyıcı hareketliliğini önemli ölçüde artırdığını göstermiştir. Bu oranda, polimer zincirleri arasındaki π–π etkileşimleri güçlenmiş ve optimum iletkenlik–Seebeck katsayısı dengesi elde edilmiştir. En yüksek güç faktörü yaklaşık 149,1 μW/mK^2 olarak %1,20 m-cresol içeriğinde kaydedilmiştir. %1,20'nin üzerindeki oranlarda ise aşırı çözücü etkileşimi nedeniyle morfolojik bozulmalar ve termolektrik verimde düşüş gözlenmiştir. Elde edilen bulgular, geri katkılama sırasında m-cresol miktarının dikkatle kontrol edilmesinin, polimer-nanotüp arayüzünde yük taşınımını optimize ederek termoelektrik performansı artırmada kritik rol oynadığını ortaya koymaktadır.

Anahtar kelimeler: anilin, akrilonitril, kopolimer, termoelektrik, m-kresol

OPTIMIZATION OF THERMOELECTRIC PROPERTIES IN A-SWNT/ POLY(ANILINE-CO-ACRYLONITRILE) COMPOSITES VIA CONTROLLED M-CRESOL RE-DOPING

ABSTRACT

The increasing global demand for energy and the ongoing energy crisis necessitate the development of sustainable and high-efficiency energy conversion technologies. In this context, thermoelectric materials have gained significant attention in recent years, owing to their ability to convert waste heat. Among various thermoelectric materials, composites of carbon nanotubes (CNTs) and intrinsically conducting polymers receive a particular interest, as they combine mechanical flexibility with reasonable power output. However, the thermoelectric efficiency of CNT/polymer composites highly depends on processing conditions, especially the choice and amount of secondary dopants used to modify chain ordering. In this study, we investigated the effect of m-cresol amount on the thermoelectric performance of amine-functionalized single-walled carbon nanotube/poly(aniline-co-acrylonitrile) composites. The composites were synthesized under identical polymerization conditions, and subsequently re-doped with different m-cresol contents (0.60%, 0.72%, 0.90%, 1.20%, 1.80%, 3.60% w/w). The re-doping procedure was carried out at room temperature, and then, the electrical conductivity (σ), Seebeck coefficient (S), and power factor (PF = $S^2\sigma$) values were determined. The results showed that increasing the m-cresol content enhanced chain alignment and charge carrier mobility up to a certain level (approximately 1.20%). At this ratio, π–π interactions between polymer chains were strengthened, leading to an optimal balance between conductivity and Seebeck coefficient. The highest power factor, approximately 149.1 $\mu W/mK^2$, was recorded at 1.20% m-cresol content. At ratios above 1.20%, morphological degradation and a decline in thermoelectric performance were observed due to excessive solvent–polymer interactions. The findings demonstrate that careful control of the m-cresol amount during re-doping plays a critical role in enhancing thermoelectric performance by optimizing charge transport at the polymer–nanotube interface.

1. GİRİŞ

Yenilenebilir enerji kaynakları, sürdürülebilir enerji üretiminde kritik bir konuma sahip olsa da, mevcut teknolojilerin verimliliğinin artırılması için atık ısının değerlendirilmesine yönelik çözümlere ihtiyaç duyulmaktadır. Bu kapsamda, güneş enerjisi sistemleri gibi yenilenebilir teknolojilerde açığa çıkan kullanılmamış ısının geri kazanılması, enerji dönüşüm zincirinin önemli bir halkasını oluşturur (Katirci et al., 2023). Küresel ölçekte artan enerji talebi ve fosil yakıt kullanımının çevresel etkileri, sürdürülebilir enerji teknolojilerinin geliştirilmesini kritik hâle getirmektedir. Yenilenebilir enerji sistemlerinde ortaya çıkan atık ısının büyük oranda değerlendirilemeden kaybedilmesi, enerji dönüşüm süreçlerinde önemli bir verimlilik kaybı oluşturmaktadır (Erden et al., 2025).

Termoelektrik (TE) malzemeler, atık ısıyı doğrudan elektrik enerjisine dönüştürebilme kabiliyetleri sayesinde enerji verimliliğini artırma ve karbon emisyonlarını azaltma açısından önemli bir çözüm sunmaktadır (He & Tritt, 2017). Özellikle düşük sıcaklık farklarının hakim olduğu sistemlerde organik ve hibrit TE malzemeler, esneklikleri, düşük maliyetleri ve çevresel uyumlulukları nedeniyle giderek daha fazla ilgi görmektedir (Zhang & Zhu, 2017; Du et al., 2018).

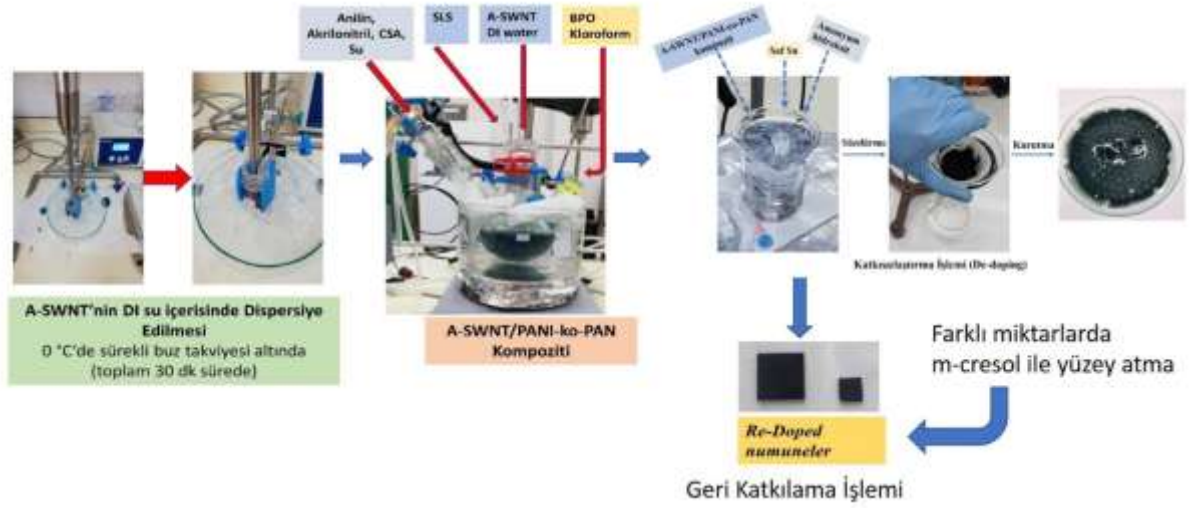
Geleneksel inorganik termoelektrik malzemeler olan Bi_2Te_3, PbTe ve $CoSb_3$ gibi bileşikler yüksek performans göstermelerine rağmen, toksisite, işlenebilirlik zorlukları ve kırılganlık gibi dezavantajlara sahiptir (Yan et al., 2011; Zebarjadi et al., 2012). Buna karşın iletken polimerler ve karbon nanotüp (CNT) tabanlı kompozitler, düşük ısıl iletkenlikleri ve çözeltide işlenebilir olmaları sayesinde yeni nesil esnek termoelektrik uygulamalar için güçlü adaylar olarak değerlendirilmektedir (Du et al., 2018; Chen et al., 2012).

İletken polimerler arasında polianilin (PANI), protonlanabilir yapısı, çevresel kararlılığı ve doping seviyesine bağlı olarak ayarlanabilir elektriksel özellikleri nedeniyle organik termoelektrik çalışmalarda öne çıkan malzemelerden biridir (Ozbay et al., 2023; MacDiarmid, 1997). PANI'nin akrilonitril (AN) ile kopolimerizasyonu, mekanik dayanımın artırılması önemli bir katkı olarak ön plana çıkmaktadır (Virji et al., 2006). Buna ek olarak, tek duvarlı karbon nanotüplerin (SWNT) polimer matrisine eklenmesi, yüksek taşıyıcı hareketliliği ve çoklu iletken ağ yapısı sayesinde Seebeck katsayısını ve güç faktörünü iyileştirmektedir (Chen et al., 2012; Lee et al., 2016).

Organik kompozitlerde nihai termoelektrik performansı belirleyen en kritik adımlardan biri ise **ikincil katkılama (re-doping)** sürecidir. Özellikle geri katkılamanın m-cresol gibi çözücü ortamların da gerçekleştirilmesi, PANI zincirlerinin daha planarlı bir konformasyona geçmesini sağlayarak zincir hizalanmasını, π–π istiflenmesini ve taşıyıcı hareketliliğini artırmaktadır (MacDiarmid, 1997; Gospodinova & Terlemezyan, 1998). Literatür, m-cresol ile yapılan bu yapı geçişinin hem elektriksel iletkenlik hem de Seebeck katsayısı/iletkenlik dengesi üzerinde belirgin iyileşme sağladığını göstermektedir (MacDiarmid, 1997; Zhang & Zhu, 2017).

Bu bağlamda, m-cresol miktarının hassas biçimde kontrol edilmesi, polimer–nanotüp arayüzündeki yük taşınım yollarını optimize etmek, taşıyıcı hareketliliğini artırmak ve kompozitin termoelektrik performansını maksimize etmek açısından kritik bir araştırma parametresi olarak değerlendirilmektedir. Bu çalışma, A-SWNT/Poli(ANI-ko-AN) kompozitlerinde farklı m-cresol oranlarına bağlı olarak meydana gelen yapısal ve elektriksel değişimleri sistematik biçimde inceleyerek optimum re-doping seviyesini belirlemeyi amaçlamaktadır.

2. MATERYAL VE YÖNTEM



Bu çalışmada kullanılan amin fonksiyonlu karbon nanotüpler (A-SWNT) Cheaptubes firmasından tedarik edilmiştir. Kloroform ($CHCl_3$) ve Soda-Lime Glass (SLG) cam altlıklar ISOLAB Chemicals, sodyum lauril sülfat (SLS) ise Fisher Chemical'dan sağlanmıştır. Kamfor sülfonik asit (CSA), benzoil peroksit (BPO), akrilonitril, anilin, m-cresol ve amonyum hidroksit Sigma-Aldrich ürünleri olup, deneylerde yalnızca anilin ön saflaştırma amacıyla damıtılmış; diğer tüm kimyasallar satın alındığı şekliyle kullanılmıştır. Tüm deneysel süreçlerde saf su tercih edilmiştir.

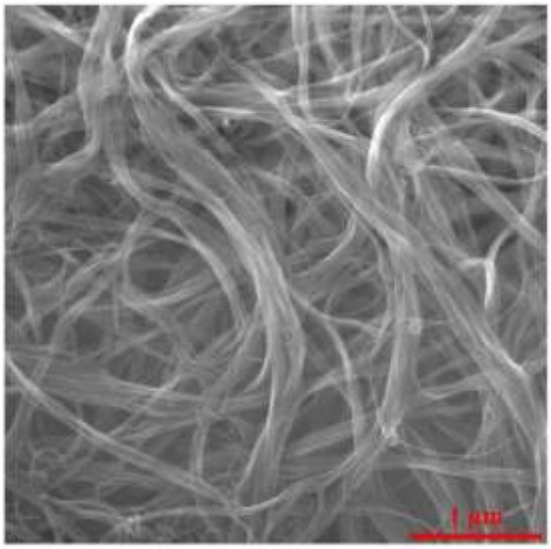
İlk aşamada A-SWNT'ler, su içerisinde homojen bir dağılım elde etmek amacıyla Bandelin HD2070 ultrasonik homojenizatör kullanılarak disperse edilmiştir. Başlatıcı olarak kullanılan BPO, kloroform içinde çözündürüldükten sonra polimerizasyonun yürütüleceği üç boyunlu balona aktarılmış ve çözücü kaybını önlemek için sisteme geri soğutucu bağlanmıştır. Saflaştırılmış anilin su içerisinde çözündürüldükten sonra akrilonitril ve katkılayıcı CSA belirli bir süre karıştırılarak çözeltiye eklenmiştir. Bu monomer karışımı daha sonra kontrollü olarak reaktöre damlatılmıştır. Reaksiyon karışımına, polimerizasyon ortamında kararlı bir emülsiyon yapısı oluşturmak amacıyla SLS eklenmiş; A-SWNT'lerin disperse edildiği süspansiyon ise uygun karıştırma süresi sonunda reaktöre ilave edilmiştir.

Polimerizasyonun sabit sıcaklıkta ilerlemesini sağlamak için su banyosu kullanılmış ve banyo sıcaklığı 60 °C'de tutulmuştur. Bu koşullarda polimerizasyon ortamının yaklaşık 55 °C'de seyrettiği belirlenmiş ve BPO'nun bu sıcaklıkta termal olarak bozunarak reaksiyonu başlattığı değerlendirilmiştir. Tüm polimerizasyon süreci 24 saat boyunca bu sıcaklıkta sürdürülmüştür. Reaksiyonun tamamlanmasının ardından kompozitler yaklaşık 25 °C'de aseton ile çöktürülmüş, elde edilen katı ürün süzülerek ayrılmış ve 45 °C'de vakumda kurutulmuştur. Numuneler daha sonra üç kez aseton ve üç kez saf su ile yıkanarak safsızlıklardan arındırılmış ve sabit kütleye ulaşana kadar yeniden kurutulmuştur.

Kurutulan kompozitlere katkı giderme işlemi uygulanmış; bu amaçla örnekler 0,1 M amonyum hidroksit çözeltisi içerisinde oda sıcaklığında yaklaşık 12 saat karıştırılmıştır. Bu işlemin ardından tekrardan vakum altında kurutulan numuneler farklı oranlarda m-cresol (%0,60 – %0,72 – %0,90 – %1,20 – %1,80 – %3,60 w/w) ile kopolimer/CSA molar oranı 2:1 olacak şekilde 24 saat karıştırılarak yeniden katkılanmıştır. Bu işlem sırasında m-cresol'ün polimer zincirlerini genişletmesi ve π–π etkileşimlerini artırması hedeflenmiştir. Yeniden katkılama aşamasından sonra kompozitler damla döküm yöntemiyle SLG cam altlıklar üzerine kaplanmış ve ince film hâline getirilmiştir. Tüm üretim süreci Şekil 1'de şematik olarak gösterilmiştir.

Üretilen ince filmlerin termoelektrik performansını belirlemek amacıyla çeşitli karakterizasyon yöntemleri uygulanmıştır. Kimyasal yapı Bruker Tensor II FT-IR spektrometresi ile incelenmiş, film kalınlıkları Taylor Hobson A profilometresiyle ölçülmüştür. Elektriksel iletkenlik değerleri ECOPIA HMS-7000 cihazı kullanılarak dört nokta prob yöntemi ile oda sıcaklığında belirlenmiştir. Kompozitlerin yüzey morfolojisi TESCAN MIRA 3 XMU taramalı elektron mikroskobunda görüntülenmiş, termoelektrik özellikler ise Linseis LSR-3/800 sistemi ile Seebeck katsayısı ve elektriksel direnç ölçümleri yapılarak değerlendirilmiştir.

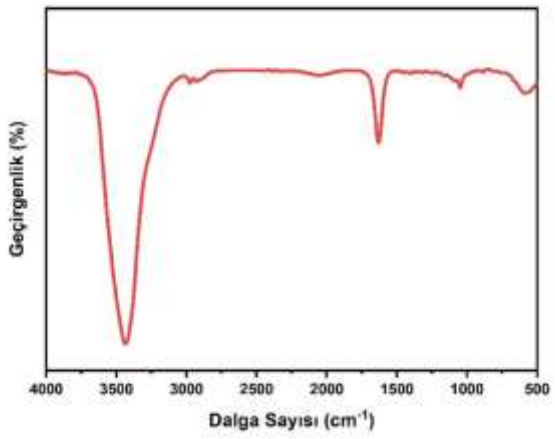
Şekil 1. A-SWNT/Poli(ANI-ko-AN) kompozitlerinin sentezi ve geri katkılanması



3. BULGULAR VE TARTIŞMA

Bu araştırmada, A-SWNT/Poli(ANI-ko-AN) kompoziti üretilmiş ve farklı miktarlarda m-cresol ile geri katkılamanın termoelektrik özelliklerine olan etkileri incelenmiştir. Sonuçlar, m-cresol oranı arttıkça polimer zincirlerinin hizalanmasının güçlendiğini ve taşıyıcı hareketliliğinin belirli bir noktaya kadar önemli ölçüde arttığını göstermiştir. Tablo 1'de görüldüğü üzere yaklaşık **%1,20 m-cresol** seviyesine kadar elektriksel iletkenlikte belirgin bir artış gözlenmiş, bu seviyede polimer-zincir düzeni maksimuma ulaşmıştır.

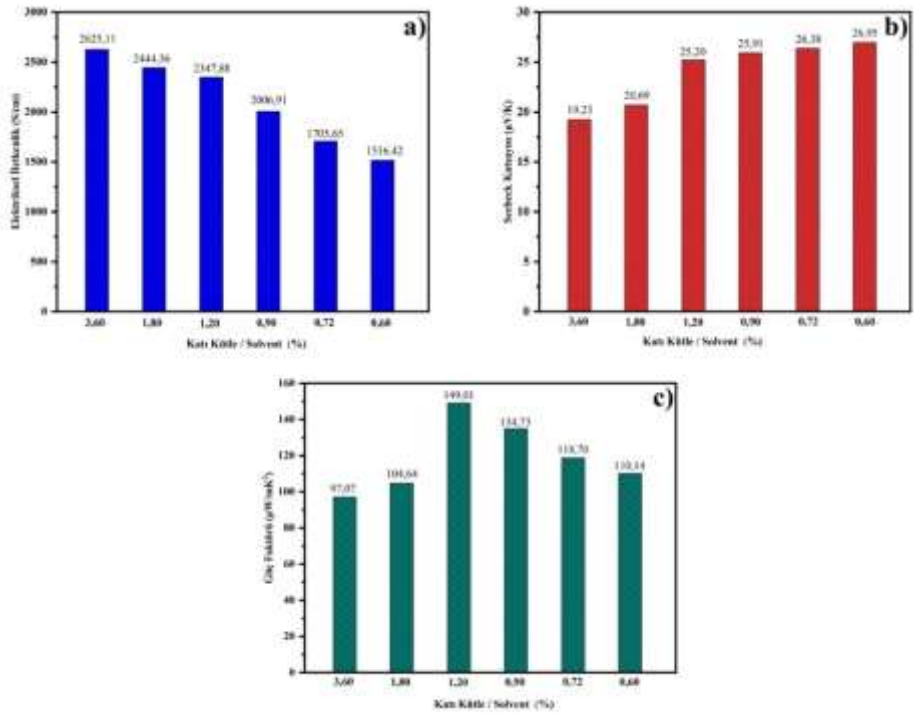
Tablo 1. m-cresol çözücüsü kullanılarak hazırlanan PANI/CSA sistemine ait çözelti parametreleri.



Solvent (mL)	PANI (mg)	CSA (mg)	Katı Kütle (mg)	Katı Kütle / Solvent % (w/w)
1	16	19,95	35,95	3,60
2	16	19,95	35,95	1,80
3	16	19,95	35,95	1,20
4	16	19,95	35,95	0,90
5	16	19,95	35,95	0,72
6	16	19,95	35,95	0,60

Şekil 2'tde farklı m-cresol oranları kullanılarak geri katkılanmış A-SWNT/Poli(ANI-ko-AN) kompozitlerine ait taramalı elektron mikroskobu (SEM) görüntüleri sunulmaktadır. Görsellerden, m-cresol miktarındaki değişimin A-SWNT morfolojisi üzerinde belirgin bir yapısal dönüşüme yol açmadığı anlaşılmaktadır. Tüm geri katkılama seviyelerinde nanotüplerin polimer matris içerisinde benzer konformasyon sergilediği ve kompozit yapıda A-SWNT'lerin homojen bir şekilde dağıldığı gözlemlenmiştir. Bu durum, re-doping sürecinin nanotüp ağ yapısını bozmadığını ve polimer–nanotüp arayüzünde sürekliliğin korunduğunu göstermektedir.

Şekil 2. Hazırlanan A-SWNT kompozitler için SEM görüntüleri.



Şekil 3'te A-SWNT içeren kompozitlere ait FTIR spektrumları sunulmakta olup, elde edilen sonuçların literatürde raporlanan bulgularla uyumlu olduğu görülmektedir (Erden et al., 2024). Spektrumlarda yaklaşık 3400 cm^{-1} bölgesinde gözlenen geniş bandın, su moleküllerine ait O–H gerilme titreşimlerinden kaynaklanabileceği değerlendirilmektedir. Bu bandın şiddetindeki değişimin, FTIR analizinde kullanılan KBr pelletlerinin nem içeriğine veya ölçüm sırasında ortamda bulunan rutubet seviyesine bağlı olarak farklılık gösterebileceği düşünülmektedir. FTIR spektrumlarında gözlemlenen 1630 cm^{-1} civarındaki karakteristik pik ise C=C iskelet gerilme titreşimlerine atfedilmekte olup, bu pik tüm kompozit numunelerinde belirgin biçimde ortaya çıkmıştır (Erden et al., 2025). Söz konusu bant, A-SWNT/kopolimer kompozit yapısının başarıyla oluştuğunu doğrulayan temel titreşim modlarından biri olarak kabul edilmektedir (Fernandes et al., 2019). Beklendiği üzere, saf A-SWNT'nin FTIR spektrumu 1630 cm^{-1} bölgesindeki söz konusu pik dışında genel olarak düşük şiddet yoğunluklarına sahiptir. Kompozit numunelerin FTIR davranışı incelendiğinde, spektral özelliklerin büyük ölçüde kopolimer matrisinin karakteristik titreşim modlarını yansıttığı görülmektedir.

Şekil 3. Hazırlanan a-SWNT kompozitlerinin de-doping sonrası FT-IR spektrumu.

A-SWNT/Poli(ANI-ko-AN) kompozitlerinin farklı m-cresol oranlarında geri katkılanmasına ilişkin elde edilen elektriksel ve termoelektrik veriler, m-cresol miktarının malzemenin taşıyıcı

taşınım mekanizması üzerinde belirleyici bir etkiye sahip olduğunu ortaya koymaktadır. Şekil 4a'da görüldüğü üzere, yüksek m-cresol oranlarında (örneğin %3,60 ve %1,80) kompozitlerin elektriksel iletkenliği belirgin şekilde artmış ve bu durum m-cresolün PANI zincirlerinin konformasyonunu "expanded-coil" formuna dönüştürerek π–π istiflenmesini güçlendirmesiyle açıklanabilir (MacDiarmid, 1997; Gospodinova & Terlemezyan, 1998). Ancak m-cresol oranı azaltıldığında zincirler arası planarlık ve taşıyıcı hareketliliği azalmakta, bu da iletkenliğin düşmesine yol açmaktadır. Bu bulgu, polimer matrisinde doping seviyesinin artmasıyla taşıyıcı yoğunluğunun yükseldiğini ve sonuç olarak iletkenliğin arttığını bildiren literatür ile uyumludur (Zebarjadi et al., 2012). Buna karşılık, Seebeck katsayısı Şekil 4b'de görüldüğü üzere iletkenliğin aksine düşük m-cresol oranlarında artış göstermiştir. En yüksek S değeri %0,60 m-cresol içeriğinde elde edilmiş olup, m-cresol miktarının yükselmesiyle Seebeck katsayısı düşmektedir. Bu durum termoelektrik malzemelerde iyi bilinen σ–S trade-off davranışıyla ilişkilidir; taşıyıcı yoğunluğunun artması iletkenliği artırırken Seebeck katsayısını düşürmektedir (He & Tritt, 2017). Dolayısıyla yalnızca iletkenliğin yüksek olması, optimum termoelektrik performansın elde edildiği anlamına gelmemektedir; Seebeck katsayısının korunması için kontrollü bir doping seviyesine ihtiyaç duyulmaktadır. Güç faktörü ($PF = S^2\sigma$) değerlerinin yer aldığı Şekil 4c ise bu iki parametre arasındaki rekabetin optimum noktada birleştiği doping seviyesini açıkça göstermektedir. PF değerinin %1,20 m-cresol içeriğinde maksimuma ulaşması, bu oranında hem yeterli zincir hizalanması sağlayacak bir iletkenlik artışı yarattığını hem de Seebeck katsayısındaki düşüşün henüz kritik seviyeye ulaşmadığını göstermektedir. Benzer şekilde, organik termoelektrik kompozitlerde optimum performansın genellikle orta seviyelerdeki doping oranlarında ortaya çıktığı literatürde de vurgulanmaktadır (Zhang & Zhu, 2017; Chen et al., 2012). Bu nedenle, bu çalışmada belirlenen %1,20 m-cresol oranı, taşıyıcı hareketliliği ile enerji filtreleme etkisi arasında en uygun dengenin sağlandığı, dolayısıyla termoelektrik performansı maksimize eden optimum geri katkılama seviyesini temsil etmektedir.

Şekil 4. A-SWNT/Poli(ANI-ko-AN) kompozitlerinin TE özellikleri a) Elektriksel iletkenlik, b) Seebeck, c) Güç faktörü

4.SONUÇ

Bu çalışmada, A-SWNT/Poli(ANI-ko-AN) kompozitlerinde farklı m-cresol seviyelerinde gerçekleştirilen geri katkılama işleminin termoelektrik performans üzerindeki etkileri kapsamlı biçimde değerlendirilmiştir. Bulgular, m-cresol miktarının polimer zincir hizalanmasını ve taşıyıcı hareketliliğini doğrudan etkilediğini, bu nedenle termoelektrik parametrelerde belirgin değişimler oluşturduğunu göstermiştir. Elektriksel iletkenlik ve Seebeck katsayısı arasındaki denge göz önüne alındığında, optimum performansın %1,20 m-cresol içeriğinde elde edildiği belirlenmiş ve bu seviyede en yüksek güç faktörü kaydedilmiştir. Sonuç olarak, m-cresol oranının kontrollü ayarlanması, polimer–nanotüp arayüzünde yük taşınımını optimize ederek esnek organik termoelektrik kompozitlerin verimini artırmada kritik bir parametre olarak ortaya çıkmaktadır.

TEŞEKKÜR

ÖZET

Günümüzde kablosuz iletişim teknolojilerinde yaşanan hızlı gelişmeler, yeni gereksinimleri ortaya çıkarmıştır. Bu taleplere karşılık geliştirilen beşinci nesil (5G) mobil iletişim teknolojisi, yalnızca geleneksel haberleşme yöntemlerini dönüştürmekle kalmamış, aynı zamanda anten sistemlerinin de yeniden tasarlanmasını zorunlu hale getirmiştir. Avrupa Komisyonu tarafından 3.5 GHz bandının kullanımı özellikle 5G uygulamaları için çok kritik bir konumdadır. MIMO mikroşerit antenler, 5G gereksinimlerini karşılamak için ideal bir teknolojidir. MIMO sistem tasarımlarında en önemli zorluk, anten elemanlarının yakın yerleşiminden doğan karşılıklı kuplajın azaltılması ve sistem performansının artırılmasıdır. Bu çalışmada, nihai olarak tasarlanan 1x2 MIMO anten yapısı 3.5GHz çalışma frekansında faaliyet gösterecek şekilde optimize edilmiştir. Anten yapısının ön yüzeyinde birbirine özdeş yama antenler olup, aralarındaki elektromanyetik etkileşimi azaltmak amacıyla dambıl şekline benzer bir izolasyon yapısı tasarlanmıştır. Anten tasarımının DGS yapısı için toprak düzleminde, simetrik olarak tasarlanan iki yarım dairesel şeklin dışında kalan alan ile ortada konumlanan bir dikdörtgen boşluk yer almaktadır. Bu yapı, yüzey akımlarının yönünü değiştirerek akımların doğrudan diğer anten elemanına bağlanmasını engeller. Böylece karşılıklı bağlaşım azaltılırken, antenin MIMO performansı iyileştirilmiş olur. Simülasyon çalışmalarında en iyi anten performansını gözlemlemek için iki farklı izolasyon ve DGS tasarımı ayrı ayrı incelenerek grafikler üzerinden karşılaştırılmalı analizi yapılmıştır. Sonuç olarak yalın anten modeline göre seçilen izolasyonlu DGS eklenmiş anten tasarımının 3.5GHz çalışma frekansında hem geri dönüş kaybında 11dB'e hem de izolasyon kaybında 6dB'e yakın bir iyileştirme sağladığı ayrıca tasarımın 2.9dBi mertebelerinde bir kazanç elde ettiği gözlemlenmiştir. Literatürdeki diğer çalışmalara kıyasla 80x50mm boyutlarına indirgenmiş olması, 5G teknolojisinin gerektirdiği yüksek performanslı, küçük boyutlu ve enerji tasarruflu anten çözümleri için önemli bir avantaj sunmaktadır. Elde edilen bulgular, gelecekte daha gelişmiş kablosuz haberleşme uygulamalarında kullanılabilecek kompakt ve yüksek verimli antenlerin geliştirilmesine katkı sağlayacaktır.

ENHANCEMENT OF ISOLATION IN 5G 1×2 MIMO PATCH ANTENNAS BY EMPLOYING DEFECTED GROUND STRUCTURE (DGS)

ABSTRACT

Recent advances in wireless communication technologies have introduced new demands. The fifth-generation (5G) mobile communication system, addressing these needs, has transformed conventional methods and required the redesign of antenna systems. The 3.5 GHz band, designated by the European Commission, is critical for 5G applications. MIMO microstrip antennas represent an ideal technology to meet the requirements of 5G systems. The major challenge in MIMO system design is to minimize the mutual coupling arising from the close placement of antenna elements and enhance overall system performance. In this study, the proposed 1×2 MIMO antenna structure was optimized to operate at the 3.5 GHz frequency band. On the front surface of the antenna, identical patch elements are placed, and a dumbbell-shaped isolation structure was designed to reduce the electromagnetic interaction between them. On the ground plane of the antenna, the DGS structure comprises vacant regions surrounding the two symmetrically designed semi-circular shapes and a centrally positioned rectangular slot. This configuration alters the direction of the surface currents, preventing them from directly coupling to the other antenna element. Consequently, mutual coupling is reduced, and the MIMO performance of the antenna is improved. In the simulation studies, two different isolation and DGS designs were individually examined to observe the optimal antenna performance, and a comparative analysis was conducted based on the obtained graphs. As a result, compared to the basic antenna model, the DGS structure achieved an improvement of approximately 11 dB in return loss and 6 dB in isolation loss at the 3.5 GHz. Furthermore, the design exhibited a gain of around 2.9 dBi. Also, the 80x50 mm dimensions compared to other studies offer a significant advantage for required high-performance, compact, and energy-efficient antenna solutions. These results advance the development of compact, highly efficient antennas for future advanced wireless communication applications.

1. INTRODUCTION

The origin of patch antennas dates back to the 1950s.Georges A. Deschamps introduced the concept of the microstrip antenna in 1953, but the practical applications of this idea remained limited due to the lack of suitable dielectric materials and manufacturing techniques. Research into microstrip antenna technology gained momentum in the 1970s. In 1972, Robert E. Munson introduced the microstrip patch antenna, demonstrating the practical applications of this structure [1]. These developments paved the way for microstrip antennas to be used in an increasingly wider range of applications.In the 1980s, the fabrication and application of microstrip antennas became widespread, and various feeding methods and patch geometries were developed to enhance performance. Furthermore, during this period, significant theoretical approaches, such as the cavity model used in antenna analysis, were introduced to the literature [2,3].

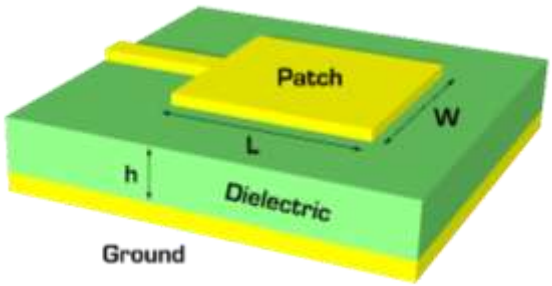

Figure 1: Patch Antenna Board Diagram

A patch antenna, also commonly known as a microstrip antenna, is a type of antenna characterized by a low-profile and planar structure. A patch antenna consists of three main components [4]:

1) The Patch: This is a radiating element made of a conductive material (typically copper). Its dimensions determine the antenna's resonant frequency.

2) The Dielectric Substrate: This layer is situated between the patch and the ground plane. Its dielectric constant (ε_r) and thickness affect the antenna's electrical size and bandwidth. Common materials used include FR-4, Rogers RT/Duroid, and Taconic.

3) The Ground Plane: This is a conductive plane that forms the backdrop of the structure. It provides an electrical return path and contributes to the directionality of the electromagnetic waves.

In order to utilize the capabilities offered by technology in the most efficient way, it is crucial to optimize the fundamental performance parameters of antennas, particularly in terms of bandwidth, directivity, and gain. Consequently, microstrip patch antennas have emerged as one of the prominent antenna types in 5G communication systems due to their compact structure, low profile, ease of fabrication, and adaptability.

MIMO (Multiple-Input Multiple-Output) systems are an ideal solution for meeting the high-performance expectations of 5G and effectively utilize multiple antenna elements for this purpose. The close proximity of these antennas causes mutual coupling, which negatively impacts system performance. Therefore, a high degree of isolation between the antennas is a key design objective [5,6].

One of the most significant challenges encountered in such systems is to improve overall system performance by increasing isolation and reducing mutual coupling, which arises from the close

placement of antenna elements. Techniques such as Defected Ground Structure (DGS) are employed to mitigate mutual coupling between antenna elements and ensure maximum performance [7,8]. DGS refers to structures implemented on the ground plane of microstrip antennas. These structures enhance antenna performance by modifying the current distribution and creating stopbands at specific frequencies [9]. Typically designed by introducing slots or voids in the ground plane, DGS is a critical element for MIMO systems, especially in 5G applications. DGS improves the isolation and overall performance of the antenna system because it disrupts the surface current paths, enabling the suppression of unwanted modes and the reduction of mutual coupling [10,11].

This study focuses on the analysis of the enhanced performance, particularly the isolation and DGS system, of a 5G MIMO patch antenna designed to operate in the 3.5 GHz frequency band. The design aims to develop a high-performance and easily integrable antenna solution that can be used specifically in urban applications. In this context, the conducted work aims to contribute to suitable antenna structures for 5G technology and serve as a reference for future communication systems.

2. ANTENNA DESIGN

2.1. Patch Antenna Dimensions

Microstrip antenna design fundamentally depends on parameters such as the resonant frequency, dielectric constant, substrate thickness, and patch dimensions. The first step in our study was to determine the operating frequency of the antenna. For this design, a resonant frequency of 3.5 GHz was targeted for 5G applications."Since the selection of the dielectric material directly affects the electromagnetic properties of the antenna, the widely used FR-4 material was chosen for this purpose. The dielectric constant of this material is set as ε_r = 4.3, and the substrate thickness is set as h = 1.6mm. Furthermore, the speed of light value used in electromagnetic calculations is c = 3x10^8m/s.

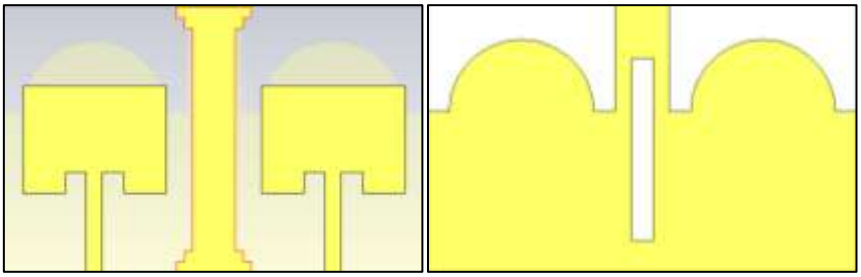
The width of the patch (W) affects the antenna's impedance matching and efficiency [12]. It is calculated using the following formula:

$$W = \frac{c}{2f}\sqrt{\frac{2}{\varepsilon_r + 1}}$$

The **effective dielectric constant**, which is required for the length of the antenna:

$$\varepsilon_{ff} = \frac{\varepsilon_r + 1}{2} + \frac{\varepsilon_r - 1}{2}\sqrt{1 + 12\frac{h}{W}}$$

The length of the patch (L) is determined by the resonant frequency, but a correction is applied due to the fringing of the electromagnetic fields at the edges:



$$L = \frac{c}{2f\sqrt{\varepsilon_{ff}}} - 0.824\ x\ h\frac{(\varepsilon_{ff} + 0.3)(\frac{W}{h} + 0.264)}{(\varepsilon_{ff} - 0.258)(\frac{W}{h} + 0.8)}$$

Consequently, the patch dimensions were determined as W = 27mm and L = 20.3mm.

2.1. Proposed Antenna Design

The designed 1x2 MIMO antenna structure has been optimized to operate at a 3.5GHz operating frequency. The antenna structure consists of two identical microstrip patch antennas

placed side-by-side. The front and rear surface views of the proposed antenna are presented in Figure-2.

(**a**) (**b**)

Figure 2: 2D View of the Proposed Antenna Layout (**a**) Front View (**b**) Back View

The patch antennas positioned on the front side are identical, and an isolation structure has been designed to reduce the mutual coupling (electromagnetic interaction) between them. The dimensional parameters of the associated patch and isolation structures are presented in Figure-3, while the corresponding numerical values for these parameters are provided in the table.

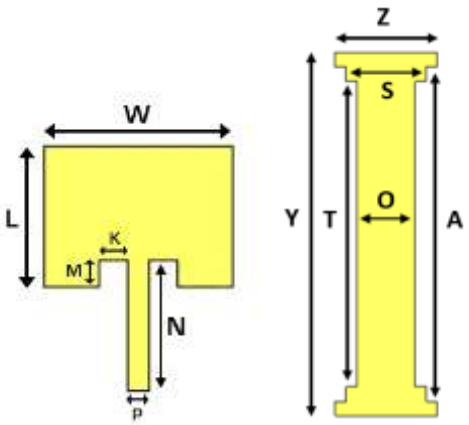


Figure 3: Representation of the Dimensional Parameters for the Patch and Isolation Designs

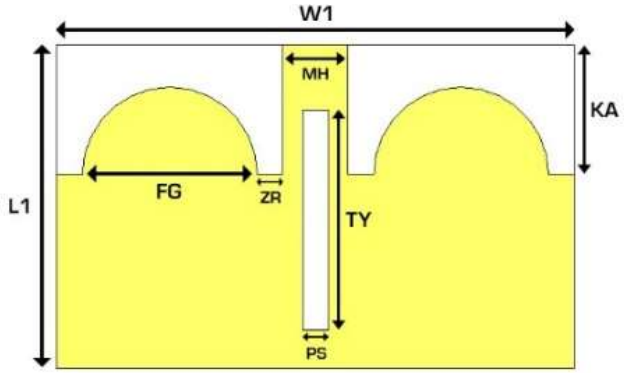
Table 1: Parameter Values for the Patch and Isolation Designs

Parameters	**Values**	**Parameters**	**Values**
W	27mm	Z	14mm
L	20.3mm	Y	50mm
K	4mm	T	42mm
M	4mm	S	11mm
N	18.9mm	O	8mm
P	3mm	A	46mm

Figure-4 presents the structure on the antenna's ground plane, which consists of two symmetrically etched semi-circular shapes and a narrow rectangular slot positioned in the center. This configuration modifies the path of the surface currents, thereby preventing currents from directly coupling to the adjacent antenna element. Consequently, mutual coupling is reduced, and the overall MIMO performance of the antenna is enhanced.



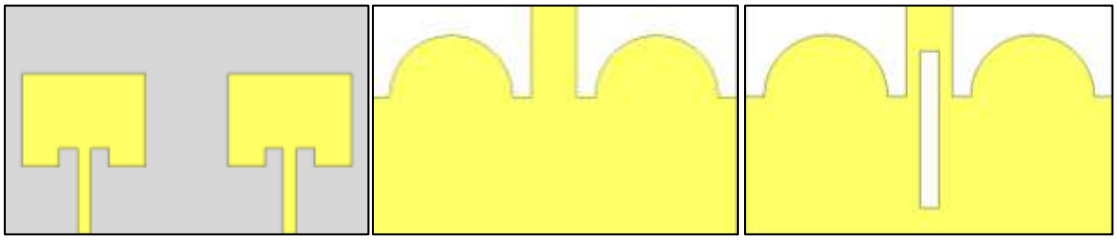


Figure 4: Representation of the Dimensional Parameters for the DGS Design

Table 2: Parameter Values for the DGS Design

Parameters	Values	Parameters	Values
W1	80mm	TY	34mm
L1	50mm	PS	4mm
FG	27mm	KA	20mm
MH	10mm	ZR	4mm

3. IMPLEMENTATION AND SIMULATION

This section presents the optimization studies performed to reach the proposed configuration of the designed 5G 1x2 MIMO. The study separately examines the performance of two distinct isolation techniques applied to the antenna's front surface and two different DGS configurations implemented on the rear-side ground plane, followed by a comparative analysis using graphical results.

(**a**) (**b**) (**c**)

Figure 5: Steps of DGS Design (**a**) Front View (**b**) View of DGS-1 (**c**) View of DGS-2

In the first phase of the design, the simple front surface structure shown in Figure 5 was kept constant. Subsequently, two DGS geometries were designed on the back ground plane to reduce the mutual coupling between the elements. The resulting $|S_{11}|$ (Return Loss) and $|S_{21}|$ (Isolation Loss/Coupling Loss) graphs obtained from the simulation are presented below.

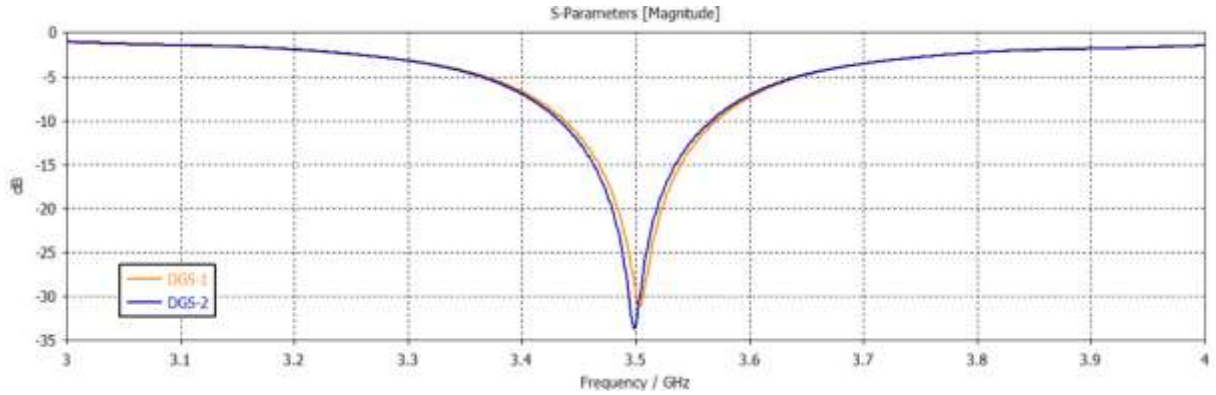

Figure 6: DGS Simulation S_{11} Graph

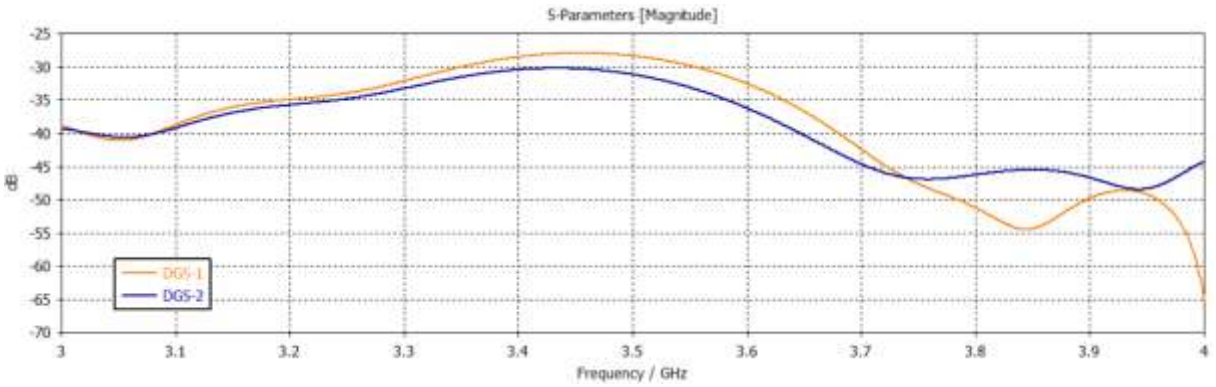

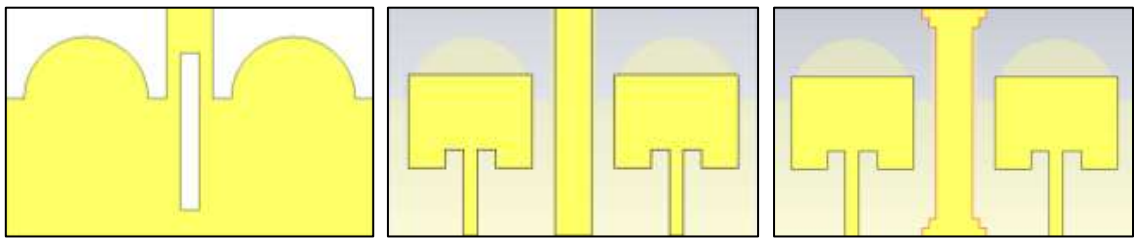

Figure 7: DGS Simulation S_{21} Graph

Table 3: Simulation Results of DGS

Antennas (DGS)	$\|S_{11}\|$	$\|S_{21}\|$
DGS-1	-29.61	-28.33
DGS-2	-33.27	-31.14

Observing Figure 6, the $|S_{11}|$ value for the DGS-2 configuration at the 3.5GHz operating frequency demonstrates superior impedance matching compared to DGS-1, reaching -33.24dB. Furthermore, in Figure 7, the $|S_{21}|$ value of -31.12dB for DGS-2 clearly reveals its enhanced effectiveness in reducing the mutual coupling between the antennas when compared to DGS-1. Consequently, the DGS-2 design proved to be the most optimal DGS configuration.

(**a**) (**b**) (**c**)

Figure 8: Steps of Isolation Design (**a**) Back View (**b**) View of Isolation-1 (**c**) View of Isolaiton-2

In this phase, with the DGS structure (Figure 5(**c**)) determined in the previous section held constant, studies were conducted to further enhance the isolation performance between the two patch antennas on the front surface. The isolation study involved a comparison between configurations achieved by placing metallic strips (or lines) between the antennas. Two different isolation structures were simulated in terms of their $|S_{11}|$ and $|S_{21}|$ parameters, and the resulting graphs are presented below.

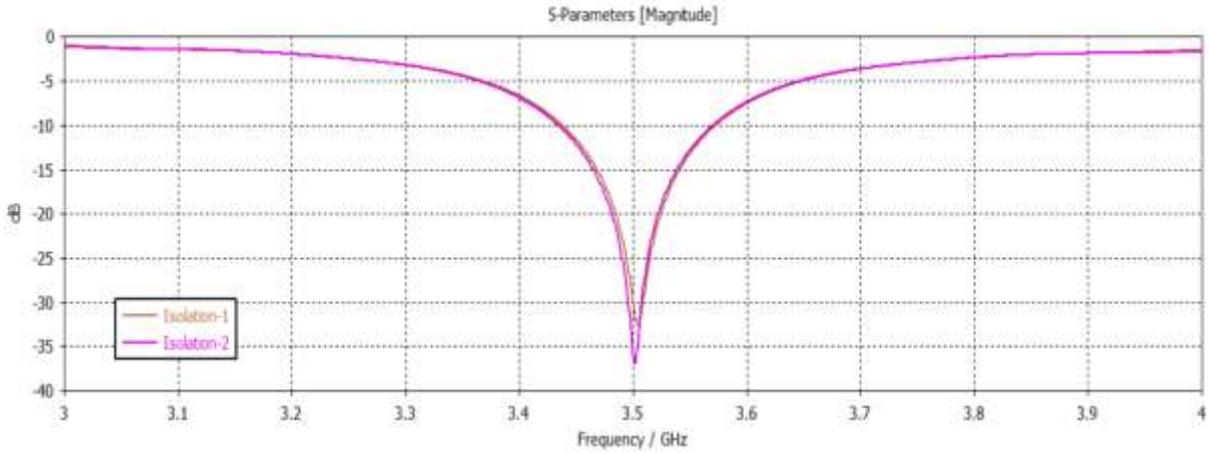

Figure 9: Isolation Simulation S_{11} Graph

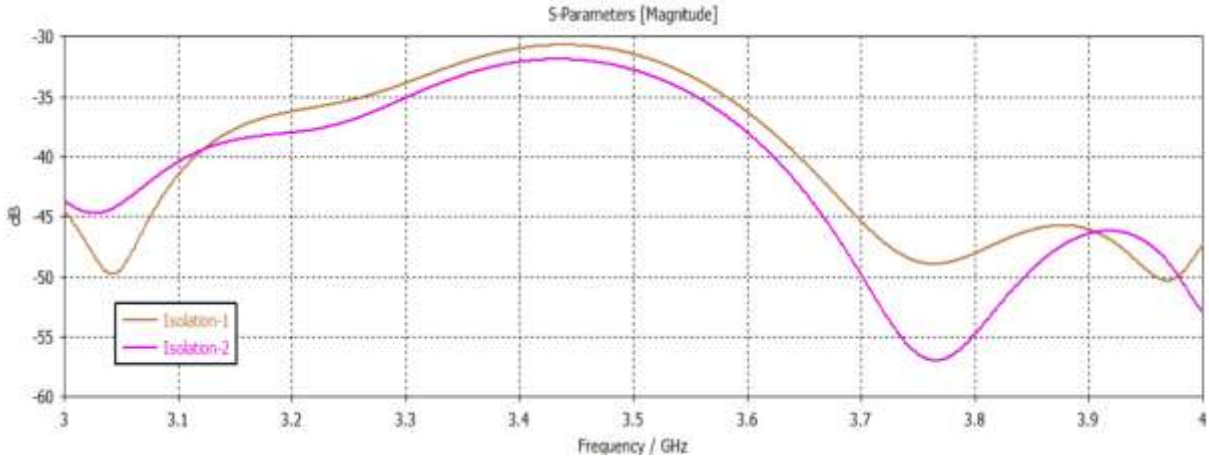

Figure 10: Isolation Simulation S_{21} Graph

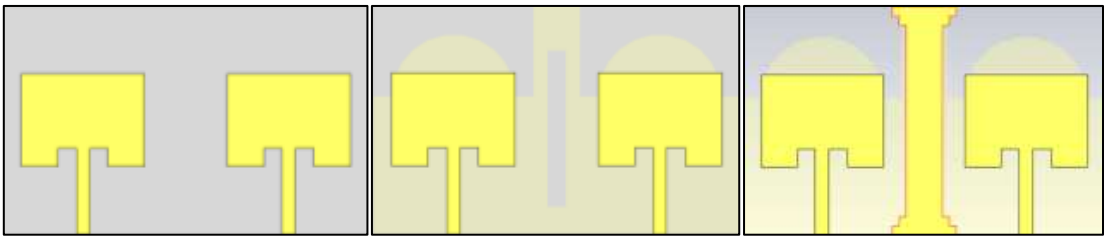

Table 4: Simulation Results of Isolation

Antennas (Isolation	$\|S_{11}\|$	$\|S_{21}\|$
Isolation -1	-29.91	-31.45
Isolation -2	-35.94	-32.77

When comparing the results of the isolation studies, a significant performance enhancement was observed in the $|S_{21}|$ parameter for the Isolation-2 structure presented in Figure 8(**c**). This demonstrates a substantial reduction in the mutual coupling between the antennas. Despite this improvement, there was only a negligible degradation in the $|S_{11}|$

parameter. Based on the results in the table, the most optimal isolation surface is the one shown in Figure 8(**c**), yielding values of -35.94 dB for $|S_{11}|$ and -32.77 dB for $|S_{21}|$.

For the proposed 1x2 MIMO antenna, the design shown in Figure 5(**c**) constitutes the DGS, while the design in Figure 8(**c**) constitutes the front-side isolation structure. In order to accurately observe the performance increase provided by the selected antenna design, a comparative analysis of the proposed antenna was performed against both the non-isolated version and the version containing only the DGS structure.

(**a**) (**b**) (**c**)

Figure 11: Comparison of the antenna designs (**a**) Base Antenna (**b**) Only DGS (**c**) Proposed Antenna

The resulting $|S_{11}|$ and $|S_{21}|$ graphs, obtained from the comparative analysis of the proposed antenna design (illustrated in Figure 11(**c**)) with the other antenna versions, are presented below.

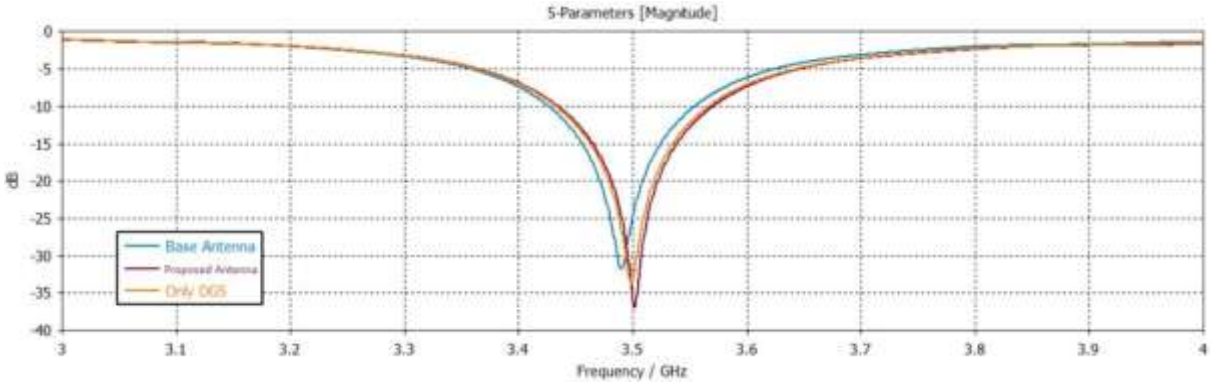

Figure 12: S_{11} Comparison Graph of the Antennas

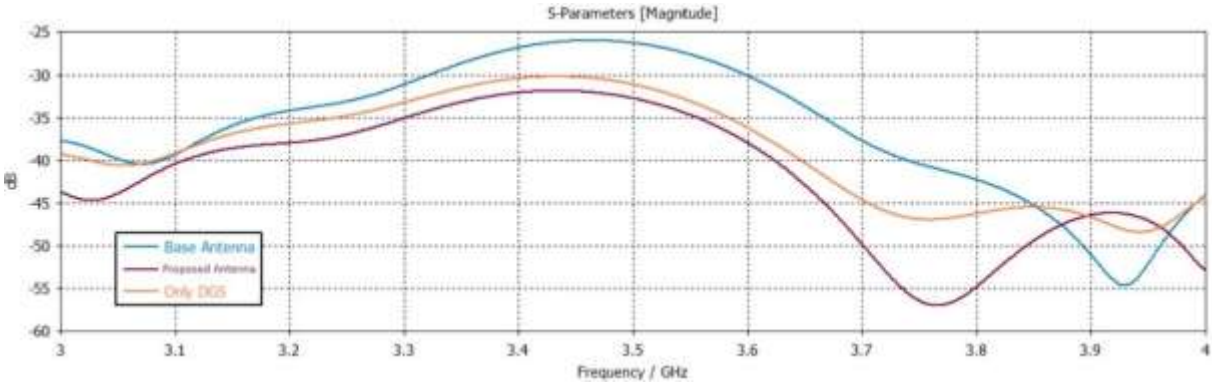

Figure 13: S_{21} Comparison Graph of the Antennas

Table 5: Simulation Results of The Antenna Designs

Antennas	$\|S_{11}\|$	$\|S_{21}\|$
Base Antenna	-24.62	-26.28
Only DGS	-33.27	-31.12
Proposed Antenna	-35.94	-32.77

The simulation results demonstrate that the designed proposed antenna, which incorporates both the DGS and the isolation structures, has yielded a remarkable improvement in the antenna's performance parameters at the 3.5GHz operating frequency, achieving values of up to -35.94 dB for $|S_{11}|$ and up to -32.77 dB for $|S_{21}|$.

A comparison of the 1x2 MIMO Antenna design with relevant antenna designs found in the literature is presented in the Table 6.

Table 6: Comparison with Similar Studies in the Literature

Reference	**Dimensions(mm)**	**Freq.(GHz)**	**Dielectric**	**S_{21} (dB)**
[13]	60x160	3.58	FR-4	-24.9
[14]	133x70	2.45/3.5	Felt Textile	-30
[15]	66x45	2.21/6	AGH4-Melinex	≤-15
[16]	100x50	3.5	Rogers 5880	-33.21
This Study	**80x50**	**3.5**	**FR-4**	**-32.77**

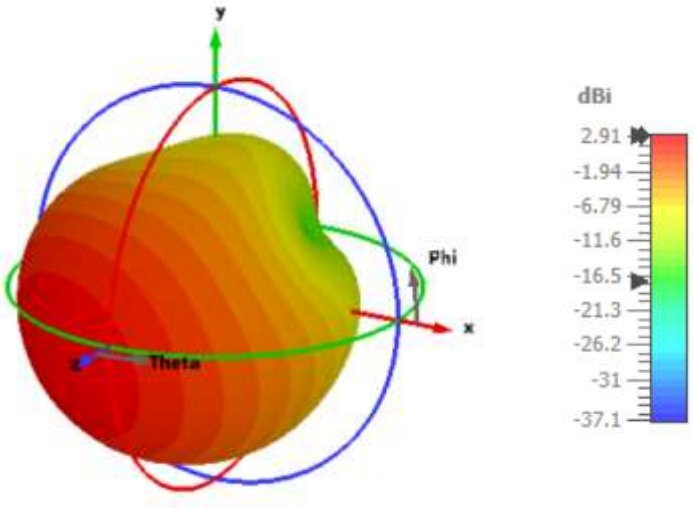

Figure 14: 3D View of Far-Field Gain Radiation Pattern

The 3D graphical values show that the designed antenna has a gain of 2.9dBi. This result, combined with the performance of our antenna, demonstrates an efficient antenna structure.

4. CONCLUSION AND COMMENTS

In this study, a 1x2 MIMO 5G antenna design was successfully realized. Both DGS and isolation structures were utilized to enhance the antenna's performance. The simulation results

demonstrated that the antenna achieved $|S_{11}|$ and $|S_{21}|$ values of -35.94 dB and -32.77 dB, respectively, at the 3.5GHz operating frequency. Furthermore, the design exhibited a gain of around 2.9 dBi and the design's compact dimensions of 80x50 offer a significant advantage for the small-sized, high-performance, and energy-efficient antenna solutions required by 5G technology. The findings will contribute to the development of compact and highly efficient antennas suitable for use in future advanced wireless communication applications.

ABSTRACT

Adhesive-based joining methods are widely used for metal-composite hybrid structures in the defense and aerospace sectors to meet the demands for lightweight and high strength. This study investigated the bonding of AA7075-T6 alloy aluminum plate to carbon fiber-reinforced epoxy matrix composite (CFRP) plates using adhesive film, and the effects of different surface preparation processes on the interfacial bond strength. Various mechanical and chemical surface preparation processes, such as glass-sand blasting, anodizing, and cross-marking, were applied to the surfaces of the aluminum plates. The CFRP plates were prepared to dimensions in accordance with the ASTM D1002 standard and then bonded to the aluminum plates with an epoxy-based adhesive film. Shear tests were applied to the prepared samples. Precision cutting was then performed for metallographic examination, and the samples were embedded in Bakelite. Optical microscope analyses were performed. The results showed that glass-sand blasting and anodizing provided significantly higher shear strength at the AA7075-T6/CFRP joint interface compared to other surface preparation methods. However, a significant decrease in bond strength was observed on cross-ribbed surfaces. The study demonstrates that AA7075-T6 alloy can be used effectively in high-performance hybrid bonds with CFRP structures with appropriate surface preparation methods.

1. INTRODUCTION

The use of lightweight materials with high specific strength has been increasing since the 1940s to increase energy efficiency and maximize performance in the aerospace, defense, and automotive industries. Advances in composite material technology, particularly in recent years, have expanded the use of polymer matrix composites (CFRP) in structural elements. However, in industrial applications, it is not always possible for a single material group to meet all design requirements such as ductility, toughness and impact resistance. Therefore, the design of "hybrid structures", which combine the ductility and toughness of metals with the lightweight and high strength properties of composites, plays a critical role in engineering [1-3].

The biggest challenge in the production of hybrid structures is the reliable joining of these materials (metal-composite), which have completely different physical and chemical properties. Conventional mechanical joining methods (riveting, bolting) cause stress concentrations, fiber ruptures, and increased weight in composite structures, while welding methods have limited applicability due to material incompatibilities [4-7]. Adhesive bonding, in this context, stands out as a strong alternative to mechanical joining because it allows materials with different properties to be joined, provides uniform stress distribution, increases corrosion resistance, and provides lightweight construction. [8-12].

The mechanical behavior and durability of adhesive joints depend largely on the interface properties between the surfaces joined by the adhesive. Failure mechanisms that can occur at the interface can occur as adhesive, cohesive, or mixed failure. The joint areas are subjected to various types of stresses, such as tension, compression, shear, separation, and peeling. Figure 1 illustrates the different types of loads that can occur on the adhesive joints. These joints can support each of the specified loads individually or can withstand the combined application of multiple loads [13, 14]. Especially in the joining of aerospace-grade aluminum alloys such as AA7075-T6 with CFRP, the structure of the natural oxide layer on the aluminum surface and surface roughness are factors that directly affect bond strength. Studies in the literature on the problems encountered in determining the mechanical properties of adhesives and ensuring reproducibility emphasize the critical importance of surface preparation processes [15]. Various mechanical and chemical treatments such as sandblasting, acid etching, and anodizing are applied to increase the surface energy and ensure mechanical locking [16].

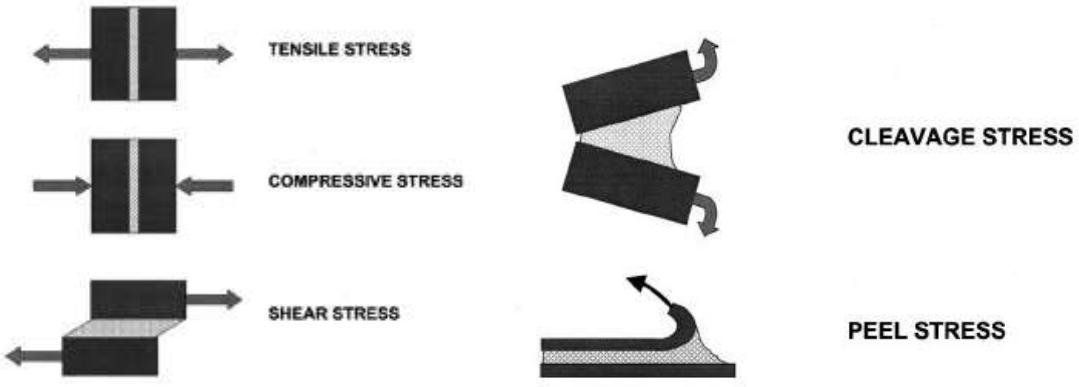

Figure 1. Different types of loads in the area of the adhesively bonded sections [10]

Öztürk [17], in their study on AA7075-T6 aluminum alloys, investigated the effects of surface roughness and surface free energy on bond strength and reported that hybrid etching methods increased strength. Similarly, Çakır and Kınay [18] investigated the effects of surface treatment and overlap length on mechanical properties in joining aluminum and glass fiber composites. However, comparative studies on the effects of different surface treatments (especially

combinations of anodizing and sandblasting) on interfacial shear strength in AA7075-T6 and CFRP hybrid structures, particularly in industrial applications, using "film adhesives" to stabilize adhesive thickness, are rarely found in literature.

This study addresses the bonding of AA7075-T6 aluminum alloy, widely used in the aerospace and defense industries, with Carbon Fiber Reinforced Polymer (CFRP) composite plates using an epoxy-based structural film adhesive. Three different surface treatments were applied to the aluminum surfaces: mechanical abrasion (cross-hatchting/Al-Cross), silica sand blasting (Al-Sandb), and glass sand blasting followed by anodizing (Al-Coating). Lap-shear tests were applied to the produced hybrid samples in accordance with ASTM D1002, and the mechanical behavior of the interface was investigated.

2. MATERIAL AND METHOD

2.1. Materials

In this research, hybrid structures formed by the joining of aluminum alloy (AA7075-T6) and CFRP materials via a Solvay MTA 240 epoxy-matrix adhesive were analyzed.

2.1.1. Aluminum plate (AA7075-T6)

This study aimed to improve the bonding performance of 7075 aluminum alloy, a frequently used material in the aerospace industry. Three different surface configurations were tested on aluminum specimens measuring 100x25x3 mm to optimize bond strength with the CFRP structure. Three specimens were used for each process type.

2.1.2. Pre-preg carbon fabric

The fabric plies were oriented in a balanced, symmetrical pattern. A total of 10 fabric layers were used to create a 2.7 mm thick sheet. The layer orientations were laid at 0°/45°/90°/-45°/0°/0°/-45°/90°/45°/0°. During the laydown, a vacuum was applied every other layer and held under vacuum for 5 minutes. Twill weaving was preferred because the composite provides equal strength in all directions.

2.1.3. Adhesive film

Epoxy-based Solvay MTA 240 Adhesive Film (MTA240/PK13-313g/m²) was used to bond the metal and composite. This adhesive was selected because it is suitable for use on both metal and composite surfaces and its pre-impregnated film structure ensures that the adhesive amount can be applied equally to all specimens during bonding.

2.2. Bonding Operation

Surface preparation is the most critical element in bonding processes, followed by curing procedures. This study aimed to create a bond between epoxy resin-based carbon fiber-reinforced composite panels and metal materials using an adhesive film containing an epoxy resin matrix. To achieve this goal, various pretreatments were applied to metal surfaces, and the effects of these treatments on bonding performance were investigated. The bonded areas of the composite panels were subjected to a surface abrasion treatment, measuring 12.5x25 mm and then all specimens were cleaned with alcohol. The areas outside the bonding area were covered with high-temperature-resistant masking tape. After the cleaning process was completed, the specimens were then bonded using the adhesive film. Figure 2 shows the bonded plates.

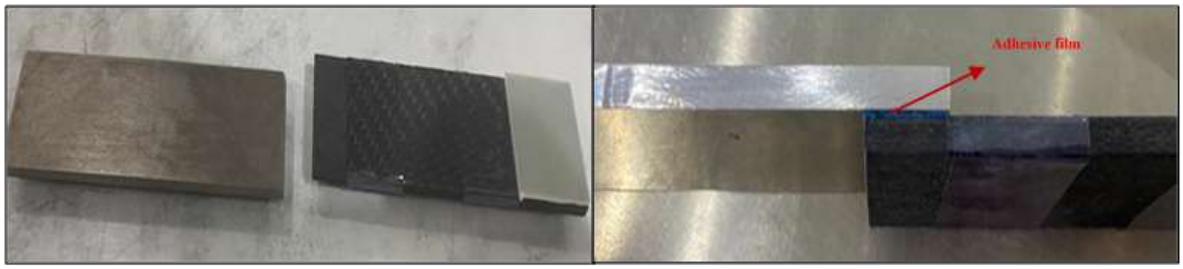

Figure 2. Joined composite-metal plates

2.3. Shear Test

The universal testing machine Instron 8503 (500 kN) was used in the tests. The tensile speed was 1.3 mm/min, as specified in the ASTM D1002 standard. The highest results for aluminum specimens after the shear test were observed in samples treated with glass sandblasting and anodizing (Al-Coating), while the lowest strength values were recorded for the specimens featuring cross-hatching patterns (Al-Cross). The resulting interfaces after the lap-shear tests are displayed in Figures 3a and 3b**.**

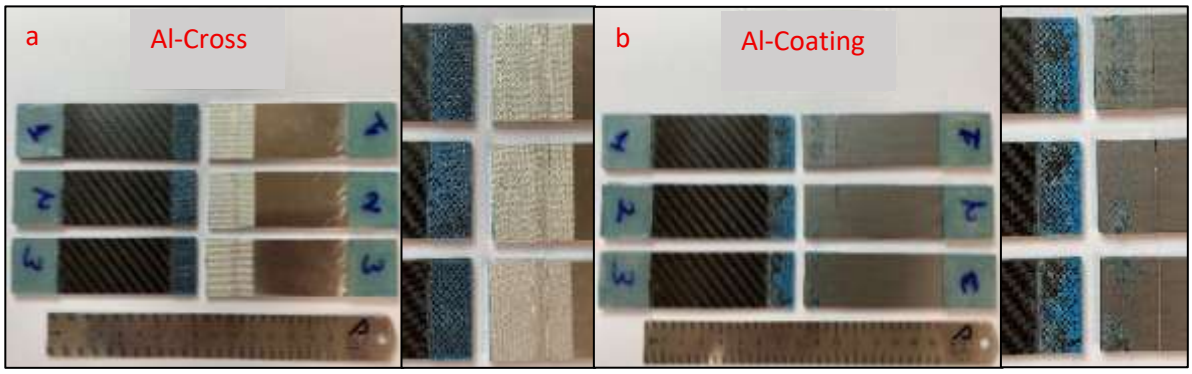

Figure 3. Visual representation of the AA7075-CFRP specimen following the shear test **a)** Al-Cross **b)** Al-Coating

2.4. Characterization

For metallographic examinations, the specimens were embedded in bakelite and subsequently subjected to grinding and polishing procedures. On the prepared specimens, investigations of the interfacial bond formed between the composite and the metal after the shear test were conducted. For these investigations, the 10x15 mm bakelite-mounted specimens were examined using an inverted optical microscope.

3. EXPERIMENTAL RESULTS

Inverted microscope images illustrating the interfacial bond between the residual adhesive and the metallic surface, following the lap-shear test of the Aluminum/CFRP specimens, are presented in Figures 4a, 4b, and 4c. In these images, the regions colored black represent the CFRP, the white regions correspond to the aluminum, and the intermediate, relatively gray regions belong to the adhesive.

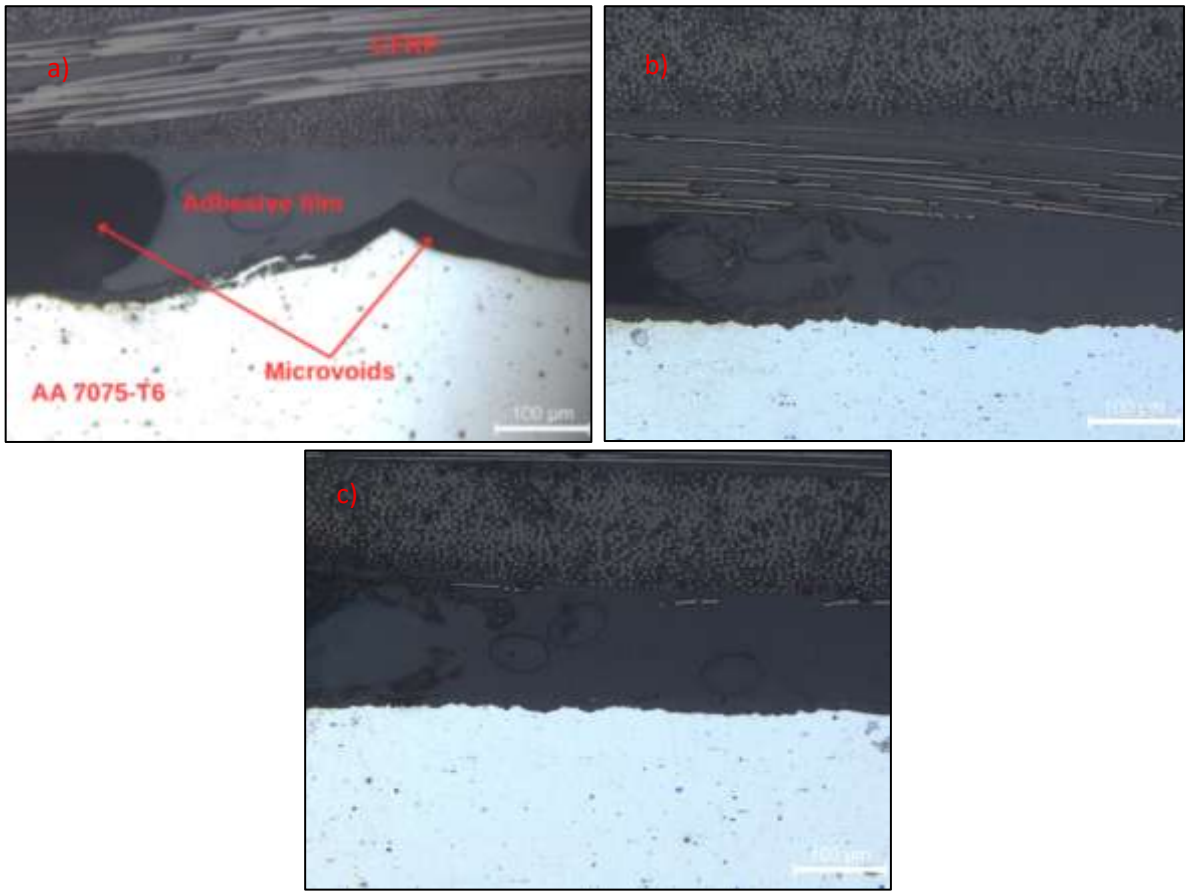

Figure 4. a) Cross-hatching patterns (Al-Cross) **b)** Sandblasting with silica sand (Al-Sandb) **c)** glass-blasting combined with anodization (Al-Coating)

In the AA 7075 specimen where cross-hatching patterns were created, regions featuring deep indentations and protrusions, burrs, and notches (or cracks) are observed on the metallic material, resulting from the material removal process during the formation of these patterns. Especially, this morphology suggests that the deformed adhesive film lacked sufficient thickness, and consequently enough volume, to effectively fill the deep recesses located particularly at the peak regions of these marks. This condition resulted in excessive micro-voids and adhesion deficiencies. Furthermore, it was observed that the adhesive was completely absent in some regions, while residual adhesive was only located within the recessed areas, accompanied by voids (Figure 4a). The very low level of adhesive presence at the end sections of the resulting traces is clearly reflected in the shear test results given in Figure 5. The cross-geometric roughness can cause stress concentrations, making it difficult for the adhesive to fully wettability or mechanically lock onto the surface.

The Al-Sandb sample exhibited a much rougher surface than the other samples. High surface roughness accompanies plastic deformation of the matrix, resulting in greater fracture energy consumption. Several areas of voids are observed between the samples and the adhesive (Figure 4b).

In this study, the adhesion strengths, the interfacial bonds between the materials, and the effects of mechanical and chemical abrasion surface treatments on the adhesion strength of the specimens were investigated. The lap-shear test graph for the specimens is provided in Figure 5. As observed, the highest strength value among the specimens was recorded for the Al-Coating specimen, which underwent glass-blasting combined with anodization, at 15.77 MPa,

while the lowest strength value of 7.30 MPa was found in the Al-Cross specimen featuring cross-hatching patterns.

In the sample, which called Al-Coating, the surface roughness profile was observed to be more stable and contain fewer pits than the Al-Sandb sample. The depth of the roughened area was observed to be greater compared to the other samples. It was also observed that the adhesive thickness and density were more dense between the two materials (Figure 4c). This indicates that the interfacial bond between the samples will be strong. It is believed that increasing the surface roughness and creating traces in different directions will be beneficial in future studies.

ABSTRACT

Metallic and ceramic foams are divided into two basic classes based on their pore structure: closed and open pore. Differences in cell structure are directly related to the manufacturing method and the parameters used. Open-pore foams, due to their large specific surface area, are preferred in heat exchangers. Ceramic foams, due to their high liquid/gas permeability and corrosion and high temperature resistance, are preferred in filtration and separation processes, and in water treatment applications where unwanted ions can be removed from solution. In this study, open-cell Al-based alumina ceramic foams with varying pore sizes were fabricated using the powder metallurgy method combined with aluminum powder and the polyurethane foam (PU) replication technique. The structure obtained after the removal of the PU at 500°C 3 hours was subsequently sintered in an open atmosphere for 6 hours at temperatures of 850°C, 900°C, and 950°C. X-Ray diffraction (XRD) analyses, scanning electron microscopy (SEM) and microstructural investigations were performed on the fabricated ceramic-coated foams. During the high-temperature oxidative sintering process conducted in an open atmosphere, alumina ceramic-coated foams with optimal properties were successfully obtained at 950 °C, achieved through the sintering mechanism resulting from the oxidation of the aluminum powders.

Keywords: Open-cell foam, Powder metallurgy, Metallic foam, Ceramic foam

1. INTRODUCTION

Advanced porous metallic and ceramic materials have played a critical role in industrial applications in recent years, owing to their unique combination of physical and thermal properties. Key advantages that distinguish these materials include characteristics such as high specific surface area, low density, chemical stability, and thermal shock resistance [1-3]. Ceramic foams, which are classified as open-cell or closed-cell based on their pore morphology, are primarily utilized in environments characterized by demanding conditions, such as molten metal filtration, catalyst support units, heat shields, and biomedical implants. [4-7]. In contrast to metallic foams, ceramic foams offer oxidation resistance and dimensional stability at elevated temperatures. Specifically, open-cell ceramic foams maximize heat and mass transfer by generating turbulent flow, owing to their interconnected pore networks that allow fluid permeability. [8]. Studies have focused on various ceramic materials such as silicon carbide (SiC), zirconia (ZrO_2), and alumina (Al_2O_3). Among these, alumina stands out for its high melting point, mechanical strength, and cost-effectiveness. [9]. Although various techniques such as "direct foaming" and "gel casting" are used in the production of ceramic foams, the polymer sponge replica method developed by Schwartzwalder and Somers is the most widely accepted technique on an industrial scale [10]. This method is based on the principle of impregnating a flexible polyurethane foam (PUF) with a ceramic slurry, removing the excess slurry, and subsequently sintering the ceramic structure by burning out the organic scaffold via applied thermal treatments. A representation of the structure obtained after the removal of the organic-based template material is provided in Figure 1.

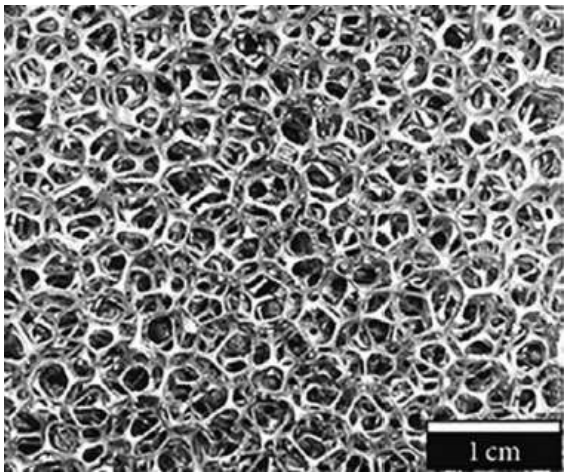

Figure 1. Open-cell metallic foam [11]

The biggest advantage of the method is that the pore structure of the starting polymer can be almost exactly copied into the final ceramic product. [12]. Recent studies have demonstrated that the fundamental challenge in ceramic foams fabricated via the replica method is optimizing the inverse correlation between mechanical strength and porosity. Betke et al. [13], investigated the influence of mixture composition on cellular alumina, while other researchers focused on the effect of the sintering temperature on microstructural defects [14]. However, while the effect of the sintering temperature on the microstructural evolution during the production of alumina-based ceramic foams is known, studies focusing specifically on the liquid phase mechanisms formed within the matrix during the sintering process and the interaction of this phase with the alumina grains are limited. The presence of the liquid phase has a significant role on the densification behavior and grain growth of the ceramic skeleton, and a detailed understanding of this mechanism is needed. [15-18]. The objective of this study is to investigate the physical changes and microstructural characteristics of open-cell pure aluminum-based alumina (Al2O3) coated ceramic foams, fabricated via the replica method using pure aluminum powder and polyurethane (PU) sponges, with respect to different sintering temperatures.

2. MATERIAL AND METHOD

2.1. Materials

In the experiments, pure Al powders with 99.9 % purity and a particle size of < 10 µm were utilized. Polyurethane (PU) sponges ($C_{25}H_{42}N_2O_6$) with pore sizes of 10, 20 ve 30 ppi (pores per inch) were selected as the organic template material. Polyvinyl alcohol (PVA) in powder form was used as the binder, and deionized water was employed as the solvent.

2.2. Sample Preparition and Process

The production process of the alumina-coated foams comprises the following stages: slurry mixture preparation, template material impregnation, drying, binder and template material removal, and sintering. During the fabrication of the specimens, the procedure followed the process flow chart presented in Figure 2.

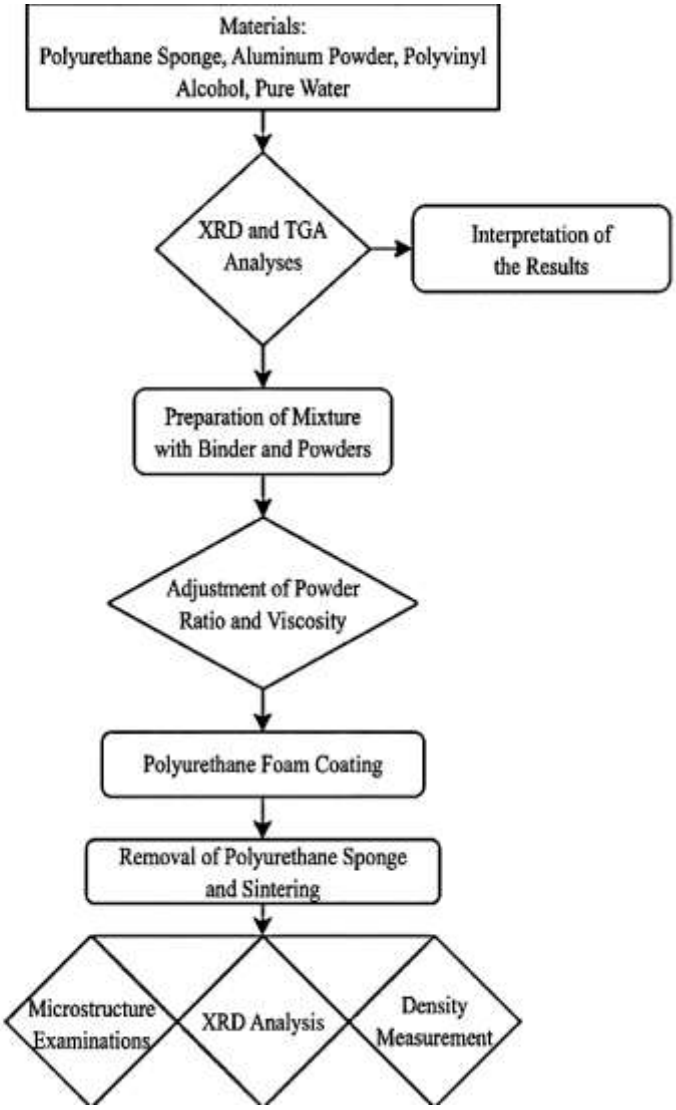

Figure 2. Process flowchart in production

Firstly, a slurry mixture was prepared by mixing deionized water and PVA using a turbula mixer, and the mixture was subsequently allowed to settle for 1 day. Moreover, pure Al powders at a 70% powder ratio determined to be optimal for viscosity, were introduced into this solution, resulting in a mechanically homogeneous slurry. PU sponges with pore sizes of 10 ppi, 20 ppi,

and 30 ppi were cut into 20x20x20 mm dimensions using a foam cutting device. The cut sponges were then immersed in the prepared mixture to ensure homogeneous coating. The coated samples were first stored at room temperature for 1 day.

The dried specimens were processed in a furnace under ambient atmospheric conditions for the removal of the binder and template material. Initially, the PVA (binder) was eliminated from the structure at 350°C for 3 hours. Subsequently, the template material (PUF) was removed from the structure by holding the specimens at 500°C for 3 hours. After the template material was removed for the sintering process, the remaining aluminum powders were sintered together at different temperatures (850 °C, 900 °C and 950 °C) under normal atmospheric conditions. Figure 3 shows the production phase of the samples and Figure 4 depicts the image of the alumina coated metallic foams after the sintering process.

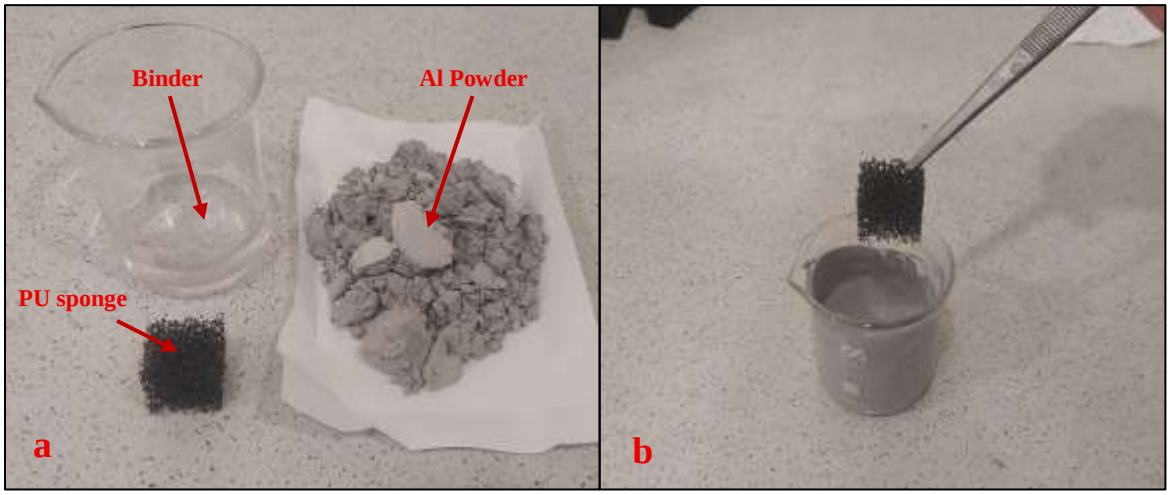

Figure 3. a) Materials which is used when studies **b)** Process for coating the template material with the prepared aluminum slurry.

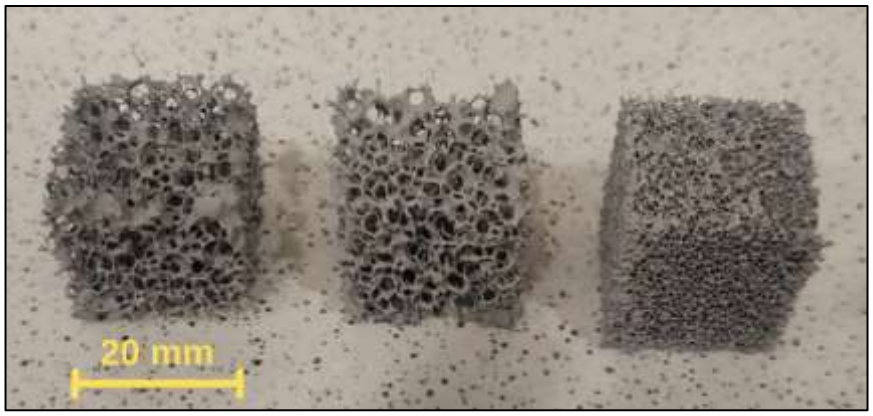

Figure 4. Sintered Al based Al_2O_3 coated foams

3. EXPERIMENTAL RESULTS

Scanning electron microscopy (SEM) analysis of the ceramic foams sintered under open atmospheric conditions was conducted using a JEOL JSM 6060 LV instrument, with the objective of investigating the sintering effects and the morphology of the resulting foam. The SEM micrographs focused on the 20 ppi foam material sintered at 950 °C. As observed in Figure 5a, after the removal of the PU template material, the aluminum powders successfully replicated the shape of the template, effectively forming the cell walls and columns. A micrograph of the fractured surface of the produced foam is presented in Figure 5b. Independent

spherical structures formed in various regions on the cell walls are noteworthy (indicated by arrows in Figure 5b). One of these structures is shown at higher magnification in Figure 5c. The Al powders introduced into the structure during the production process are <10 µm in size, which is observable in Figure 5d. The size of these coarse spherical structures formed on the cell walls typically ranges from 50 to 100 µm.

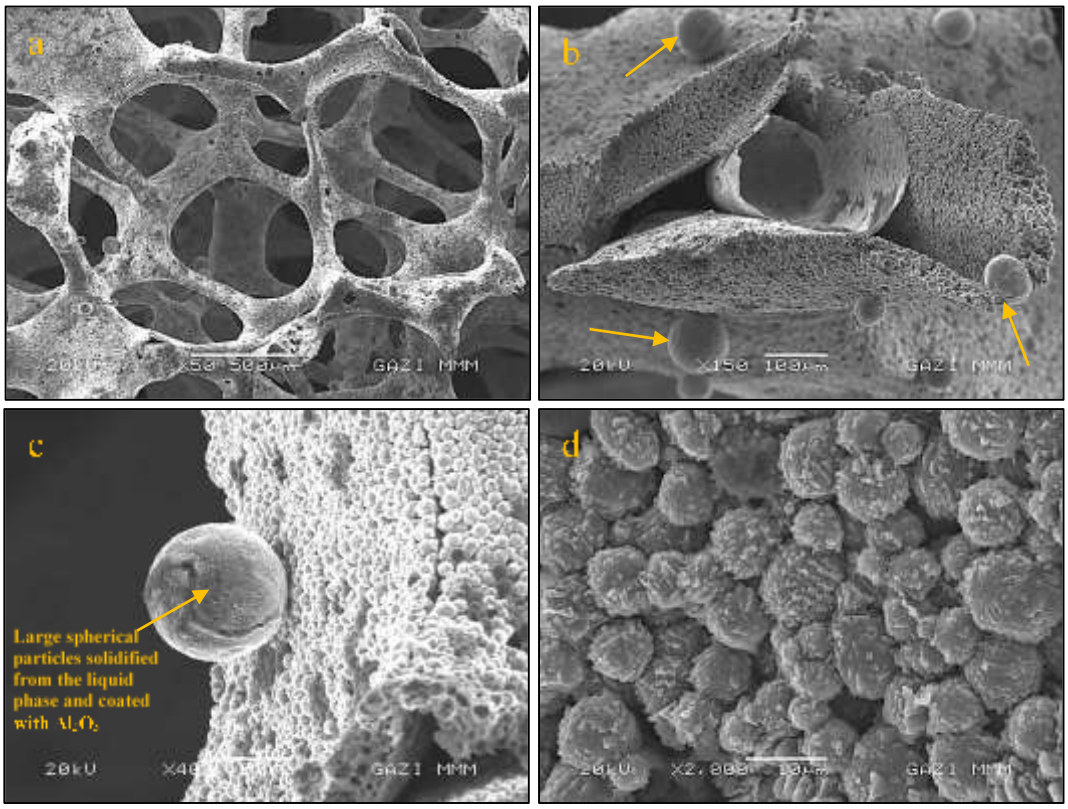

Figure 5. SEM micrographs of the alumina foam sintered at 950°C at different magnifications: **a)** general view, **b)** viewed across the fractured surface, **c)** Solid Al grown in liquid form and coated with alumina and **d)** Initial size alumina coated Al particles

During high-temperature sintering in an open atmosphere, the liquid phase formed in certain sections of the cell walls was observed to migrate towards the surface via capillary action, subsequently forming and solidifying into a spherical shape. The stability of the foam structure, which did not fully transition into the liquid phase or collapse despite the high sintering temperature (950 °C), can be attributed to the rapid and excessive oxidation of the Al particles in the open atmosphere sintering environment, which resulted in the formation of an alumina (Al_2O_3) layer on the powder surfaces. The angular pointed structures clearly visible on the surface of Al powder particles in Figure 5d are oxide structures formed under open atmospheric conditions during the sintering process.

The spherical structures formed in the produced samples were identified as containing dense Al_2O_3, as determined by the XRD analysis given in Figure 6. Generally, peak intensities indicate that the alumina content on Al surfaces increases with increasing sintering temperature. However, the highest alumina content is observed in the XRD analysis of foam sintered at 900°C. This may be attributed to the increased oxidation rate of the sinter medium by leaving the furnace door partially open for a certain period of time. This condition enhances the formation of Al_2O_3 on the surface of the Al powders within the furnace atmosphere.

ÖZET

Türkiye benzeri gelişmekte olan ülkelerde demir ve çelik sektörü Avrupa ülkelerine kıyasla hala aktif olarak rol oynamaktadır. Demir ve çelik sektörü kendi içerisinde bir çok dinamiği barındırmaktadır metal hurda da bu dinamiklerin en başında karşımıza çıkmaktadır. Türkiye için metal hurdanın önemi Avrupa ve dünya ülkeleri ile karşılaştırıldığında başı çekmektedir çünkü Türkiye'deki demir ve çelik üretiminin %70'e yakını elektrikli ark ocakları ile sağlanmaktadır. Bu durumda metal hurdaların Türkiye'deki kullanımlarında diğer ülkelere kıyasla daha dikkat edilmesi ve önlemler alınması gerektiğini ortaya koymaktadır. Ülkemize yüksek tonajla giriş yapan ve çeşitli ülkelerden gelen bu malzemelerin kontrol edilmesinin gerektiği çok açık ortadadır. Mevcut kontrol mekanizmaları incelendiğinde otomatik bant sistemleri, gözle yapılan çeşitli eksperlik işlemleri karşımıza çıkmaktadır. Bu çalışmada yapay zeka, YOLO V12 gibi görüntü işleme araçları kullanılarak resimler makine öğrenmesi ile sisteme öğretilmiştir.

INVESTIGATION OF RELATIONSHIPS OF LSI INDEX WITH MILD STEEL CORROSION COUPONS

ABSTRACT

Corrosion and scale formation in water systems are significant issues that directly affect the operational efficiency of industrial facilities. One of the most commonly used parameters to monitor these processes is the Langelier Saturation Index (LSI), which predicts the tendency of water to form or dissolve scales. However, since the LSI value is theoretically based on scaling equilibrium, it may not directly reflect the actual corrosion behavior on metal surfaces. This study aims to investigate the relationship between LSI values and metal corrosion rates by employing corrosion coupons in water systems with different chemical compositions. In the experimental study, coupons made of carbon steel were exposed to water environments with varying LSI values for a specified duration. Throughout the testing period, parameters such as pH, temperature, total dissolved solids (TDS), calcium hardness, and alkalinity were regularly measured, and LSI values were calculated accordingly. At the end of the exposure period, the coupons were removed, and corrosion rates were determined through weight loss measurements. The study emphasizes that the LSI should not be considered solely as a theoretical parameter but should be evaluated in conjunction with experimental corrosion observations. Coupon tests under different LSI conditions allow for monitoring corrosion behavior and enable more informed decisions for mitigating corrosion risks in water systems. This approach contributes to the development of effective corrosion management and control strategies in industrial water systems.

Keywords: Langelier Saturation Index (LSI)**,** corrosion coupons, water treatment, water chemicals

INTRODUCTION

The water treatment sector is of great importance all over the world, especially in terms of the efficiency and healthy operation of industrial cooling towers. Cooling towers are very encounter to corrosion due to the appropriate environment inside the cooling tower like the flow of solution that contains dissolved salts, the temperature, the microbiological growth etc [1]. That is why monitoring corrosion in cooling towers is as essential as its occurrence. Corrosion monitoring in industrial cooling towers can be performed using various methods. One is the traditional method, which involves inserting a corrosion coupon and then calculating metal loss. Another is corrosion measurement using online devices. Various institutions market their devices for this technology, but the traditional method was chosen and applied in this study. The most important determinants of the corrosion potential of water include the temperature, pH, dissolved gases, the concentration of sulfate, chloride, and chlorine residual [2]. When all these parameters come together, they reveal the corrosion rate and are linked to the dissolved iron ratio in the systems. Many corrosion monitoring indices are used today. The most commonly used are the Langelier saturation index (LSI) and the Ryznar stability index (RSI). Factors influencing the LSI include pH, total dissolved solids (TDS), temperature, calcium levels, and alkalinity. LSI is a qualitative index that only indicates that the sample in question tends to deposit or corrode. RSI was used to complement LSI and quantify the results. LSI is the most effective indicator for water potential and determination [3]. Formulations made via Excel or some special programs created with the software can be used in LSI index calculations.

MATERIAL AND METHODS

Mild steel corrosion coupons were applied to nine cooling towers constructed at an industrial facility and stored under suitable conditions for two months. Weights were measured before the coupons were installed and then re-weighed using precision scales after their removal.

Figure 1. Mild steel corrosion coupon after placement to the system

Figure 1 shows a mild steel corrosion coupon removed from its envelope. The envelope contains the manufacturer's standards. This information is crucial for future calculations. Although the envelopes contain weight information, re-measurement is considered more accurate. All coupons used in this study were taken from unopened envelopes and used in accordance with the standards. The envelopes were opened and the coupons were first visually inspected for any previous corrosion.

Figure 2. Mild steel corrosion coupon placement area

The dark coupon at the bottom of figure 2 is a mild steel corrosion coupon. It is incorporated into the system at the cooling tower return water level. Water flow must be maintained continuously and in direct contact with the coupon; otherwise, measurements cannot yield meaningful data. Measurements taken during periods of excessive cooling tower downtime will also result in similar data issues. Coupons are typically held for two months. Longer holding periods are possible, but frequent checks increase the reliability of the data obtained. Events such as maintenance stops and sudden malfunctions within the facility affect coupon performance. When the system becomes stationary and the corrosion inhibitor is not dosed or circulated, we observe an increase in the corrosion rate. Corrosion rate was calculated in mils per year (mpy) and according to ASTM G1-03 using the formula below [4].

Eql (1) Corrosion Rate = (K x W) / (A x T x D)

where:

K = a constant (see table 1.)

T = time of exposure in hours,

A = area in cm2,

W = mass loss in grams, and

D = density in g/cm3

Table 1. Corrosion rate calculation constant choose [6,7]

Corrosion Rate Units Desired	Constant (K) in Corrosion Rate Equation
mils per year (mpy)	3.45×10^6
inches per year (ipy)	3.45×10^3
inches per month (ipm)	2.87×10^2
millimetres per year (mm/y)	8.76×10^4
micrometres per year (um/y)	8.76×10^7
picometres per second (pm/s)	2.78×10^6
grams per square meter per hour (g/m2 ·h)	$1.00 \times 10^4 \times D$
milligrams per square decimeter per day (mdd)	$2.40 \times 10^6 \times D$

The Langelier saturation index (LSI) is calculated from the values of electrical conductivity or total dissolved solids, calcium, alkalinity, pH and temperature. In practice, the conductivity, pH and temperature are calculated [5]. In conclusion, if we reduce it to its simplest form difference between the actual pH of the solution and pHs calculated [6,7].

Eql (2) LSI = LSI = pHactual – pHs

The Langelier Saturation Index (LSI), which evaluates the tendency of a water sample to either dissolve or precipitate calcium carbonate, is widely utilized as an empirical parameter for assessing water stability [8]. Although LSI is not a direct measure of corrosive activity, it reflects the propensity of water to form or inhibit the formation of a calcium carbonate protective layer. Such a scale layer can provide a physical barrier that limits the contact between water and system components such as pipelines, boilers, and heat-exchange surfaces. In the absence of this protective film, the water is characterized as aggressive, increasing the likelihood of corrosion processes. Highly corrosive water may lead to structural degradation of system elements and can pose public health risks due to the mobilization of lead or other heavy metals [9, 10]. Conversely, excessive scale formation can impair system performance, reduce efficiency, and necessitate maintenance or equipment replacement. The interpretations of both the traditional Langelier Saturation Index (LSI) and the modified LSI proposed by Carrier are derived from the table 2 parameter values [11,12].

Table 2. LSI index parameters [13]

LSI<0	Water is undersaturated with respect to calcium carbonate. Undersaturated water has a tendency to remove existing calcium carbonate protective coatings in pipelines and equipment.
LSI=0	Water is considered to be neutral. Neither scale-forming nor scale removing.
LSI>0	Water is supersaturated with respect to calcium carbonate (CaCO3) and scale forming may occur.

The LSI index and the mpy results of the corrosion coupons were evaluated together to obtain meaningful data.

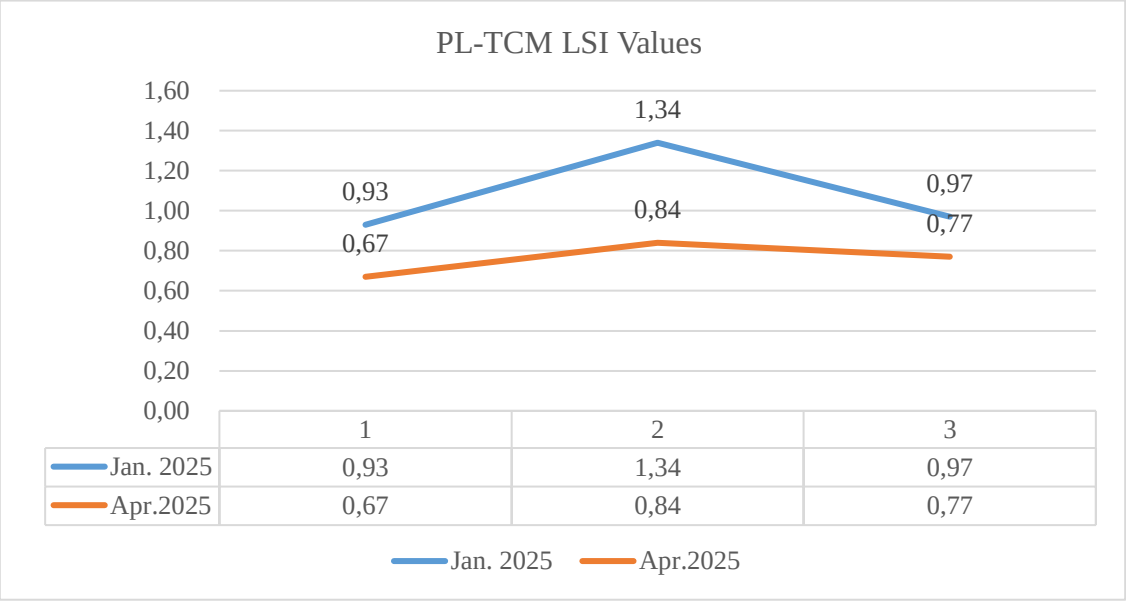

Figure 3. LSI Index of PL-TCM January-April

Figure 3 shows the LSI indices for the cooling tower named PL-TCM for the months of January and April. The corrosion value of this tower was measured as 0.16 mpy in January and 0.10 mpy in April. According to LSI analysis results, there is a tendency for lime formation. According to the corrosion coupon analysis results, there is no corrosive hazard in the tower. The warning about the tendency for scale formation may be due to imbalances in pH and calcium hardness.

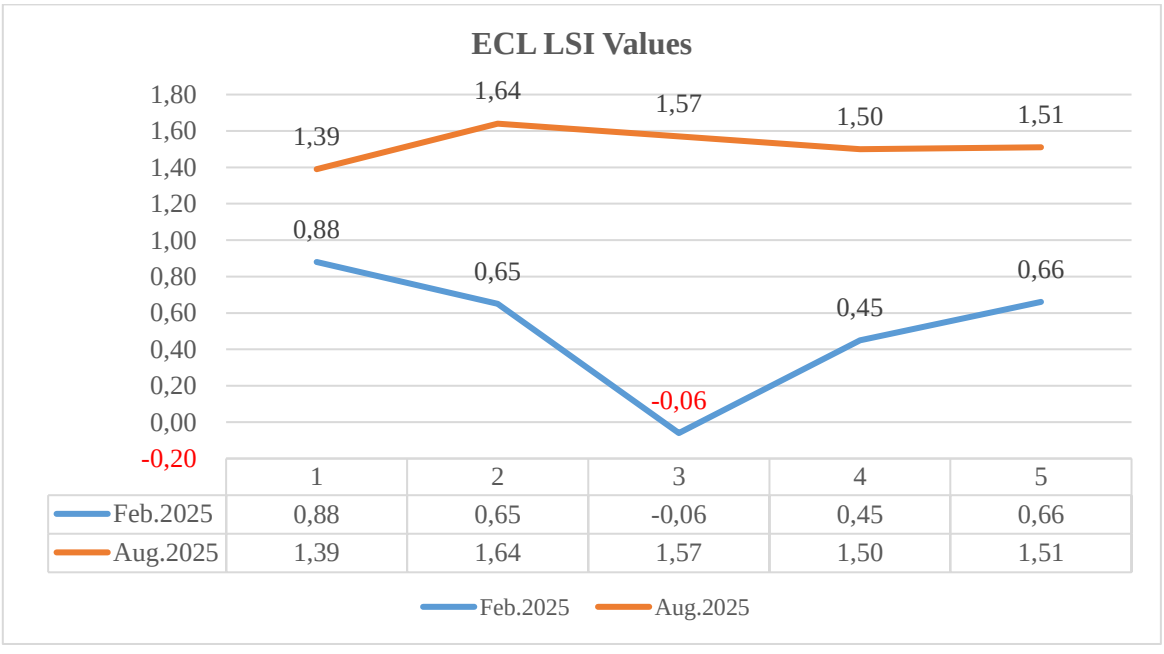

Figure 4. LSI Index of ECL February-August

According to the analysis made on the ECL tower, another cooling tower within the same facility, the LSI data for February and August are given in figure 4. The corrosion rate value was measured as 0.27 in February and 0.41 in August.

CONCLUSION AND EVALUATION

Although the LSI values in February and August are 90% in favor of scale formation, it is observed that the corrosion rate increases in February.When we examine Graph 2, we see that although February's values are on the scale-forming side, the corrosion rate has increased due to the water shifting to the aggressive side. Because the index only provides a value based on specific parameters, we must make the assessment accordingly. As the sources of hardness in water decrease, the corrosion rate increases accordingly. Although the index calculation provides us with a scale formation, the corrosion rate can never be reset, so an evaluation is necessary. Because hardness in water acts as a natural corrosion inhibitor, the decrease in February caused the corrosion rate in the tower to increase.

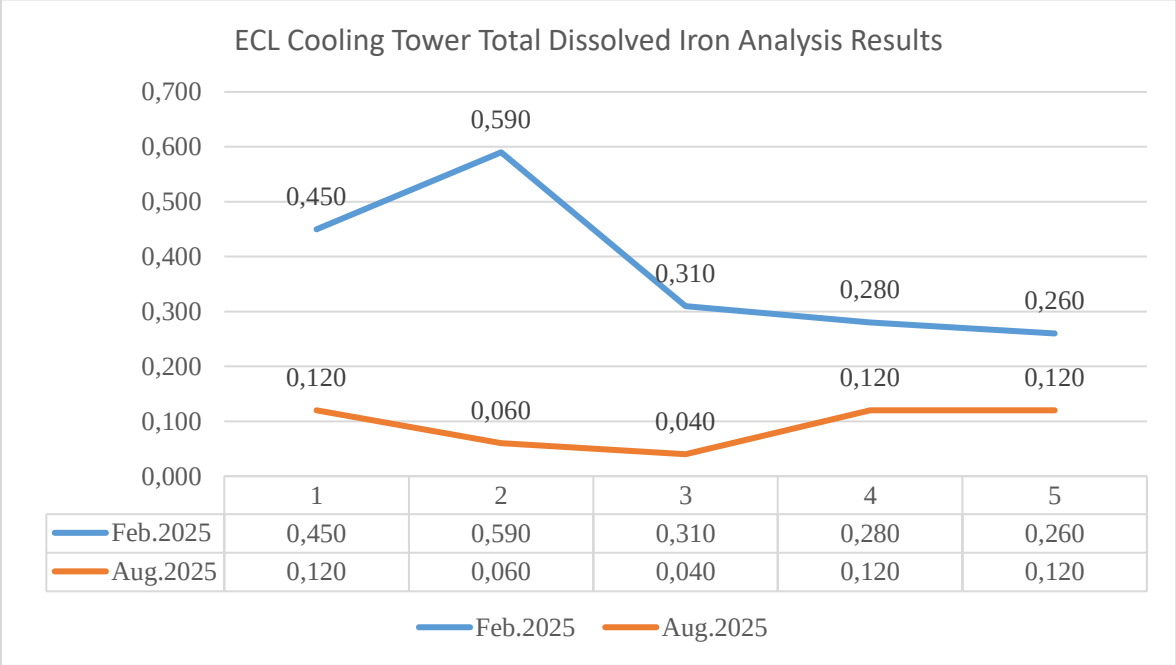

Figure 5. Total dissolved iron test results

Figure 5 shows the total dissolved iron analyses for February and August. Although the LSI values for both months are on the scale, we can say that the LSI values in February eventually reached the neutral side and metal dissolution in the system increased as the water became more aggressive. As a result, the LSI index overlaps with the corrosion rate in the system to a certain extent, and there is even a significant interaction between it and the amount of iron and hardness in the system.

ÖZET

Demir çelik sektörü, hammadde hazırlama, sinterleme, kok üretimi, yüksek fırın prosesleri, çelik üretimi ve haddeleme gibi çok aşamalı ve yoğun kimyasal reaksiyonların gerçekleştiği kompleks bir endüstriyel yapıya sahiptir. Bu süreçler sırasında kullanılan veya yan ürün olarak ortaya çıkan çeşitli kimyasal maddeler, çalışanların maruz kalabileceği önemli mesleki riskler oluşturur. Başta karbon monoksit (CO), kükürt dioksit (SO_2), azot oksitler (NO_x), hidrojen sülfür (H_2S) gibi zehirli gazlar olmak üzere metal oksit dumanları, ağır metal partikülleri, asit-baz çözeltileri, yağlayıcı ve soğutucu kimyasallar ile uçucu organik bileşikler (UOB) sektördeki temel kimyasal tehlikeler arasında yer almaktadır. Bu maddelere solunum, deri teması veya sindirim yoluyla maruziyet; akut zehirlenme, solunum yolu irritasyonu, dermatit, göz tahrişi, merkezi sinir sistemi etkilenimi ve uzun dönemde mesleki astım, kronik obstrüktif akciğer hastalığı (KOAH) ve bazı kanser türleri gibi ciddi sağlık sorunlarına yol açabilmektedir. Bu nedenle kimyasal risk etmenlerinin doğru şekilde tanımlanması, proses bazlı tehlike analizlerinin yapılması, çalışma ortamı ölçümlerinin düzenli olarak gerçekleştirilmesi ve mühendislik kontrollerinin etkin biçimde uygulanması kritik önem taşır. Bunun yanında kişisel koruyucu donanımların doğru seçimi, çalışanlara yönelik sürekli eğitim programları ve uluslararası standartlara uygun kimyasal yönetim sistemleri, sektörde güvenli çalışma ortamı oluşturmanın temel unsurlarını oluşturmaktadır. Bu çalışma, demir çelik sektöründe karşılaşılan kimyasal risk etmenlerini kapsamlı biçimde değerlendirerek, maruziyet kaynakları, sağlık etkileri ve kontrol yöntemleri üzerine bütüncül bir çerçeve sunmayı amaçlamaktadır.

Anahtar Kelimeler: Demir çelik, zehirli gazlar, kimyasal risk etmenleri, sağlık.

CHEMICAL RISK FACTORS IN THE IRON AND STEEL INDUSTRY

ABSTRACT

The iron and steel industry possesses a complex industrial structure in which multi-stage and intensive chemical reactions occur, including raw material preparation, sintering, coke production, blast furnace processes, steelmaking, and rolling operations. Various chemical substances used during these processes or generated as by-products create significant occupational risks to which workers may be exposed. Toxic gases such as carbon monoxide (CO), sulfur dioxide (SO_2), nitrogen oxides (NOx), and hydrogen sulfide (H_2S), along with metal oxide fumes, heavy metal particles, acid-base solutions, lubricating and cooling chemicals, and volatile organic compounds (VOCs), constitute the primary chemical hazards in the sector. Exposure to these substances through inhalation, skin contact, or ingestion may lead to acute poisoning, respiratory irritation, dermatitis, eye irritation, central nervous system effects, and, in the long term, serious health outcomes such as occupational asthma, chronic obstructive pulmonary disease (COPD), and certain types of cancer. Therefore, the accurate identification of chemical risk factors, the implementation of process-based hazard analyses, regular workplace environmental measurements, and the effective application of engineering controls are of critical importance. Additionally, the proper selection of personal protective equipment, continuous training programs for employees, and chemical management systems compliant with international standards constitute the fundamental components of creating a safe working environment within the sector. This study aims to provide a comprehensive assessment of chemical risk factors encountered in the iron and steel industry by presenting an integrated framework on exposure sources, health effects, and control strategies.

Keywords: Iron and steel, toxic gases, chemical risk factors, health

1.Introduction

The iron and steel sector are considered one of the cornerstones of economic, technological, and infrastructural development in today's industrialized societies. A wide range of industries, including construction, automotive, energy, machinery manufacturing, defense, transportation, and infrastructure projects, meet a significant portion of their needs for durable and high-performance materials through iron and steel production [1]. Therefore, the sector is of critical importance not only in terms of production volume but also in terms of its strategic position in the global supply chain. However, the fact that these large-scale production activities rely on intensive chemical processes causes various risks for sector employees, the environment, and industrial environmental health. The most prominent of these risks are the chemical risk factors that can arise at every stage of production [2]. Steel production is a complex process involving numerous thermal and chemical reactions, starting from the ore preparation stage and continuing through sintering, pelletizing, coke production, blast furnace processes, steel production (BOF and EAF), secondary metallurgical processes, continuous casting, and rolling. Each of these processes inherently involves the use of chemical substances, chemical reactions, and the formation of byproducts [3]. For example, carbon monoxide (CO), nitrogen oxides (NOx), sulfur oxides (SOx), and various organic toxic compounds; polycyclic aromatic hydrocarbons (PAH), volatile organic compounds such as benzene and toluene arising from coke production; hydrogen sulfide (H_2S), carbon dioxide (CO_2), and metal oxide dusts formed in blast furnace processes; heavy metal-containing fumes, dioxins, and furans arising in electric arc furnaces (EAF); toxic flux fumes and refractory material dusts released in secondary metallurgy are among the most well-known examples of these risks [4]. It is known that chemical risk factors arise not only during the production phase, but also in auxiliary operations such as storage, transportation, sampling, maintenance, waste management, and energy production [5]. Therefore, chemical risk management has become a multidimensional field across the industry that requires high technical knowledge and a systematic approach in terms of both occupational hygiene and process safety. Particularly heavy metal dusts (lead, cadmium, chromium, nickel), ultrafine particles (PM1, PM2.5), acid vapors (HCl, HF), combustion gases, oxidizing agents, chemical mixtures that can create explosive atmospheres, and hazardous substances that can react at high temperatures pose a serious threat to industry workers [6].

One of the main reasons why chemical risk factors are such a significant problem in the iron and steel industry is that most production processes take place under high temperature and high pressure [7]. These conditions accelerate the instantaneous reactions of chemical substances, increase their volatility, and facilitate their dispersion into the working environment. Thermal decomposition products caused by high temperatures, combustion gases, and metal fumes often contain particles that are invisible to the naked eye but are respirable. These particles can enter the body through the respiratory tract of workers, causing acute and chronic occupational diseases. Particularly with long-term exposure, health problems such as COPD, pneumoconiosis, carcinogenic effects, nervous system damage, hematological disorders, skin irritations, and eye damage may occur [8]. Similarly, leaks, spills, and vaporization events that may occur during the dilution, mixing, or feeding of chemicals used in production facilities are other factors that make it difficult to control chemical risks [9]. Lubricants, hydraulic fluids, refractory coating chemicals, pH regulators, surface cleaners, corrosion inhibitors, and various auxiliary chemicals used in the iron and steel industry also pose risks in terms of occupational hygiene. Some of these substances are flammable, irritating, or toxic and can endanger worker safety if proper ventilation, personal protective equipment (PPE), and process control systems are not used [10].

Chemical risk factors directly affect not only worker health but also environmental health and

facility safety. Improperly stored or disposed of chemicals can contaminate soil, groundwater, and surface water [11]. The ignition of chemical substances due to high temperatures can increase the risk of fire and explosion. Furthermore, when flue gas treatment systems are inadequate, chemical compounds released into the atmosphere negatively impact regional air quality and lead to violations of national and international emission standards. Therefore, the proper management of chemical risks is not only an occupational health and safety requirement but also indispensable in terms of legal compliance, sustainability, and corporate responsibility [12]. In recent years, with the widespread adoption of international standards (ISO 14001, ISO 45001, REACH, OSHA, etc.), new technical applications for assessing, monitoring, and controlling chemical risks in the iron and steel industry have gained importance [13]. Emissions measurement systems, chemical exposure monitoring devices, process control automation, artificial intelligence- supported risk prediction systems, and advanced ventilation technologies used in modern iron and steel plants make chemical risk management more effective. However, since it is not possible to completely eliminate risks, human-centered practices such as occupational hygiene measurements, continuous training, safety procedures, improvement of PPE use, and emergency management remain important [14]. In this context, a comprehensive examination of chemical risk factors in the iron and steel industry is critical, both in terms of worker health and safety and the sustainability of production processes [15]. The purpose of this article is to scientifically evaluate the chemical risks arising in all stages of iron and steel production, explain the mechanisms of these risks, analyze exposure levels, and present effective control methods within an academic framework. Furthermore, challenges encountered in chemical risk management and areas requiring improvement will be addressed in light of current industry practices, international standards, and recent research. Thus, the aim is to contribute to the academic literature and provide an assessment that serves as a guide for practitioners [16].

1. Chemical Hazard Sources in Iron and Steel Production Processes

1.1. Raw Material Preparation and Ore Enrichment

The initial stages of the iron and steel production chain, including raw material preparation**,** crushing and grinding**,** classification**,** magnetic separation**,** flotation**,** sintering, and pellet preparation, involve numerous chemical hazards due to mineralogical transformations, chemical reactions, and dust and gas emissions [17]. The chemical risk factors that arise at this stage directly affect both worker health and process safety.

The chemical hazard sources encountered on an industrial scale, classified by process and consistent with the literature, are detailed below:

1.1.1 Dust generated during the iron ore crushing and grinding stage [18]

- ✓ Iron oxide dusts containing hematite, magnetite, limonite, and siderite
- ✓ Free silica (SiO_2) in fine fractions
- ✓ Alumina (Al_2O_3) and clay minerals associated with impurities in the ore
- ✓ Trace elements of toxic metals found in blast furnace and sinter raw materials

Health risks: Silicosis, chronic obstructive pulmonary disease (COPD), metal fume fever, heavy metal toxicity.

1.1.2 Chemical Risks in Raw Material Storage and Transfer Stages

Oxidation and heating reactions [19]**:**

- ✓ Self-heating in fine ore piles,
- ✓ Oxidative heat release in ores containing copper and magnetite,
- ✓ High temperatures causing CO, CO_2, and VOC emissions.

Moisture and ore interactions [20]**:**

As a result of contact with moisture in ore piles:

- ✓ Acid mine drainage
- ✓ H_2S gas formation as a result of reaction with sulfide minerals

1.2. Sintering Plant

Sintering is a thermochemical process based on the agglomeration of fine-grained ore, coke dust, and various additives at temperatures ranging from 1200 to 1300 °C to produce sinter in the form of pieces suitable for use in blast furnaces [21,22]. This process is a production stage that generates numerous chemical hazards due to high heat and oxidation-reduction reactions. Gas and emission values obtained from an example iron and steel plant production process are shared and interpreted below.

Table 1. Average Concentrations in Sintering Gases

Pollutant	Average Concentration	Typical Range	Legal Limit (EU BAT)*	Description
Dust (PM)	25 mg/Nm³	18–35 mg/Nm³	10–20 mg/Nm³	After bag filter
NOx	320 mg/Nm³	270–360 mg/Nm³	180–350 mg/Nm³	Thermal + Fuel NOx
SOz	180 mg/Nm³	120–240 mg/Nm³	50–200 mg/Nm³	Coke sulfur effect
CO	950 mg/Nm³	700–1200 mg/Nm³	No limit (critical for occupational health)	Unburned areas
COz	16 vol.%	15–18%	–	Carbon cycle associated with the blast furnace
Oz	6.2 vol.%	5.5–6.8%	–	Draft control result
VOC	4 mg/Nm³	2–6 mg/Nm³	2–20 mg/Nm³	Organic pollutants
PAH	0.08 mg/Nm³	0.05–0.12 mg/Nm³	–	Including benzo(a)pyrene
HCl	6 mg/Nm³	3–9 mg/Nm³	1–10 mg/Nm³	PVC-containing recovery dusts
HF	1.2 mg/Nm³	0.6–1.5 mg/Nm³	0.5–2 mg/Nm³	Fluorinated minerals
Dioxin/Furan (PCDD/F)	0.20 ng/Nm³ (I- TEQ)	0.15–0.35	0.04–0.20	Most critical toxic compound

*BAT: Best Available Techniques (EU Environmental Legislation)

The sinter gas emission values given in Table 1 show that the sintering process in a typical

integrated iron and steel plant carries multidimensional risks in terms of both the environment and occupational health. Most emissions are close to the EU BAT (Best Available Techniques) reference limits; however, critical threshold values are reached for some pollutants (especially dust, CO, and dioxin/furan). This indicates that process control is generally stable but optimization is needed for certain emission types.

PM, in particular, is the characteristic and most prominent pollutant of sintering and can remain above BAT limits despite the use of bag filters. High CO values indicate that complete combustion cannot be achieved in some areas of the bed, posing a serious exposure risk, not only environmentally but especially in terms of occupational health. SO_2 **and** NOx levels are mostly compliant with regulations but are sensitive to the sulfur content of the coke used and combustion conditions. Although organic pollutants such as VOC **and** PAH are low, the carcinogenic types within PAH require continuous monitoring. HCl **and** HF indicate that the raw material composition is heterogeneous and that chlorine and fluorine contained in recovered dusts, in particular, affect the process. PCDD/F levels, which are close to the BAT upper limit, confirm once again that the sintering process is a high-risk point for dioxin formation.

Overall, the table shows that although the sintering process is controlled by modern gas treatment systems, it requires process optimization and raw material management for critical pollutants; it also shows that the data obtained must be considered in conjunction with occupational health risk assessment. In this context, fuel quality, air distribution, heat profile, and the performance of treatment equipment stand out as the most sensitive control parameters for reducing emissions.

Table 2. Heavy Metal Emissions from Sintering

Heavy Metal	Emission	Typical Industry	Source
Pb (Lead)	0.65	0.4–1.2	Ore and recycled powder
Zn (Zinc)	1.8	1–3	Scrap dust and recycling
As (Arsenic)	0.04	0.02–0.06	Trace elements in iron ore
Cd (Cadmium)	0.01	0.005–0.02	Ore impurity
Hg (Mercury)	0.003	0.002–0.006	Minerals containing organic
Total Cr	0.15	0.10–0.25	Ore and refractory wear
Ni (Nickel)	0.2	0.12–0.28	Ore content

The data presented in Table 2 allows for a comparative assessment of heavy metal emissions from the sintering process, both in absolute values and in terms of typical industry ranges. The measurements obtained show that most heavy metal components, particularly Pb, Zn, and Ni, fall within the typical ranges reported in the industry literature. Specifically, the Zn (1.8 mg/Nm³) and Pb (0.65 mg/Nm³) values are consistent with the average levels observed in facilities where recycled dust is incorporated into the process flow. However, the fact that elements with high toxicity coefficients, such as As, Cd, and Hg, were measured at low concentrations can be considered an indicator of the quality of the raw materials used and the effectiveness of the gas purification system.

It is understood that emissions from elements such as Cr and Ni vary depending on ore content and refractory wear. The table provides a comprehensive overview of the heavy metal emission profile of the sintering process, revealing that parameters such as the mineralogical structure of

the raw material, the recycling rate, and the condition of the process equipment are decisive factors in emission levels. In this context, the data emphasizes the importance of process-controlled improvement efforts, particularly interventions aimed at increasing metal recovery and treatment efficiency.

Table 3. Sinter Plant Emission Sources and Percentage Distribution

Process Step	**Dust (%)**	**NO_x (%)**	**SO_2 (%)**	**CO (%)**	**Description**
Raw material preparation (crushing-screening)	22	–	–	–	Powder main source
Mixer-blender line	8	–	–	–	If humidity is low, dust increases
Sintering machine (combustion zone)	55	82	88	91	Primary chemical emission source
Cooling area	10	8	7	5	Gas discharge from hot material
Recycling & crushers	5	5	5	3	Mechanical abrasion dusts

When examining the types and proportional distribution of emission sources associated with the sintering process in Table 3, it is seen that the sintering machine has a dominant position, particularly in chemical gas emissions. The sintering machine accounts for 82% of total NOx emissions, 88% of SO_2, and 91% of CO, demonstrating that it is the main pollutant source in the process. This situation shows that the sintering bed area, where high-temperature combustion and reduction reactions occur intensively, plays a critical role in the formation of chemical emissions. In terms of dust emissions, the distribution is more widespread, with raw material preparation (22%) and the main sintering area (55%) accounting for the majority of the total dust load. This result indicates that both mechanical crushing and screening processes and the physical-chemical reactions occurring on the sintering bed contribute to dust formation. Furthermore, the 8% dust emission observed in the mixer, mixer- line supports the notion that moisture control is a decisive parameter in dust formation.

The contribution of the cooling zone to emissions is relatively low, with limited increases (in the range of 5–8%) observed, particularly for NOx and SO_2, due to gases released from hot material. In the recycling and crusher lines, low rates for all pollutants (in the range of 3–5%) are noteworthy, indicating a more limited emission load due to mechanical abrasion.

Overall, the table shows that the critical point where chemical gas emissions are concentrated in the sintering process is the sintering machine, while both mechanical and thermochemical processes play a decisive role in dust emissions. This distribution contributes to the clear definition of the points that need to be focused on in process control and emission reduction strategies.

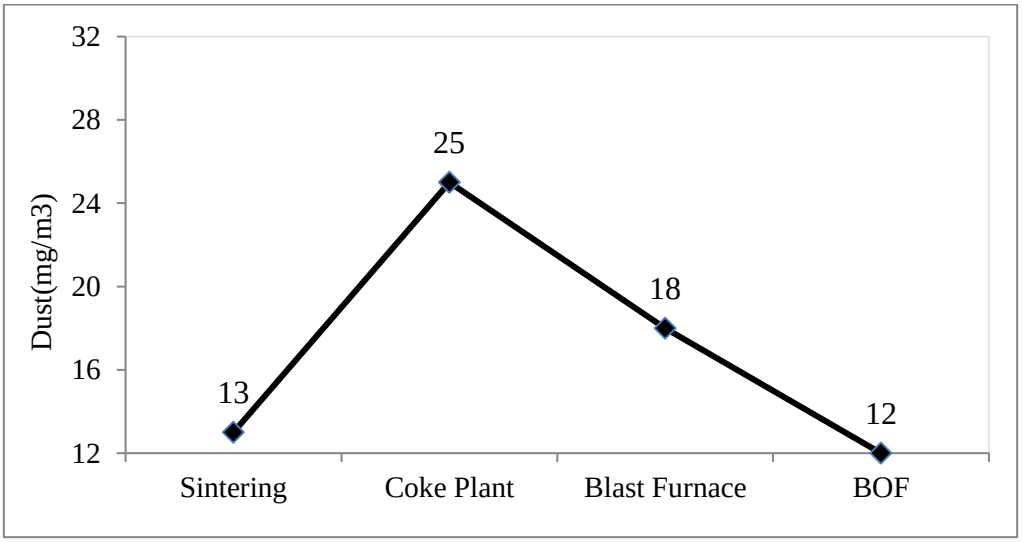

Figure 1. Dust emission values in iron and steel plants

Figure 1 shows a comparative view of dust concentrations measured in different processes in iron and steel production. The highest dust emissions were recorded in the Electric Arc Furnace (EAF) and Coke Oven processes, indicating that these units are more risky operations in terms of particle formation. The BOF process has the lowest dust values, indicating the effectiveness of the applied purification systems. Sintering and secondary metallurgy stages produce medium-level emissions. Overall, the graph reveals a clear difference in emissions between processes and that some stages require more intensive control. CO emission values in iron and steel plants are given in Figure 2.

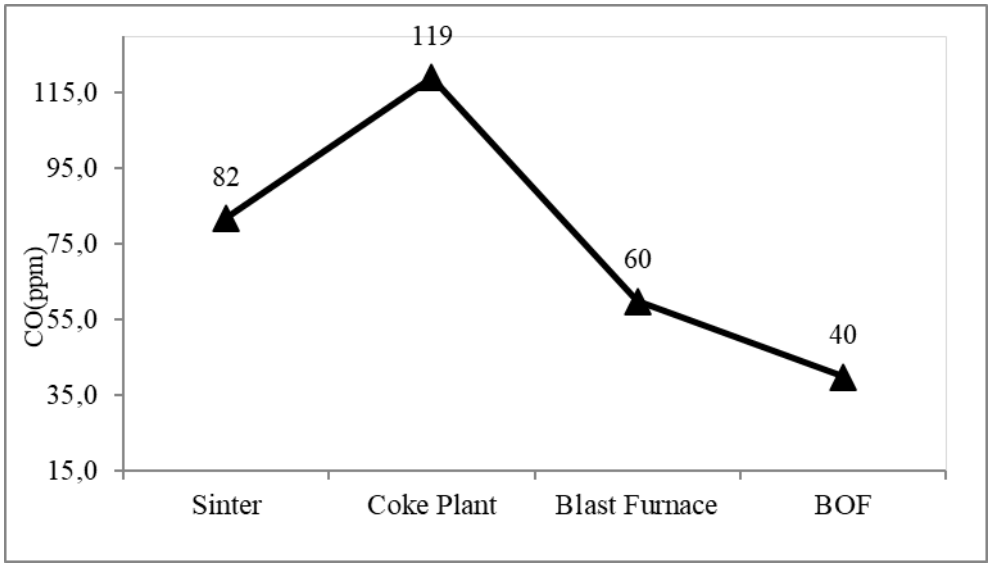

Figure 3. CO emission values in iron and steel plants.

CO (carbon monoxide) emissions in iron and steel plants are a critical pollutant parameter, particularly in coke batteries, sintering plants, and blast furnace processes, due to combustion inefficiency, incomplete oxidation, and raw gas leaks. CO concentrations are sensitive to process conditions and are typically measured in the hundreds to thousands of ppm range in combustion chambers and blast furnace outlet gases. Controlling emissions requires ensuring complete combustion**,** optimizing the combustion air and fuel ratio**,** improving closed-loop gas

collection systems**, and** effectively utilizing continuous emission monitoring systems (CEMS). Sudden increases in CO levels are often indicative of combustion instability**,** fuel-air imbalance**, or** gas leaks, making it a critical early warning parameter for process safety and worker health.

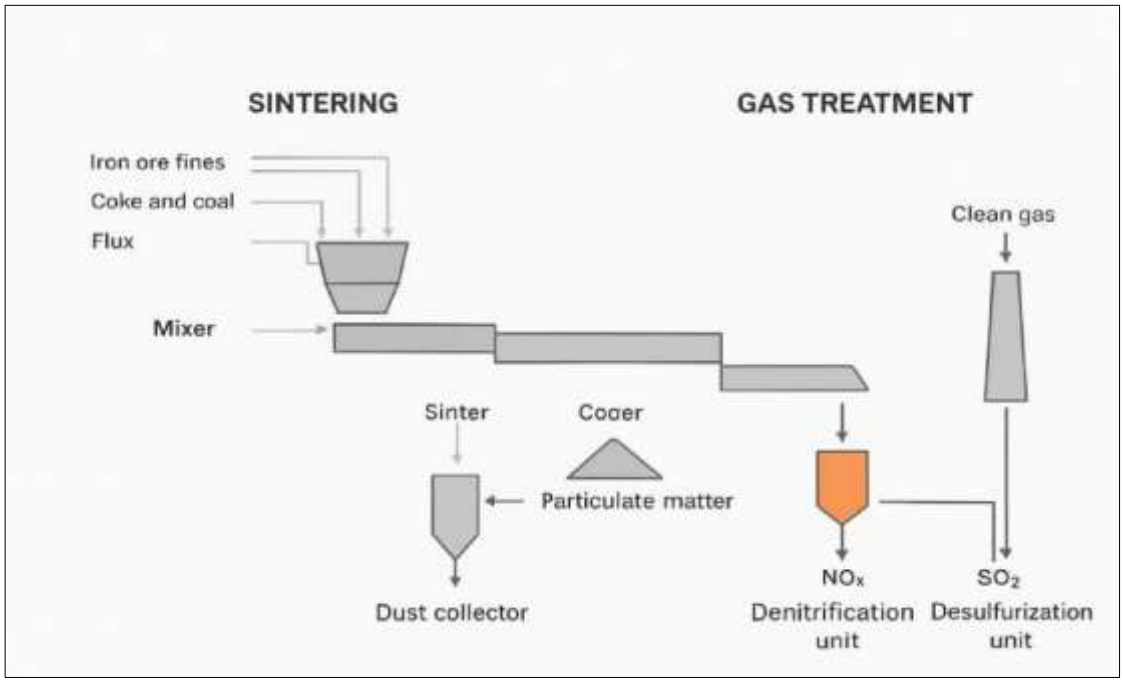

Figure 3. Sintering and gas purification system process flow diagram [23].

The sintering and gas purification system process flow diagram is shown in Figure 3. Chemical hazards in raw material preparation and ore enrichment processes, which constitute the first stage of the iron and steel industry, occur in a wide range, such as dust and metal particles, VOCs, heavy metals, corrosive liquids, flotation reagents, sinter and pellet gas emissions, fuel oil combustion products, acidic drainage gases, and CO, NOx and SOx emissions generated during the process.

If these hazards are not controlled, they can lead to serious occupational diseases, environmental pollution, and process safety problems among workers.

1.3. Coke Production

During high-temperature coal pyrolysis in coke batteries, numerous volatile chemicals are released. The main chemical hazards in metallurgical coke production are concentrated in this stage. Coal pyrolysis occurs at temperatures of 1000–1200 °C inside the furnace [24]. The gases formed during pyrolysis that are critical to occupational health are shown in Table 4.

Table 4. Gases formed during pyrolysis that are critical for occupational health

Gas	Source of Formation	Health Risk
CO (Carbon monoxide)	Thermal decomposition of coal	Toxic, suffocating
H_2S (Hydrogen sulfide)	Decomposition of sulfur compounds	Neurotoxicity, risk of lethal dose
HCN (Hydrogen cyanide)	Nitrogen compounds	Acute toxicity, rapid effect
NHs (Ammonia)	Decomposition of nitrogenous organic structures	Corrosive, respiratory irritant
SO2 / SOx	Sulfur content	Respiratory irritant
NOx	High-temperature reactions	Risk of pulmonary edema
Benzene, Toluene, Xylene (BTX)	Volatile aromatic hydrocarbons	Carcinogenic / hematotoxic
PAHs (Benzo[a]pyrene, etc.)	Pyrolysis of organic structures	High carcinogenic effect
VOCs	Coke oven gas components	Explosive/toxic

In metallurgical coke production, when coal undergoes pyrolysis in an oxygen-free environment at temperatures between 1000-1200 °C, the thermal decomposition of the coal's organic matrix releases a multi-component gas mixture. This gas phase presents a complex structure containing combustible components with high calorific value, such as hydrogen (H2), methane (CH4), and carbon monoxide (CO), as well as toxic and corrosive components, such as hydrogen sulfide (H2S), ammonia (NH3), and hydrochloric acid (HCl). In addition, organic volatiles such as benzene, toluene, xylene (BTX), and polyaromatic hydrocarbons (PAH) are also formed intensively during this process.

The quantity and character of the gas composition are closely related to the petrographic properties of the coal, the volatile matter content, the furnace temperature profile, and the carbonization time. This gas mixture is both an important energy source in terms of process efficiency and carries critical risk factors in terms of occupational health, environmental management, and the performance of gas treatment systems. Therefore, accurately monitoring the formation mechanism and component distribution of pyrolysis gases is essential for optimizing the coking process and controlling environmental emissions. The coke oven and gas treatment flowchart is shown in Figure 4.

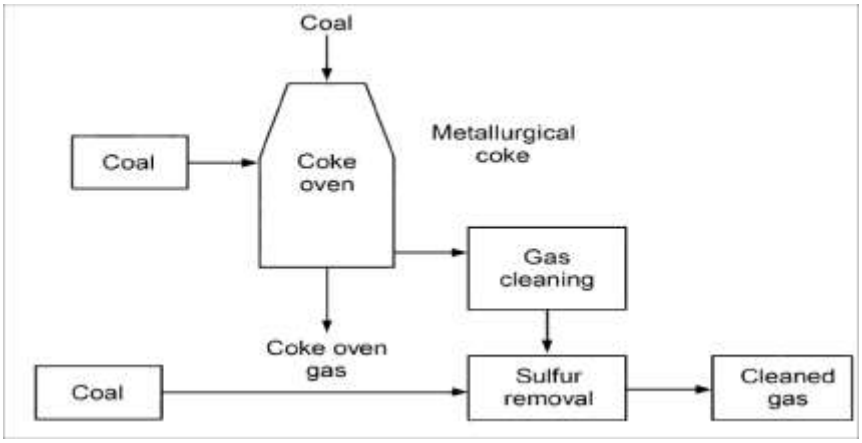

Figure 4. Coke oven and gas treatment flowchart [25].

The Coke Oven and Gas Treatment Flowchart shows the basic stages of the metallurgical coke production process and the operation of the by-product gas treatment line from a holistic perspective. The diagram covers the process starting with the feeding of coal into the coke oven, resulting in high-temperature pyrolysis, the production of metallurgical coke as a solid product, and the formation of coke oven gas. The flowchart further highlights that the resulting coke oven gas undergoes sequential treatment processes gas cleaning, desulfurization, and final gas purification—to make it suitable for industrial use. The diagram clearly illustrates the interdependence between coke production and gas purification processes and reflects the importance of process integration in terms of environmental performance and occupational safety through an analytical approach.

2. Conclusions and Recommendations

The iron and steel industry is a sector with a high level of chemical risk due to its multi-stage process structure and production line based on intensive chemical reactions. This study addresses the chemical hazards arising in the sector from a holistic perspective, systematically examining the effects of toxic gases, metal oxide fumes, volatile organic compounds, heavy metal particles, and other process-related harmful agents on worker health. The findings show that chemical exposures are not only a natural consequence of the process; deficiencies in measurement, monitoring, engineering controls, and managerial practices also increase risk levels.

The iron and steel industry is one of the sectors with the highest risk class in terms of chemical risk factors. Exposure to toxic gases, metal vapors, carcinogens, and solvents can lead to acute and chronic health effects. These risks can be significantly reduced through effective engineering controls, regular monitoring, appropriate PPE use, and process improvements. Compliance with international standards and a continuous improvement approach are critical for both protecting worker health and ensuring sustainable production.

In order to establish a sustainable occupational health and safety approach in the sector, it is essential to accurately identify chemical risk factors, perform process-based hazard analyses, and implement control strategies that comply with international standards. In this context, the widespread use of closed system designs, the use of effective ventilation and purification technologies, regular environmental measurements, and increased use of reliable personal protective equipment play a critical role in reducing exposure. In addition, continuous training of employees, keeping chemical management plans up to date, and evaluating all processes within the scope of an integrated risk management system will contribute significantly to the development of a safety culture across the sector.

In conclusion, controlling chemical risks in the iron and steel industry requires a multi-layered approach that goes beyond technical measures alone, supported by corporate governance, employee participation, regular monitoring, and science-based decision-making mechanisms. Efforts undertaken within this framework will enable both the protection of worker health and the transformation of production processes into more sustainable, efficient, and safe operations.

ÖZET

Molibden (Mo) ve onun alaşımları, yüksek sıcaklıklı uygulamalarda tercih edilen malzemelerdir çünkü yüksek erime sıcaklığı, düşük ısıl genleşme oranı, termal şoklara karşı üstün direnç ve ısıl yorgunluğa karşı olağanüstü bir dayanıklılık gibi niteliklere sahiptirler. Fakat, saf molibdenin yüksek sıcaklıklardaki yeniden kristalleşme sıcaklıkları, dayanıklılık ve aşınma direncinde artan ihtiyaçları karşılamada çeşitli kısıtlamalarla karşılaşabilir. Bu sebeple, saf molibdenin yüksek ısıda aşınmaya karşı daha iyi bir direnç göstermesi için, Mo matrisli kompozitler tasarlanmıştır. Mo matrisli kompozitler, genelde yüksek sıcaklık koşullarında faaliyet gösteren uygulamalarda kullanılan yapısal bileşenler için daha dayanıklı ve etkili bir seçenek sunmaktadır. Bu çalışma molibden (Mo) içerisine farklı oranlarda (hacimce % 3, 6 ve 9) samaryum oksit (Sm_2O_3) ilave edilerek toz metalürjisiyle üretilen kompozitlerin mikroyapısal gelişiminin incelenmesi ve sertliğinin arttırılması amaçlamaktadır. Buna ilaveten üretilen kompozitin yoğunluk ve sertlik özellikleri de incelenmiştir. Mikroyapı incelemeleri için SEM-EDS analizi kullanılırken, yoğunluk için Arşiment prensibi ve sertlik için Vikers sertlik testi kullanılmıştır. Mikroyapı sonuçları (hem SEM hem de MAP) Sm_2O_3 partiküllerinin Mo matrisinde nispeten homojen dağıldığını göstermiştir. XRD sonuçları Mo ile Sm_2O_3 arasında herhangi bir fazın oluşmadığını göstermiştir. Deneysel yoğunluklarda ve bağıl yoğunluklarda düşüşler meydana gelmiştir. %9 Sm_2O_3 ilavesinde deneysel yoğunluk 8.8 g/cm^3 iken bağıl yoğunluk % 88.2 olarak ölçülmüştür. Mekanik özellik olarak değerlendirilen sertlik sonuçlarına göre sertliklerde belirgin artış olmuştur. En yüksek sertlik %9 Sm_2O_3 ilavesinde 318.2 HV0.5 olarak ölçülmüştür. Bu değer katkısız Mo matrisine göre sertliğin yaklaşık %77.5 oranında arttığını göstermiştir.

Anahtar kelimeler: Mo, Sm_2O_3, kompozit, mikroyapı, sertlik

MICROSTRUCTURE, DENSITY AND HARDNESS EVOLUTION OF Mo-Sm_2O_3 COMPOSITES

ABSTRACT

Molybdenum (Mo) and its alloys are preferred materials in high-temperature applications because they possess qualities such as high melting point, low thermal expansion rate, superior resistance to thermal shock, and exceptional resistance to thermal fatigue. However, the recrystallization temperatures of pure molybdenum at high temperatures can present various limitations in meeting the increasing demands for durability and wear resistance. For this reason, Mo-matrix composites have been designed to provide pure molybdenum with better resistance to wear at high temperatures. Mo matrix composites offer a more durable and effective option for structural components used in applications operating under high-temperature conditions. This study aims to investigate the microstructural development and increase the hardness of composites produced by powder metallurgy by adding samarium oxide (Sm_2O_3) at different ratios (3%, 6%, and 9% by volume) to molybdenum (Mo). In addition, the density and hardness properties of the produced composite were also investigated. SEM-EDS analysis was used for microstructure investigations, while the Archimedes principle was used for density and the Vikers hardness test was used for hardness. Microstructure results (both SEM and MAP) showed that Sm_2O_3 particles were relatively homogeneously distributed in the Mo matrix. XRD results showed that no phase formed between Mo and Sm_2O_3. Decreases occurred in experimental densities and relative densities. At 9% Sm_2O_3 addition, the experimental density was 8.8 g/cm^3, while the relative density was measured as 88.2%. According to the hardness results, which were evaluated as a mechanical property, there was a significant increase in hardness. The highest hardness was measured as 318.2 $HV_{0.5}$ with a 9% addition of Sm_2O_3. This value indicates that the hardness increased by approximately 77.5% compared to the Mo matrix without any additions.

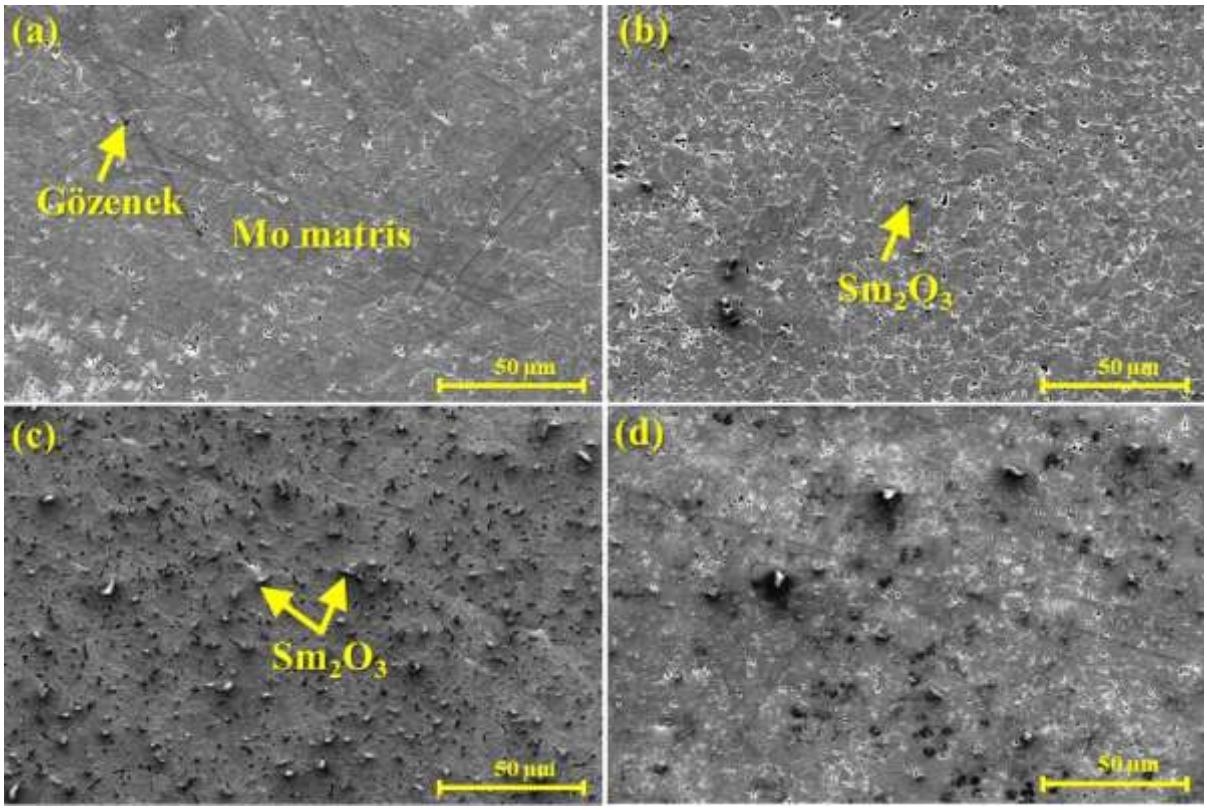
Keywords: Mo, Sm_2O_3, composite, microstructure, hardness

1. GİRİŞ

Dünya genelinde enerji kullanımı sürekli bir yükseliş göstermektedir. İnsanlığın hayatta kalabilmesi için enerji tüketimini aşağı çekmesi gerekmektedir. Bu hedefe ulaşmanın en belirgin yolu, makinelerin ısıya maruz kalan bölgelerindeki malzemelerin işleme sıcaklığını yükselterek enerji üreten makinelerin termal verimliliğini yükseltmektir [1]. Molibden (Mo) ve alaşımları, yüksek erime noktası, düşük termal genleşme, termal şoka karşı mükemmel direnç ve termal yorgunluğa karşı olağanüstü dayanıklılıkları nedeniyle yüksek sıcaklık uygulamaları için tercih edilen malzemelerdir [2,3]. Mo ve alaşımları son yıllarda itina ile geliştirilmektedir. Bu konu hakkında elde edilen bulgular pek çok yayında yer almıştır, bunlardan bazılarını örnek olarak gösterebiliriz [4–6]. Elbette, bu tür yüksek sıcaklığa dayanıklı bileşimlerin en büyük sorunu, metal alaşımlarında sıkça karşılaşılan dayanıklılık (sünme direnci) ile kırılma dayanıklılığı arasındaki çelişkidir [7,8]. Bu yüzden, saf molibdenin yüksek sıcaklıklarda aşınmaya karşı daha iyi direnç göstermesi amacıyla Mo matris kompozitleri tasarlanmıştır. Mo matris kompozitleri, genelde yüksek sıcaklık uygulamalarında kullanılan yapısal elemanlar için daha sağlam ve etkili bir seçenek sunar. Cheng vd. [9]'nin yaptığı çalışmada La_2O_3 ilaveli Mo–La_2O_3 kompozitleri (0, 0,5, 1,0, 1,5 ve 2,0 ağırlıkça %) ince tane yapıları ve artan yeniden kristalleşme sıcaklıkları sergilemiştir. Kompozitler, %0,5–1,0 ağırlıkça La_2O_3'te önemli ölçüde artırılmış mukavemet (saf Mo'dan 100 MPa daha fazla) ve uzama (saf Mo'nun iki katı) gösterir, ancak uzama %1,5 ağırlıkça'nın üzerinde azalır. Güçlendirme, tane içi ve tane sınırı mekanizmaları yoluyla gerçekleşir ve sünek kırılma, tane arası parçacıklarda mikro çatlak çekirdeklenmesinden etkilenir. Testler, %1,0–1,5 ağırlıkça La_2O_3'te optimum mukavemet ve uzama özellikleri olduğunu gösterir; yüksek sıcaklıkta deformasyon, tane arası ve tane içi hasarın etkisiyle mikro boşluk birleşmesi ve mikro çatlak yayılımını içerir. Jing vd. [10], oda sıcaklığı ile yüksek sıcaklıklarda üstün mekanik özelliklere sahip nano yapılı Mo-ZrC alaşımını, nano boyutlu ZrC dağılımı ve arayüz kontrolü ile geliştirmişlerdir. Mo-ZrC alaşımının üstün mekanik özellikleri ve ısıya dayanıklılığı, nano boyutlu ZrC parçacıklarının dağılım güçlendirilmesi, ince taneli güçlendirme ve tane sınırlarının temizlenmesi gibi etkilerinin bir araya gelmesinden kaynaklandığı bildirilmiştir. Bu araştırma, molibden (Mo) içine çeşitli oranlarda (hacimce % 3, 6 ve 9) samaryum oksit (Sm_2O_3) eklenerek toz metalürjisi ile elde edilen kompozitlerin mikroyapısının incelenmesi ve sertlik seviyesinin yükseltilmesi hedeflenmektedir. Ayrıca, üretilen kompozitin yoğunluk ve sertlik özellikleri de değerlendirilmektedir.

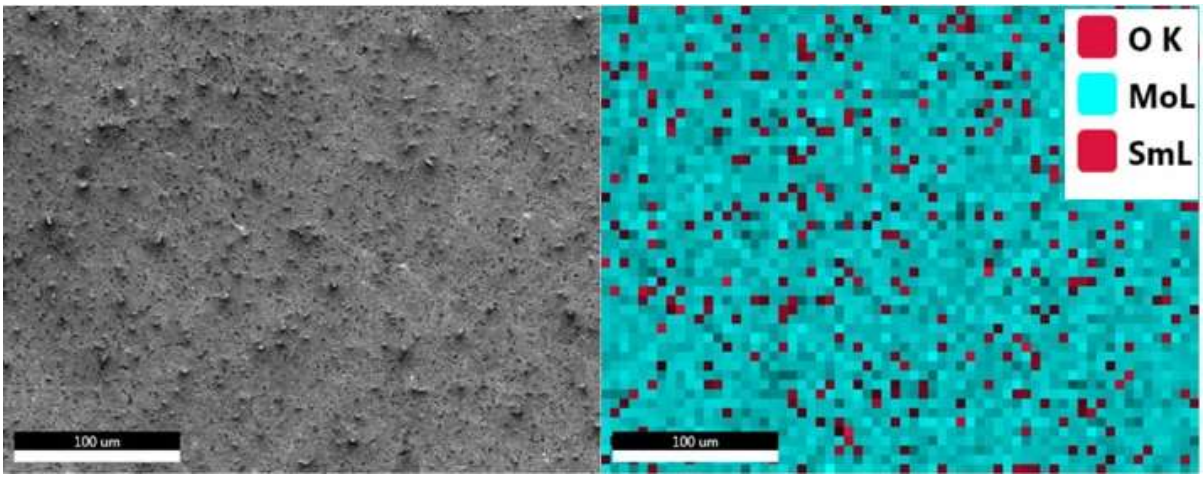
2. DENEYSEL ÇALIŞMALAR

Mo matrisli, Sm_2O_3 takviyeli kompozit malzemelerin toz metalürjisi ile üretilmiştir. Üretimde kullanılan tozlar Mo, %99.95 saflıkta ve 10 µm tane boyutuna sahip; Sm_2O_3 ise %95 saflıkta ve -325 mesh tane boyutuna sahiptir. Kompozitlerin üretiminde kullanılan toz bileşim oranları Tablo 1'de verilmiştir.



Tablo 1: Toz bileşim oranları

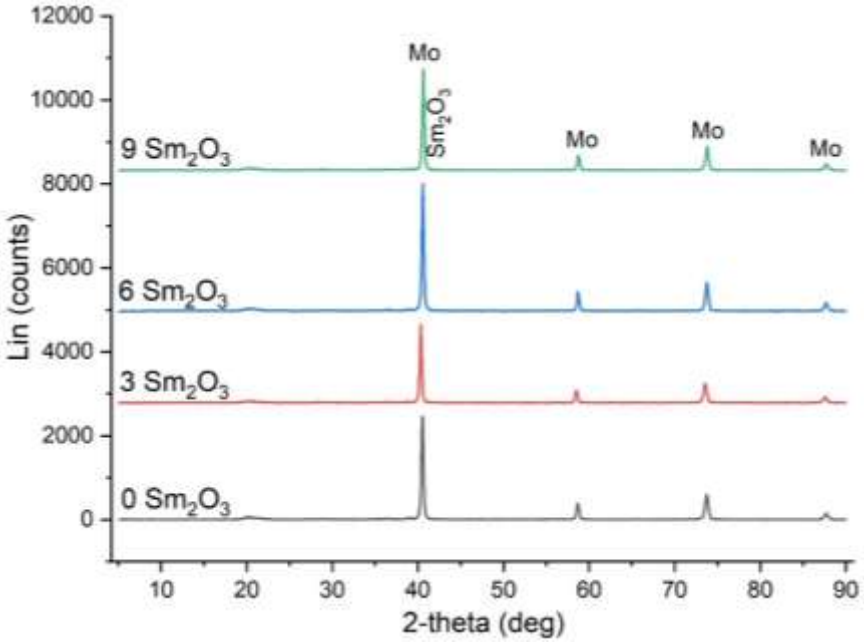
Numune grubu	Bileşim (% hacim)	
	Mo	Sm_2O_3
1	100	-
2	97	3
3	94	6
4	91	9



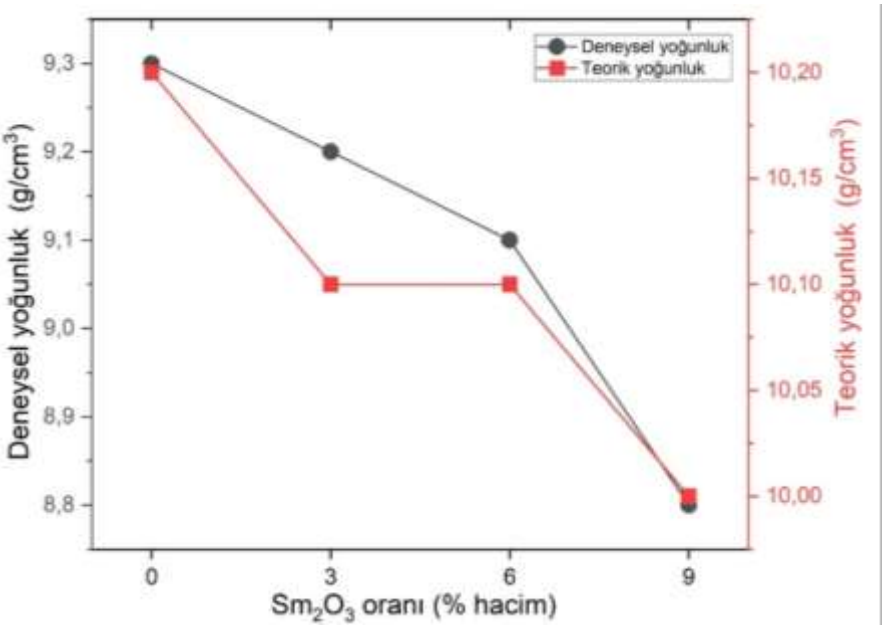
Öncelikle, tozlar Tablo 1'de belirtilen oranlarda 1 saat boyunca bir toz karıştırma mikserinde (turbula) karıştırılmıştır. Ardından, bu toz karışımı, SPECAC GS15011 marka ve model bir hidrolik pres ile 20 mm çapında ve 5 mm kalınlığında pelletler haline getirilmiştir. Bu işlem sonucunda elde edilen pelletler, PROTHERM PTF 18/50/300 marka ve model yüksek sıcaklıkta çalışan bir tüp fırında argon gazı ortamında 1750 °C'de 1 saat süreyle sinterlenmiştir. Metalografik numune hazırlığı tamamlandıktan sonra, numuneler mikroyapı analizi için Murakami çözeltisi kullanılarak dağlanmıştır. Numunelerin faz yapısı ve mikroyapı analizi bir taramalı elektron mikroskobu ve bir X-ışını difraktometresi aracılığıyla da incelenmiştir. Numunelerin deneysel yoğunlukları, Arşimet ilkesine ve ASTM B962-08 standardına dayanarak belirlenmiştir. Bağıl yoğunluklar, deneysel yoğunlukların teorik yoğunluklara bölünmesi ile hesaplanmıştır. Numunelerin sertlik değerleri, mikrosertlik cihazı kullanılarak 500 gramlık bir yük altında 15 saniyelik bir bekleme süresiyle ölçülmüştür.

3. SONUÇLAR ve TARTIŞMA

Üretilen kompozitlerin SEM görüntüleri Şekil 1'de verilmiştir. Mo matrisi içerisinde Sm_2O_3 partikülleri homojen olarak dağılmıştır. Bu durum ayrıca Şekil 2'deki MAP analizi ile de desteklenmektedir. Partiküllerin homojen dağılımı hem mekaniksel hemde fiziksel özelliklere olumlu etki etmektedir. SEM incelemelerinde ayrıca çok azda olsa gözenek oluşumu görülmektedir.

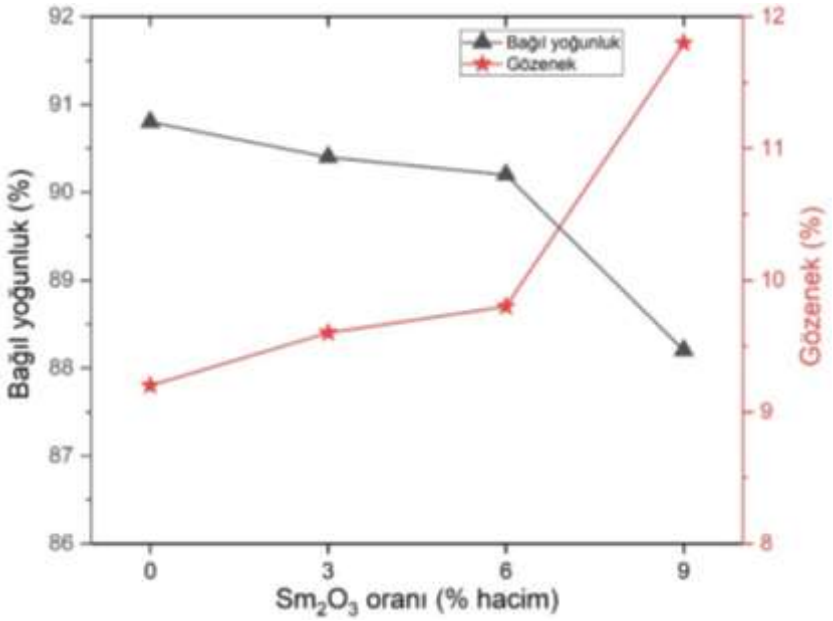


Şekil 1: SEM görüntüleri: (a) 0 Sm_2O_3, (b) 3 Sm_2O_3, (c) 6 Sm_2O_3 ve (d) 9 Sm_2O_3



Şekil 2: Mo-6 Sm_2O_3 kompozitin MAP analizi

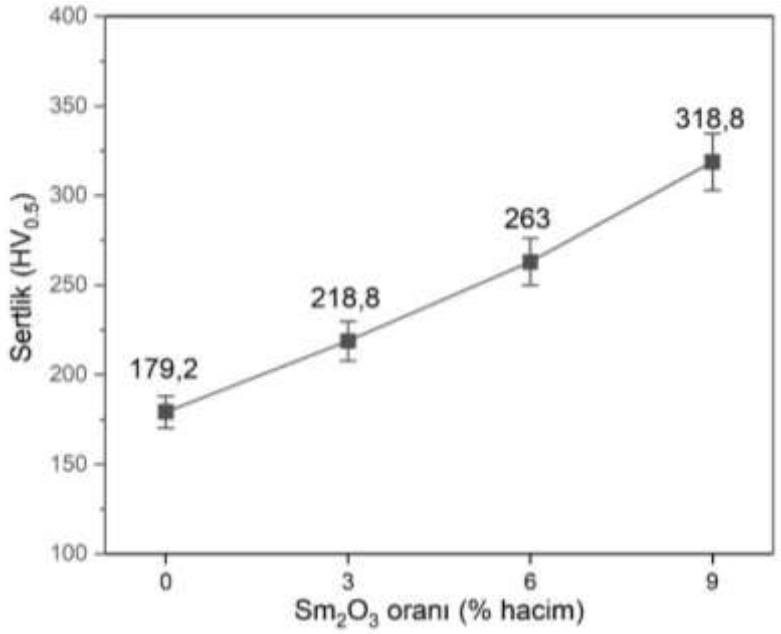
Şekil 3'de XRD analizi grafiği verilmiştir. Mikroyapıda kompoziti oluşturan Mo ve Sm_2O_3 haricinde herhangi bir faz oluşmamıştır. Üretim esnasında numunelerde herhangi bir oksit oluşmadığı da XRD grafiğinden anlaşılmaktadır.



Şekil 3: Mo-Sm_2O_3 kompozitlerin XRD analizi

Mo matrisine ilave edilen Sm_2O_3 partiküllerin deneysel yoğunluk üzerine etkisi Şekil 4'de verilmiştir. % 0, 3, 6 ve 9 Sm_2O_3 katkısına bağlı olarak sırasıyla deneysel yoğunluklar 9.3, 9.2, 9.1 ve 8.8 g/cm^3 olarak ölçülmüştür. Bu durum Sm_2O_3'ün yoğunluğunun (8.35 g/cm^3) Mo'ya göre (10.2 g/cm^3) düşük olmasından kaynaklanmaktadır.

Şekil 4: Mo-Sm_2O_3 kompozitlerin deneysel ve teorik yoğunlukları



Deneysel yoğunlukların teorik yoğunluklara bölünmesiyle bağıl yoğunluklar hesaplanmıştır. Bağıl yoğunluklardan yola çıkarak kompozitlerin gözenekleri bulunmuştur. Şekil 5'de kompozitlerin bağıl yoğunlukları ve gözenek miktarı verilmiştir. Sm_2O_3 ilavesiyle bağıl yoğunluklarda azalma olurken, gözenek miktarında artış meydana gelmiştir.

Şekil 5: Mo-Sm_2O_3 kompozitlerin bağıl yoğunluklar ve gözenek miktarı

Mekanik özellik açısından bilgi edinmek amacıyla yapılan sertlik testi sonuçları Şekil 6'da verilmiştir. % 0, 3, 6 ve 9 Sm_2O_3 katkısına bağlı olarak sırasıyla sertlikler 179.2, 218.8, 263 ve 318.8 $HV_{0.5}$ olarak ölçülmüştür. Bu değer katkısız Mo matrisine göre sertliğin yaklaşık %77.5 oranında arttığını göstermiştir. Bir malzemenin içinde bulunan gevrek fazlar, kristal yapıdaki kusurlar veya eksik atomlar gibi dislokasyon hareketini engelleyerek malzemenin dayanımını artırabilir. Dislokasyonlar, kristal yapı içinde hareket eden kusurlar veya bozukluklardır ve malzemenin şekil değiştirmesine yol açan mekanik stresler altında hareket ederler. Ancak,

gevrek fazlar bu dislokasyon hareketini engelleyerek malzemenin plastik deformasyonunu sınırlar ve dayanımını artırır. Yapıdaki sert fazlar, malzemenin yük taşıma kapasitesini artırarak sertlikte belirgin bir artışa neden olur. Bu da malzemenin daha dayanıklı olmasını sağlar [11,12].

Şekil 6: Mo-Sm_2O_3 kompozitlerin sertlik grafiği

4. GENEL SONUÇLAR

Toz metalürjisi yöntemiyle üretilen Mo-Sm_2O_3 kompozitlerin mikroyapı, yoğunluk ve sertlik değerlendirmesine üzerine yapılan genel sonuçlar aşağıdaki gibidir.

1) Sm_2O_3 partikülleri kompozit içinde bağıl olarak homojen dağılmıştır. Bunun hem mekanik hem de fiziksel özelliklere olumlu yansıdığı düşünülmektedir

2) Yapıda XRD sonuçlarına göre Mo ve Sm_2O_3 fazları tespit edilmiştir. Herhangi bir oksitlenme meydana gelmemiştir.

3) Sm_2O_3 partiküllerinin ilavesiyle deneysel yoğunluklarda, bağıl yoğunluklarda kısmen azalma olurken, belirli seviyede gözeneklerde artış olmuştur.

4) Sm_2O_3 partiküllerinin Mo matrisine ilavesiyle dislokasyonların kilitlenmesi sonrasında sertliklerde artışlar meydana gelmiştir.

BAKIR MATRİSLİ KOMPOZİTLERİN GELİŞTİRİLMESİ: BİR LİTERATÜR ÇALIŞMASI

Serkan ISLAK

Kastamonu Üniversitesi, Mühendislik ve Mimarlık Fakültesi, Makine Mühendisliği Bölümü, Kastamonu

ORCID: 0000-0001-9140-6476

e-mail: serkan@kastamonu.edu.tr

ÖZET

Titanyum, magnezyum, bakır ve alüminyum gibi metaller, karbürler (silisyum karbür, bor karbür, titanyum karbür vb.), nitrürler (bor nitrür, titanyum nitrür, alüminyum nitrür), oksitler (alüminyum oksit, zirkonyum oksit, titanyum oksit) ve nanopartiküllerle (karbon nanotüp, grafen, karbon nanofiber) bir araya getirilerek metal matris kompozitleri (MMK) meydana getirilir. Bu malzemelerin temel özellikleri arasında artırılmış özgül mukavemet, sertlik, üst düzey aşınma direnci, iyi sönümleme özellikleri, yüksek korozyon direnci ve düşük ağırlık bulunmaktadır. Bakır (Cu) ve bakır alaşım ürünleri, mükemmel elektrik ve ısı iletimi, korozyona karşı gösterdiği dayanıklılık, estetik görünümü ve antimikrobiyal özellikleri sayesinde ısıtma ve soğutma sistemleri, deniz suyunu taşıyan borular ve hem evsel hem de sanayi amaçlı su sistemleri gibi birçok endüstriyel alanda yaygın olarak kullanılmaktadır. Ancak, bu olumlu özelliklerine karşın, saf bakırın sertliği düşüktür, dayanıklılığı zayıftır ve aşınmaya karşı direnci son derece sınırlıdır. Bu sınırlamaların üstesinden gelmek için bakır matrisli MMK üretimi son derece popüler bir konudur. Yukarıda bahsedilen takviyelerin bakır matrisine ilave edildiği MMK'lar döküm, toz metalurjisi, kaplama vb. işlemlerle üretilmektedir. Özellikle toz metalurjisi yöntemlerinden spark plazma sinterleme, seçici lazer sinterleme ve sıcak presleme son teknolojik üretim yöntemleridir. Kaplama yöntemlerinden ise termal sprey kaplamaları yüzey kompozitlerin üretiminde kullanılmaktadır. Buradaki amaç optimum elektriksel ve termal iletkenliğe sahip ve iyileştirilmiş mekanik özelliklere sahip daha kompakt bakır matrisli kompozit malzemelerin geliştirilmesidir.

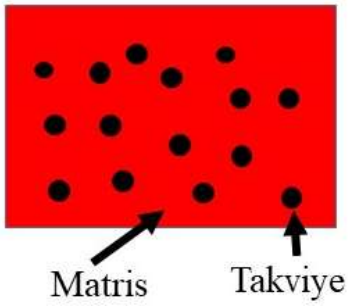
Anahtar kelimeler: MMK, bakır, kompozitler

DEVELOPMENT OF COPPER-MATRIX COMPOSITES: A LITERATURE REVIEW

ABSTRACT

Titanium, magnesium, copper, and aluminum, carbides (silicon carbide, boron carbide, titanium carbide, etc.), nitrides (boron nitride, titanium nitride, aluminum nitride), oxides (aluminum oxide, zirconium oxide, titanium oxide), and nanoparticles (carbon nanotubes, graphene, carbon nanofibers) are combined to form metal matrix composites (MMCs). The key properties of these materials include increased specific strength, hardness, high wear resistance, good damping properties, high corrosion resistance, and low weight. Copper (Cu) and copper alloy products are widely used in many industrial fields, such as heating and cooling systems, seawater pipes, and domestic and industrial water systems, thanks to their excellent electrical and thermal conductivity, corrosion resistance, aesthetic appearance, and antimicrobial properties. However, despite these positive characteristics, pure copper has low hardness, weak durability, and extremely limited resistance to wear. To overcome these limitations, the production of copper matrix MMCs is an extremely popular topic. MMCs, to which the above-mentioned reinforcements are added to the copper matrix, are produced by processes such as casting, powder metallurgy, and coating. Among powder metallurgy methods, spark plasma sintering, selective laser sintering, and hot pressing are the latest technological production methods. Among coating methods, thermal spray coatings are used to produce surface composites. The objective here is to develop more compact copper matrix composite materials with optimal electrical and thermal conductivity and improved mechanical properties.

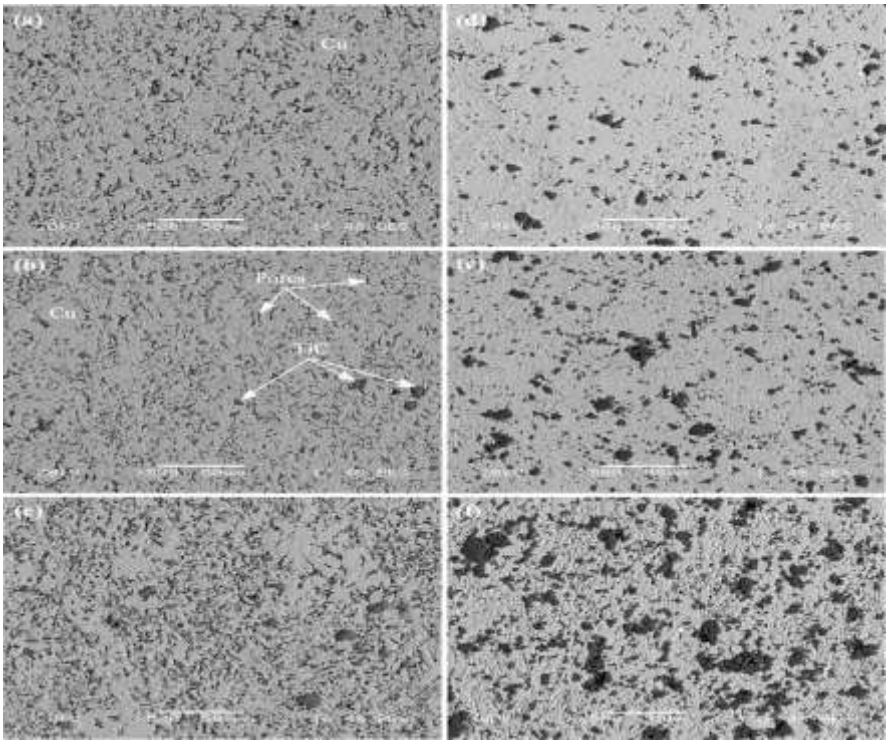
Keywords: MMC, copper, composites



1. GİRİŞ

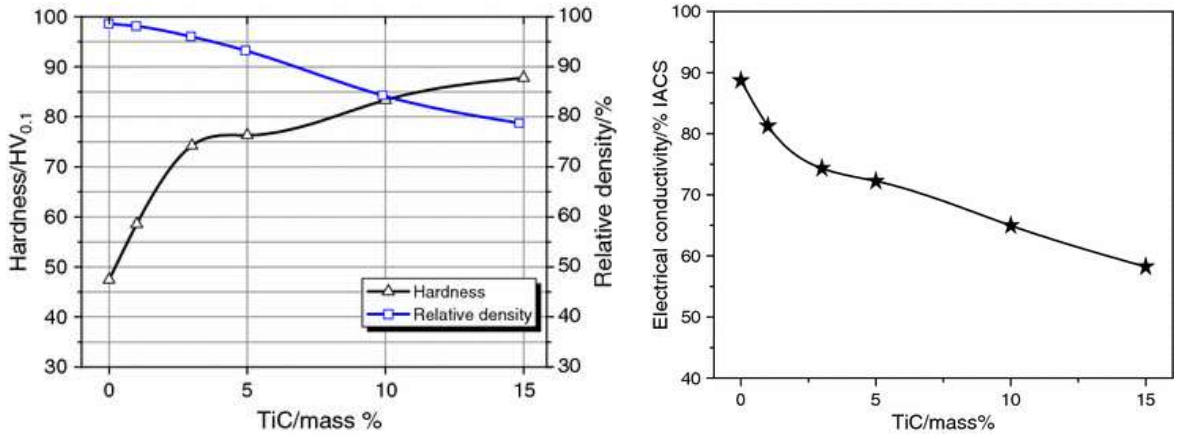
Bakır ve bakır alaşımları, ticaret metallerinin en önemli kategorilerinden birisini teşkil eder. Harika elektrik ve ısı iletkenlikleri, yüksek korozyon direnci, üretim kolaylığı, iyi dayanıklılıkları ve yorulmaya karşı direnci sayesinde sıkça kullanılırlar. Genelde manyetik özelliğe sahip değillerdir. Rahatlıkla lehimlenebilir ve sert lehim uygulamalarına açıktırlar; birçok bakır ve bakır alaşımı çeşitli gaz, ark ve direnç kaynaklama yöntemleriyle bir araya getirilebilir. Süs eşyaları için, belirli renklerde standart alaşımlar kolaylıkla temin edilebilir. Bakır alaşımları, hemen hemen her türlü doku ve parlaklıkta cilalanıp parlatılabilir. Mevcut kaplama seçeneklerini artırmak amacıyla kaplanabilir, organik malzemelerle kaplanabilir veya kimyasal şekilde renklendirilebilirler [1]. Düşük mukavemet ve zayıf aşınma direnci, Cu ve alaşımlarının en büyük sınırlamasıdır [2].

Bakırın içine herhangi bir alaşım elementi eklendiğinde iletkenliğinin önemli ölçüde düşeceği oldukça iyi bilinmektedir. Gümüş, bakırın iletkenliği üzerinde en az zararlı etkiye sahiptir, ancak gümüş oldukça maliyetlidir. Alaşım elementlerinin sebep olduğu katı çözelti güçlendirmesinin olumsuz etkilerini önlemek adına, bakır bazlı materyallerin mekanik özelliklerini ve aşınma dayanımını artırmak için güçlendirici partiküllerin (dağılım güçlendirmesi) kullanılması iyi bir tercih olmaktadır [3,4]. Bakır matrisli MMK üretmek Cu ve alaşımlarını mukavemetlendirmede etkili bir çözüm olmaktadır.



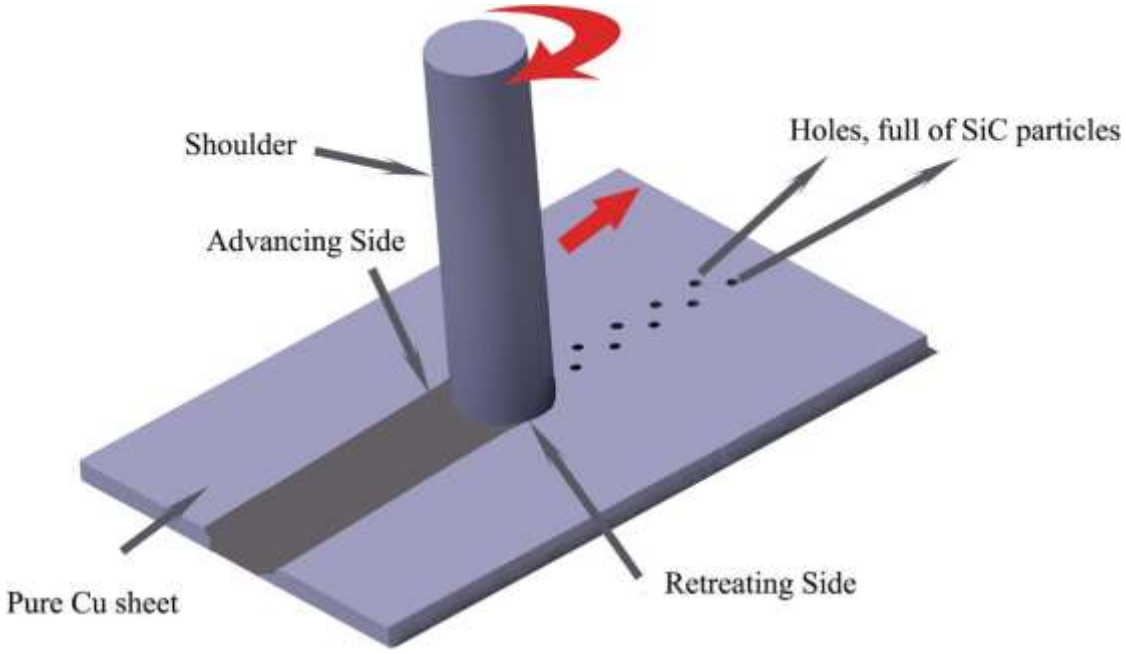
2. BAKIR MATRİSLİ KOMPOZİT MALZEMELER

Matrisin Cu olduğu ve en az iki takviye ile güçlendirilen malzemeler Cu matrisli kompozit malzemelerdir. Cu burada yükün takviyeye iletiminde rol oynarken, takviye ise yükü taşıma vazifesine sahiptir. Şekil 1'de matrisin bakır olduğu basit bir kompozit malzeme gösterimi verilmiştir.

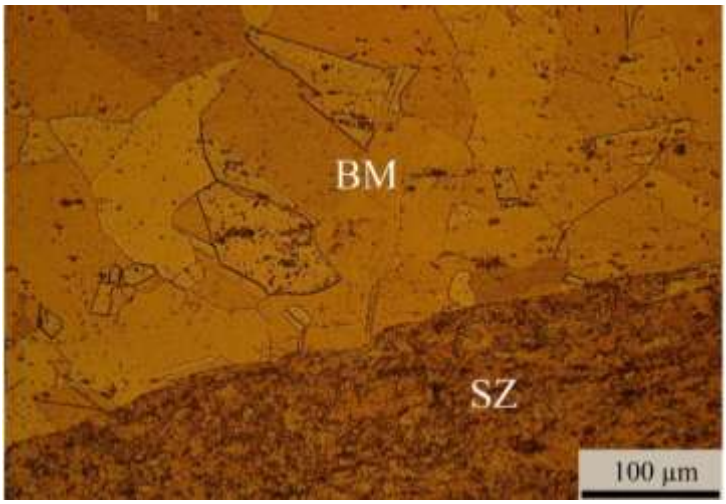


Şekil 1: Kompozit malzeme gösterimi

Literatürde takviyenin şekline ve sayısına bağlı olarak birçok çalışma yapılmıştır. Buytoz vd. [5] sıcak presleme yöntemiyle Cu matrisli TiC takviyeli kompozitleri üretmişler ve mikroyapı ve termal özellikleri incelemişlerdir. Yapılan çalışmada kompozitlerin mikroyapı görüntüleri Şekil 2'de verilmiştir. Mikroyapıda TiC'lerin nispeten homojen dağıldığı görülmüştür. Çalışmada yapılan sertlik ölçümü ve elektriksel iletkenlik ölçümü de Şekil 3'de verilmiştir. TiC takviyesiyle kompozitin güçlendiği görülmüş olup, kısmen de elektriksel iletkenlik düşmüştür.



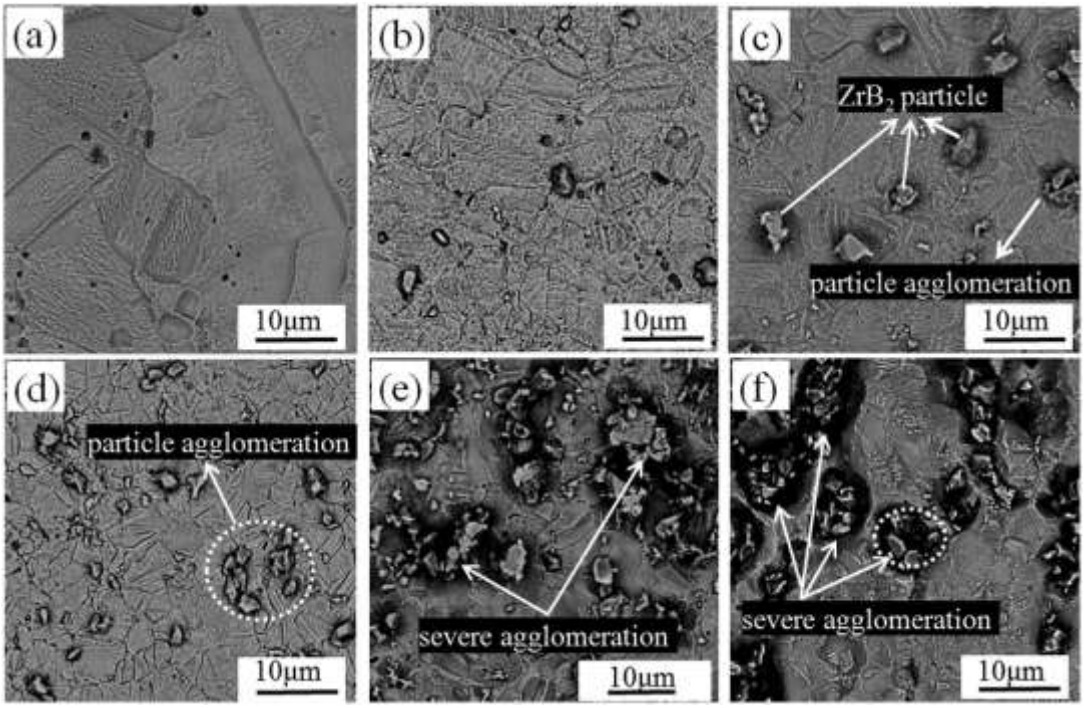
Şekil 2: Cu–TiC kompozitlerinin SEM mikrografları: a) Cu takviyesiz, b) Cu-1 kütle% TiC, c) Cu-3 kütle% TiC, d) Cu-5 kütle% TiC, e) Cu-10 kütle% TiC ve f) Cu-15 kütle% TiC [5].



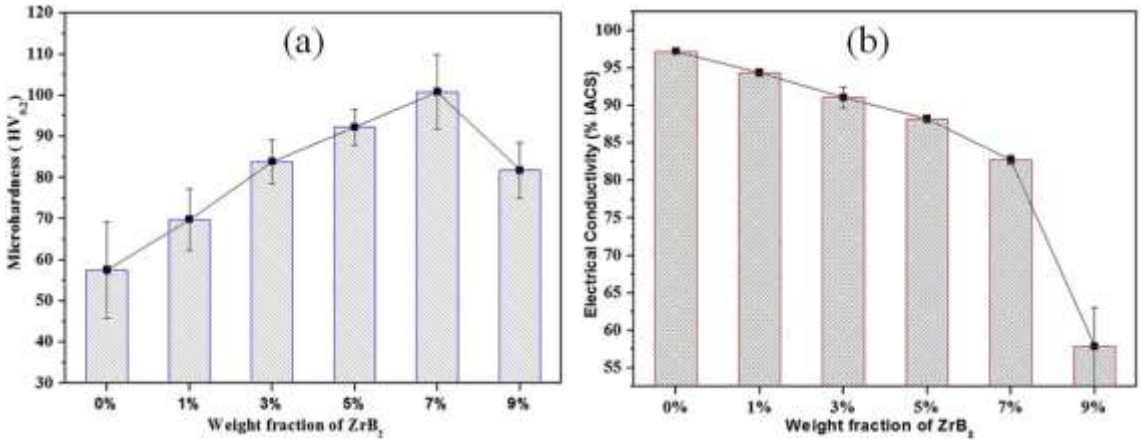
(a) (b)

Şekil 3: (a) Sertlik ve bağıl yoğunluk ve (b) elektriksel iletkenlik [5].

Akramifard vd. [6] sürtünme karıştırma kaynağı (FSP) ile Cu-SiC kompozitleri üretmiştir. İşlem şematiği Şekil 4'de verilmiştir. İnce mikro yapı ve döküm kusurlarının olmaması, FSP'nin başlıca avantajlarıdır. FSP sırasında, özel olarak tasarlanmış pim ve omuzlu döner alet (sarf malzemesi olmayan) plakaya daldırılır ve istenen yönde hareket ettirilir [7]. Üretilen kompozitin mikroyapısı Şekil 5'de verilmiştir.

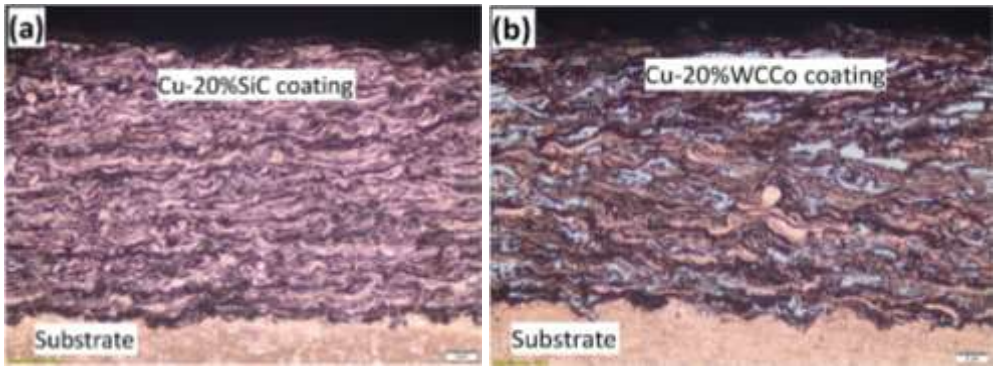


Şekil 4: Pimin hareket ve dönme hareketi ve Cu/SiC'nin imalatı [7].

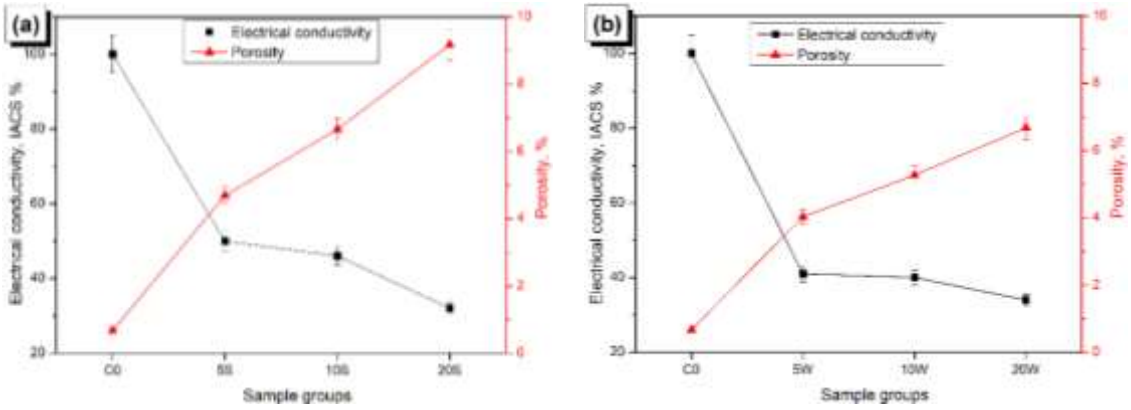


Şekil 5: Esas metal (BM) ve kompozit katman olan stir zone (SZ)'un optik mikroyapısı [7].

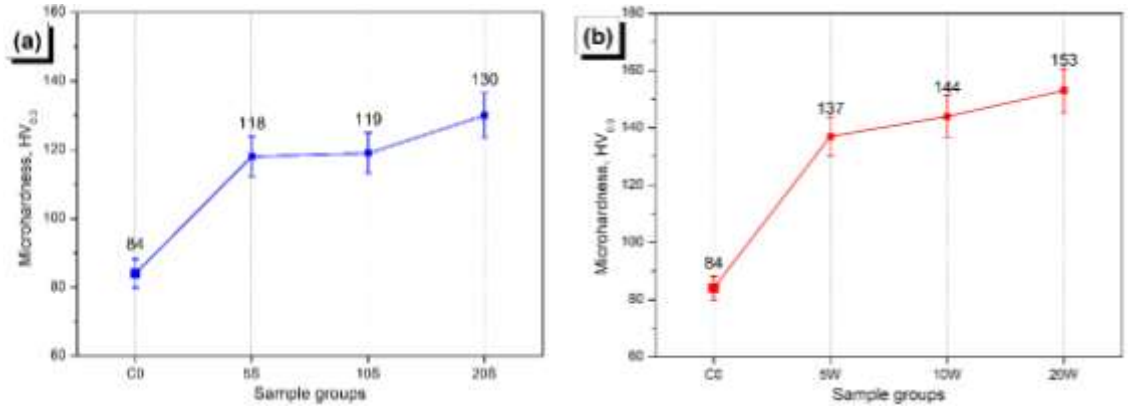
Wang vd. [8] sıcak presleme sinterleme tekniği ile Cu-ZrB_2 kompozitlerini üretmişlerdir. Üretilen kompozitlerde ZrB_2'lerin kümeleştiği gözlemlenmiştir (Şekil 6). Belirli bir takviye miktarına kadar sertliğin arttığı, elektriksel iletkenliğin ise belirli bir seviyeye kadar çok fazla düşmediği görülmüştür (Şekil 7).



Şekil 6: ZrB_2/Cu kompozitlerinin SEM yüzey morfolojileri: (a) saf Cu, (b) %1,0 ağırlıkça ZrB_2, (c) %3,0 ağırlıkça ZrB_2, (d) %5,0 ağırlıkça ZrB_2, (e) %7,0 ağırlıkça ZrB_2, (f) %9,0 ağırlıkça ZrB_2 [8].



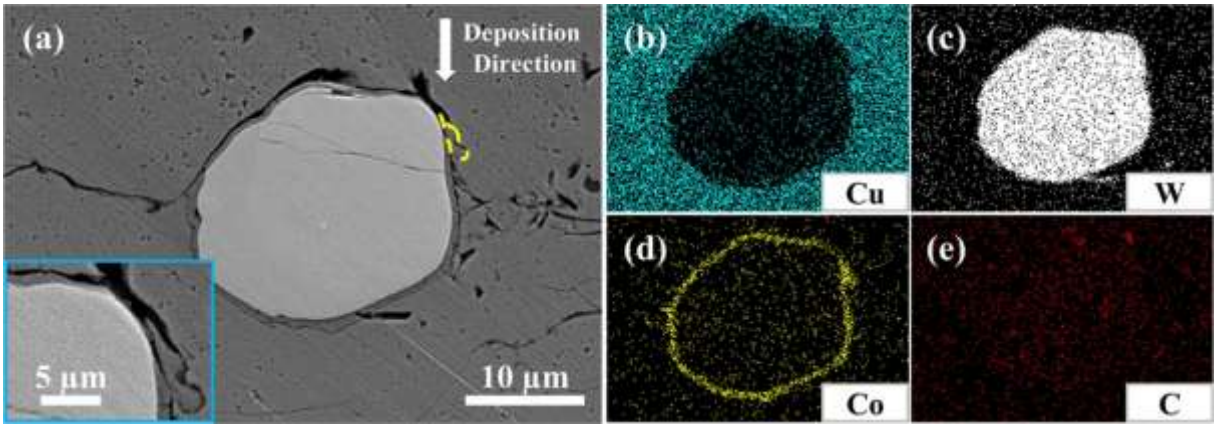
Şekil 7: (a) ZrB_2/Cu kompozitlerinin mikro sertliği ve (b) elektriksel iletkenliği.



Cu matrisli kompozit malzemeler kaplama katı olarak da literatürde üretilmiştir. Özorak ve Islak [9] plazma püskürtme yöntemi ile Cu alt tabaka yüzeyine uygulanan Cu-SiC/WCCo kompozit kaplamaların mikro yapı, aşınma ve korozyon özellikleri üzerine çalışmışlardır. Matrise eklenen intermetalik fazlar ve seramik partiküller kaplama tabakalarının sertliğini ve aşınma direncini artırırken, elektriksel iletkenliğini azalttığı raporlanmıştır.

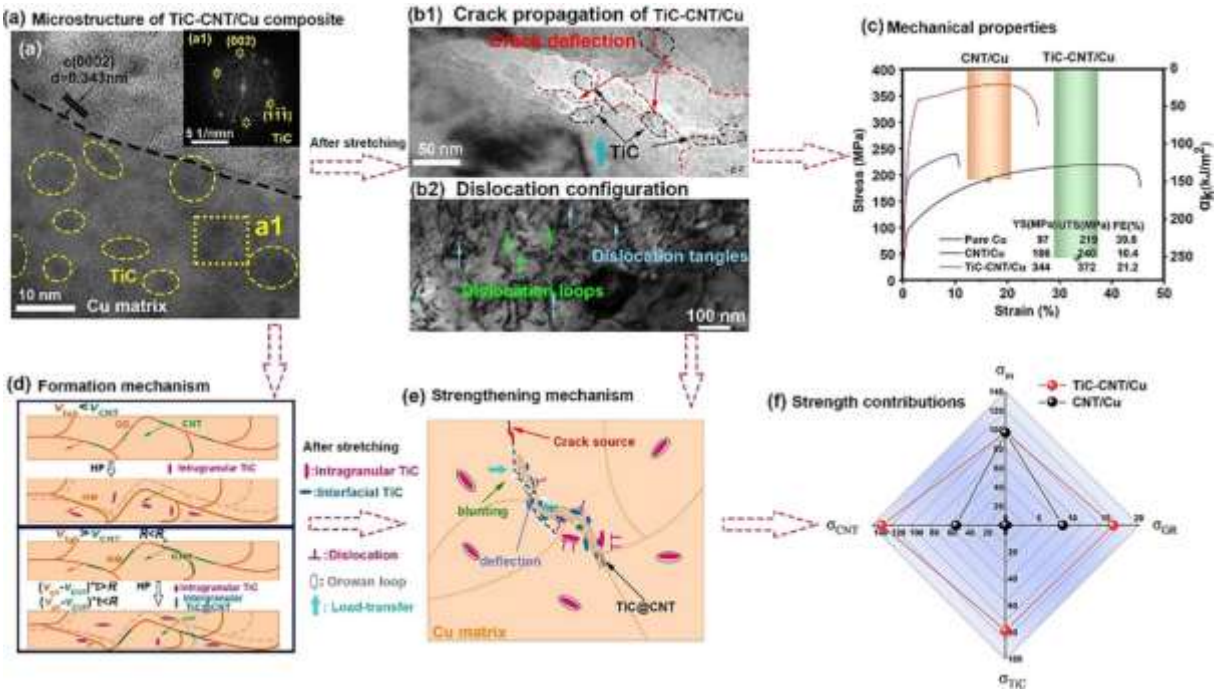
Şekil 8: (a) Cu-SiC kaplama ve (b) Cu-WCCo kaplama [9].

Şekil 9: Elektriksel iletkenlik: (a) Cu-SiC kaplama ve (b) Cu-WCCo kaplama [9].



Şekil 10: Sertlik değerleri: (a) Cu-SiC kaplama ve (b) Cu-WCCo kaplama [9].

Ngai vd. [10] sıcak sıkıştırma toz metalurjisi ve kıvılcım plazma sinterleme (SPS) yoluyla Cu–Ti_3SiC_2 metal matris kompozitlerin üretimini analiz etmişlerdir. Çalışma, kompozitlerdeki takviye parçacıklarının 800 °C ve üzeri sıcaklıklarda kararsız olduğunu ve bunun Ti_3SiC_2'nin TiC ve/veya diğer karbürlere ve $TiSi_2$'ye ayrışmasına yol açtığını ortaya koymuştur. Saflığı korumak için işleme sıcaklıkları 750 °C'yi geçmemelidir. 750 °C'de sıcak sıkıştırma ve SPS ile üretilen kompozitler, 950 °C'de sinterlenenlere kıyasla daha düşük yoğunluk sergilerler, ancak elektrik direnç değerleri benzer ve nispeten daha düşüktür.



Zhang vd. [11] Q235 çeliği yüzeyinde Cu matrisli CoWC takviyeli kompozitlerini soğuk sprey yöntemiyle üretmişlerdir. %20 ağırlık oranında Co@WC (Cu20(Co@WC)) içeren kaplama, Cu

kaplamasına kıyasla üstün korozyon direnci göstermektedir ve seramik içeriğinin artırılmasıyla daha da geliştirilme potansiyeline işaret etmektedir. Şekil 11'de Cu20(Co@WC) kaplamanın tipik SEM görüntüsü ve EDS haritalaması verilmiştir.

Şekil 11. Cu20(Co@WC) kaplamanın tipik SEM görüntüsü ve EDS haritalaması [11].

Feng vd. [12] CNT ve yerinde intragranüler TiC'nin çift nanofazı ile takviye edilmiş Cu matris kompozitinde mukavemet-süneklik dengesinin sağlanması üzerine çalışmışlardır. Sonuçlar, CNT yüzeyindeki arayüzey TiC'nin epitaksiyel büyümesini (yani, CNT(0002)//TiC(200)) ve TiC ile Cu matrisi arasında yarı tutarlı bir arayüzün oluşumunu ortaya koydu; bu, arayüzey bağlanma mukavemetini etkili bir şekilde artırabilir ve CNT'nin yük transfer verimliliğini optimize edebilir.

Şekil 12. TiC-CNT/Cu kompozit malzemenin mikromorfolojisi ve güçlendirme mekanizmalarının şematik diyagramı [12].

3. GENEL SONUÇLAR

Titanyum, magnezyum, bakır, alüminyum, karbürler, nitrürler, oksitler ve nanopartiküller, artırılmış mukavemet, sertlik, aşınma direnci ve korozyon direnci gibi gelişmiş özelliklere sahip metal matrisli kompozitler (MMC'ler) oluşturmak için kullanılır. Bakır ve alaşımları, mükemmel elektriksel ve termal iletkenlikleri nedeniyle çeşitli endüstrilerde yaygın olarak kullanılır, ancak saf bakırın düşük sertlik ve dayanıklılık gibi sınırlamaları vardır. Bu sorunları gidermek için, daha iyi iletkenlik ve mekanik özellikler elde etmeyi amaçlayan döküm, toz metalurjisi (kıvılcım plazma sinterleme ve sıcak presleme dahil) ve termal püskürtme ve soğuk sprey kaplamaları gibi yöntemler kullanılarak bakır matrisli MMC'ler geliştirilmektedir.

ÖZET

Antimikrobiyal peptitler (AMP'ler), küresel ölçekte artan antimikrobiyal direnç (AMR) sorununa karşı umut vadeden biyolojik moleküller arasında yer almaktadır. Doğal bağışıklık sisteminin evrimsel olarak korunmuş bileşenleri olan AMP'ler; bakteri, mantar, virüs ve parazitlere karşı geniş spektrumlu aktivite göstermektedir. Amfipatik ve katyonik yapıları, mikrobiyal zarları seçici biçimde hedef alarak konak hücrelerine zarar vermeden etkili olmalarını sağlar. Yapısal olarak α-sarmal, β-tabaka, prolin açısından zengin, uzamış (lineer) ve halkasal formlar olmak üzere farklı konformasyonlar sergileyen AMP'ler, bu çeşitlilik sayesinde farklı etki mekanizmaları ve biyolojik dayanıklılıklar göstermektedir.AMP'ler yalnızca doğrudan antimikrobiyal etkilere sahip olmayıp, aynı zamanda immünmodülatör ve yara iyileştirici özellikleriyle de dikkat çekmektedir. Bu nedenle "konak savunma peptitleri" (HDP'ler) olarak da tanımlanmaktadır. Son yıllarda (2020–2025) AMP'lerin yapı–aktivite ilişkileri üzerine yapılan çalışmalar, kimyasal olarak modifiye edilmiş türevlerin geliştirilmesini ve farmakolojik özelliklerinin iyileştirilmesini sağlamıştır. D-amino asit ikamesi, halkalaşma ve lipidilasyon gibi yapısal düzenlemeler; proteolitik yıkıma karşı dayanıklılığı, biyoyararlanımı ve terapötik etkinliği artırmaktadır. Klinik olarak Brilacidin**,** Pexiganan**,** Omiganan**,** Novexatin **ve** Iseganan gibi AMP temelli adaylar; bakteriyel deri enfeksiyonları, diyabetik ülserler, mukozit ve fungal enfeksiyonlara karşı olumlu sonuçlar göstermektedir. Ayrıca, AMP'ler çevre dostu ve biyolojik olarak parçalanabilir özellikleri sayesinde tarım, veterinerlik ve biyomalzeme mühendisliği gibi farklı alanlarda da potansiyel uygulama alanı bulmaktadır. Bununla birlikte, in vivo kararlılık, sitotoksisite ve yüksek üretim maliyetleri AMP'lerin geniş ölçekli kullanımı önündeki temel engellerdir. Peptit optimizasyonu, formülasyon geliştirme ve kontrollü salım sistemleri üzerine yürütülen

çalışmalar bu sınırlamaların aşılmasına katkı sağlayacaktır. Genel olarak AMP'ler, antibiyotik direncine karşı yeni nesil antimikrobiyal ve immünmodülatör ajanlar olarak önemli bir araştırma ve uygulama potansiyeline sahiptir.

Anahtar Kelimeler: Antimikrobiyal peptitler, antibiyotik direnci, yapı-aktivite ilişkisi, biyoteknoloji, klinik uygulamalar.

ANTIMICROBIAL PEPTIDES: STRUCTURAL DIVERSITY, MECHANISMS, AND CLINICAL PERSPECTIVES

ABSTRACT

Antimicrobial peptides (AMPs) represent a promising class of bioactive molecules with significant potential to address the global crisis of antimicrobial resistance (AMR). As evolutionarily conserved components of innate immunity, AMPs display broad-spectrum activity against bacteria, fungi, viruses, and parasites. Their amphipathic and cationic nature allows selective disruption of microbial membranes while preserving host cell integrity. Structurally, AMPs encompass diverse conformations—including α-helical, β-sheet, proline-rich, extended, and cyclic forms—each contributing to distinct mechanisms of action and biological stability. Beyond their direct antimicrobial effects, AMPs exert crucial immunomodulatory and wound-healing functions, acting as multifunctional host defense peptides (HDPs). Recent research (2020–2025) has expanded the understanding of AMP structure–activity relationships and enabled the development of chemically modified analogues with enhanced pharmacological properties. Modifications such as D-amino acid incorporation, cyclization, and lipidation improve peptide stability, resistance to proteolytic degradation, and therapeutic efficacy. Currently, several AMPs are advancing through clinical development, including Brilacidin, Pexiganan, Omiganan, Novexatin, and Iseganan, which demonstrate promising results against bacterial and fungal infections as well as inflammation-related disorders. In addition to their medical applications, AMPs have potential uses in agriculture, veterinary medicine, and biomaterial engineering as eco-friendly and biocompatible antimicrobial agents. Despite these advances, challenges such as limited in vivo stability, cytotoxicity, and high production costs remain obstacles to their widespread implementation. Ongoing efforts in peptide optimization, formulation, and delivery systems are expected to overcome these barriers. Overall, AMPs hold great promise as next-generation anti-infective and immunomodulatory agents, offering an innovative strategy to combat the increasing prevalence of antibiotic-resistant pathogens.

Keywords: Antimicrobial peptides, antibiotic resistance, structure–activity relationship, biotechnology, clinical applications.

INTRODUCTION

The global escalation of antibiotic-resistant pathogens constitutes one of the most pressing threats to human health in the 21st century. Bacterial strains such as Methicillin-resistant Staphylococcus aureus (MRSA), Pseudomonas aeruginosa, and Klebsiella pneumoniae have developed multidrug resistance, rendering conventional antibiotics increasingly ineffective (Ventola, 2015). The World Health Organization (WHO) has declared antimicrobial resistance (AMR) a top global priority, warning that without new interventions, routine infections and surgical procedures may become life-threatening. Against this backdrop, antimicrobial peptides (AMPs) have emerged as promising candidates to bridge the widening gap in the antibiotic discovery pipeline. AMPs are evolutionarily conserved molecules that play a central role in innate immunity across bacteria, plants, invertebrates, and vertebrates. Since their discovery in the early 1980s—beginning with cecropins from insects and defensins from mammals—AMPs have been recognized for their broad-spectrum antimicrobial activity and their rapid, non-specific mode of action (Bahar & Ren, 2013). Unlike traditional antibiotics that target specific metabolic pathways, AMPs primarily act by disrupting microbial membranes through electrostatic interactions. Their cationic and amphipathic nature allows selective binding to negatively charged bacterial membranes while sparing host eukaryotic cells, thereby minimizing cytotoxicity (Boparai & Sharma, 2020).

Over the past two decades, extensive biochemical and structural studies have revealed that AMPs possess multifunctional properties extending beyond direct microbial killing. They modulate host immune responses, promote tissue repair, and exhibit antiviral and anticancer activities (Hemshekhar et al., 2016). In addition, advances in high-throughput sequencing and computational peptide design have accelerated AMP discovery, contributing to the identification of more than 3,500 unique peptides cataloged in databases such as APD3. These developments underscore the translational promise of AMPs as next-generation therapeutics capable of addressing the global antimicrobial crisis. As the scientific community intensifies efforts to combat AMR, the study of AMPs continues to offer critical insights into both fundamental biology and innovative therapeutic design(Fjell et al., 2012).

STRUCTURAL DIVERSITY OF AMPS

Antimicrobial peptides (AMPs) represent one of the most structurally diverse groups of biomolecules in nature. Their architecture is intimately linked to their function, influencing membrane affinity, stability, and specificity toward microbial targets. Based on secondary structure and physicochemical characteristics, AMPs can be broadly classified into four major groups: α-helical, β-sheet, extended (linear or flexible), and cyclic peptides. This structural diversity reflects their evolutionary adaptation to diverse ecological niches and microbial threats (Koehbach & Craik, 2019). α-helical peptides, exemplified by LL-37 (human cathelicidin) and magainins (from amphibians), adopt amphipathic α-helices upon interaction with lipid membranes. Their amphipathic nature—featuring segregated hydrophobic and hydrophilic faces—allows them to insert into microbial membranes and form transient pores. The helical conformation often arises only in membrane-mimicking environments, underscoring the role of lipid interactions in peptide folding (Rosengren et al., 2002). These peptides typically display rapid, non-specific lytic activity against a broad range of bacteria, fungi, and viruses. β-sheet peptides, such as mammalian defensins and porcine protegrins, contain multiple cysteine residues forming disulfide bridges that stabilize their tertiary structure. This configuration imparts exceptional resistance to thermal and enzymatic degradation (Bowerman & Nilsson, 2012). Beyond antimicrobial action, β-sheet peptides are also known for immunomodulatory functions, including chemotactic activity and regulation of

cytokine release. Because of their conformational rigidity, β-sheet AMPs exhibit high selectivity but may show reduced activity in lipid-rich environments compared to α-helical types. Proline-rich AMPs (PR-AMPs) form a distinctive subclass primarily found in insects, such as apidaecins, drosocins, and oncocins. Unlike membrane-active peptides, PR-AMPs penetrate bacterial cells and interact with intracellular targets, notably ribosomal subunits or the heat shock protein DnaK, thereby inhibiting protein synthesis. Their mechanism is highly specific, leading to bacteriostatic rather than bactericidal effects. This unique intracellular mode of action has sparked interest in their development as antibiotics against multidrug-resistant Gram-negative bacteria (Mishra et al., 2018). Extended or unstructured peptides, including indolicidin and histatins, lack a stable secondary structure in aqueous solution but adopt defined conformations upon membrane interaction. These peptides are rich in aromatic residues such as tryptophan and proline, which facilitate insertion into microbial membranes and binding to nucleic acids. Their flexibility enables adaptation to different lipid environments, broadening their spectrum of activity (Rath et al., 2005). Cyclic peptides, such as plant-derived cyclotides and primate θ-defensins, represent the most stable AMP class due to head-to-tail cyclization and multiple disulfide linkages. This cyclic backbone confers extraordinary resistance to proteolytic degradation, extreme pH, and temperature variations, making them ideal scaffolds for therapeutic engineering. Cyclotides, for instance, are being investigated as oral peptide drugs owing to their inherent stability in the gastrointestinal tract (Ji et al., 2024). Recent advances in structural biology—particularly NMR spectroscopy and X-ray crystallography—have provided detailed insights into AMP conformations, self-association, and membrane interactions (Haney et al., 2019). These studies reveal that structure-function relationships are far from uniform; even small amino acid substitutions can profoundly alter activity, selectivity, and toxicity. Consequently, rational design of synthetic AMPs increasingly relies on computational modeling and molecular dynamics simulations to optimize peptide architecture for desired biological effects. Together, the structural plasticity and biochemical versatility of AMPs underpin their wide-ranging potential as novel therapeutics in the post-antibiotic era (Table 1).

Table 1: Structural Classes of Antimicrobial Peptides

Structural Class	Representative Peptides	Key Features
α-helical	LL-37, Magainin	Linear, amphipathic, disrupt membranes
β-sheet	Defensins, Protegrins	Disulfide bonds, immune modulation
Proline-rich	Apidaecin, Drosocin	Intracellular targets, protein synthesis inhibition
Cyclic	Cyclotides, θ-defensins	High stability, protease resistance

MECHANISMS OF ACTION

AMPs neutralize pathogens through a combination of physical disruption and biochemical interference, making them among the most versatile molecules in innate immunity. Their mechanisms of action can be broadly classified into membrane-targeting and non-membrane-targeting pathways, although many peptides exhibit overlapping modes that depend on concentration, environment, and microbial membrane composition (Shai, 2002).

Membrane-Targeting Mechanisms

The most recognized activity of AMPs is their ability to interact directly with microbial membranes, which are typically rich in negatively charged phospholipids such as phosphatidylglycerol and cardiolipin. This contrasts with the zwitterionic nature of mammalian cell membranes, enabling AMPs to discriminate between host and pathogen cells (Huang & Li, 2025). Upon approaching the bacterial surface, electrostatic attraction facilitates peptide binding and accumulation on the membrane, leading to permeabilization via several distinct models:

Barrel-Stave Model

Peptides such as alamethicin insert perpendicularly into the membrane, forming transmembrane pores where hydrophobic residues interact with lipids and hydrophilic residues line the pore lumen (Murray et al., 2016).

Toroidal Pore Model

Observed in magainins and melittin, this model involves peptide-induced curvature where lipid headgroups bend inward to form mixed peptide–lipid pores, leading to ion leakage (Sengupta et al., 2008).

Carpet Model

Peptides align parallel to the membrane surface, covering it like a "carpet." At critical concentrations, they disrupt bilayer integrity, resulting in micellization and complete membrane dissolution (Shai, 2002). These physical disruptions rapidly lead to loss of membrane potential, leakage of cytoplasmic contents, and cell death within minutes. Importantly, such mechanisms are non-specific to biochemical targets, minimizing the probability of resistance development—a key advantage over conventional antibiotics (Lazzaro et al., 2020).

Non-Membrane Mechanisms

Beyond their membrane activity, many AMPs exert intracellular effects after translocation into microbial cells. Proline-rich AMPs (PR-AMPs), such as apidaecin and drosocin, inhibit protein synthesis by binding to bacterial ribosomes or the chaperone protein DnaK, blocking post-translational folding of nascent polypeptides (Scocchi et al., 2016). Other AMPs target essential enzymatic pathways or interfere with DNA and RNA synthesis, leading to replication arrest. Indolicidin, for instance, binds DNA through intercalation, while histatins in saliva generate reactive oxygen species that compromise mitochondrial activity in fungal pathogens (Mansour et al., 2014).

Immunomodulatory and Signaling Functions

In addition to their direct antimicrobial effects, antimicrobial peptides (AMPs) function as key immunomodulatory molecules within the host defense system. Peptides such as LL-37 and β-defensins activate chemokine receptors including CCR6 and FPR2, thereby promoting the recruitment of neutrophils, macrophages, and dendritic cells to sites of infection (Mookherjee et al., 2020). They also modulate cytokine networks by suppressing pro-inflammatory mediators like TNF-α and IL-1β, while enhancing anti-inflammatory cytokines such as IL-10. Owing to their dual ability to kill pathogens and orchestrate immune responses, AMPs are often referred to as "host defense peptides" (Hancock, 2000). Beyond immunomodulation, they contribute to wound healing by stimulating angiogenesis and promoting keratinocyte migration.

Across a wide range of species—from insects to humans—epithelial cells synthesize AMPs and related polypeptides as central effector molecules of the innate immune response (Zasloff,

2002). These peptides exhibit broad-spectrum activity against bacteria, viruses, and fungi, and also play a role in regulating the natural microbiota (Boman, 2000). In human skin, four major AMPs have been identified: the β-defensins hBD-1, hBD-2, hBD-3 (Harder et al., 1997), and the sole human cathelicidin, hCAP-18. The active C-terminal fragment of hCAP-18, consisting of 37 amino acids, is known as LL-37 (Frohm et al., 1997). Chronic wounds often fail to heal due to the presence of multispecies pathogenic biofilms, which protect bacteria from immune clearance and certain antibiotics. LL-37, with its combined anti-biofilm, antimicrobial, and immunomodulatory properties, can circumvent many of these challenges, and its topical application offers advantages by avoiding barriers associated with systemic peptide delivery (Duplantier & van Hoek, 2013).

Combined and Synergistic Effects

Recent studies have revealed that AMPs often work synergistically—either with other peptides or conventional antibiotics—to enhance antimicrobial efficacy and overcome biofilm-associated tolerance. For example, combining AMPs with β-lactams or aminoglycosides can restore drug sensitivity in resistant bacterial strains. This multifaceted activity, encompassing physical disruption, intracellular inhibition, and immune modulation, underscores the unique therapeutic promise of AMPs as multifunctional agents capable of addressing diverse infectious challenges while reducing the emergence of resistance (Haney et al., 2019).

LITERATURE TRENDS AND ADVANCES (2020–2025)

Between 2020 and 2025, antimicrobial peptide (AMP) research has experienced exponential growth, reflecting the urgent global need for new therapeutic strategies against antibiotic-resistant infections. Bibliometric analyses of databases such as PubMed, Scopus, and Web of Science show a steady increase in AMP-related publications, particularly in the fields of computational peptide design, synthetic biology, and translational medicine (Agüero-Chapin et al., 2022). The COVID-19 pandemic further accelerated this research momentum by emphasizing the demand for broad-spectrum antivirals and immunomodulatory agents, areas in which AMPs have demonstrated considerable promise (Ramazi et al., 2022). A major trend in recent years is the integration of artificial intelligence (AI) and machine learning (ML) into peptide discovery. Using predictive algorithms, researchers can now design de novo peptides with optimized antimicrobial potency, selectivity, and reduced cytotoxicity. Databases such as DBAASP, APD3, and CAMP R4 have been enriched with structural and activity data, providing large-scale datasets for AI-driven models. Computational pipelines combining molecular dynamics simulations and neural network analysis have enabled in silico screening of thousands of peptide analogues before experimental validation (Veltri et al., 2018). These tools have dramatically shortened the drug development timeline and lowered the cost of AMP optimization.mParallel to computational advances, chemical and hybrid peptide engineering has produced a new generation of AMPs with improved pharmacokinetic profiles. Strategies such as D-amino acid substitution, peptide cyclization, and lipidation enhance proteolytic resistance and membrane affinity. Hybrid constructs that fuse AMP motifs with polymeric or nanoparticle carriers have been shown to increase bioavailability and tissue penetration (Wang & Li, 2016). Moreover, peptidomimetics—synthetic analogues that mimic AMP structure and charge distribution—are emerging as stable, cost-effective alternatives suitable for large-scale production.

Clinically, the translation of AMPs from bench to bedside is steadily progressing. As of 2025, more than 40 peptide-based antimicrobials are under active preclinical or clinical evaluation. Among them, Brilacidin and Pexiganan are leading candidates that have reached Phase II–III trials for bacterial skin infections, oral mucositis, and even COVID-19-related inflammatory

complications (Mookherjee et al., 2020). Omiganan has shown efficacy as a topical treatment for catheter-associated infections, while Novexatin targets fungal onychomycosis with favorable safety outcomes. Notably, the antimicrobial peptide Iseganan has been tested for oral mucositis prevention in cancer therapy patients, reflecting diversification into supportive care settings (Cresti et al., 2024). The field has also seen growing interest in multifunctional AMPs that exhibit antibacterial, antiviral, antifungal, and anticancer activities. Several studies highlight AMPs' dual role as immunomodulators—capable of enhancing cytokine balance, promoting wound healing, and modulating inflammatory pathways (Lazzaro et al., 2020). These findings have reshaped the perception of AMPs from purely bactericidal molecules to host defense peptides (HDPs) with systemic physiological relevance. Finally, a noteworthy trend in recent literature is the emergence of bioinformatics-driven AMP taxonomy and structure–activity relationship (SAR) analyses. Researchers are now classifying AMPs not only by structure but also by mechanism, sequence motif, and spectrum of activity. Phylogenetic studies indicate convergent evolution of AMP families across kingdoms, suggesting strong selective pressure to maintain antimicrobial function despite sequence divergence. Collectively, the 2020–2025 period has been transformative, characterized by technological convergence, expanding clinical validation, and a paradigm shift toward personalized and precision peptide therapeutics (Reyes et al., 2024) (Table 2).

Table 2. Selected AMPs in Clinical or Preclinical Development

Peptide Name	Therapeutic Target	Clinical Status
Omiganan	Catheter-related infections	Phase III completed
Pexiganan	Diabetic foot ulcers	Phase III ongoing
Brilacidin	Bacterial skin infections, COVID-19	Phase II/III
Novexatin	Onychomycosis	Phase II
Iseganan	Oral mucositis prevention	Phase II completed

THERAPEUTIC AND INDUSTRIAL APPLICATIONS

AMPs are increasingly explored for medical, veterinary, and agricultural applications due to their potent antimicrobial and immunomodulatory properties. Clinically, they are being developed as topical antimicrobials, systemic anti-infectives, and anti-biofilm coatings for medical implants (Lazzaro et al., 2020). The rapid emergence of antibiotic-resistant pathogens has intensified the search for alternative therapeutics, placing AMPs among the most promising candidates (Sobanbua et al., 2020). Their broad-spectrum activity and effective defense mechanisms against diverse microbes make them strong potential substitutes for conventional antibiotics (Van Der Weide et al., 2020). Unlike many traditional antibiotics, which often act bacteriostatically, AMPs typically exert rapid bactericidal effects (Wang et al., 2020). Among the numerous AMPs produced by the human body, cathelicidins and defensins are the most extensively studied. Several naturally occurring AMPs have progressed toward therapeutic use for conditions including oral mucositis, cystic fibrosis–associated lung infections, cancer, and topical skin infections (Wang et al., 2020). Cathelicidins demonstrate antibacterial activity against pathogens such as Group A Streptococcus, Escherichia coli, Group B Streptococcus, and Staphylococcus aureus, while defensins—classified as α- and β-defensins—have shown antiviral effects against adenovirus, influenza virus, herpesvirus, and papillomavirus in vitro (Sader et al., 2020). In dermatology, research increasingly focuses on the role of AMPs in

conditions such as atopic dermatitis and psoriasis, where they help prevent secondary infections (Sader et al., 2020). These findings collectively support the growing interest in AMPs as next-generation anti-infective therapeutics. In agriculture, synthetic pesticides have long been used to control plant diseases and insect pests; however, their extensive application has raised concerns regarding environmental and human health. As a result, AMPs—particularly those derived from plants—are gaining attention as low-toxicity, natural, and highly effective antimicrobial agents. Many plant AMPs are encoded by genes expressed at low basal levels but strongly upregulated upon pathogen attack. Following pathogen stimulation, multiple AMPs can be simultaneously produced in different organs of the same plant (Mith et al., 2015). Plant AMPs typically target pathogens in a nonspecific manner, making it difficult for microbes to develop resistance, which enhances their suitability for improving disease resistance in crops (Goyal & Mattoo, 2014). Beyond pathogen defense, plant AMPs also participate in regulating plant growth and development, and several have shown beneficial therapeutic effects in human disease models. Structural features—including amino acid composition, net charge, hydrophobicity, amphipathicity, and folding tendencies—collectively influence AMP antimicrobial potency and specificity. With broad potential applications in agriculture, food preservation, breeding technologies, and medicine, plant-derived AMPs are now recognized as promising alternatives to conventional antibiotics (Tang et al., 2018).

CHALLENGES AND FUTURE DIRECTIONS

AMPs are expected to become widely used in the near future as significant alternatives due to the growing problem of antibiotic resistance in bacteria (Aguilar-Toalá et al., 2020). Their ability to exhibit strong activity at minimal concentrations, their cost-effectiveness, and their broad-spectrum mechanisms of action make them promising candidates for expanded use across many sectors, from food to textiles (Chelliah et al., 2020). Although the therapeutic and industrial applications of AMPs are rapidly expanding, several major challenges still hinder their widespread clinical and commercial adoption, including production costs, stability issues, rapid degradation by serum proteases, and pharmacokinetic limitations that arise in large-scale applications (Mahlapuu et al., 2016). The structural heterogeneity of AMPs can lead to high efficacy against specific target organisms while resulting in reduced performance against others, increasing the need for rational design and optimization studies (Fjell et al., 2012). One of the most significant barriers to clinical use is the inability to completely eliminate host toxicity and the resulting narrow therapeutic window; therefore, peptide engineering and formulation strategies aimed at reducing toxicity in both natural and synthetic derivatives have gained substantial importance (Mookherjee et al., 2020). Another limiting factor is the loss of activity in physiological environments with high salt and serum content, largely due to weakened membrane interactions, making peptide optimization and appropriate carrier/formulation strategies essential (Haney & Hancock, 2013). Nevertheless, advances in artificial intelligence and computational methods are expected to accelerate AMP discovery and optimization, and rational design strategies coupled with nanocarriers are anticipated to enable the development of more stable, less toxic, and therapeutically superior AMPs (Szymczak & Szczurek, 2023). Beyond medical applications, AMPs are also expected to gain importance in agriculture as biocontrol agents and potential biopesticides; notably, insect- and plant-derived peptides may provide dual protection by exhibiting both antimicrobial and insecticidal effects while triggering induced systemic resistance mechanisms in plants (Dho et al., 2023). Peptides derived from Bacillus species have demonstrated antimicrobial activity against phytopathogens and, in some cases, toxicity against insects, offering environmentally friendly alternatives for integrated pest management and attracting growing research interest in this field (Ajuna, 2024). Molecular engineering approaches—such as cyclization, the incorporation of D-amino acids,

and terminal modifications—combined with nanotechnological carriers that provide controlled release represent some of the most promising strategies to enhance AMP stability and efficacy in agricultural field applications (Brizuela et al., 2025). Despite these promising developments, several issues remain unresolved under field conditions, including UV stability, interactions with proteases on soil and plant surfaces, and economically sustainable large-scale production. Therefore, successful implementation of AMPs in agriculture and medicine will require the parallel advancement of interdisciplinary research and regulatory standardization (Mahlapuu et al., 2016; Dho et al., 2023).

ÖZET

Bor (B), bitkilerin sağlıklı büyüme, gelişme ve üreme süreçlerinin sürdürülebilmesi için gerekli olan temel mikro besin elementlerinden biridir. Bitki fizyolojisinde çok yönlü görevler üstlenen bor; hücre duvarı biyosentezi, zar bütünlüğünün korunması, karbonhidrat ve enerji metabolizması, lignin sentezi, azot ve fenolik bileşiklerin taşınımı, polen tüpü uzaması ve döllenme süreçlerinde kritik rol oynar. Bor eksikliği durumunda, hücre bölünmesi ve uzaması aksar; kök gelişimi yavaşlar, çiçeklenme ve meyve tutumu azalır, dokularda nekrotik lekeler ve deformasyonlar görülür. Bu durum, bitkisel verim ve kalite kayıplarına neden olurken; aşırı bor birikimi ise toksik etki göstererek yapraklarda kloroz, nekroz ve büyüme duraklaması gibi olumsuzluklara yol açabilir. Bu nedenle, toprakta ve bitki dokularında optimal bor dengesinin korunması, sürdürülebilir tarımsal üretim için büyük önem taşımaktadır. Beslenmedeki fizyolojik işlevlerinin yanı sıra, bor ve bor içeren bileşikler – özellikle **borik asit** ve **boratlar** – son yıllarda **insektisidal ve antimikrobiyal özellikleri** nedeniyle dikkat çekmektedir. Bu bileşiklerin, böceklerin beslenme davranışlarını, enzim aktivitelerini ve fizyolojik dengelerini bozarak ölümle sonuçlanan etkiler oluşturduğu bildirilmiştir. Ayrıca bor bileşikleri, hedef dışı organizmalara düşük toksisite göstermeleri, çevrede kalıntı bırakmamaları ve biyolojik olarak parçalanabilir olmaları nedeniyle çevre dostu pestisit alternatifleri arasında değerlendirilmektedir. Bor temelli bitki besleme ve zararlı yönetimi yaklaşımlarının entegre edilmesi, kimyasal insektisit kullanımını azaltarak çevreye duyarlı, güvenli ve sürdürülebilir tarım sistemlerinin geliştirilmesine katkı sağlayabilecek yenilikçi bir strateji olarak öne çıkmaktadır.

Anahtar Kelimeler: Bor, borik asit, tarımsal üretim, zararlı yönetimi, sürdürülebilir tarım

ROLE OF BORON AND BORON COMPOUNDS IN CROP PRODUCTION AND INSECT PEST MANAGEMENT

ABSTRACT

Boron (B) is an essential micronutrient required for maintaining healthy plant growth, development, and reproduction. It plays versatile roles in plant physiology, including cell wall biosynthesis, maintenance of membrane integrity, carbohydrate and energy metabolism, lignin synthesis, and transport of nitrogen and phenolic compounds. Moreover, boron is crucial in pollen tube elongation and fertilization processes. Deficiency in boron disrupts cell division and elongation, slows root growth, reduces flowering and fruit set, and causes necrotic lesions and deformation in tissues, ultimately leading to significant yield and quality losses. On the other hand, excessive boron accumulation can result in toxicity symptoms such as chlorosis, necrosis, and growth inhibition. Therefore, maintaining an optimal boron balance in soil and plant tissues is vital for achieving sustainable crop productivity and quality. Beyond its nutritional significance, boron and boron-containing compounds—particularly **boric acid** and **borates**—have gained considerable attention for their **insecticidal and antimicrobial properties.** These compounds can alter insect feeding behavior, enzyme activities, and physiological balance, ultimately causing mortality. Due to their low toxicity to non-target organisms, biodegradability, and minimal environmental residue, boron-based agents are considered eco-friendly alternatives to synthetic pesticides. Integrating boron-based plant nutrition and pest management strategies may reduce the reliance on conventional chemical insecticides, supporting the development of safer, environmentally responsible, and sustainable agricultural systems. Thus, boron emerges as a promising element that bridges plant nutrition and biological pest control in modern crop production.

Keywords: Boron, boric acid, crop production, pest management, sustainable agriculture.

INTRODUCTION

Boron (B) is one of the seven essential micronutrients required for the optimal growth and development of higher plants. The physiological importance of boron was discovered in 1910, and it was identified in many plant species. In 1923, studies conducted by Warington confirmed that boron is an essential micronutrient for plant growth and development and highlighted its physiological significance (Nielsen, 1988). Although boron was discovered in 1808 by Sir Humphry Davy and Joseph Louis Gay-Lussac, its agricultural significance was not recognized until the early 20th century, when its deficiency was associated with physiological disorders in crops such as sugar beet, alfalfa, and cauliflower (Ahmad et. al., 2006). The effective utilization of boron by plants depends on maintaining adequate and balanced levels of this element in both the soil and plant tissues. Possible ionic imbalances in the soil and within plant tissues may lead to insufficient boron nutrition, resulting in noticeable deficiency symptoms (Deliboran & Savran, 2017).

Boron, which plays a role in carbohydrate metabolism and transport, also has physiological functions in root development as well as in flower and fruit formation (Finck, 1969). It is further reported to be involved in auxin and phenol metabolism, cell membrane and cell wall structure, tissue differentiation, membrane permeability, root elongation, pollen germination and pollen tube growth, sugar transport, leaf elongation and expansion, the regulation of respiration and transpiration, and in enhancing plant resistance not only to viral and fungal diseases but also to insect damage (Deliboran & Savran, 2017). Since boron deficiency primarily affects the growing points of plants, growth slows considerably. Leaves and branches become brittle and easily broken. Under severe deficiency, the growing points die and growth comes to a complete halt. Necrotic spots appear on the leaves, followed by a purplish dark green coloration and downward curling. Moreover, as soluble proteins, chlorophyll, and apical reaction activities decrease within the leaf, stomatal constriction is observed, reducing carbon dioxide movement within the stomata (Dell & Huang, 1997). Deformations in fruits, yellowing at leaf tips, dieback of shoots, fruit drop, abnormalities in peel tissue, and bushy growth due to the death of shoot tips are among the typical symptoms of boron deficiency (Freeman et. al., 1994.; Hartman et. al., 1980.).

Chemically, boron is not found freely in nature; instead, it occurs as B_2O_3 in combination with oxides of other elements (Kemp, 1956). Due to its tendency to form bonds with oxygen, many different boron–oxygen compounds exist. Metal–boron–oxygen compounds are generally referred to as borates. In nature, boron is found in minerals containing sodium, calcium, and magnesium oxides combined with crystal water, known as boron ores or boron salts (Duman, 2003). The simplest boron compounds include boron oxide and boric acid. The calcium-containing form is known as “colemanite,” the calcium–sodium form as “ulexite,” and the sodium-based form as “borax.” Boron is a nonmetal element (atomic number 5), commonly occurring in nature as borates and boric acid. Major natural sources include minerals such as borax ($Na_2B_4O_7•10H_2O$), colemanite ($Ca_2B_6O_{11}•5H_2O$), and ulexite ($NaCaB_5O_9•8H_2O$); many of these are mined in Türkiye, which holds the largest boron reserves in the world. Türkiye possesses 66% of the world's total boron reserves. The country’s known reserves of boron minerals amount to 665,879,243 tons. However, Türkiye ranks second after the United States in boron ore production, with a share of 42.17%. Considering that a comprehensive study determining the precise locations and quantities of Türkiye’s boron reserves has not yet been conducted, it is possible that Türkiye may in fact hold an even larger portion of global reserves. The United States follows Türkiye, holding 13.24% of global reserves. The remaining boron reserves are found in Argentina, Bolivia, Chile, China, Iran, Kazakhstan, Peru, and Russia (bor

5). These reserves, totaling 800 million tons, account for 63% of the world's boron reserves. Türkiye meets 95% of the global raw boron demand with these reserves (Önocak, 1990)

The mobility and availability of boron in soils depend on pH, organic matter, and climatic factors. Many unique properties of boron minerals and their derivatives make them irreplaceable (Göncü, 1982). Borates, which dissolve easily in water, are odorless white crystalline granules or powders. Boron oxide is also a frequently encountered boron compound; notably, boric acid that evaporates from oceans enters the atmosphere and returns to the soil through rain and snow, spreading over wide areas via groundwater and surface water (Demirtaş, 2010). In alkaline soils, boron becomes immobile and inaccessible, whereas in acidic or sandy soils it can leach easily, leading to deficiency conditions (Vera-Maldonado et. al., 2024). A significant portion of plant-available boron in soils is bound to organic matter. Therefore, soils rich in organic matter generally have higher boron levels (Table 1).

Table 1. Agronomic functions and significance of boron in crops.

Agronomic Role	Physiological Function	Implications
Cell wall synthesis	Cross-linking of RG-II pectin chains	Structural stability and growth
Sugar transport	Enhancement of phloem mobility	Improved energy distribution
Reproductive development	Pollen germination and tube growth	Fruit/seed set increase
Nutrient uptake	Interaction with Ca, N, and P	Better nutrient use efficiency

DIFFERENT APPLICATION AREAS OF BORON

Boron minerals can be used in their raw form, but they are generally utilized after being processed into refined boron compounds and end-products (Velioğlu et. al., 1999). Boron is widely used in many industrial sectors, particularly in the glass and detergent industries. In addition, it has an extensive range of applications, from fertilizers and agricultural chemicals to flame-resistant materials, electronics and space technologies, and the agriculture and livestock sectors (Yeşildağ, 2008). For example, it is used in insecticides, ceramics, nuclear reactors, biological growth regulators, photography, plastic and textile industries, fire extinguishers, adhesives, wafer production, cosmetics, electrical herbicides and insulation, and disinfectants (Figure 1). (Doonan & Lower, 1978; Velioğlu et. al., 1999). In the field of health, boron compounds are used in the treatment of osteoporosis and rheumatoid arthritis, in the healing of brain tumors through Boron Neutron Capture Therapy (BNCT), in burn treatments, wound healing, and as antiseptics in lens solutions, ointments, gargles, and eye drops (Kuru & Yarat, 2017).

Figure 1. Different application areas of boron

BORON AND BORON COMPOUNDS IN INSECT PEST MANAGEMENT

Boron-containing compounds have gained considerable scientific attention as promising alternatives in pest management due to their unique chemical structures, environmental compatibility, and broad-spectrum activity against various insect species. Turkey holds the world's largest boron reserves, with an annual production capacity of approximately 3.3 million tons. Elemental boron rarely occurs in pure form in nature; instead, it exists predominantly as borate minerals—oxygen–boron complexes that serve as precursors of a wide array of industrial and agricultural boron compounds (Gore & Schal, 2004). Commercially available boron compounds include borax (sodium tetraborate decahydrate), disodium octaborate tetrahydrate, boric acid, boron oxide, boron carbide, boron nitride, boron trichloride, boron tribromide, and boron trifluoride. Although these substances have diverse industrial applications, the insecticidal properties of boric acid and borate salts have become especially relevant in the search for safer alternatives to synthetic insecticides (Ware, 2000; Sarwar, 2016). Boric acid is one of the oldest inorganic insecticides used in agriculture and public health. It is water-soluble, non-volatile, odorless, and commonly found as a white crystalline powder, characteristics that support its long-term use in household pest control, particularly against cockroaches. Boric acid primarily acts as a stomach poison by interfering with metabolic and digestive processes, ultimately causing insect mortality. Although its precise mode of action is not yet fully elucidated, numerous studies show that boron minerals damage the foregut and midgut epithelium, impair nutrient absorption, and prevent insects from meeting their essential energy requirements (Cochran, 1995; Habes et al., 2006; Büyükgüzel et al., 2013). Another well-supported mechanism involves the abrasive effect of boric acid on the insect cuticle. By adsorbing the waxy epicuticular layer, boric acid accelerates desiccation and increases water loss. In addition to these direct toxic effects, boric acid exhibits sterilizing properties that reduce fecundity and limit population growth, an important advantage in long-term pest suppression programs (Civelek & Dursun, 2013). Compared with conventional chemical insecticides, boron compounds show lower toxicity to humans and domestic animals (Murray, 1998; Weir &

Fisher, 1972). They are inexpensive, highly soluble in water, and notably, despite more than a century of use, there is no evidence of insect resistance to boron-based compounds (Cox, 2004). This characteristic provides a significant advantage in managing pests that have developed resistance to many synthetic chemicals. Boron-containing compounds also play important roles in non-insecticidal applications, including wood preservatives, flame retardants, ceramic and glass manufacturing, and pesticide-free household formulations. They may enter the environment through energy production processes such as coal combustion. In apiculture, boric acid is used in in-hive traps due to its extremely low toxicity to honey bees and classification as a minimally hazardous compound (Atkins, 1987; Harper et al., 2012). Furthermore, boron compounds have demonstrated antifungal potential and are used in pharmaceutical formulations. Despite their extensive use against household pests, research on the effects of boron compounds on stored-product pests remains limited. Korunić et al. (2017) reported that disodium octaborate tetrahydrate effectively controlled *Sitophilus oryzae* (Linnaeus, 1763) without reducing grain bulk density. Additional studies showed that dust and wettable powder formulations of the same compound (F3DOTZ) were highly effective against both *S. oryzae* and *Rhyzopertha dominica* (Korunić & Fields, 2020). A mixture of boric acid and silica (40 g per kg wheat) caused mortality in all developmental stages of *Trogoderma granarium* Everts, 1899 (Falah & Azher, 2020). Laboratory studies further revealed that a combination of 1% boric acid and 10% sucrose reduced populations of *Aedes albopictus* (Skuse) by 98% (Xue & Barnard, 2003). A substantial body of literature documents the physiological and biochemical effects of boric acid on insects. Reported impacts include insecticidal action (Xue & Barnard, 2003; Cruz et al., 2010; Büyükgüzel et al., 2013; Gwokyalya & Altuntaş, 2019), destruction of gut lining and midgut ultrastructure (Cochran, 1995; Habes et al., 2006; Büyükgüzel et al., 2013), reduced fecundity (Kilani-Morakchi et al., 2009), alterations in cuticle composition (Kilani-Morakchi et al., 2005), changes in protein activity and biological fitness (Hyrsl et al., 2007), and induction of oxidative stress (Hyrsl et al., 2008; Büyükgüzel et al., 2013). Recent findings show that boric acid suppresses cellular immunity and induces genotoxic effects in *Galleria mellonella* larvae (Gwokyalya & Altuntaş, 2019), indicating its broad impact on multiple physiological pathways. Collectively, the available scientific evidence highlights boron-containing compounds as highly promising candidates for environmentally friendly pest management. However, the limited number of studies focusing on stored-product pests and the incomplete understanding of the molecular basis of boron toxicity underscore the need for further research. Expanding knowledge on boron compounds may contribute significantly to developing sustainable pest-control strategies that reduce dependence on conventional chemical insecticides.

FUTURE RESEARCH DIRECTIONS

Boron-containing compounds, particularly boric acid and borates, have demonstrated multifaceted potential across agriculture, pest management, and industrial applications. Their unique chemical properties, environmental compatibility, and broad-spectrum activity against diverse insect species distinguish them from conventional synthetic insecticides. The compounds' mode of action encompasses both direct toxic effects—such as disruption of digestive physiology, damage to midgut and foregut tissues, and abrasive effects on the cuticle—and indirect influences, including reduced fecundity, alterations in reproductive processes, and suppression of immune responses. These characteristics collectively contribute to effective pest suppression without the widespread development of resistance, a critical advantage given the growing issue of pesticide resistance in many agricultural and public-health pests.

Beyond their insecticidal activity, boron compounds exhibit low toxicity to mammals and beneficial organisms, including honey bees, making them suitable for integrated pest management and environmentally conscious agricultural practices. Their multifunctional applications—from wood preservation, flame retardancy, and ceramics to pharmaceuticals and fertilizers—underscore the versatility of boron derivatives and highlight their economic and ecological significance. Additionally, Turkey's extensive boron reserves position the country as a global leader in boron production, offering opportunities for both industrial and agricultural utilization of these compounds in cost-effective ways.

Despite the demonstrated promise, significant knowledge gaps remain. Most studies have focused on household and a limited number of stored-product pests, leaving many economically important insect species underexplored. Furthermore, the molecular, physiological, and biochemical mechanisms underlying boron toxicity are not yet fully elucidated. Species-specific responses, environmental interactions, and long-term ecological impacts require comprehensive evaluation to ensure effective and sustainable deployment. Moreover, optimizing formulations, application methods, and concentrations tailored to target pests while minimizing non-target effects is necessary to maximize efficacy.

In conclusion, boron-containing compounds emerge as highly promising tools for sustainable pest management, offering an environmentally friendly and resistance-resilient alternative to conventional insecticides. By integrating these compounds into broader pest-management strategies and continuing interdisciplinary research on their mechanisms, efficacy, and ecological safety, it is possible to achieve effective pest control while minimizing environmental impact. Expanding our understanding and application of boron-based compounds holds considerable potential for enhancing agricultural productivity, protecting stored products, and contributing to more sustainable and responsible pest-management practices globally.

E-mail: makifkalender@selcuk.edu.tr /

ABSTRACT

Global climate change, unregulated water use, and increasing population pressure have led to a continuous decline in available water resources, particularly in arid and semi-arid regions. This situation adversely affects agricultural production, threatens food security, and causes significant geomorphological changes due to the decline in groundwater levels. The Konya Closed Basin is among the regions most affected by this process, with the increasing occurrence of sinkholes in recent years serving as a striking indicator. Within the basin, the Karapınar district stands out as one of the driest areas in Türkiye. According to 29 years of meteorological data, the average annual precipitation in the district is 279.5 mm. Due to its sparse vegetation and limited forest cover, the region is highly susceptible to wind erosion. These conditions necessitate a more conscious and planned use of water resources in agricultural production. In this study, the irrigation water requirements of the main crops grown in the Karapınar district were determined for the years 2004, 2014, and 2024 (in ten-year intervals). The irrigation water requirements (mm) were calculated using the CropWat 8.0 software developed by the FAO, while data on crop cultivation areas (da) were obtained from the Turkish Statistical Institute (TÜİK). The results indicated that the total irrigation water requirement of crops in the district was 368.5 million m³ in 2004, 426.8 million m³ in 2014, and 689.6 million m³ in 2024. These findings reveal a significant increase in irrigation water demand over the past two decades in Karapınar. This trend poses a serious threat to the sustainability of existing water resources and highlights the necessity of improving water management, enhancing irrigation efficiency, and adopting crop patterns compatible with changing climatic conditions.

Keywords: Crop Water Requirement, CropWat, Karapınar, Irrigation Water Requirement

1. INTRODUCTION

In the context of an increasingly evident global climate change and the growing pressure on water resources, the sustainability of agricultural production -particularly in arid and semi-arid regions- faces a serious threat. As one of the most vulnerable zones of the Konya Closed Basin, understanding the long-term dynamics of agricultural water use in the Karapınar district is essential for identifying the drivers of rising water demand and assessing the depletion rate of existing resources. In this regard, the need for a more efficient, more resilient, and more conscious water management approach for the future has become an inevitable necessity.

In recent years, the accelerating decline in groundwater levels within the Konya Closed Basin has been driven largely by the reliance of agricultural irrigation on groundwater resources. High-water-demand cropping patterns and extensive irrigated areas have pushed groundwater withdrawals to critical levels. Evaluations of measurements obtained from groundwater observation wells across the basin reveal that groundwater levels declined by an average of 1.09 meters per year between 2000 and 2020 (DSİ, 2020; Kalender, 2023). The study conducted by Üstün et al. (2007) further demonstrated that even a 1-meter annual decline in groundwater levels can trigger various environmental and hydrogeological problems in the Konya Closed Basin.

The rapid decline in groundwater levels weakens the load-bearing capacity of karstic voids, leading to roof collapses and triggering sinkhole formation. Carbonic acid generated by the interaction of groundwater with carbon dioxide gradually dissolves carbonate rocks such as limestone, dolomite, and marl; the collapse of voids with weak roofs composed of marl and clayey carbonates results in the development of sinkholes (Orhan et al., 2020). While sinkholes occurred only once or twice per year from the 1920s to the early 2000s, their annual frequency has risen to around forty over the past decade. The cumulative number of sinkholes detected in the Konya Basin to date has reached 2,240 (Çankal & Alkın, 2024). The increasing incidence of sinkholes in Karapınar serves as a strong warning regarding the uncontrolled use of water resources and clearly demonstrates that water must be treated as a strategic asset in all agricultural practices in the region. Accordingly, the aim of this study is to comparatively determine the irrigation water requirements of major agricultural crops grown in the Karapınar district for the years 2004, 2014, and 2024, and thereby reveal the long-term trend in agricultural water demand in the region.

2. MATERIALS AND METHODS

Karapınar, one of the 31 districts of Konya province, is one of Turkey's most important agricultural regions. With a population of approximately 50,000, the district is located 94 km east of the city center (Figure 1). Built on a plain, it is known to be one of the oldest settlements. Known as one of the few tourism areas in Türkiye with its location on the historical Silk Road, its interesting geological structure, its crater lakes with different water characteristics and its uniqueness in the world, Karapınar is also one of the rare regions that can prevent erosion (Anonymous, 2025).

Figure 1. Location of Karapınar district in Konya province

Karapınar, located within the Konya Closed Basin, stands out as one of the regions in Turkey that receives the least rainfall. According to 29 years of observation data, the district's average annual rainfall is 279.5 mm, and due to its sparse vegetation and sparse forest cover, it is extremely vulnerable to wind erosion (T.C. Konya Valiliği, 2025). 22.1% of the areas subject to wind erosion in Turkey occur in and around Karapınar (Bozyiğit and Güngör, 2011). Brown soils predominate in the northeast and southwest of Karapınar, while hydromorphic alluvial soils predominate in the northeast. Soil types such as regosols, black sand dunes, and sierozem soils are also present (Bozyiğit and Güngör, 2011). Total agricultural area information for Karapınar for the years 2004, 2014, and 2024 is provided in Table 1. The size of Karapınar's agricultural land has approximately doubled since 2004, and by 2024, this was due to a significant decrease in total fallow land. Vegetable and grain production areas have increased. Karapınar's share of agricultural land within Konya province has decreased over the years, and this decrease in total fallow land has been a contributing factor.

Table 1. Total agricultural area sizes for Karapınar and Konya provinces (TÜİK, 2025)

Karapınar	Agricultural Area Size (ha)		
	2004	2014	2024
Fruits, Beverages and Spices Crops	1411	203,3	405,1
Fallow	147 485	67 951,4	9500
Vegetable	884	1256	3337,5
Cereals and Other Crop Products	88 497	77 103,8	111 672,3
Total	238 277	146 514,5	124 914,9
Konya Province Total	2 617 944	1 909 248,67	1 884 603,42
Share of Karapınar	% 9,1	% 7,7	% 6,6

The main crops cultivated in Karapınar in 2004, 2014, and 2024 and their production quantities are shown in Table 2. While production of more than half of these crops has increased over the years, barley, watermelon, melon, and grape production has decreased. Based on the crops listed in the table, total production is calculated as 424,122 tons, 1,245,297 tons, and 2,725,336 tons for 2004, 2014, and 2024, respectively. Production has increased by approximately 545% over the past 20 years.

Table 2. Production quantities of main products grown in Karapınar (TÜİK, 2025)

Karapınar	Production Quantity (tons)		
	2004	2014	2024
Wheat	81727	90480	191526
Maize	48765	245802	758777
Barley	66058	29512	35974
Sugar Beet	156729	420020	1101833
Clover	52872	392275	320000
Potato	10513	6749	121123
Carrot	-	13275	135000
Tomato	-	33488	52000
Watermelon	2800	4020	400
Melon	4000	9016	930
Apple	398	172	7710
Grape	260	488	63

Although total agricultural production has increased significantly, the district's population has remained virtually unchanged (Anonymous, 2025). The stagnation of the population and the increase in production have significantly increased the pressure on agricultural water resources in the region and accelerated the rate of increase in irrigation water demand. In parallel, the study demonstrates the changes in irrigation water requirements for major crops grown in the district over time.

CropWat 8.0 and CLIMWAT 2.0 for CROPWAT software developed by FAO were used to calculate irrigation water. Climate data for Karapınar was obtained from CLIMWAT 2.0 for CROPWAT. Crop growing periods and crop growth coefficients (Kc) for some crops were taken from the crop water consumption guide published by TAGEM (2017).

Total irrigation water requirement was calculated in cubic meters (m^3) or tons by multiplying the crop irrigation water requirement (mm) obtained from CropWat by the crop area (da) of the crop. Crop planting areas are compiled from TÜİK (2025). The values obtained represent net irrigation water requirements, and irrigation efficiency is not considered. Crop irrigation water requirement (mm) data were assumed to be the same for the same crop in three years (2004, 2014, and 2024).

3. RESEARCH RESULTS AND DISCUSSION

This section provides a comparative assessment of the planting areas, net irrigation water requirements, and changes over time for the main agricultural crops cultivated in the Karapınar district in 2004, 2014, and 2024. The data obtained reveal the impact of the expansion trend in agricultural production on water resources and, in particular, how changes in crop patterns affect irrigation water demand. When the calculated crop water consumption values for three different years are considered, along with the differences in total planting areas and the decline in groundwater levels, it is clear that agricultural water use in Karapınar is becoming increasingly critical.

The planting areas and net irrigation water requirements of the main crops cultivated in the Karapınar district in 2004 are given in Table 3. Total planting area was 892,790 m³, and total irrigation water requirement was 368,499,147 m³. The average irrigation water requirement per decare was 412.8 mm.

The total net irrigation water requirement for crops grown in the Karapınar district was calculated as 368.5 million m^3 in 2004, 426.8 million m^3 in 2014, and 689.6 million m^3 in 2024. Accordingly, irrigation water requirement has increased 1.87-fold over a 20-year period. In addition to the increase in total planting area, the decrease in the planting area of some crops with relatively low water requirements (barley, rye, oats, cumin) and the increase in the planting area of some crops with high water requirements (maize, sugar beet, clover) directly contribute to this situation.

Decreased precipitation, particularly due to global warming, has also led to a decline in groundwater levels in the region. Considering the level changes over the years in the five

observation wells located in Karapınar, significant level drops are evident (DSİ, 2020). Information on the observation wells is provided in Table 6.

Table 6. Level changes in the level observation wells in Karapınar (DSİ, 2020)

District	Location	Water Levels (m) and Years	Level Change (m)
Karapınar	Akören	32,71 - 43,35 (2015-2020)	-10,64
	Kesmez	44,00 - 52,66 (2015-2020)	-8,66
	Cumhuriyet	54,09 - 57,67 (2015-2020)	-3,58
	Akçayazı	47,96 - 61,47 (2015-2020)	-13,51
	Gülfet Yayla	27,63 - 65,92 (2000-2020)	-38,29

Studies in the literature conducted in arid and semiarid regions demonstrate the critical importance of irrigation scheduling for the sustainable management of water resources. Numerous studies have analyzed the water requirements of crops in different climates using CropWat software, emphasizing that water deficits increase during periods of insufficient rainfall, making accurate timing and effective irrigation programs essential. Studies in water-scarce regions such as Burkina Faso, Rwanda, India, Tunisia, and Botswana have demonstrated that CropWat significantly contributes to accurate crop water requirement calculations, better monitoring of soil water balance, and more efficient water use (Some et al., 2006; Rose et al., 2019; Herrero Batalla et al., 2014; Mal and Sen, 2025; Haj-Amor, 2020; Moseki, 2025). Appropriate irrigation timing for the growing season, particularly in semiarid regions, has been shown to have a decisive impact on crop yield. These assessments are consistent with the findings obtained in Karapınar. The expansion of the cultivation area of high-water-consuming crops in the district has led to a rapid increase in total irrigation needs; at the same time, the significant decline in groundwater levels has demonstrated that irrigation management now requires more precise planning. Therefore, in Karapınar, as in other arid regions, supporting irrigation programs with scientifically based software is a critical requirement for efficient water use and sustainable production.

4. CONCLUSION AND RECOMMENDATIONS

This study comparatively analyzed the cultivation areas, production quantities, and net irrigation water requirements of the main agricultural products grown in the Karapınar district for the years 2004, 2014, and 2024. The findings indicate that Karapınar is highly vulnerable to water scarcity due to its arid and semi-arid climate, and that agricultural water demand has increased significantly over the last 20 years.

When evaluated in terms of crop pattern, planting areas, and production quantities, total production increased from 424,000 tons in 2004 to 2.7 million tons in 2024 (a 545% increase), demonstrating a significant expansion in agricultural activities. Conversely, the district's population remained virtually constant over the same period, indicating that the pressure on water resources caused by increased production stems from agricultural production rather than human consumption. Furthermore, the shift in crop pattern is a significant driver of the increase in water demand. While the area under cultivation for low-water-demand crops like barley, oats, rye, and cumin has decreased, the area under cultivation for high-water-demand crops like maize, sugar beet, and clover has expanded significantly. This change negatively impacts the sustainability of agricultural water use in the region.

Analyses of irrigation water requirements clearly demonstrate this trend. Total net irrigation water requirements, which were 368.5 million m³ in 2004, reached 426.8 million m³ in 2014, and 689.6 million m³ in 2024. This represents a 1.87-fold increase in water demand over the past 20 years. An examination of the tables reveals that maize, sugar beet, clover and wheat, in particular, account for a significant portion of total irrigation water requirements, both in terms of crop area and total water consumption. The fact that maize's irrigation water needs exceeded 242 million m³ in 2024 indicates that the region's water budget has reached a critical point.

Meanwhile, levels measured in five groundwater observation wells in Karapınar indicate that this pressure on the water budget is directly reflected in groundwater levels. The average drop in groundwater levels between 2000 and 2020 was calculated as -1.8 m/year; drops exceeding 8-13 meters were recorded over a five-year period in locations such as Akçayazı, Akören, and Kesmez. The most striking drop, at -38.29 meters over 20 years, was observed in the Gülfet Yayla well. This rapid decline in groundwater levels demonstrates that agricultural activities are currently unsustainable and increases geomorphological risks such as sinkhole formations.

In light of these findings, several recommendations can be developed. The uncontrolled growth of crops such as maize, clover and sugar beet, which require high water consumption, is rapidly depleting the basin's water budget. A transition to a water-friendly cropping pattern has become a strategic necessity for the region. A return to relatively low-water-demand crops such as barley, oats, rye, and cumin should be encouraged. Traditional irrigation methods, which persist in Karapınar, significantly increase water losses. Supporting the transition to systems such as drip and sprinkler irrigation will increase water use efficiency. To make these technologies economically accessible, support and subsidy mechanisms should be established for farmers. Illegal wells should be identified, water withdrawal permits should be reissued according to the current water budget, and wells should be integrated with monitoring systems. If the decline in groundwater levels continues, agricultural production will be at significant risk, and sinkhole formation will become more widespread. Alternative methods such as rainwater harvesting, small storage structures, surface runoff collection, and the use of reclaimed water for agricultural irrigation will reduce groundwater dependency. Karapınar's sand dunes, regosols, and brown soils have low water holding capacity and are susceptible to erosion. Therefore, organic matter applications (farm manure, compost), mulching techniques, and proper planning of soil tillage timing will improve the plant-water relationship and support production with less irrigation water. Continuous training for farmers on efficient water use, soil-plant-water relationships, irrigation scheduling, and adaptation to climate change should be provided; the field application of technological innovations should be supported.

The Karapınar district is one of Turkey's most vulnerable agricultural production areas due to its arid climate, low rainfall, the threat of wind erosion, and rapidly declining groundwater levels. The study's findings clearly demonstrate that if current water use trends continue, the region's water sustainability is at serious risk. Therefore, a holistic approach to water management should be adopted; a water-efficiency-based production approach is essential for the region's future.

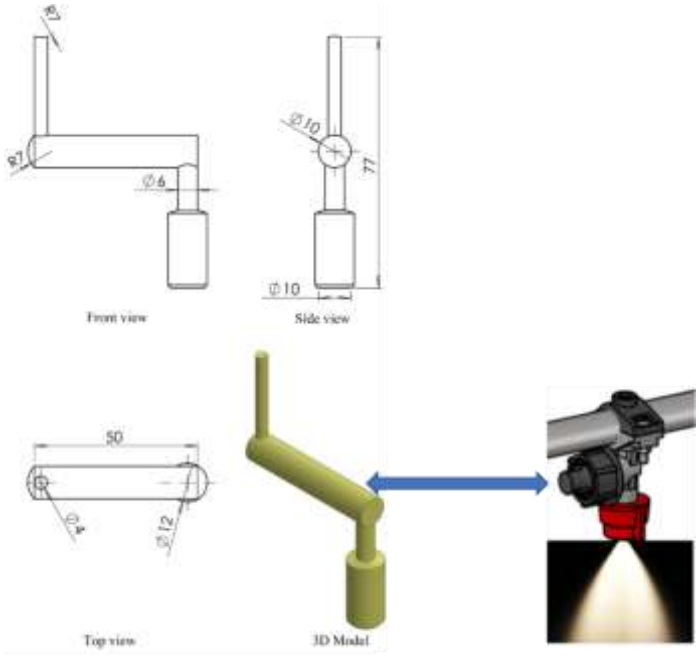
ABSTRACT

The uniform distribution of pesticides to the target with minimal loss is directly related to the internal flow uniformity of the spray nozzles. The internal structure of standard spray nozzles, by design, contains sudden cross-sectional constrictions. The aforementioned geometric changes result in the disruption of the velocity profile within the flow channel. This, in turn, gives rise to the formation of sharp velocity gradients, an increase in turbulent kinetic energy, and sudden pressure drops in the constriction regions. It is imperative to note that these flow irregularities have the potential to exert a detrimental influence on the quality of pulverization and the homogeneity of the spray distribution. This phenomenon can be attributed to the propensity of such irregularities to give rise to the development of vortex structures and to the weakening of jet stability. Consequently, it is imperative to quantitatively ascertain the effect of the internal geometry of spray nozzles on flow characteristics for the purpose of optimising design. In this study, the behaviour of the flow in the nozzle body channel was analysed in detail at three different pressure levels (2, 3 and 4 bar) by means of computational fluid dynamics (CFD) methods. Experimental flow measurements were conducted in order to establish boundary conditions. The theoretical velocity values that were calculated were then compared with the simulation results. In the context of CFD analyses, the velocity, pressure, and turbulent kinetic energy distributions within the nozzle body were evaluated at each pressure level. This facilitated the identification of discrepancies in flow characteristics. The findings demonstrated that analyses conducted at an operating pressure of 3 bar exhibited the strongest concordance with the experimental data. Furthermore, it was revealed that selecting the appropriate operating pressure could create a more stable, symmetrical, and energy-efficient profile for the flow inside the nozzle. These findings provide a scientific basis for future optimisation studies aimed at eliminating flow irregularities caused by internal geometry and improving atomisation performance in spray nozzle design.

Keywords: Spray nozzle, computational fluid dynamics (CFD), velocity profile, pressure drop, turbulent kinetic energy

INTRODUCTION



The uniform distribution of pesticides to the target is directly related to the internal flow uniformity of the spray nozzles. In this context, the design characteristics and operating parameters of sprayers directly influence the effectiveness of agricultural pest control (Çomaklı, 2017). The liquid pesticide contained within the sprayer tank is pressurised prior to being discharged into the atmosphere through the function of the spray nozzles. It should be noted that a certain level of pressure loss occurs during this process, due to friction along the inner surface of the hose, particularly at the elbow sections where the flow direction changes. In hydraulic pipe systems that are designed for the direction and transportation of fluids, elbow joints that facilitate alterations in flow direction and reducers that enable diameter transitions between pipes are among the most frequently utilised connection components (Andrew, 2011). In the domain of fluid transfer systems, elbow components assume a pivotal role in facilitating optimal flow conditions. This is attributable to their direct impact on the velocity and pressure distributions of the fluid, thereby ensuring efficient redirection of flow (Danışmaz, 2023). In hydraulic hose and pipe systems, pressure losses occur to a certain extent due to the resistance generated during fluid flow. In particular, examination of the flow behaviour in elbow regions is of critical importance for understanding and improving overall system performance (Korkmaz and Tıkız, 2023). Elbow components, where directional changes occur within sprayer pressure hose systems, play a pivotal role in overall system performance by directly influencing the flow's velocity and pressure parameters. The turbulence, vortex formation, and pressure losses that arise in such connection components have a significant impact on both flow efficiency and distribution accuracy. It is imperative to comprehend the distribution of flow within the flow-directing elbows, otherwise referred to as nozzle heads, through which pressurised fluid passes prior to reaching the spray nozzle. This understanding is of paramount importance for the design and optimisation of hoses and connection components in the sprayer pressure line. The time-consuming and costly nature of experimental studies increases the importance of numerical analysis methods, which can provide fast and reliable results. In a study conducted by Özkan (2011), the flow characteristics of the existing model were examined using the computational fluid dynamics software FLUENT in order to design a new 90° elbow that could provide lower pressure loss compared to conventional connection components. In their study, Bostancı and Ünalan (2012) conducted a numerical investigation into the flow of incompressible turbulence in a square-section elbow with a 90° bend. In the course of the study, the researchers compared various turbulence models with the experimental results, concluding that the RNG k-ε model was the most suitable for square-section elbows. Danışmaz (2023) investigated the flow behaviour of water and water-based Al_2O_3 nanofluid in an elbowed pipe under constant heat flux surface boundary conditions and at low Reynolds numbers using computational fluid dynamics. In their study, Korkmaz and Tıkız (2023) examined various bend diameters and bending defects, which are frequently encountered during pipe manufacturing, in order to detect deformation errors. They also determined the associated pressure losses using the k-ε turbulence model. In this context, the design and modelling of components within flow lines can be carried out in a shorter time and at a lower cost by using simulation techniques. This enables effective and economical solutions to flow-related problems. Computational Fluid Dynamics (CFD) is an approach that enables the sequential solution of flow problems with complex geometries, encountered in real-life applications, through the use of differential equations expressed by numerical methods. This is particularly useful in cases where analytical solutions are not feasible (Chung, 2002).

In this study, the influence of elbow geometries - located within the pressure hose systems of sprayers widely used in agricultural applications - on overall system performance was examined

in detail using the CFD method. In particular, the velocity gradients, pressure drops, and turbulence structures that occur in elbow regions were analysed comprehensively. These regions are of particular interest as they are where the fluid is forced to change direction and constitute the main source of energy losses. The numerical analyses were conducted using ANSYS Fluent, and the three-dimensional flow domain of the nozzle head - representing the critical region immediately preceding the spraying process - was modelled in great detail. An investigation was conducted on a cone-jet nozzle with a 2.4 mm orifice diameter, a model that has been widely adopted within the industry. The model was defined through the application of boundary conditions that align with the operational parameters across a range of three distinct pressures. Following the execution of the simulations, a comparative analysis was conducted on variations in key flow parameters. These parameters included, but were not limited to, velocity distributions, static and dynamic pressure changes, and turbulence kinetic energy distributions. The findings, both quantitative and qualitative, demonstrate the pivotal role of elbow geometry in hydraulic system efficiency and spray quality. Furthermore, they identify the critical parameters that should be considered during the design of optimised sprayer systems in terms of energy efficiency and wear resistance.

MATERIALS AND METHODS

In the present study, an analysis was conducted of the flow domain within a spray nozzle head manufactured from polyamide material, which features a 90° bend. The nozzle head comprises two distinct sections, as illustrated in Figure 1a and 1b: a 4 mm fluid inlet diameter and a 10 mm outlet surface diameter situated immediately upstream of the cone-jet nozzle. In the present study, the inlet velocity and pressure values of the 2.4 mm orifice spray nozzle utilised in the research conducted by Çomaklı and Sayıncı (2022), entitled “Determination of Orifice Flow Velocity in a Cone-Jet Nozzle by Experimental and Computational Fluid Dynamics (CFD) Methods”, were adopted as the target outlet values.

(a) (b)

Figure 1. (a) Technical drawings of the spray nozzle head flow domain, (b) Flow within the spray nozzle head

Theoretical calculations were performed to determine the inlet velocity values for three distinct operating pressures (2, 3, and 4 bar) utilising the general volumetric flow rate equation. (Equation (1)). The preceding study determined that the theoretically calculated inlet velocities were consistent with the experimental data with an accuracy of 96%. In the context of this study, the inlet velocity values were considered as a reference point, with the outlet velocities of the spray nozzle head being targeted and examined accordingly. The three-dimensional flow domain of the spray nozzle head was modelled in SolidWorks 2023, and subsequently analysed using the CFD method within the ANSYS 2021 R1 Workbench environment. The outlet velocities obtained were then compared with the inlet velocity values from the previous study, and a detailed evaluation was conducted.

The general equation for flow rate (volumetric flow rate) is as follows:

$$Q = A \cdot V \tag{1}$$

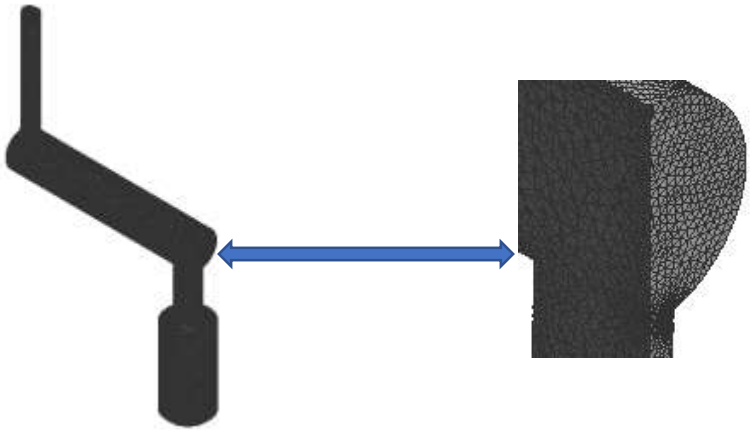
Where, Q is the volumetric flow rate ($m^3\ s^{-1}$), A is the cross-sectional area (m^2), and V is the fluid velocity ($m\ s^{-1}$).

In the experimental calculations of the orifice outlet velocity, water was selected as an incompressible and constant-density fluid, and these properties were defined in the ANSYS Fluent model. The inlet diameter of the spray nozzle head was measured to be 4 mm, and it was used in the determination of the Reynolds numbers based on the calculated flow velocities. In practice, the pressurised pesticide solution contained within the sprayer tank is delivered to the spray nozzle head through a 13 mm diameter pressure line. The flow from the pressure line to the nozzle head is directed through 90° turns, and the flow in this inlet region generally occurs in a turbulent regime. The Reynolds number is defined as the ratio of inertial forces to viscous forces and is utilised to ascertain the flow regime. For flow in circular pipes, the Reynolds number was calculated using the following equation (2). In order to ascertain whether the flow in the spray nozzle head was laminar or turbulent, the Reynolds number was evaluated using the following equation.

Reynolds number equation:

$$Re_D = \frac{\text{Inertial forces}}{\text{Viscous forces}} = \frac{\rho \cdot V \cdot D}{\mu} \tag{2}$$

Where Re_D: Reynolds number, ρ: the fluid density (998 $kg\ m^{-3}$), V: the fluid velocity ($m\ s^{-1}$), D: the inlet diameter (m), μ: the dynamic viscosity (0.001 Pa.s)



The inlet velocities calculated for three different operating pressures (2, 3, and 4 bar), along with the corresponding Reynolds numbers determined based on these velocities, are presented in Table 1.

Table 1. Calculated velocity values and Reynolds numbers for different operating pressures

Operating pressure (bar)	Inlet velocity of the spray nozzle head ($m\ s^{-1}$)	Reynolds Number
2	2.610	10400
3	3.169	12620
4	3.710	14790

It is acknowledged that flow occurs in a turbulent regime when the Reynolds number is 4000 or higher. According to the data presented in Table 1, the lowest Reynolds number measured at the inlet of the spray nozzle head was determined to be 10.400, and the flow was therefore considered turbulent.

Kibar et al. (2021) conducted a study on the pressure drop in banjo elbows, which are extensively employed in high-pressure applications. The study utilised the standard k–ε turbulence model. Çavdar et al. (2020) demonstrated a preference for the standard k–ε turbulence model when examining the pressure and velocity variations occurring in the internal flows of solenoid valves utilised in the domain of pneumatic control. In a study conducted by Shabani et al. (2019), the standard k–ε turbulence model was employed to simulate the pressure distribution and losses caused by turbulent flows in a circular pipe elbow with and without guide vanes. In view of the findings of the literature review and the converging-diverging diameter structure of the spray nozzle head, it was determined that the standard k-ε turbulence model would be utilised as the turbulence model in this study. As demonstrated in Figure 2, the numerical solution mesh of the spray nozzle head was presented. In order to achieve a higher level of accuracy in the critical transition regions of the flow domain, a denser mesh structure was generated by activating the 'capture' and 'proximity' options. In order to ensure mesh independence of the solution, mesh structures with three different element sizes were generated, and the mesh parameters are presented in Table 2. The numerical analyses were performed using ANSYS Fluent, with the standard k–ε turbulence model being employed and adaptive meshing techniques being applied to enhance the accuracy of the solution.

(a) (b)

Figure 2. (a) Flow domain mesh structure, (b) Detailed sectional mesh structure

In the context of the flow domain of the spray nozzle head, three distinct mesh structures were generated. Of these, the mesh with an element size of 0.4 mm was selected on the basis that it predicted the experimental velocity values with high accuracy and enabled rapid solution convergence. As illustrated in Table 2, the number of elements determined through a trial method is presented, with said determination based on the selected element sizes.

Table 2. Number of cells determined to achieve the closest match to the theoretical velocity value

Element size (mm)	Number of elements	Number of adaptive elements	Theoretical velocity (m s^{-1})	CFD velocity (m s^{-1})	Accuracy (%)
0.3	940737	1045653	0.510	0.531	96
0.4	511784	571778	0.510	0.512	99
0.5	325260	368079	0.510	0.504	98

A series of numerical analyses were conducted on the flow domain of the spray nozzle head. The results obtained after 5000 iterations used an adaptive mesh resolution of 0.4 mm. These analyses were performed under three distinct boundary conditions, representing different operating pressures. The experimental and simulation velocity values obtained at the conclusion of each 1000-iteration period under an operating pressure of three bar are presented in Table 3. Polyamide, a material frequently preferred in engineering applications, was selected for the construction of the spray nozzle head.

Table 3. Outlet values obtained after each 1000 iterations using the number of cells determined to achieve the closest match to the theoretical velocity value

Iteration number	Inlet (m s^{-1})	Outlet (m s^{-1})	Theoretical (m s^{-1})	Accuracy (%)
1000	3.169	0.512	0.510	99.6
2000	3.169	0.513	0.510	99.4
3000	3.169	0.514	0.510	99.2
4000	3.169	0.512	0.510	99.6
5000	3.169	0.512	0.510	99.6

Governing Equations

The CFD simulations conducted in this study were based on the fundamental conservation equations governing fluid behaviour (mass and momentum). In accordance with the definition of the computational domain as single-phase, comprising solely water flow, the equations were evaluated under the assumption of incompressible flow. To ascertain the internal flow characteristics within the spray chamber, the steady-state form of these conservation equations was solved.

Conservation of mass (Continuity equation):

$$\frac{\partial u}{\partial x}+\frac{\partial v}{\partial y}+\frac{\partial w}{\partial z}=0 \quad (3)$$

Here, ρ represents the fluid density (kg m^{-3}), and u, v, w are the velocity components in the x, y, and z directions, respectively (m s^{-1}).

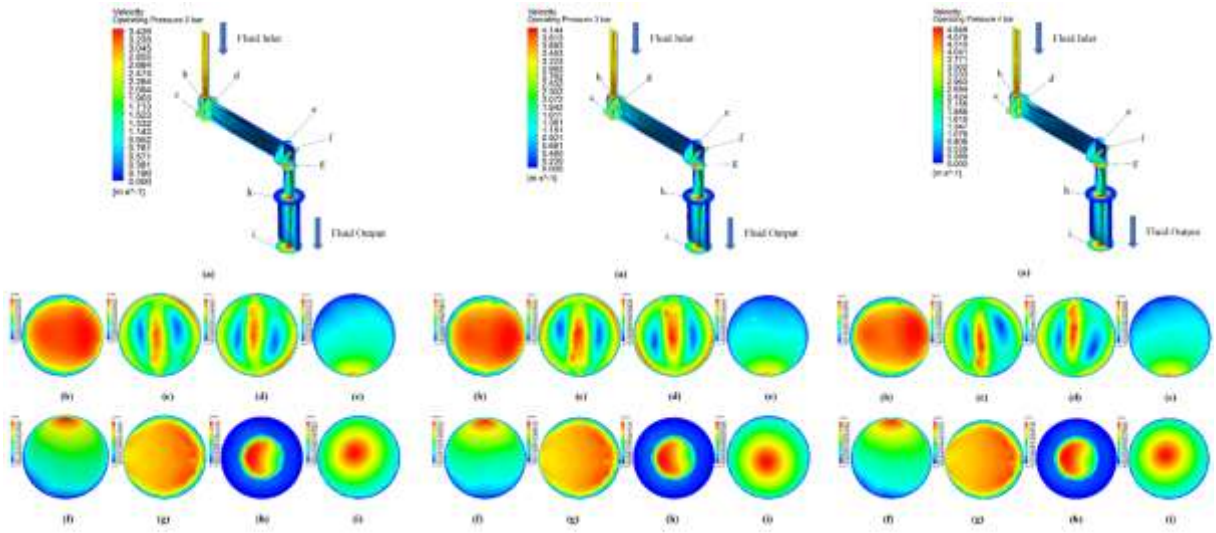
Conservation of momentum (Navier-stokes equations):

$$\rho\left(\frac{\partial u}{\partial t}+u\frac{\partial u}{\partial x}+v\frac{\partial u}{\partial y}+w\frac{\partial u}{\partial z}\right)=-\frac{\partial p}{\partial x}+\rho g_x+\mu\vec{\nabla}^2 u \quad (4)$$

$$\rho\left(\frac{\partial v}{\partial t}+u\frac{\partial v}{\partial x}+v\frac{\partial v}{\partial y}+w\frac{\partial v}{\partial z}\right)=-\frac{\partial p}{\partial y}+\rho g_y+\mu\vec{\nabla}^2 v \quad (5)$$

$$\rho\left(\frac{\partial w}{\partial t}+u\frac{\partial w}{\partial x}+v\frac{\partial w}{\partial y}+w\frac{\partial w}{\partial z}\right)=-\frac{\partial p}{\partial z}+\rho g_z+\mu\vec{\nabla}^2 w \quad (6)$$

In this context, the symbol p denotes the static pressure (Pa), μ is the dynamic viscosity (Pa·s), and g_x, g_y, g_z are the components of gravitational acceleration (m s^{-2}).



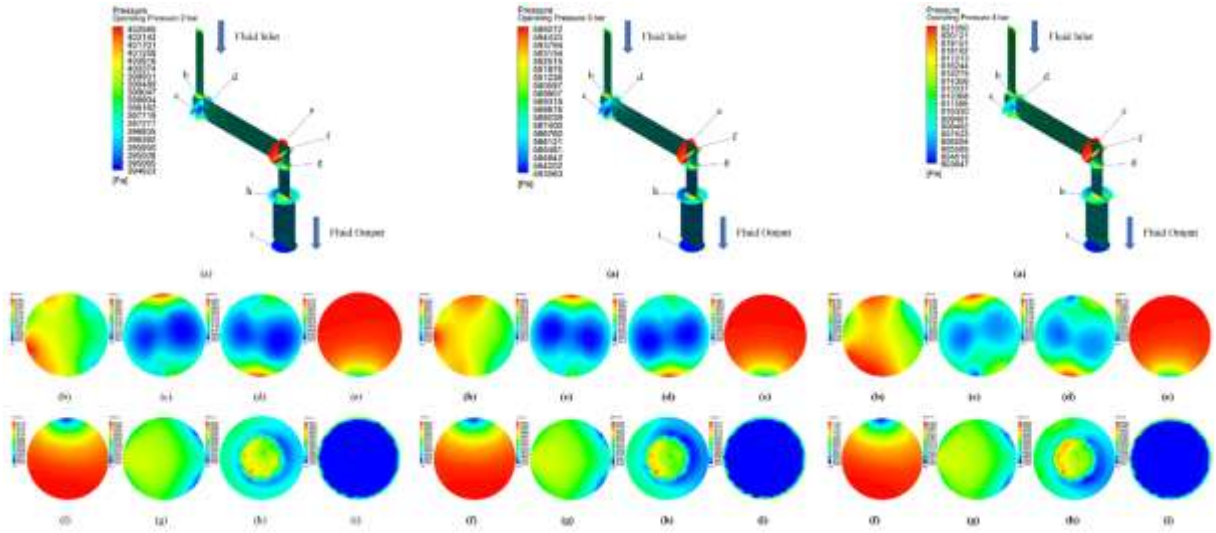
RESULTS AND DISCUSSION

In this study, the theoretical and computational fluid dynamics velocity results for the nozzle head at three different operating pressures are presented in Table 4. The research findings indicate that the theoretical outlet velocities were verified with an accuracy of over 99% at all three pressure levels. The computational fluid dynamics results for the spray nozzle head exhibited the highest agreement with the experimental results at an operating pressure of 3 bar. It was observed that the outlet velocity of the nozzle head increased with the rise in operating pressure.

Table 4. Calculated velocity values and CFD results for different operating pressures

Operating pressure (bar)	Inlet velocity (m s^{-1})	Outlet velocity (m s^{-1})	Theoretical outlet velocity (m s^{-1})	Accuracy (%)
2	2.610	0.423	0.420	99.2
3	3.169	0,512	0,510	99.6
4	3.710	0.601	0.597	99.3

The distributions of velocity, pressure, and turbulence kinetic energy obtained at the operating pressures were presented in detail through visualisations on selected cross-sectional planes. These planes had been chosen to reveal the effects of geometric features such as the 90° turning regions, diameter transitions, and the cone-jet nozzle inlet section within the nozzle head. In the three analyses under consideration, image (a) is representative of the general flow field, whilst images (b)-(i) illustrate the distributions on various cross-sectional planes selected along the flow path. Figure 3 presents the velocity distributions obtained along the flow path within the nozzle-head system under three different operating pressures.

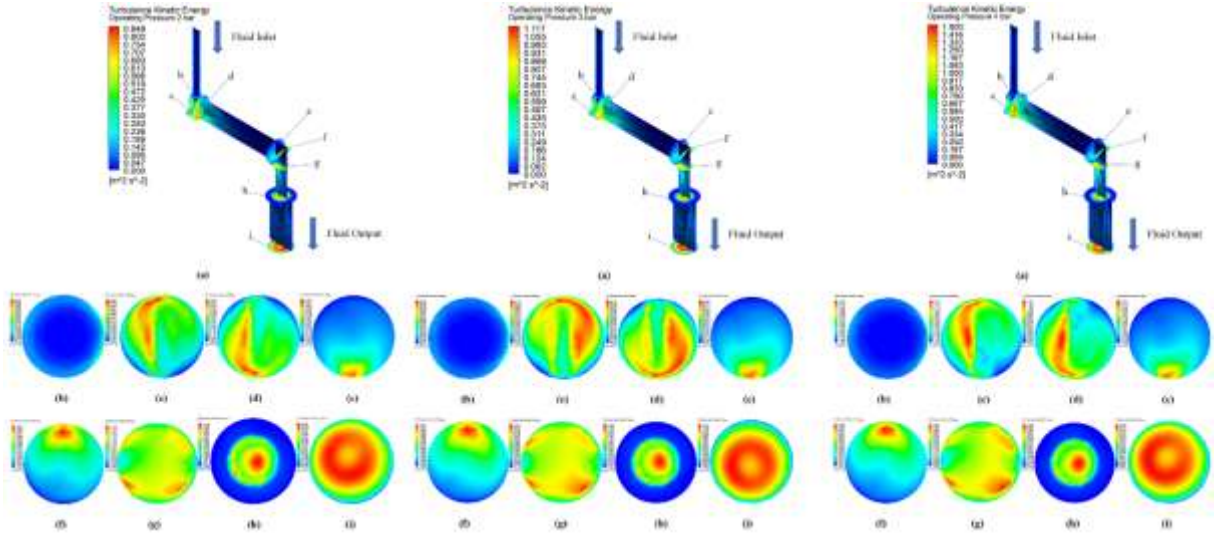


(a) (b) (c)

Figure 3. Velocity distributions at (a) 2 bar, (b) 3 bar, and (c) 4 bar operating pressures

In the configuration of the pipe (b), the flow velocity within the 4 mm diameter pipe section in the vicinity of the inlet achieves its maximum value within the flow domain for all operational pressures. The velocity distributions at all pressure levels exhibit a concentration at the centre, a gradual decrease towards the walls, and an asymmetric pattern. In planes (c) and (d), where the diameter of the spray nozzle head abruptly increases from 4 mm to 10 mm and the flow direction is altered by 90°, the velocity is observed to decrease at all pressure levels due to the consequences of sudden expansion and rotation, resulting in the formation of an asymmetric pattern from the centre towards the outer regions. This behaviour is indicative of the influence of turbulent structures and secondary flows generated by the change in flow direction and the geometric expansion. As the pressure increases, the two-lobed velocity structures induced by the turning motion become more pronounced. In plane (e), where the diameter remains constant at 10 mm, the velocity decreases across the flow region at all pressure levels due to the preceding expansion. In plane (f), although the diameter remains constant, the centrifugal forces generated by the elbow geometry distort the velocity distribution at all pressure levels, causing the flow to shift towards one side. As the pressure increases, the velocity asymmetry becomes more pronounced due to the intensified centrifugal effects. In plane (g), the sudden reduction of the cross-sectional diameter to 6 mm increases the velocity, resulting in a more focused and homogeneous flow profile. In the plane (h), as the diameter expands to 12 mm, the velocity remains relatively high at the centre while decreasing markedly towards the walls. The occurrence of the highest flow velocity at the 4-bar operating pressure can be interpreted as an indication that the acceleration of the flow is not adversely affected by the diameter variations. In the initial configuration (i), the diameter undergoes a further reduction to 10 mm, thereby inducing a concentration of the velocity distribution at the centre and the formation of a more uniform profile. It is evident that the velocity values exhibit an overall increase across all cross-sections as the operating pressure rises. It has been demonstrated that the geometric effects engender equivalent flow characteristics across the entire range of pressure levels. The 4-bar operating pressure is defined as the condition in which the flow attains its maximum velocities and demonstrates the most intense turbulence intensity.

As illustrated in Figure 4, the pressure distributions obtained along the flow path are presented for the system containing a spray nozzle head with a 90° change in flow direction under three different operating pressures.



(a) (b) (c)

Figure 4. Pressure distributions at (a) 2 bar, (b) 3 bar, and (c) 4 bar operating pressures

In the (b) plane, the static pressure reaches its maximum levels in the sections in close proximity to the inlet region. As the operating pressure increases, a consistent rise in pressure is observed throughout the entire inlet region. The pressure distributions at the inlet cross-section exhibit higher values at the centre, decreasing progressively towards the walls. It is evident that planes (c) and (d) represent the critical regions where the flow undergoes a sudden expansion from 4 mm to 10 mm and a 90° change in direction. At all pressure levels, the sudden expansion causes a drop in pressure, and the change in flow direction makes the pressure distribution asymmetric. As the pressure increases, high-pressure pockets become more pronounced along the side walls, whilst low-pressure cores emerge in the regions that are distant from the centre. Subsequent to the sudden expansion, the pressure profile in the 10 mm constant-diameter segment begins to re-establish equilibrium in the plane (e). As the pressure is increased from 2 bar to 3 and 4 bar, the pressure gradient increases concomitantly. Plane (f) demonstrates that the geometry of the elbow causes a shift in the pressure distribution, resulting in an evident asymmetry across the section. As the operating pressure increases, the centrifugal effect causes the pressure to rise along the outer curvature and decrease along the inner curvature. In plane (g), the sudden reduction of the cross-sectional diameter from 10 mm to 6 mm causes an abrupt increase in pressure within the section. It has been demonstrated that, at the 4-bar operating pressure, this region exhibits the most pronounced pressure concentration. The reduction in cross-sectional area causes the fluid to accelerate, leading to the accumulation of pressure concentration at the centre. In plane (h), the augmentation of the diameter to 12 mm engenders a diminution in pressure distribution, with reduced values at the centre and elevated values in proximity to the walls. At elevated pressure levels, turbulence cores induced by the expansion become distinctly visible. In plane (i), the narrowing of the geometry back to 10 mm consolidates the pressure distribution at the centre. It has been demonstrated that, under all pressure levels, pressure values decrease in proportion to the increase in flow velocity towards the outlet surface. Consequently, as pressure increases, pressure levels rise in all regions; however, the geometric effects continue to produce the same flow patterns. The regions of directional change, expansion, and contraction generate significant asymmetry and turbulence structures in the pressure distributions. The geometry of the nozzle head generates pressure peak and trough regions along the flow path, thereby significantly altering the overall flow balance.

As illustrated in Figure 5, the distributions of turbulence kinetic energy (TKE) of the spray nozzle head at three distinct operating pressures are presented in detail across the (b)-(i) planes.

(a) (b) (c)

Figure 5. Turbulent kinetic energy distributions at operating pressures of (a) 2 bar, (b) 3 bar, and (c) 4 bar.

In the configuration delineated by plane (b), the turbulence kinetic energy remains low at all pressure levels. Even as the operating pressure increases, turbulence generation remains limited because the flow does not encounter any major geometric changes. In planes (c) and (d), flow separation and the formation of vortex structures are precipitated by the sudden expansion and change in flow direction. Turbulence kinetic energy manifests an asymmetric and sharp increase from the centre towards the outer regions. As the operating pressure increases, the dual-core turbulence structures become more pronounced. In the case of plane (e), within the straight-flow region characterised by a constant diameter of 10 mm, a significant decrease in turbulence kinetic energy has been observed across all pressure levels. In plane (f), the presence of the elbow geometry leads to the deflection of the flow towards the outer curvature, thereby resulting in the formation of high turbulence kinetic energy. As the operating pressure increases, the centrifugal effects become stronger, and the asymmetry in turbulence kinetic energy becomes more pronounced. In the configuration represented by the letter g, the abrupt reduction in the cross-sectional area to 6 mm leads to an increase in flow velocity, consequently resulting in a substantial rise in turbulence kinetic energy. The 4-bar pressure level resulted in the most significant turbulence intensification. In the case of plane (h), the sudden expansion of the cross-section to a diameter of 12 mm results in a significant reduction in turbulence kinetic energy. In the context of plane (i), the geometry undergoes a renewed contraction, thereby stabilising the flow and concentrating the turbulence kinetic energy distribution towards the centre. At an operating pressure of 4 bar, a pronounced turbulence core has been observed to form in the outlet region. In summary, the geometric effects (90° turning, expansion, and contraction) yielded analogous flow characteristics across all pressure levels. As the operating pressure increased, the magnitude of the turbulence kinetic energy, the spatial extent of its distribution and the prominence of its peak regions all became more pronounced.

CONCLUSION

The present study investigates the internal flow characteristics of a spray nozzle utilised in plant protection machinery. The investigation is conducted under three distinct operating pressures (2, 3, and 4 bar), employing the CFD method as the investigative approach. In the numerical analyses, particular attention was given to the flow behaviour in the 90° sharp turning regions, at points of sudden diameter change and at the outlet surface. The results of the velocity distribution study indicate that the flow accelerates in specific regions and develops into an asymmetric pattern throughout the system when it undergoes a 90° change in direction within the nozzle body. This finding demonstrates that the acceleration observed in the flow is primarily influenced by the geometric configuration, particularly in the turning and expansion regions. A thorough examination of the pressure distributions indicated that geometric variations and directional changes within the system gave rise to pronounced asymmetries in the pressure field. In particular, the pressure irregularities observed in planes (c)-(d) and (h) were interpreted as indicators of complex flow structures arising from turbulence, turning motions, and diameter transitions. It was determined that the turbulence kinetic energy increases markedly in regions where turning and sudden diameter changes occur. It is evident that these turbulence intensities have a substantial impact on the quality of flow and exit profiles within the nozzle body. The findings demonstrate that enhancements in spray characteristics can be achieved without altering the structural design of the spray nozzle. Instead, optimisation of operating parameters, such as pressure, can be sufficient to enhance performance. This finding is of significance for achieving effective, controlled, and homogeneous spray performance in agricultural applications.

ÖZET

İnsanlığın başlangıcından bu yana bitkiler geleneksel tıpta kullanılmıştır. *Helichrysum* cinsindeki birçok tür tıbbi özellikler sergiler ve geleneksel tıpta kullanılmaktadır. Asteraceae, bitkiler alemindeki en büyük familyalardan biri ve aynı zamanda en çok endemik tür barındıran familyadır. Toplam 489 endemik tür barındıran Asteraceae familyasının endemizm oranı %36,3'tür. Asteraceae familyası üyeleri dünyanın hemen hemen her yerine dağılmıştır. Özellikle Amerika'nın güneybatısında, Meksika'da, Brezilya'nın güneyinde, Akdeniz Bölgesi'nde, güneybatı Asya'da, Orta Asya'da, Güney Afrika'da ve Avustralya'da bulunmaktadır. Helichrysum Gaertner, dünya çapında yaklaşık 500 türe sahip, oldukça yaygın bir Asteraceae familyası cinsidir. Türler, yüksek morfolojik çeşitlilikleri nedeniyle birçok alt türe ayrılmaktadır. Helichrysum türlerine Güney Avrupa, Güneybatı Asya, Güney Hindistan, Güney Afrika, Sri Lanka, Avustralya ve Madagaskar ev sahipliği yapmaktadır. *Helichrysum* cinsi, Türkiye florasında 20 farklı tür içeren toplam 26 taksonla temsil edilmektedir. Bu türlerin 14'ünün Türkiye'ye endemik olması dikkat çekicidir. *Helichrysum pallasii* (Spreng.) Ledeb. hem süs bitkilerinde hem de geleneksel tıpta kullanılmaktadır. Tıbbi bitkilerden elde edilen özler ve uçucu yağlar, bitkilerin kimyasal yapısını, antibakteriyel ve diğer tedavi edici özelliklerini incelemek için dünya çapındaki laboratuvarlarda kullanılmaktadır. Rize'nin Anzer yaylasından alınan *H. pallasii*'nin toprak üstü kısımlarının sekonder uçucu metabolit içeriği incelenmiştir. GC-MS cihazı kullanılarak otuz farklı bileşen tanımlanabilmiştir. Heptadekan (%9,79), İzofitol (%9,32), Fiton (%9,31), Heksadekan (%6,82), Oktadekan (%5,05), Miristat etil (%4,27) ve alfa Himachelen (%4,11), önemli biyolojik aktivite gösteren dikkate değer bileşenlerdir.

Anahtar kelimeler: GC-MS, kimyasal bileşim, tıbbi bitkiler

SECONDARY VOLATILE METABOLITE COMPOSITION OF *Helichrysum pallasii* COLLECTED ANZER HIGHLAND/RİZE

ABSTRACT

Since the beginning of human existence, plants have been utilised in traditional medicine. Many species in the genus *Helichrysum* exhibit medicinal properties and are used in traditional medicine. Asteraceae is one of the largest families in the plant kingdom and also the family that contains the most endemic species. The endemism rate of the Asteraceae family, which contains a total of 489 endemic species, is 36.3%. Members of the Asteraceae family are distributed almost everywhere on earth. It is especially found in the southwest of America, Mexico, the south of Brazil, the Mediterranean Region, southwest Asia, Central Asia, South Africa and Australia Helichrysum Gaertner is a genus in the Asteraceae family that is quite common, with about 500 species worldwide. The species are separated into many subspecies due to their high morphological variation. Southern Europe, South-West Asia, South India, South Africa, Sri Lanka, Australia, and Madagascar are home to Helichrysum species. The genus *Helichrysum* is represented in Turkish flora by a total of 26 taxa, which include 20 different species. Remarkably, 14 of these species are endemic to Türkiye. *Helichrysum pallasii* (Spreng.) Ledeb. is employed both ornamentally and in traditional medicine. Extracts and essential oils from medicinal plants are being used in labs all around the world to study the chemical makeup, antibacterial, and other therapeutic qualities of plants. The secondary volatile metabolite content of aerial portions of *H. pallasii* that were taken from the Anzer highland of Rize was examined. Using GC-MS device thirty distinct components could be identified. Heptadecane (9,79%), Isophytol (9,32%), Phytone (9,31%), Hexadecane (6,82%), Octadecane (5,05%), Myristate ethyl (4,27%), and alpha Himachelene (4,11%) were notable constituents that exhibited significant biological activity.

Key words: GC-MS, chemical composition, medicinal plants

INTRODUCTION

One of the largest families in the kingdom of plants, Asteraceae also has the highest number of endemic species. With 489 endemic species, the Asteraceae family has an endemism rate of 36.3% (Güner, 2013). The Asteraceae family is found practically everywhere on the planet. Southwest America, Mexico, southern Brazil, the Mediterranean region, southwest Asia, Central Asia, South Africa, and Australia are among the regions where it is most prevalent (Bremer, 1994).

There are 600 species of the genus *Helichrysum* in the Asteraceae family worldwide, however only 27 taxa—15 of which are endemic—represent this species in Turkey's Flora. (Bayer et al., 2007; Şenol et al., 2011; Davis et al., 1975; Davis et al., 1988; Güner et al., 2000). Additionally, several *Helichrysum* species can be found in Australia, Sri Lanka, southern India, and Southwest Asia (Lourens et al., 2008). Members of the genus *Helichrysum* (Asteraceae) are often dwarf perennial shrubs or aromatic herbs (Van Vuuren et al., 2006) that are grown on sandy or loamy soils at elevations ranging from sea level to 1700 m (Perrini et al., 2009; Mancini et al., 2011; Leonardi et al., 2013).

According to Davis and Kupicha (1975), Helichyrsum pallasii (Spreng.) Ledeb. is found at elevations of 1700–3600 meters on steppe and rocky slopes.

For a variety of biological effects, including antioxidant (Czinner et al., 2001; Tepe et al., 2005), antimicrobial activity (Albayrak et al., 2010), and anti-inflammatory (Sala et al., 2003), the plants are typically used in traditional medicine and are preferred as a herbal tea in Türkiye and other parts of the world.

H.pallasii collected from the Anzer Highland of Rize was investigated regarding its secondary volatile metabolite composition using SPME supported GC-MS device.

MATERIAL AND METHODS

Plant Material and Pre-Analysis Preparation

Helichrysum pallasii was collected from its natural habitat in the Anzer Highland, Rize (Türkiye). (2561m, 40°32'7"N - 40°30'9"E). Aerial parts of Helichrysum pallasii collected at the flowering time were used as plant material (Fig. 1).

Fig. 1: Collecton site of *Helichrysum pallasii* (Anzer/Rize)

Coordinate information of the location where the plants were collected was taken with the Garmin etrex 30x device.

The samples were dried in a fan oven until they reached constant weight (40°C for 3 days). The dried samples were then stored in a cold storage facility (+4°C). After being ground in a grinder, the dried samples were weighed to 0.2 grams for volatile component analysis

GC/MS Analysis

Volatile component analysis was performed using the SPME (Solid Phase Microextraction) method on a Shimadzu GC/MS-OP2020 instrument located in the Plant Analysis Laboratory of the Faculty of Agriculture at Recep Tayyip Erdoğan University. SPME analysis is a convenient method performed with a ground, dry sample without the need for solvents. The method is based on the absorption of essential oils by a fused silica fiber coated with a polymeric stationary phase, followed by desorption of the absorbed substances by heating at the injection port. (Fig. 2).

Fig2: SPME supported GC-MS device

Helium (1 mL/min) was used as the carrier gas in GC-MS analyses performed by electrospray ionization (EI) with the CP 5MS (30 m × 0.25 mm internal diameter, 0.25 µm film thickness). The oven was set to operate at a rate of 2 ℃/min from 40 ◦C to 240 ℃ and then at an isothermal temperature of 220 ℃ for 20 minutes. The temperature of the injector and detector was 240 °C. The compounds were identified by comparing their linear retention indices (LRIs) with a series of n-hydrocarbons and by comparing their retention times with those of pure original samples. The alkane series is C8-C24 or 2.5. Mass spectra were taken at 70 eV, and area normalization was used to calculate the percentage composition. After the compounds were separated on the gas chromatography column, each ion-mass spectrum was recorded, and the compounds were identified using the Shimadzu FFNSC library (Flavor & Fragrance Natural & Synthetic Compounds GC/MS Library).

RESULTS

Using GC-MS device twenty eight distinct components could be identified. Heptadecane (9,79%), Isophytol (9,32%), Phytone (9,31%), Hexadecane (6,82%), Octadecane (5,05%), Myristate ethyl (4,27%), and alpha Himachelene (4,11%) were notable constituents that exhibited significant biological activity (Table 1, Figure 1).

Table 1: Volatile oil constituents detected in *H. pruinatum* collected from the Cimil Highland in Rize

Rank	**Volatile Oil Compound (%)**	
1	Tetradecane	1,37
2	β-Caryophyllene	3,29
3	**α-Himachalene**	**4,11**
4	α-Curcumene	2,39
5	β-Selinene	1,17
6	α-Zingiberene	1,70
7	σ-Cadinene	1,90
8	γ-Cadinene	2,62
9	Tridecylaldehyde	1,87
10	Germacrene B	1,58
11	Tridecyl alcohol	2,00
12	**Hexadecane**	**6,82**
13	γ-Eudesmol	2,40
14	Hedione	3,45
15	(E)-citronellyl tiglate	1,22
16	α-Bisabolol oxide B	2,81
17	Octyl 2-Furan carboxylic acid	3,85
18	**Heptadecane**	**9,79**
19	Methyl Myristate	1,45
20	α-Bisabolone oxide A	3,59
21	Octyl caprylate	2,44
22	Pentadecanol	1,21
23	**Ethyl myristate**	**4,27**
24	**Octadecane**	**5,05**
25	**Phytone**	**9,31**
26	Nonadecane	3,86
27	**Isophytol**	**9,32**
28	Eicosane	1,35
Total	**100%**	

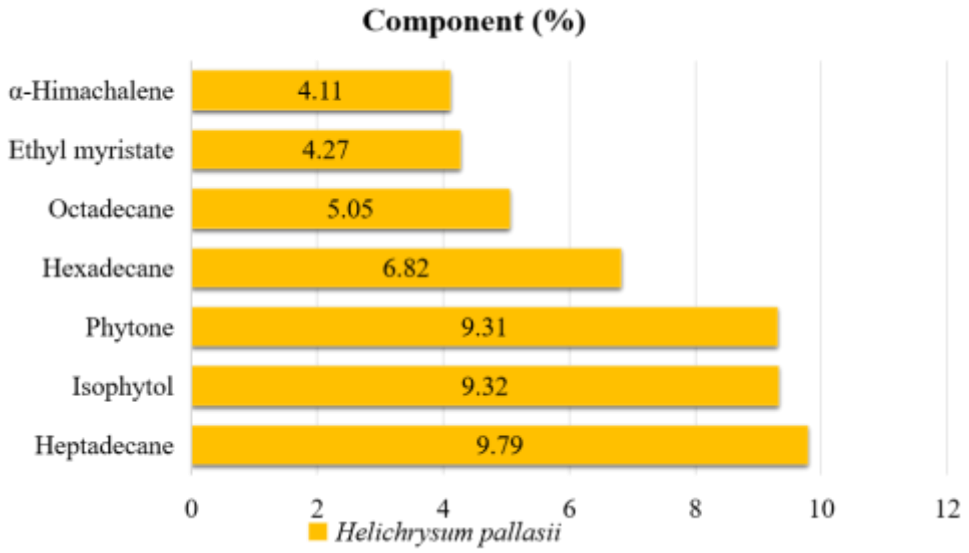

Fig. 3: Volatile oil constituents with high ratios detected *H. pallasii* collected from the Anzer Highland in Rize

Volatile components are displaying important biological activities, which can be seen in Table 2.

Table 2: Biological activities of some selected volatile oil components

Component	**Biological activity**	**References**
Heptadecane	antimicrobial	Bai et al. (2024)
Isophytol	antioxidant, anti-inflammatory, and antimicrobial effects.	Islam et al. (2018)
Phytone	antimicrobial	Lima et al. (2020)
Hexadecane	Antibacterial and antioxidant activity	Yogeswari et al. (2012)
Octadecane	antimicrobial activity	Kayode et al. (2018)
Ethyl Myristate	Antibacterial and antifungal activity	Jumina et al. (2019)
α-Himachelene	Antibacterial activity	Elbouzidi et al. (2025)

DISCUSSION

Yurteri et al. (2021) found α-Springene (34.89%), (-)-Isoledene (7.11%), δ-Selinene (5.79%), Aristolen (5.09%), β-Caryophy (4.76%) and α-Patchoulene (4.74%) as main components in flowers of *H. pallasii*.

Studies about the volatile oil composition of this species seems to be rare.

The yield and composition of volatile oil are influenced by a number of factors, including plant genetics, growth stage, geographic and environmental factors (such as climate, altitude, and soil type), agricultural practices and methods (such as plant density, water availability, and harvesting time), plant part used, extraction technique, and storage conditions (Mugao, 2004).

H.pallasii samples should be collected from different locations to provide more data and further conclusions.

ÖZET

Hypericum L. (Sarı kantaron, Hypericaceae) cinsi, Antarktika hariç dünyanın her kıtasında doğal olarak yetişen 484 tür içermektedir. Bu cinse ait bitkiler farmakolojide oldukça önemlidir. *Hypericum* cinsi, Türkiye florasında yaygın olarak bulunmaktadır. Türkiye, 43'ü endemik olan 89 türüyle Hypericum cinsi için önemli bir merkezdir. Bu cinsin üyeleri farmakolojide oldukça önemlidir; özellikle *Hypericum perforatum* L., bol miktarda bulunan sekonder metabolitleri ve fitokimyasallarının sergilediği biyoaktiviteler nedeniyle kapsamlı bir şekilde incelenmiştir. *H. pruinatum* Boiss. And Bal., Türkiye'nin yüksek rakımlarındaki (1500-2500 m deniz seviyesi) volkanik yamaçlarda ve kayalık çıkıntılarda doğal olarak yetişen çok yıllık otsu bir bitkidir. Bu nadir tür, dağılım alanı Kuzey Türkiye ve Gürcistan ile sınırlıdır. Önceki çalışmalarda, *H. pruinatum*' un iyi belgelenmiş hiperisin, hiperforin, organik asitler ve flavonoid içeriğiyle büyük bir farmasötik potansiyele sahip olduğu bildirilmiştir. *H. pruinatum*' un toprak üstü kısımları Rize'den toplanmıştır. Sekonder uçucu metabolit bileşimi, SPME destekli GC-MS cihazı kullanılarak analiz edilmiştir. Önemli biyolojik aktiviteler gösteren 31 farklı sekonder uçucu yağ bileşeni tespit edilmiştir. En dikkat çekici bileşenler Cadina-1(6),4-dien <10betaH-> (%13,80), delta Cadinene (%11,7), beta Chamigrene (%9,68), beta Selinene (%9,36), gama Cadinene (%11,97), Hendacane (%7,47) ve alfa Copaene (%4,48) olmuştur.

Anahtar kelimeler: GC-MS, kimyasal bileşim, tıbbi bitkiler

RIZE' DEN TOPLANAN *HYPERICUM PRUINATUM*' UN UÇUCU YAĞ KOMPOZISYONU

ABSTRACT

The genus *Hypericum* L. (St. John's wort, Hypericaceae) includes 484 species, naturally occurring on every continent in the world except Antarctica. Herbs belonging to this genus are very important in pharmacology. The Hypericum genus is well represented in the Turkish flora Türkiye is an important center for the genus Hypericum with the presence of 89 species, of which 43 are endemic. Members of this genus are very important in pharmacology; in particular, *Hypericum perforatum* L. has been studied extensively for its abundant secondary metabolites and for the bioactivities exhibited by its phytochemicals. *H. pruinatum* Boiss. And Bal. is a perennial herbaceous plant which grows naturally in igneous slopes and rock ledges at high altitudes (1500–2500 msea level) of Türkiye. This is a rare species, distribution area of which is limited to Northern Türkiye and Georgia. In previous studies, *H. pruinatum* was reported to have great pharmaceutical potential with its well documented contents of hypericin, hyperforin, organic acids, and flavonoids. Aerial parts of *H. pruinatum* was collected from Rize. Its secondary volatile metabolite composition was analyzed using SPME supported GC-MS device. 31 different secondary volatile oil components were detected displaying important biological activities. The most remarkable components were Cadina-1(6),4-diene <10betaH-> (13,80 %), delta Cadinene (11,7 %), beta Chamigrene (9,68 %), beta Selinene (9,36 %), gamma Cadinen (11,97 %), Hendacane (7,47 %) and alpha Copaene (4,48 %).

Key words: GC-MS, chemical composition, medicinal plants

INTRODUCTION

Numerous civilisations were known to have existed in Anatolia, a well-known region in Turkey. Because of these facts, people have settled in this area, contributing to the current richness of culture. Additionally, Turkey has a variety of meteorological and geological conditions that result in a wide diversity of plants. Three plant geographical regions can be found in Turkey: the Mediterranean, Irano-Turanian, and Euro-Siberian. Compared to European nations, their geomorphology, topography, soil diversity, and geological altitude variations range from 0 to 5,000 meters. They have deep valleys, unique ecosystem species, and are less impacted by the ice age (Anonymous 2007).

The medicinal use of *Hypericum* species dates back 2,400 years, and its wound-healing effects, in particular, have been known since the 5th century BC. In the 1st century AD, the famous Greek physicians Galen and Dioscorides identified *H. perforatum* as a diuretic and wound-healing herb and recommended it for the treatment of menstrual disorders (Çırak and Kurt, 2014).

According to Istikoqlou et al. (2010), famous British botanists Gerard (1597) and Withering (1796) reported that Native American Indian tribes were well acquainted with Hypericum species and had used these plants as antipyretics and cough medicines for centuries.

Hypericum species have been used as a healing herb for centuries to relieve pain caused by nervous disorders, menstrual cramps, sciatica, arthritis, and stomach ailments, as well as to treat some skin conditions (Kaçar and Azkan, 2010).

The *Hypericum* L. (Hypericaceae) family is widely distributed and has flourished in a variety of settings across the globe. There are around 484 species in this genus worldwide (Meseguer and Sanmartín, 2012). Türkiye is a major *Hypericum* species gene center. According to the most recent revision, Turkey's flora contains 96 species of Hypericum, 46 of which are endemic (Guner et al., 2012). According to reports, the Aegean and Central Anatolia Region has more endemic species in Eastern and Southeastern Anatolia, whereas the Mediterranean Region has the highest number of endemic Hypericum species (Akgöz, 2013).

Numerous *Hypericum* species have been utilised in traditional medicine throughout the world, including Türkiye (Guclu et al., 2019). Numerous biological characteristics, including antidepressant (Butterweck et al., 2002), antibacterial, antioxidant, antiviral (Dall'Agno etal., 2003), antifungal (Cakir et al., 2005), and anticancer effects (Guclu et al., 2019), have been documented for Hypericum species. Additionally, a number of conditions, including bedwetting (Baytop, 1999), eczema (Tahir et al., 2017), Alzheimer's disease, haemorrhoids (Baytop, 1999), digestive problems (Kültür, 2007) gastric disorders, cardiovascular diseases (Kültür, 2007), wound healing (Öztürk et al., 2007), and burns (Baytop, 1999).

H. pruinatum collected from the Anzer Cimil Highland of Rize was investigated regarding its volatile oil composition using SPME supported GC-MS device.

MATERIAL AND METHODS

Plant Material and Pre-Analysis Preparation

H. pruinatum sample was collected from İkizdere-Cimil Highland (1995m, 40°44'3"N-40°46'37"E (Fig. 1)

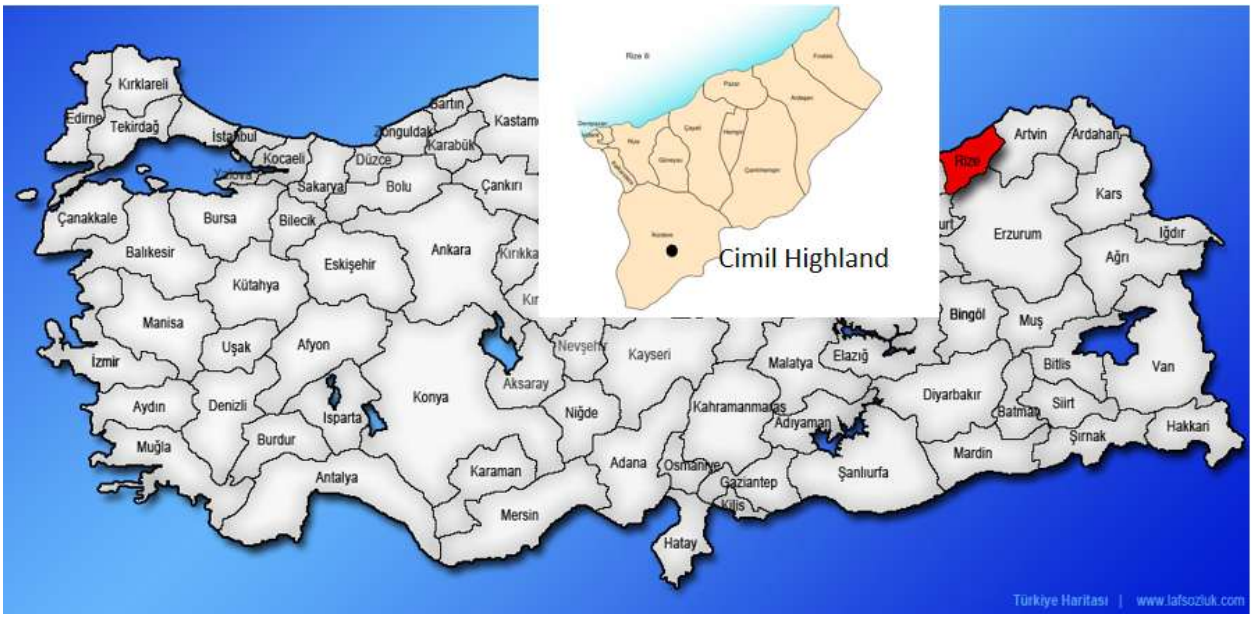

Fig. 1: Collecton site of *Hypericum pruinatum* (Cimil/Rize)

Coordinate information of the location where the plants were collected was taken with the Garmin etrex 30x device.

The samples were dried in a fan oven until they reached constant weight (40°C for 3 days). The dried samples were then stored in a cold storage facility (+4°C). After being ground in a grinder, the dried samples were weighed to 0.2 grams for volatile component analysis.

GC/MS Analysis

Volatile component analysis was performed using the SPME (Solid Phase Microextraction) method on a Shimadzu GC/MS-OP2020 instrument located in the Plant Analysis Laboratory of the Faculty of Agriculture at Recep Tayyip Erdoğan University. SPME analysis is a convenient method performed with a ground, dry sample without the need for solvents. The method is based on the absorption of essential oils by a fused silica fiber coated with a polymeric stationary phase, followed by desorption of the absorbed substances by heating at the injection port. (Fig. 2).

Fig2: SPME supported GC-MS device

Helium (1 mL/min) was used as the carrier gas in GC-MS analyses performed by electrospray ionization (EI) with the CP 5MS (30 m × 0.25 mm internal diameter, 0.25 µm film thickness). The oven was set to operate at a rate of 2 ℃/min from 40 ◦C to 240 ℃ and then at an isothermal temperature of 220 ℃ for 20 minutes. The temperature of the injector and detector was 240 °C. The compounds were identified by comparing their linear retention indices (LRIs) with a series of n-hydrocarbons and by comparing their retention times with those of pure original samples. The alkane series is C8-C24 or 2.5. Mass spectra were taken at 70 eV, and area normalization was used to calculate the percentage composition. After the compounds were separated on the gas chromatography column, each ion-mass spectrum was recorded, and the compounds were identified using the Shimadzu FFNSC library (Flavor & Fragrance Natural & Synthetic Compounds GC/MS Library).

RESULTS

Volatile oil constituents detected in *H. pruinatum* collected from the CimilHighland in Rize is shown in Table 1 and Fig . 1. Totally 31 volatile oil components could be detected using GC-MS analysis.

Table 1: Volatile oil constituents detected in *H. pruinatum* collected from the Cimil Highland in Rize

Rank	**Volatile Oil Compound (%)**	
1	**Hendecane**	**7.47**
2	Tridecane	2.76
3	alfa Cubebene	1.06
4	**alfa Copaene**	**4.48**
5	beta Elemene	0.80
6	Tetradecane	0.60
7	alfa Gurjunene	2.74
8	beta Cedrene	2.59
9	Aromadendrene	1.,4
10	alfa Patchoulene	0.50
11	alfa Humulene	1.00
12	Alloaromadendrene	2.99
13	**10-β(H)-Cadina-1(6),4-diene**	**13.80**
14	alfa Amorphene	1.32
15	**beta Selinene**	**9.36**
16	**beta Chamigrene**	**9.68**
17	**delta Cadinene**	**8.74**
18	**Gamma Cadinene**	**11.97**
19	Caryophyllene oxide	0.66
20	Hexadecane	1.89
21	Viridiflorol	0.64
22	alfa Acorenol	0.58
23	Epi alfa Muurolol	1.21
24	delta Eudesmol	1.95
25	alfa Bisabolol	2.03
26	Heptadecane	2.52
27	Octadecane	0.80
28	Phytone	0.56
29	Nonadecane	2.06
30	Heneicosane	1,42
31	Tetracosane	0.79
	Total	100%

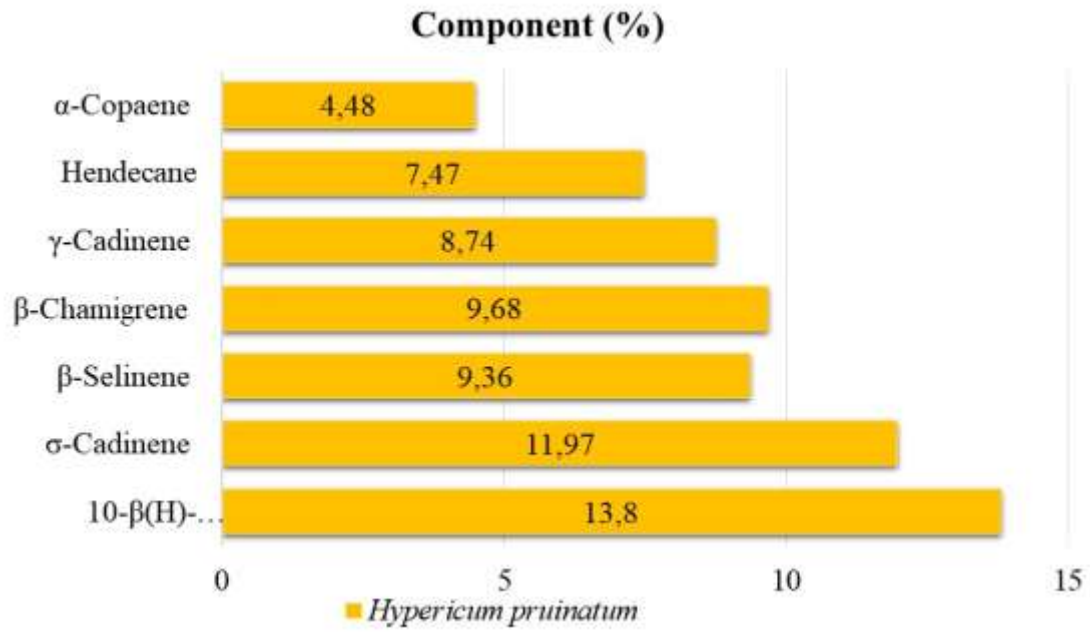

Fig. 3: Volatile oil constituents with high ratios detected *H. pruinatum* collected from the Cimil Highland in Rize

31 different secondary volatile oil components were detected displaying important biological activities. The most remarkable components were Cadina-1(6),4-diene <10betaH-> (13,80 %), delta Cadinene (11,97 %), beta Chamigrene (9,68 %), beta Selinene (9,36 %), gamma Cadinene (8,74 %), Hendacane (7,47 %) and alpha Copaene (4,48 %).

Biological activities are displaying important biological activities, which can be seen in Table 2.

Table 2: Biological activities of some selected volatile oil components

Cadina-1(6),4-diene <10betaH-	antimicrobial activity	Kačániová et al. (2022)
δ-Cadinene	Antibacterial, antimicrobial and antioxidant activity	Kačániová et al. (2022)
β-Chamigrene	antibacterial activities and cytotoxic activities	Dias et al. (2005)
β-Selinene	Antibacterial activity	Keawsa-arda et al. (2012)
γ-Cadinene	Antioxidant activity	Kundu et al. (2013)
Hendecane	Anti-Allergic and Anti-Inflammatory Activity	Choi et al. (2020)
α-Copaene	antioxidant and antigenotoxic activity	Turkez et al. (2014)

DISCUSSION

In the literature, Cirak & Bertoli (2013) detected β-selinene (15%), caryophyllene oxide (9%), β-caryophyllene (8%), and γ-muurolene (7%) in *H. pruinatum* volatile oil.

Akdeniz et al. (2023) published Germacrene D (22.47%), α-cadinol (12.73%), and δ-cadinene (9.59%) for *H. pruinatum.*

Factors affecting volatile oil yield and composition include plant genetics, growth stage, geographical and environmental conditions (like climate, altitude, and soil type), agricultural methods and practices (plant density, water availability, and harvesting time), plant part used, extraction method, and storage condition (Mugao, 2004).

To provide more data, *H. pruinatum* samples should be collected from different locations.

ÖZET

Bu çalışmada, full bridge evirici devresinin giriş hattında oluşan ripple değerleri incelenmiş ve bu dalgalanmaların elektrolitik ve film kapasitörler yardımıyla nasıl azaltılabileceği gösterilmiştir. Ripple, eviricinin giriş DC hattında istenmeyen dalgalanmalara sebep olmakta ve sistem performansını olumsuz etkilemektedir. Deneysel olarak gerçekleştirilen ölçümlerde, yalnızca elektrolitik kapasitör kullanıldığında yüksek genlikli giriş dalgalanmaları gözlenirken, uygun değerlerde elektrolitik ve film kapasitör birlikte kullanıldığında ripple seviyesinin önemli ölçüde azaldığı tespit edilmiştir. Elde edilen sonuçlar, evirici tasarımlarında DC link kapasitörlerinin kritik bir rol oynadığını ve doğru kapasitör seçiminin sistem güvenilirliğini, verimini ve elektromanyetik uyumluluğunu artırdığını ortaya koymaktadır.

REDUCTION OF INPUT RIPPLE BEHAVIOR IN FULL BRIDGE INVERTERS BY USING CAPACITORS

ABSTRACT

In this study, the input ripple behavior of a full-bridge inverter circuit is investigated, and the effectiveness of electrolytic and film capacitors in reducing these ripples is demonstrated. Input ripples on the DC link not only decrease system efficiency but also increase thermal stress, electromagnetic interference (EMI), and total harmonic distortion (THD). Experimental measurements show that while large electrolytic capacitors are effective in suppressing low-frequency ripple, adding film capacitors significantly reduces high-frequency oscillations observed on the MOSFET drain–source voltage waveforms. The results highlight that the combined use of electrolytic and film capacitors improves the reliability, efficiency, and electromagnetic compatibility of inverter systems.

Keywords: Full Bridge Inverter, Input Ripple, Electrolytic Capacitor, Film Capacitor, DC Link, Power Electronics

1. Giriş

Güç elektroniğinde eviriciler (invertörler), doğru akımı (Direct Current) alternatif akıma (Alternating Current) dönüştüren birimlerdir. Çıkış gerilimi, uygulama yerine göre değişiklik gösterebilir. Türkiye'de şebekelerde 220 V, 50 Hz. AC çıkış kullanılırken, askeri standartlarda 115 V ve 400 Hz. AC çıkış tercih edilmektedir. Çok çeşitli evirici topolojileri mevcuttur. Ancak askeri uygulamalarda sağlamlık, az komponent kullanımı ve basitlik nedeniyle tam köprü (full bridge) evirici topolojisi sıkça tercih edilmektedir. Aynı zamanda bu topoloji hem endüstriyel hem de evsel uygulamalarda yaygın olarak kullanılmaktadır [6], [1].

Eviricilerin güvenilir çalışması, yalnızca anahtarlama devresinin tasarımına, yazılım tasarımına veya sistem mimarisine bağlı değildir. Giriş DC hattının kalitesine de doğrudan bağlıdır. Evirici girişinde oluşan dalgalanmalar (ripple), sistemin verimliliğini ve ömrünü etkileyen kritik parametrelerden biridir. Yüksek genlikli ripple; yarı iletken elemanlarda ek ısınmaya, elektromanyetik girişim (EMI) seviyelerinin artmasına ve çıkış AC dalga formunda bozulmaya sebep olarak toplam harmonik bozulmayı (THD) yükseltebilir. Bu nedenle, giriş ripple'ının azaltılması yalnızca performans açısından değil, aynı zamanda güvenilirlik ve standartlara uyumluluk açısından da önemlidir [2], [4], [5].

Bu çalışmada, elektrolitik kapasitörlerin yanı sıra film kapasitörlerin evirici girişinde ripple azaltmadaki etkisi incelenmiştir. Osiloskop ölçümleri ile desteklenen deneysel sonuçlar, uygun kapasitör seçiminin giriş gerilimi üzerindeki dalgalanmaları önemli ölçüde düşürdüğünü göstermektedir. Böylece eviricinin daha kararlı çalıştığı ve sistemin uzun vadeli dayanıklılığının arttığı ortaya konmuştur [3].

2. Teorik Arka Plan

2.1. Kapasitör Tiplerinin Evirici Giriş Ripple'ına Etkisi

Evirici DC girişinde kullanılan kapasitörlerin türü, sistemin dinamik performansını doğrudan belirler. Pratikte üç farklı kapasitör tipi yaygın olarak kullanılmaktadır: elektrolitik, film ve seramik kapasitörler. Bu kapasitörlerin her biri farklı frekans aralıklarında bastırma etkisine sahiptir ve bu nedenle tamamlayıcı şekilde kullanıldığında sistem performansı önemli ölçüde artar [2], [8], [10].

Elektrolitik kapasitörler, yüksek kapasite değerleri sayesinde düşük frekanslı dalgalanmaları bastırmada etkilidir. Ancak yüksek ESR ve ESL değerlerine sahip olduklarından, anahtarlama sırasında oluşan yüksek frekanslı geçici rejimlerde yeterince hızlı tepki veremezler. Bu durum, drain–source dalga formlarında gözlenen ani tepe gerilimlerinin (overshoot) ve ring davranışlarının temel sebeplerinden biridir [2], [6], [7], [8], [9].

Film kapasitörler düşük ESR ve düşük ESL özellikleri sayesinde yüksek frekanslı akım bileşenlerini çok daha etkin şekilde süzer.Elektrolitik kapasitörlere paralel bağlandıklarında DC baranın empedansı geniş bir frekans bandında düşmektedir. Böylece hem düşük frekans hem de yüksek frekans bileşenleri aynı anda bastırılabilir. Deneysel sonuçlarda film kapasitör eklenmesiyle tepe drain–source gerilimlerinin azalması doğrudan bu etkiye işaret etmektedir. Seramik kapasitörler, özellikle sınıf I dielektrik yapıda olanlar (C0G, NP0) çok düşük ESL ve ESR sunarak birkaç MHz'e kadar olan frekanslarda etkin filtreleme sağlar. Ancak kapasiteleri küçük olduğu için tek başlarına kullanılamaz, film kapasitörlerle birlikte tamamlayıcı rol oynarlar [2], [6], [8], [9], [10].

Bu nedenle modern evirici tasarımlarında DC link genellikle çok seviyeli bir kapasitör bankasından oluşturulur [2], [10]:

Yüksek kapasite → elektrolitik

Orta frekans → film

Çok yüksek frekans → seramik

Bu yaklaşım, güç elektroniği literatüründe "çok katmanlı kapasitör yaklaşımı (multi-layer capacitor strategy)" olarak anılmakta ve özellikle geniş bant aralıklı yarı iletkenlerin (SiC / GaN) kullanıldığı uygulamalarda zorunlu hale gelmektedir [2], [8].

2.2. Ripple Teorisi

Güç elektroniği devrelerinde ripple, doğru akım (DC) hatlarında görülen istenmeyen dalgalanmalardır. Bu dalgalanmalar; eviricinin yüksek frekansta anahtarlama yapması, yük değişimleri ve enerji depolama elemanlarının sınırlı kapasitesi nedeniyle oluşur. Evirici, yapısı gereği dinamik bir yük gibi davrandığından, besleme kaynaklarının bu yapıya uygun tasarlanması gerekir.

Ripple genliği temel olarak kapasitör değerine, yük akımına ve anahtarlama frekansına bağlıdır. Matematiksel olarak:

$$(1)\ \Delta V = \frac{I_{ripple}}{C * f}$$

- ΔV: Kapasitör uçlarında oluşan dalgalanma gerilimi (V)
- I_{ripple}: Ripple akımı (A)
- C: Kullanılan kondansatör kapasitesi (F)
- f: Anahtarlama frekansı veya ilgili harmonik frekans (Hz)

Formülden görüldüğü üzere, kapasitör değeri arttıkça dalgalanma gerilimi azalır. Bu yüzden inverter DC girişinde genellikle yüksek değerli elektrolitik kondansatörler tercih edilir. Elektrolitik kondansatörler büyük kapasite değerleri sunarak düşük frekanstaki dalgalanmaları etkin şekilde bastırır.

Bununla birlikte, yalnızca kapasite değeri değil, kondansatörün ESR (Equivalent Series Resistance) değeri de ripple üzerinde belirleyici bir parametredir. Düşük ESR değerine sahip kapasitörler daha düşük ısı üretir ve ripple'ı daha etkin azaltır. Ripple akımı kapasitör üzerinden geçtiğinde, ESR nedeniyle ek bir gerilim düşümü oluşur:

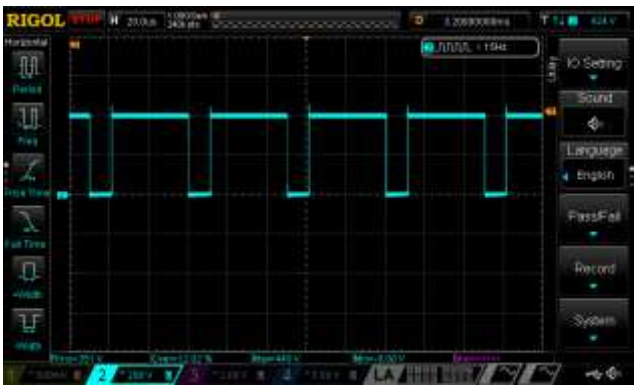
$$(2)\ V_{ESR} = I_{ripple} * ESR$$

Dolayısıyla toplam ripple gerilimi şu şekilde ifade edilebilir:

$$(3)\ \Delta V_{total} = \frac{I_{ripple}}{C * f} + I_{ripple} * ESR$$

Bu nedenle kapasitör seçimi yapılırken yalnızca kapasite büyüklüğüne değil, aynı zamanda ESR değerine ve ömür parametrelerine de dikkat edilmelidir. Bu özellikleri sayesinde film kapasitörler sıklıkla tercih edilmektedir.

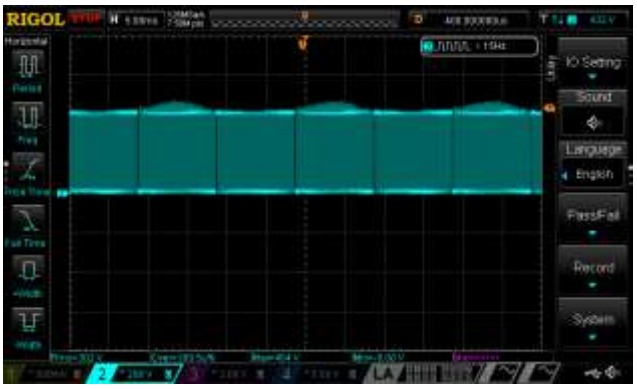
3. Deneysel Çalışmalar



Bu çalışmada, evirici girişindeki ripple davranışı doğrudan DC linkten ölçülmek yerine, MOSFET drain–source uçlarında gözlemlenmiştir. Bu dalga formları, DC baradaki dalgalanmaların ve parazitik endüktansların etkilerini daha net göstermektedir.

Deney düzeneğinde 400 µF toplam elektrolitik kapasite (8×39 µF + 2×47 µF) kullanılmış, ESR değerini düşürmek için kapasitörler paralel bağlanmıştır. Buna ek olarak 2 adet 10 µF film kapasitör eklenmiştir. Anahtarlama frekansı 20 kHz olarak seçilmiştir. Ölçümler 100:1 passive prob ile MOSFET'in VDS uçlarında yapılmıştır.

Farklı değerlerde film kapasitör eklenerek MOSFET drain–source dalga formları incelenmiş ve sonuçlar Tablo 3'de verilmiştir.



Şekil 1 (a)

Şekil 1 (b)

Şekil 8. 2kW MOSFET drain–source dalga formları 0x film kapasitesi: (a) Time/Div: 5 ms, (b) Time/Div: 20 µs

Drain Source değeri maksimum 464 Vdc değerine çıkmaktadır. Sistemin daha stabil çalışması için ESR değerinin daha da düşmesi için yüksek frekansları daha iyi bastırmak için anahtarlama elemanlarının bacaklarına yakın film kapasitörler eklenerek deneyler gerçekleştirilmiştir. Deneylere ait osiloskop görüntüleri ve elde edilen sonuçlar aşağıda sunulmaktadır.

DC bara değeri	Film kapasitör değeri	Ölçülen Drain-Source Gerilimi
400 µF Elektrolit + 20 µF Film	0 µF	464 Vdc
400 µF Elektrolit + 20 µF Film	1 nF x 2	464 Vdc
400 µF Elektrolit + 20 µF Film	15 nF x 2	440 Vdc
400 µF Elektrolit + 20 µF Film	330 nF x 2	432 Vdc
400 µF Elektrolit + 20 µF Film	4.7 µF x 2	424 Vdc

4. Sonuçlar ve Tartışma

Bu çalışmada, tam köprü evirici devresinde giriş ripple davranışı MOSFET drain–source uçlarındaki dalga formları üzerinden incelenmiştir. Ölçümler, girişte kapasitör bulunmadığında drain–source geriliminde yüksek genlikli zıplamalar ve belirgin ring davranışı oluştuğunu göstermiştir. Bu durum, DC link enerjisinin ani akım değişimlerini karşılamakta yetersiz kaldığını ve parazitik endüktansların baskın hale geldiğini ortaya koymaktadır.

Elektrolitik kapasitörlere paralel bağlanan film kapasitörler, düşük ESR ve düşük ESL özellikleri sayesinde yüksek frekanslı salınımları etkin biçimde bastırmıştır. Bu sayede drain–source dalga formunda daha düşük tepe değerler elde edilmiş, hızlı sönümlenen ring davranışı gözlenmiştir.

Sonuçlar, evirici tasarımında elektrolitik ve film kapasitörlerin birlikte kullanımının hem düşük frekanslı giriş ripple'ını hem de yüksek frekanslı zıplamaları bastırmak açısından kritik önem taşıdığını göstermektedir. Bu yaklaşım, sistem güvenilirliğini artırmakta, yarı iletkenlerin ömrünü uzatmakta ve elektromanyetik uyumluluğu geliştirmektedir.

ABSTRACT

Polymer electrolyte fuel cells (PEFCs) have gained considerable attention owing to their high efficiency, fast start-up capability, and low-temperature operation. Their ability to generate electricity cleanly, with water as the only byproduct, makes them strong candidates for transportation, stationary power, and portable energy applications. The large-scale deployment of PEFCs, however, depends strongly on the performance and durability of their components, particularly the polymer electrolyte membrane (PEM). Perfluorosulfonic acid (PFSA) membranes such as Nafion® remain the benchmark due to their high proton conductivity and acceptable stability, yet their high cost, limited high-temperature robustness, and classification as persistent PFAS chemicals motivate the development of more sustainable alternatives. Nanocellulose-based sandwich-type membranes have recently been proposed as a promising solution, as the introduction of gas-barrier interlayers can suppress radical formation by reducing reactant crossover, thereby enhancing membrane durability. Membrane diffusivity plays a critical role in PEFC operation because it governs water transport, directly influencing membrane hydration, proton conductivity, and overall performance; insufficient diffusivity can cause dehydration or flooding, leading to substantial ohmic and mass-transport losses. In this study, the effective diffusivity of nanocellulose-based sandwich-type membranes with varying interlayer thicknesses is predicted using experimentally measured hydrogen crossover current densities within a resistances-in-series framework. Understanding and accurately predicting these diffusivity values provides a foundation for rational membrane design, enabling the development of next-generation PEMs with improved water management, durability, and fuel cell performance.

Keywords*:* Polymer electrolyte fuel cells; Effective diffusivity; Nanocellulose; Sandwich-type membranes; Hydrogen crossover; Membrane durability

Introduction

The global energy landscape is undergoing a rapid transition toward cleaner and more sustainable technologies as nations work to mitigate climate change and reduce greenhouse gas emissions. In this context, hydrogen has emerged as a promising energy carrier because it can be produced from renewable resources and used without generating carbon emissions at the point of use [1]. Its versatility (being usable in gaseous, liquid, or solid forms) makes hydrogen suitable for a wide range of applications, including transportation, industrial processes, and stationary power generation [2]. Among these applications, fuel cell electric vehicles (FCEVs) are expected to play a central role in achieving net-zero targets in the automotive sector [3].

Proton exchange membrane fuel cells (PEFCs) are one of the most commercially advanced fuel cell technologies. A typical PEFC assembly consists of bipolar plates, gas diffusion layers (GDLs), catalyst layers, and a polymer electrolyte membrane (PEM). Nafion, a perfluorosulfonic acid (PFSA) ionomer, has long been the benchmark PEM material due to its high proton conductivity, mechanical robustness, and chemical stability [4]. Despite these advantages, membrane durability remains a major barrier for long-term PEFC operation. Reactive oxygen species (ROS), particularly hydroxyl (HO·) and hydroperoxyl (HOO·) radicals generated from hydrogen peroxide in the presence of divalent metal ions, can attack and degrade the PFSA backbone, leading to thinning, pinhole formation, and ultimately membrane failure.

To address these challenges, numerous strategies have been investigated to enhance membrane resistance to chemical degradation [5] [6] [7]. These include the development of hydrocarbon-based ionomers with inherently higher oxidative stability and the incorporation of reinforcing fillers. Nanocellulose has recently attracted significant attention as a sustainable reinforcement material due to its abundance, biodegradability, low cost, and excellent mechanical properties. It has been widely used as an additive in PEMs, typically at low loadings [8].

A recent study by Yang et al. [9] introduced a new membrane design in which a nanocellulose (NC)-poly(vinyl sulfonic acid) (PVS) blend layer is sandwiched between two Nafion films to serve as an internal gas barrier (Fig. 1). This structure was shown to significantly mitigate hydrogen crossover and enhance chemical durability, demonstrating the potential of sandwich-type membranes for long-lasting PEFC operation. However, the performance of such membranes is strongly dependent on the thickness of the interlayer, and the previous work considered only a single thickness. Numerical optimization therefore requires knowledge of how the gas barrier layer thickness influences hydrogen crossover.

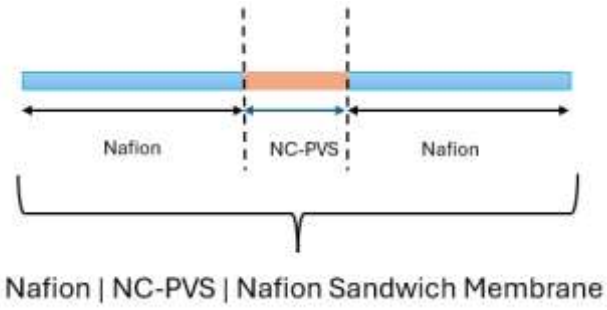

Fig. 1 Schematic representation of nanocellulose-based sandwich-type membrane.

Hydrogen crossover is governed largely by the effective diffusivity of hydrogen through the ionomer and any intermediate layers. Yet, no literature data exist for the effective diffusivity of hydrogen in nanocellulose-based sandwich-type membranes. To address this gap, the present

study proposes an approach to estimate the effective diffusivity of hydrogen in these layered membranes. The method first evaluates the effective diffusivity of hydrogen in pure Nafion and in NC-PVS membranes using available experimental data. These values are then used to estimate the effective diffusivity for multilayer sandwich configurations with varying interlayer thicknesses.

The results provide essential insights for future design and optimization of nanocellulose-based sandwich-type membranes. Ultimately, establishing a reliable approach to predict effective diffusivity will support performance-driven thickness optimization and guide the development of durable PEMs for next-generation PEFCs.

Methodology

Hydrogen crossover current density (I_{cross}) depends on the effective diffusivity of hydrogen in the ionomer ($D_{H_2}^{\text{eff}}$) and the total membrane thickness (t_{total}). It can be calculated using the following expression:

$$I_{cross} = \frac{nF\, D_{H_2}^{eff} \Delta p_{H_2}}{RT t_{total}} \tag{1}$$

where n is the number of electrons involved in hydrogen oxidation, F is Faraday's constant (96,485 C/mol), R is the universal gas constant (8.314 $J/(mol.K)$), T is the operating temperature of the fuel cell (80 ℃) and Δp_{H_2} is the hydrogen partial pressure gradient between the anode and cathode.

For a multilayer membrane, the total diffusive resistance in the through-plane direction is the sum of the individual resistances of each layer. Thus, the total diffusive resistance of the nanocellulose-based sandwich-type membrane can be written as [10]:

$$\frac{t_{total}}{D_{H_2}^{eff}} = \frac{t_{NC-PVS}}{D_{NC-PVS}} + \frac{t_{total} - t_{NC-PVS}}{D_{Nafion}} \tag{2}$$

where t_{NC-PVS} is the thickness of NC-PVS interlayer, D_{NC-PVS} is the hydrogen diffusivity in the NC-PVS interlayer and D_{Nafion} is the hydrogen diffusivity in the Nafion layers. Rearranging Eq. (2) yields an explicit expression for the effective hydrogen diffusivity of the sandwich-type membrane:

$$D_{H_2}^{eff} = \frac{t_{total}}{\frac{t_{NC-PVS}}{D_{NC-PVS}} + \frac{t_{total} - t_{NC-PVS}}{D_{Nafion}}} \tag{3}$$

Hydrogen diffusivity in polymer electrolytes depends on temperature, pressure, and relative humidity. Therefore, accurate estimation of $D_{H_2}^{\text{eff}}$ under the relevant operating conditions is essential for predicting hydrogen crossover current density. The approach outlined above provides a means to estimate the effective hydrogen diffusivity of nanocellulose-based sandwich-type membranes and, consequently, to evaluate their impact on PEFC performance.

Results and Discussion

In the experimental study given in Ref [9], the average hydrogen crossover current densities for pure Nafion and the NC–PVS sandwich membrane (with an NC–PVS ratio of 10:1 in the interlayer) were measured as 3.5 and 2.7 mA/cm², respectively. Using Eq. (1), the effective diffusivity of hydrogen in Nafion was calculated to be 4.8×10^{-10} m^2/s, which is consistent with values reported in the literature [11]. Under the same operating conditions (80 °C and 95%

relative humidity), the effective diffusivity of hydrogen in the NC–PVS-based sandwich membrane was determined to be 2×10^{-10} m^2/s.

Fig. 2 illustrates the variation of effective hydrogen diffusivity as a function of total membrane thickness for several NC-PVS interlayer thicknesses (0.1, 0.5, 2, and 4 µm). In all cases, the effective diffusivity increases with total membrane thickness due to the larger contribution of the outer Nafion layers, which exhibit higher hydrogen diffusivity than the NC-PVS interlayer.

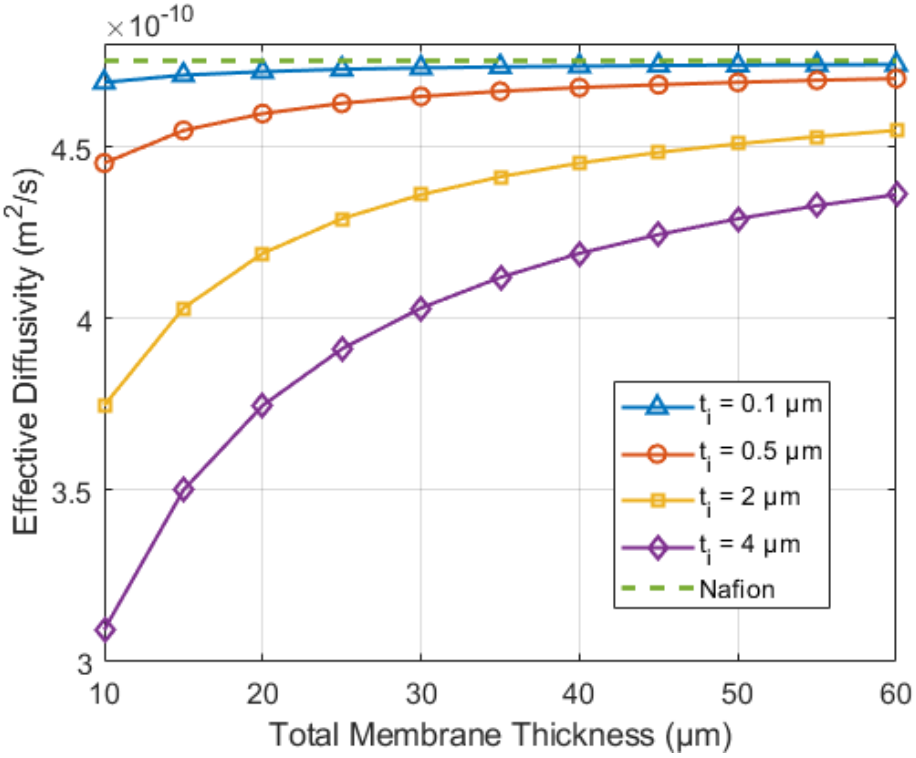

Fig. 2 Effective diffusivity of hydrogen vs total membrane thickness at different NC-PVS interlayer thicknesses.

For the 0.1 µm interlayer, the calculated effective diffusivity remains close to the Nafion benchmark because the NC–PVS layer represents only a small fraction of the overall resistance. The diffusivity slightly increases with increasing total thickness. This corresponds to only almost 1.1% deviation from the Nafion value across the entire thickness range, indicating that very thin NC–PVS layers minimally influence hydrogen crossover.

Increasing the interlayer thickness to 0.5 µm results in a more noticeable reduction in diffusivity, particularly for thinner membranes. At 10 µm, the effective diffusivity decreases to 4.5×10^{-10} m²/s, representing an approximately 7% reduction relative to Nafion. However, as membrane thickness increases, the influence of the interlayer diminishes. At 60 µm, the diffusivity reaches 4.7×10^{-10} m²/s, approaching the Nafion benchmark.

A much stronger effect is observed for 2 µm interlayer thickness. At 10 µm, the effective diffusivity drops to 3.7×10^{-10} m²/s, corresponding to an about 22% reduction compared to Nafion. As the membrane becomes thicker, diffusivity gradually increases, reaching 4.5×10^{-10} m²/s at 60 µm. Although the trend is similar to thinner interlayers, the diffusivity remains substantially below the Nafion value across the full thickness range.

The impact is most pronounced for the 4 µm interlayer, where the NC–PVS layer accounts for a large portion of the total membrane thickness. The effective diffusivity is reduced to

3.1×10^{-10}m²/s at 10 µm (approximately 36% lower than Nafion) indicating a strong gas-barrier effect. Even at 60 µm, the diffusivity reaches only 4.4×10^{-10}m²/s, still approximately 9% below Nafion. This demonstrates that increasing interlayer thickness effectively suppresses hydrogen permeation.

Conclusions

This study proposes an approach to predict the effective diffusivity of hydrogen in nanocellulose-based sandwich-type membranes. These findings highlight an important design trade-off. In the literature, reducing membrane thickness is a common strategy for mitigating ohmic losses and improving fuel cell performance. However, thin membranes are significantly more sensitive to the presence of an NC–PVS barrier layer. This reduction directly translates to lower hydrogen crossover current density, enhancing chemical durability. At larger total thicknesses, the differences between interlayer cases become smaller, suggesting that performance benefits from a gas-barrier layer are more impactful in ultra-thin membranes. Future work will focus on predicting PEFC performance with these membranes and optimizing interlayer thickness using a one-dimensional mathematical model.

ÖZET

Pes planus, ayak kavsinin normalden düşük ya da tamamen düz olmasıyla karakterize edilen bir ayak deformitesidir ve tedavi edilmediğinde ağrıya ve yürüme bozukluklarına neden olabilir. Bu çalışmada, pes planus (düz tabanlık) tespitine yönelik ayak taban görüntülerinin derin öğrenme tabanlı yöntemler ve meta-sezgisel optimizasyon algoritmaları ile otomatik olarak sınıflandırılması amaçlanmıştır. Çalışmada kullanılan veri seti, 137 normal ve 421 pes planus olmak üzere toplam 558 ayak taban görüntüsünden oluşmaktadır. İlk aşamada, MobileNetV2 tabanlı, transfer öğrenme yaklaşımı kullanan bir evrişimsel sinir ağı (CNN) model olarak tasarlanmış ve standart hiperparametrelerle eğitilmiştir. Bu temel model için test doğruluğu 0.8359 olarak elde edilmiştir. İkinci aşamada, CNN mimarisine ait temel hiperparametreler (öğrenme oranı, dropout oranı, taban modelinin eğitilebilir katman oranı, veri artırma şiddeti vb.) meta-sezgisel yöntemler olan genetik algoritma (GA), gri kurt optimizasyonu (GWO) ve parçacık sürü optimizasyonu (PSO) ile optimize edilmiştir. Optimizasyon sürecinde, her hiperparametre kümesi için model eğitilmiş doğruluk değeri hesaplanmıştır. Elde edilen sonuçlar, GA ve GWO'ya kıyasla en yüksek performansın PSO ile optimize edilen CNN yapısında elde edildiğini ve test doğruluğunun 0.8984' e yükseldiğini göstermiştir. Sonuç olarak, meta-sezgisel yöntemlerle hiperparametre optimizasyonunun, pes planus gibi klinik açıdan önemli ayak deformitelerinin otomatik tespitinde CNN tabanlı sistemlerin başarımını artırdığı; özellikle PSO yaklaşımının tıbbi görüntü sınıflandırma problemlerinde etkili ve umut vadeden bir optimizasyon aracı olduğu ortaya konmuştur.

PES PLANUS TANISINDA CNN HİPERPARAMETRELERİNİN META-SEZGİSEL YÖNTEMLERLE OPTİMİZASYONU

ABSTRACT

Pes planus is a podiatric condition characterized by a reduced or absent foot arch. If left untreated, this condition can result in discomfort and walking impairments. The objective of this study is to develop a system that can automatically classify foot arch images for the purpose of identifying pes planus, or flat feet. This will be achieved by employing deep learning-based methods and meta-heuristic optimization algorithms. The dataset utilized in the present study encompasses a total of 558 foot sole images, comprising 137 images of normal feet and 421 images of pes planus feet. In the initial phase, a convolutional neural network (CNN) model was developed and trained using standard hyperparameters. This model was based on MobileNetV2 and utilized a transfer learning approach. The test accuracy for this baseline model was obtained as 0.8359. In the subsequent phase, the fundamental hyperparameters of the CNN architecture (learning rate, dropout rate, the proportion of trainable layers in the base model, intensity of data augmentation, etc.) were optimized through the utilization of meta-heuristic methodologies, namely genetic algorithm (GA), grey wolf optimization (GWO), and particle swarm optimization (PSO). During the process of optimization, the model training accuracy value was calculated for each hyperparameter set. The findings demonstrated that the CNN structure optimized using PSO yielded the highest performance, surpassing GA and GWO, and the test accuracy increased to 0.8984. In conclusion, meta-intuitive methods for hyperparameter optimization have been shown to improve the performance of CNN-based systems in the automatic detection of clinically significant foot deformities such as pes planus. Specifically, the PSO approach has been demonstrated to be an effective and promising optimization tool for medical image classification problems.

1-INTRODUCTION

The human foot is considered to be one of the most complex anatomical structures in the body, performing a vital function in the proper functioning of the lower limbs. This structure is capable of adapting to different surfaces and can support the entire body weight by providing the flexibility and support necessary for the person to stand and move (walk) [1]. Pes planus, or flat feet, is a deformity that frequently occurs in this complex structure. It is characterized by the collapse of the medial longitudinal arch, the outward rotation of the heel, and the prominence of the bony protrusion on the inner side of the ankle bone. The collapse of the medial longitudinal arch has the potential to induce alterations in the structure of the lower limbs, which can result in the manifestation of pain, various injuries, and an increased risk of limited movement. A range of studies have demonstrated that the prevalence of pes planus varies between 10.27% and 17.1%. It has been observed in the extant literature that there are notable variations in the prevalence of foot disorders among different racial and ethnic groups, which are associated with variations in foot structure. While some studies have found that the condition resolves spontaneously within the first ten years of life, other research indicates that it becomes permanent with advancing age. For instance, the prevalence of pes planus in individuals aged 18 to 25 was reported to be 29%, and it was observed that this condition did not disappear with age. In light of these findings, early foot examinations are of paramount importance in order to prevent the condition from becoming a problem for individuals in later years [2].

The posterior tibial tendon performs the function of a powerful internal rotator of the foot and plays a critical role in both maintaining the medial longitudinal arch of the foot and counteracting posterior foot reversion deformity. [3]. Consequently, any dysfunction in the tendon may result in the development of pes planus. For these reasons, early diagnosis is important to prevent the progression of pes planus in individuals. Radiography is currently the preferred primary imaging modality for diagnosing pes planus. This method facilitates the use of various radiographic measurements for the purpose of determining the severity of the deformity. However, the extent to which these different radiological parameters are associated with specific damage to the posterior tibial tendon (PTT) and the supporting structures of the medial longitudinal arch of the foot has not yet been fully determined [4]. At present, the diagnosis of tendon dysfunction and associated secondary supporting structure injuries is largely based on magnetic resonance imaging (MRI) [5].

Deep learning, a branch of machine learning and artificial intelligence, has precipitated substantial advancements in the healthcare sector, most notably in the domain of orthopedics. The capacity of deep learning to analyze intricate algorithms and derive conclusions has led to its significant role in domains such as diagnostic processes, treatment strategies and the prediction of surgical outcomes. In the domain of medicine, deep learning has emerged as a particularly salient method in the analysis of medical visual materials. The utilization of deep learning algorithms, endowed with the capacity to employ neural networks, has been demonstrated to facilitate the successful detection of intricate structures in imagery, such as X-rays or magnetic resonance (MR) scans. This capacity enables the diagnosis of various disorders [6].

A review of the literature reveals that studies aimed at diagnosing pes planus have employed a variety of methods, including visual assessment, footprint analysis, pressure distribution measurements, and radiographic angles. It is evident that a number of these studies employ image processing or traditional machine learning approaches. In recent years, however, there

has been a significant increase in the number of studies utilizing deep learning techniques based on CNNs for the classification of pes planus and other foot deformities.
